India's fertility is projected to reach replacement level by 2015, Bangladesh by 2020, and Nepal and Pakistan by 2030 (see Fig. 1). The prospects for the continuation of past downward trends are good. Recent surveys indicate that at least 20 percent of births are unwanted in Pakistan, Nepal, and the high-fertility northern states of India. However, a desire for two sons is still prevalent in these parts of South Asia. Acting on this preference implies a fertility rate of over four births per woman unless sex-selective abortion becomes widespread. Similar strong preferences for sons exist in East Asia, but the desire for two sons has subsided into a desire for one (see *Fertility Transition: China*; *Fertility Transition: East Asia*). The most likely prognosis is that the remaining high-fertility parts of South Asia will follow this example.

Fertility Transition: Southeast Asia

The population of Southeast Asia was only one third the size of Europe's in 1950 (182 million compared to 547 million in Europe), but by 2050, the population of Southeast Asia is projected to be 25 percent larger

than Europe's (786 million vs. 628 million, United Nations 1999, pp. 442–3). This dramatic reversal is the product of a lag, of about a century, in the demographic transitions of the two regions. Fertility began to decline in several northwestern Europe countries during the last quarter of the nineteenth century and spread to all of Europe over the first half of the twentieth century. Fertility in Southeast Asia first showed signs of decline in a few countries in the late 1960s, and then moved downward, at varying speeds, throughout the region from the 1970s to the 1990s. Although fertility in Southeast Asia is likely to approach the replacement level (around two births per woman) early in the twenty-first century, the force of demographic momentum and the power of compound rates of growth will continue to expand the population of Southeast Asia relative to Europe (and North America).

Southeast Asia consists of the 11 countries that lie between the Indian subcontinent and China (see Fig. 1). While there are common geographical, historical,

and cultural features of Southeast Asia, diversity is the hallmark of the region (Reid 1988, 1993, Wolters 1999). Indonesia, one of the world's most populous countries, comprises about 40 percent of population of the region as a whole (see Table 1). The other largest countries are the Philippines and Vietnam, each with estimated populations of more than 75 million in 2000, and Thailand at approximately 60 million. At the other extreme are the microstates of Brunei and East Timor, each with less than a million people. Singapore, a city-state, has a population of only 3.5 million, and Laos is only slightly larger at 5 million (Table 1). Myanmar (Burma) at 45 million, Malaysia with 22 million, and Cambodia with a population of 11 million are the other countries in the region.

The major geographical and cultural divisions are between mainland and insular Southeast Asia and between the lowlands and uplands within each region (and country). The populations of the mainland countries generally practice Buddhism while Islam is the major religion of Indonesia, and Christianity is the predominant religion of the Philippines. While part of Malaysia (Peninsular Malaysia) is on the mainland, it is usually considered as belonging to insular Southeast Asia because the Malay population of Malaysia shares a common language, religion, and cultural heritage with much of the Indonesian population. The lowland countryside of both mainland and insular Southeast Asia consists of villages knitted together by small and medium size market towns. Wet (irrigated) rice agriculture is the predominant feature of the countryside, but rubber, oil palm, coconut, and sugar plantations (and small holdings) as well as mining remain as legacies of the colonial export economies that once dominated the region. Every country has remote highland and mountainous regions, which are often populated by cultural and religious minorities (a

minority in one country is sometimes the dominant cultural group in neighboring countries).

Located along the major sea route between the great civilizations of East Asia and South Asia, the 'plural society' has been one of the defining features of Southeast Asia, which has been relatively open and absorptive of peoples, ideas, and cultural practices from elsewhere. In the twentieth century, assimilation into Southeast Asian societies and interethnic relations became more difficult with the creation of 'national' states and the translation of cultural differences by religion, language, and region into political categories with differential status and rights. Throughout the region, the 'overseas Chinese' continue to be over-represented in commercial and professional occupations. Over the centuries, a good share of Chinese-origin peoples have intermarried and blended with local populations in many Southeast Asian countries, but there remains a segment of the Chinese population that has been residentially and socially segregated even after three or four generations of local residence (Cushman and Wang 1988, Reid 1996, Chaps. 1–3).

The new Southeast Asian economies are dominated by the major metropolitan areas, including Jakarta, Surabaya, Bangkok, Singapore, Manila, Rangoon, Kuala Lumpur, and Ho Chi Minh City. These major cities typically originated as trading and administrative areas along major rivers or coastal ports. At the present time, these cities are bustling metropolises with large-scale manufacturing, commercial, service, and governmental functions. Contemporary indicators of development in Southeast Asia, including very low levels of mortality and almost universal secondary schooling, are approaching the prevailing standards of developed countries. The economic crisis that hit the region in 1997 notwithstanding, the

prevailing trajectory of Southeast Asia appears to be heading along the lines of the modernizing East Asian countries of Japan, Korea, and Taiwan.

1. A Demographic Overview

The major demographic attributes and trends of Southeast Asia, based on the latest UN population estimates and projections, are reported in Table 1. The extraordinary pace of demographic and social change in the region is registered in the measures of life expectancy and the total fertility rate (a summary measure of annual fertility expressed in terms of the average number of births per woman) from the late 1960s to the late 1990s. Over this 30-year period, the average life expectancy in Southeast Asia increased from 48 years to 66 years and fertility declined from almost six births per woman to less than three. These rates of change are unprecedented in the historical record and have only been exceeded in the modern era by several East Asian countries. In the late 1960s, the only countries in the region with life expectancy above 60 were Singapore and Brunei, although Malaysia was not far behind. Thirty years later, every country had life expectancies above 60, except for Cambodia, East Timor, and Laos (the poorest countries in the region). The declines in fertility are no less pervasive. Even in the relatively poor countries of Myanmar (Burma) and Vietnam, fertility has dropped below three children per couple. Fertility is below the replacement level of two births per couple in Singapore and Thailand.

The broad picture of rapid fertility decline conceals significant variations from country to country. For example, there has been very little socioeconomic development and only modest demographic change in Laos and Cambodia, countries that were victims of the Indochina wars of the 1960s and 1970s. After the 'victory' of the Khmer Rouge in 1974, the mortality rate may have doubled as a result of executions and starvation during the Pol Pot regime (United Nations 1999, p. 124, Heuveline 1998). There are signs of fertility declines in the UN data for Laos, Cambodia, and East Timor, but the absolute levels of fertility remain very high in these countries. Much further along the path of fertility decline are the large countries of Vietnam and Myanmar, although economic conditions in these countries remain far below the rest of the region (Haugton 1997, Myint 1991).

Fertility dropped below the replacement level in Singapore in the late 1970s (Saw 1999). Perhaps the most celebrated case of rapid fertility decline in the region is Thailand, where fertility declined from more than six births per woman in the 1960s to less than two births per woman in less than 30 years (Knodel et al. 1996, Hirschman et al. 1994). Fertility declines have also been registered in other Southeast Asian countries with estimates of total fertility rates ranging between

three and four births in Malaysia, the Philippines, and Indonesia (Hirschman and Guest 1990a, Palmore et al. 1995). The case of falling fertility in Indonesia is particularly salient, given the size of the country and its major influence on the region as a whole.

2. Explanations of Fertility Decline in Southeast Asian Countries

The postponement of marriage has contributed modestly to the temporal decline in fertility in several Southeast Asian countries, but the major component has been declines in marital fertility (Retherford and Cho 1973, Hirschman and Guest 1990a). Declines in marital fertility are due primarily to increased contraceptive use. Indeed other factors, such as decreases in spouse mortality and reduced durations in breastfeeding, would probably have led to rising marital fertility in the absence of increased contraceptive practice. The underlying question is what has caused the increase in contraceptive use.

There are two widespread interpretations for the widespread adoption of contraception and rapid fertility declines in the region: the efficacy of family planning programs and the rapid pace of socioeconomic change in the region. These interpretations are not incompatible, and in their classic study, John Knodel and colleagues conclude that Thailand's reproductive revolution is due to the combination of four factors: rapid social and economic development, a favorable cultural setting (female autonomy and weak intergenerational influences in reproductive decisions), a latent demand for fertility control, and an effective national family planning program (Knodel et al. 1987). The challenge for the field has been to test the relative significance of these explanatory factors in different times and places. At present, the research record points to a broad mosaic of varied patterns and causes without a simple overarching interpretation.

The fundamental prerequisite for fertility transitions is a mortality transition, especially declines in infant and child mortality. In Southeast Asia, mortality declines began in the decade after World War II, as antibiotics, other aspects of modern medicine, and preventive health programs were introduced and spreading in many Southeast Asian countries. The continuing pace of mortality declines in the region is shown in Table 1. According to demographic transition theory, declines in mortality and other aspects of socioeconomic change are predicted to increase pressures on families and married couples to lower their desired number of children and to increase their 'demand' for family planning.

In almost every Southeast Asian country, there have been empirical studies that find the predicated associations between modern characteristics and lower levels of fertility. Social change, or modernization, is usually indexed by a variety of individual level characteristics,

such as female education and employment, urban residence and nonagricultural employment, exposure to the mass media, and ownership of modern goods. Such associations, however, do not explain how macrochanges (in society as a whole) lead to individual-level modernization nor whether cross-sectional associations reflect actual historical (over time) patterns of social change. Hirschman and colleagues (Hirschman and Guest 1990b, Hirschman et al. 1998) have attempted to explain fertility declines in four Southeast Asian countries (Indonesia, Philippines, Malaysia, and Thailand) from 1970 to 1990 in terms of changes in provincial level measures of social change in the status of women, the economic roles of children, and infant mortality. Although based on fertility transitions still in process, the findings are consistent with the logic of demographic transition theory, albeit with wide variations in the significance of specific independent variables over time and across countries.

Impressionistic evidence would suggest that governmentally sponsored family planning programs have been the major reason for rising contraceptive use in Thailand, Indonesia, and other Southeast Asian countries with declining fertility. Family planning programs were instituted in many Southeast Asian countries in the 1970s, just about the same time that fertility began to edge downward in the region. Several authors have attributed the decline of fertility in Indonesia to a very successful family planning program there (Freedman et al. 1981, Hull et al. 1977, Ross and Poedjastoerti 1983), and some observers attribute the slower declines in fertility in Malaysia and the Philippines to relatively less energetic family planning programs in these countries. These conjectures, however, are very difficult to evaluate empirically because the emergence and characteristics of family planning programs are correlated with other determinants of fertility decline, most notably socioeconomic development.

One analytical approach to this question is to measure the spatial pattern of fertility decline relative to the geographical location of family planning clinics and aspects of the program that may provide family planning information or contraceptives. The problem with this approach is that the location of family planning clinics may be endogenous, i.e., program resources such as clinics are directed to populations with very high fertility (just as police stations are often located in high crime areas). Moreover, contraceptives are available from nongovernmental outlets such as private clinics and drugstores. These conditions mean that empirical tests of the impact of family planning programs on fertility decline are extraordinarily difficult to estimate empirically.

Using econometric techniques to control for the endogenous role of family planning inputs, Gertler and Molyneaux (1994) find that almost all of the fertility decline in Indonesia from 1982 to 1987 was due to rising incomes and education and that very little

of the fertility decline could be attributed directly to family planning efforts. These findings do not rule out the interpretation that the Indonesian family planning programs played an important role through the provision of readily available means for fertility control (and at a modest cost) for women who were already motivated to limit their number of births, which is what Robinson and Rachapaetayakom (1993) argue was the major role of the Thai family planning program. Family planning programs may play a more influential role in the origins of a fertility transition than on its continuation.

Govindasamy and DaVanzo (1992) conclude that public policies, other than family planning programs, have been more influential in promoting more rapid fertility declines among the Chinese and Indian populations than among the Malay population of Malaysia during the 1970s and 1980s. The Malaysian government provided educational and economic subsidies (as part of an affirmative action program) for Malays that reduced the costs of children in a rapidly modernizing society. Leete (1996) adds the additional interpretation that Malay fertility has remained high because of the resurgence of Islam and pronatalist cultural values. There are, however, quite wide variations in levels and trends of Malay fertility between Singapore and Malaysia and across states in Malaysia that raise questions about a simple cultural or religious preference for high fertility (Hirschman 1986, Jones 1990).

Perhaps the single most important cultural characteristic of Southeast Asia is the relatively high status of women, especially when compared with East Asia and South Asia (Reid 1988, pp. 162–72, Van Esterik 1982). While women still face many socioeconomic obstacles in Southeast Asia, the situation is quite different from the patriarchal societies of East and South Asia. Southeast Asian kinship systems are typically bilateral with equal importance attached to the husband's and wife's families. For the most part, there is no strong sex preference for children in Southeast Asia (Wongboonsin and Ruffolo 1995) nor are there strong prescriptions on residence with the groom's family after marriage. Cultural variables are difficult to quantify, especially at the microlevel, which makes it difficult to estimate their relative role in shaping fertility levels and change, but it seems likely that greater freedom for women to pursue nonfamilial roles and to influence household decision making have been important factors in the region's rapid fertility decline.

3. The End of the Fertility Transition in Southeast Asia

If the current pace of decline continues, replacement-level fertility (two children per woman) should be reached early in the twenty-first century in most

countries and regions of Southeast Asia. Indeed, if the recent history of East Asia, and Singapore, is any guide, modern fertility levels may not stop at the replacement level, but continue to decline below the level of fertility needed to replace the parental generation. The explanations for these rapid fertility declines, although still hotly debated, are likely to be the complex interplay of rapid socioeconomic change, organized family planning programs, and spatial and social diffusion processes that vary in significance and intensity over time.

An additional factor that is likely to accelerate the decline of fertility is the postponement and perhaps decline in marriage. The most celebrated case is Singapore, where the 'the flight from marriage' and declining fertility among the highly educated population prompted the government to organize social activities to encourage unmarried persons in their twenties and thirties to marry and have babies (Leete 1994, p. 815, Yap 1995). The trend toward marital postponement throughout the region has been underway for 30 years, but the 1990 round of censuses revealed how far the trend had progressed. In Malaysia, Thailand, and the Philippines, from 13 to 15 percent of women in their early thirties remained unmarried (Jones 1995, 1997).

The figures for marital postponement are even higher in cities and among those with higher education. In several countries of Southeast Asia, the average age at marriage of women and men is older than in many Western countries. Since the historical pattern in Southeast Asia was of young and universal marriage, this is a remarkable transformation in custom. Perhaps, there may be a lag in the adjustment of social institutions to replace traditional match-making arrangements. Another hypothesis is that some highly educated men in Southeast Asia may prefer to marry women with lower educational attainment who are considered to more likely to follow traditional gender roles than highly educated women.

Although there is likely to be an adjustment in marriage patterns before high levels of celibacy are reached, the current pattern of marital postponement is certain to likely to accelerate the downward trend in fertility in most Southeast Asian countries. Indeed, the fertility transitions in Southeast Asia are among the most rapid in the developing world, and the trend may accelerate. Nonetheless, rates of rapid population growth of 2 percent per annum during much of the second half of the twentieth century and subsequent demographic momentum will lead to continued rapid growth of the population of Southeast Asia during the first half of the twenty-first century.

C. Hirschman

Fertility Trends in the Formerly Socialist Countries of Europe

The Formerly Socialist Countries of Europe (FSCE) include Albania, Bulgaria, Hungary, Poland, and Romania, as well as the newly independent states, namely the Czech Republic and the Slovak Republic from the former Czechoslovakia; Belarus, Estonia, Lithuania, Latvia, Moldova, Russia, and Ukraine from the former USSR; Croatia, Bosnia and Herzegovina, Slovenia, Macedonia, and Yugoslavia from the Socialist Federated Republic of Yugoslavia; and

finally the eastern *Länder* of Germany, which from May, 1949 to October 3, 1990 formed an independent state—the German Democratic Republic (GDR).

Relatively heterogeneous demographically, the FSCE have *grosso modo* followed a common pattern during the twentieth century, namely a late onset and high speed of the fertility transition as compared to Western and Northern Europe; a specific environment of family economics and other family policies applied under the socialist system during the four post-war decades; and a rapid transition from a centralized to a market economy since the beginning of the 1990s.

1. The Fertility Transition

The fertility transition started during the last quarter of the nineteenth century in the more industrialized and urbanized Czech Republic (which was part of the Austro-Hungarian Empire until 1918), in the former GDR (Western Prussia), and in Hungary (the Kingdom of Hungary in the Austro-Hungarian Empire). Elsewhere (Albania excluded), the beginning of a stable fertility decline may be dated to about the first two decades of the twentieth century, though exact estimation is difficult because of social troubles and wars in 1912–20 (Coale 1969, Pavlik 1991). The completed fertility (CF) of women born in 1910, a central cohort whose reproductive behavior reflected fertility dynamics during the first half of the twentieth century, was below 2.5 births per woman in the Czech Republic, the GDR, and Hungary (as it was in England and Wales), about 3.0 in Bulgaria and Slovakia (as in The Netherlands), and between 3.5 and 4.0 in Poland, Rumania, Yugoslavia, and Russia (Festy 1991). In general, the FSCE followed the West European fertility transition pattern between the two World Wars, and on the eve of World War II, Albania was the only country not to have begun its fertility transition.

2. Trends after World War II

Fertility in the FSCE in the second half of the twentieth century was marked by a notable deviation from the Western and Northern European pattern. While fertility rose throughout the West after the 1950s (see *Baby Booms and Baby Busts in the Twentieth Century*), in the FSCE it continued to decline without interruption, reaching the then European low in the early 1960s (Sardon 1998). In Hungary, the TFR fell below 2 in 1961, in Romania in 1964, in the Czech Republic in 1967, in the Ukraine in 1965, and in Russia in 1968. The TFR level necessary for generation replacement (at least 2.1) was still maintained in Poland, the GDR, Belarus, Bulgaria, Moldova, and all of Yugoslavia,

but this was mainly caused by a lowering of child-bearing age, which fell by two years between 1950 and 1965 (see *Fertility Change: Quantum and Tempo*), while cohort fertility continued to fall.

Furthermore, in Yugoslavia the relatively high national fertility level concealed strong regional and ethnic variance: while the TFR was about 3.5 in Bosnia and Herzegovina in 1965, 3.7 in Macedonia, and 3.1 in Montenegro, it was approaching replacement level in the other Yugoslav republics: 2.02 in Croatia, 2.4 in Slovenia and Serbia. Within Serbia, again an enormous difference existed between Kosovo, where the TFR exceeded six births per woman in the mid-1960s (as it did in Albania), and the other two autonomous provinces, Central Serbia and Vojvodina, where it was 2.03 and 2.13, respectively.

From the mid-1960s, when the fertility decline took new speed in Western Europe (see *Demographic Transition, Second*), the TFR stabilized for almost two decades at values of 2.0 to 2.5 in Central and Eastern Europe. Thus in the 1970s and 1980s the FSCE once again had the highest fertility levels in Europe. The stabilization of fertility in the FSCE might be explained by a particular 'socialist' type of family formation resulting from policies of social paternalism towards the family, especially toward the young family, applied throughout the FSCE since the beginning of the 1950s. Under the conditions generated by these policies, based on the principles of social egalitarianism and state guarantees of equal and universal access to education and health services, family formation (marriage and childbearing) became one of the first stages of an adult's social adaptation. It often was a condition for independent housing arrangements and it preceded a definitive choice of profession. This resulted in younger childbearing and in a strong compression of fertility around the modal age at childbearing. Furthermore, this policy stimulated the development of a two-child family system. Throughout the FSCE, the proportion of women who were childless at age 50 was very close to the natural level of sterility, i.e., about 10 percent. At the same time, families with four and more children were rare, especially in the countries that had a high level of industrialization in the pre-socialist period (the GDR, the Czech Republic, Hungary, Slovenia).

In the countries where economic modernization had not been achieved by World War II (those east of the 'Hajnal line'), the traditions of early and universal marriage as well as early childbearing persisted, because the 'gentle' socialist form of industrialization avoided the explosion of unemployment, a drop in living standards, and mass rural-urban exodus.

Another factor explaining the stabilization of (or even slight increase in) fertility was the special pronatalist policies implemented between the mid-1960s and the mid-1980s throughout the FSCE, again with the exception of Albania (Henry and McIntyre 1981). Based on an array of incentives such as family

allowances, birth payments, paid maternity and post-maternity leave, and subsidized credit, these policies aimed at stimulating second-, third- and fourth-order births (Klinger 1991). The most powerful pronatalist incentives were introduced in Hungary, Czechoslovakia, Bulgaria, and the GDR, where they substantially influenced period fertility indicators, and less strongly the fertility of female cohorts born around 1950 (± 5 years). The strongest growth in cohort fertility was observed in Hungary, where CF rose from 1.9 for women born in 1942-45 to 2.03 in the cohort of 1961. In Czechoslovakia, CF gained less, from 2.03 in the cohort of 1943 to 2.1 in the cohort of 1952-58, while in the GDR and Bulgaria, the pronatalist measures only stopped the decline and stabilized cohort fertility (at around 1.8 in the former for the cohorts born in 1952-58 and 2.05 in the latter in the cohorts born in 1945-57). Thus, all these incentives were unable to raise cohort fertility to replacement level. In 1983-86, the USSR repeated this pronatalist policy experiment, but without any restrictions on abortion, and obtained the same result in its European republics, namely a short-term increase of the period TFR to 2.2 in 1984-87, followed by a rapid decline after the fall of the Soviet Union in 1988. In Romania and Poland, the pronatalist measures were more modest. Finally, in Yugoslavia, child allowance payments were decentralized and increased for lower-income families, which suggests a social policy orientation rather than a purely pronatalist policy (Henry and McIntyre 1981).

The availability of induced abortion was another key element of the family policies of a number of FSCE countries. Following the example of a Soviet abortion law passed in November 1955, all the FSCE except the GDR and Albania liberalized induced abortion during the late 1950s. Later, the abortion law became more restrictive again in Romania (1966), Bulgaria (1968), Czechoslovakia (1973), and Hungary (1974). These restrictions had little long-term effect on fertility because they were accompanied by an extension in contraceptive use, encouraged by the governments to protect women's reproductive health (see *Fertility Control: Eastern Europe*). Only in Romania, where the level of modern contraceptive use was very low, did the strongest ban on abortion ever (implemented on 1 November, 1966 by Decree 770) result in the most spectacular rise in fertility in post-war Europe: the TFR increased from 1.92 in 1966 to 3.67 in 1967. Fertility fell quickly again, after 1969 however, and later amendments reinforcing Decree 770 (in 1974, in 1984, and in 1986) had only a very weak influence on trends in the TFR.

The main results of these fertility-stimulating and restrictive incentives were a strong shift in fertility to younger ages (the cohort MAC—mean age at childbearing—decreased to 25 ± 1 years) and a greater compression of fertility spacing toward its natural limits within the frame of the two-child system, with a

Figure 1

Evolution of period and cohort fertility indicators in the formerly socialist countries of Europe

CF in the region of 1.9 births per woman (see Fig. 1). In the GDR, where fertility compression was relatively moderate by FSCE standards, about 60 percent of fertility was concentrated in the age range of 19–25 years in the mid-1970s. By the beginning of the 1980s, this pattern of reproductive behavior had spread throughout the FSCE except for Albania, the autonomous province of Kosovo and, probably, Macedonia.

In the early 1980s, when the crisis of the socialist system emerged throughout the FSCE and was absolutely obvious in Poland and the former Yugoslavia, the first signs of a corrosion of the 'socialist' pattern of family formation also became visible. This showed up in an increase in the mean age at childbearing (Hungary, the GDR, Czech Republic, Croatia, Slovenia), followed by a decrease in TFR since the mid-1980s. In Central Serbia and the autonomous province of Vojvodina, where the economic crisis began earlier, the MAC started to rise in the early 1970s while fertility was below replacement level. Only in the European republics of the USSR, Poland, Bosnia and Herzegovina, Macedonia, and Kosovo was the fertility decrease accompanied by a reduction in the MAC until the mid-1990s.

With the collapse of the socialist system in Europe (1989–1991) and the disappearance of the social and economic support of the 'socialist' pattern of family formation, fertility plummeted in all FSCE countries. In the ex-GDR, the Czech Republic, the Slovak Republic, Romania, and the newly independent states of the former USSR, the first reaction of fertility to the social changes has been described as a paralyzing shock that led to an abrupt but brief fall in the mean age at childbearing due to a decrease in fertility rates at all ages. Subsequently MAC began to increase while

the TFR decreased. The most spectacular fertility drop occurred in the former GDR, where the TFR fell from 1.56 in 1989 to 0.77 in 1993–1994. In the rest of the FSCE, fertility followed the trends of the late 1980s, except perhaps a little faster. It seems that the economic troubles definitively brought the fertility of women born in 1962–65 down below the level that would have been reached otherwise. The fertility of younger women has been checked too, but this may perhaps be made up later (Philipov and Kohler 1999). Moreover, a rapid rise in out-of-wedlock births is observed all over the FSCE and is especially remarkable in Estonia, where the proportion of births outside marriage rose from 20.7 percent in 1985 to 51.6 percent in 1997. In the former GDR, the increase was from 33.8 percent to 44 percent, in Slovenia from 19.1 percent to 32.7 percent, in Latvia from 14.4 percent to 34.8 percent and in Bulgaria from 11.7 percent to 30.1 percent.

In summary, it seems likely that a new pattern of family formation is now emerging in the FSCE, characterized by later marriage and by late and diversified fertility similar to that observed in Western Europe. This observation is supported by the stabilization of (or even a slight increase in) period fertility observed in the former GDR, Moldova, Romania, and the Czech Republic in the second half of the 1990s, in contrast to the fertility decline still going on elsewhere in the FSCE. At the present time it is, however, impossible to draw any definitive conclusions about the near future of fertility in the FSCE. What the future will bring depends in large part on the political stability and the economic situation in these countries.

Feud and Internal War: Legal Aspects

Feuding and internal war are two types of violent collective conflict. Long of interest to anthropologists, feuding and internal war may be most common in simple, kin-based societies, but, as lethal violence between modern urban gangs attests, are not confined to those settings. A central issue for scholars has been the relationship between feuding and internal war and the state's system of social control or law: are feud and internal war the antithesis of law or the functional equivalent of law? In fact, they are neither. The emergence over the past quarter-century or so of a new field of sociological inquiry known as conflict management provides a new conception of the relationship, one in which law and violence are similar, though not identical, ways of handling disputes triggered by similar, though not identical, social conditions (Black 1976, 1993).

1. The Terms 'Feud' and 'Internal War'

Scholars use two strategies to define the terms 'feud' and 'internal war,' strategies that might be labeled qualitative and quantitative, respectively. The qualitative strategy treats feud and war as distinct subtypes of violence; the quantitative strategy locates feud and war at different points on the same continuum of violence.

The work of Keith Otterbein exemplifies the qualitative strategy, the more common of the two. In an influential paper, Otterbein and Otterbein (1965) isolate three types of violence: feuding, internal and external war. Feuding the Otterbeins define as violence within a political community; internal war as violence between political communities within a society; and external war as violence between societies. Useful though these distinctions may be for some purposes, they do not appear to be necessary to answer the central theoretical question: what explains violent conflict? Otterbein and Otterbein found that the best predictor of feuding in a society is not the complexity of political organization but the presence of co-resident

related males organized for mutual self-protection or 'fraternal interest groups.' In a later paper, Otterbein (1968) reports that fraternal interest groups are also strongly associated with internal war (compare Ericksen and Horton 1992). If the same variable predicts both types of violence, much of the rationale for treating them as qualitatively distinct disappears.

The quantitative strategy is used by Donald Black. Black has developed a field of sociological inquiry known as social control or conflict management that addresses the myriad ways in which people and groups handle disputes. Diverse though conflict management behavior is, Black argues that it can be reduced to five 'elementary forms': negotiation, avoidance, toleration, self-help (or aggression), and third-party settlement (such as mediation, arbitration, or adjudication). Each elementary form can be found at different structural levels: among individuals, organizations, nations. For Black, there is therefore no sharp discontinuity between interpersonal, group, and international self-help. However, self-help does vary in the amount of violence it entails. Measures of the violence of self-help include the presence and lethality of weapons, the number of people attacked, the reciprocity of the violence, and whether the assault is accompanied by torture or mutilation. On this line of thought, feud and war (as well as other forms of self-help, such as assault, homicide, and retaliatory killing) differ not in kind but in degree: war is more violent. (Consistent with it, the remainder of this entry will refer to both feuding and internal war as feuding, except where it is important to distinguish the two.) In practice, there is often an additional contrast: the parties to war are usually large groups, such as societies (external war) or tribes (internal war) while feuds are contested by smaller groups, such as families. In the quintessential war, then, armies trade multiple rounds of lethal violence, seek to slaughter as many of the enemy as possible, and exempt nobody from attack. In the quintessential feud, antagonistic families kill at least once, abide by the principle of 'a life for a life,' and avoid targeting women, children, and non-kin.

2. Feuding and Its Alternatives

Although feuding has been practiced in many societies, there is no such thing as a feuding society. Only some conflicts give rise to feuds, even among those people well known for feuding, such as medieval Icelanders (Miller 1990), highland Albanians (Hasluck 1954), and Australian aborigines (see, e.g., Warner 1958). For instance, while homicides between families may precipitate prolonged and bitter feuds, those within families are likely to attract nothing more than some criticism and avoidance of the killer (see, e.g., Peters 1967).

Even when homicides, insults to honor, or other offenses occur within relationships that can result in a feud, a feud is rarely inevitable. In many societies, the victims's kin have the option of accepting compensation from the offender's kin in lieu of retaliation (see, e.g., Boehm 1984). Whether they agree to compensation or launch an attack (which may then trigger a counterattack) depends on a variety of factors, including their social status relative to that of the other side, and the nature and number of cross links between them (see Black 1993, Chap. 3). If they decide to seek compensation, they can arrange payment either by directly negotiating with the other side or, more frequently, by calling upon the services of a third-party skilled in the resolution of conflict, such as a mediator. Among the Nuer (of Sudan), for instance, a third-party known as the Leopard-Skin Chief traditionally intervened in disputes, such as homicides, with a view to having the parties agree to settle the case non-violently through a transfer of cattle from the killer's kin to the victim's kin (Evans-Pritchard 1940, pp. 150–76). The Leopard-Skin Chief could not force the parties to resolve the matter peaceably; nor did he referee the merits of the dispute; the only tools available to him were his powers of persuasion and his threat of supernatural sanctions if the parties did not settle. The Leopard-Skin Chief's mediation was most likely to succeed in disputes between neighbors and acquaintances: if the parties were intimates his intervention was likely to be unnecessary; if they were relative strangers his efforts were likely to be disregarded.

3. The Relationship Between Law and Feud

The noted anthropologist, Paul Bohannan (1967, p. xiii) once wrote that 'there are basically two forms of conflict resolution: administered rules and fighting. Law and war.' Later developments in the sociology of conflict management reveal that Bohannan's dichotomy is too simple. Recall Black's analysis of the five elementary forms, a scheme that goes beyond law and warfare to include negotiation, avoidance, toleration, and non-legal forms of third-party settlement. However, even though Bohannan's dichotomy neglects these additional forms, it may be correct in pitting law and war as opposites, as radically contrasting ways of handling conflict.

3.1 Law and Feud as Opposites

The idea that law and violence are fundamentally opposed is a popular one. Where law represents order and reason and civilization, feud represents disorder, passion, and tribalism. Pospisil (1968, p. 392) articulates a central tenet of this position when he states:

That law stands in opposition to feud and that the latter is the antithesis of the former ... is well documented in those societies in which feuds are stopped by legal decisions of the over-all authority who either has enough power to enforce his will or possesses the skill to persuade the quarrelling parties to accept his solutions.

In reality, however, law does not invariably strive to eliminate violence. Early states appear to tolerate feuding (see, e.g., Otterbein and Otterbein 1965). Moreover, even when law does seek to bring fighting to an end it often must do so with tactics and procedures similar to those used by the protagonists. If the parties persist in pursuing their conflict violently, the only way to stop them is to use overwhelming force. However, in employing violence to end violence, the law becomes not so much a party outside the feud as a more powerful party that wins the feud. That law's authority ultimately rests on physical force blurs the distinction between law and feud.

3.2 Law and Feud as Complementary

A second view is that law and feud are complementary institutions, at least where law is unavailable. Several eminent anthropologists, including Evans-Pritchard (1940) and Max Gluckman (1956) view feuding and the threat of feuding as a mechanism by which social order is attained and maintained in stateless societies. Evans-Pritchard, for instance, studied the Nuer who have a segmentary lineage system under which opposing kinship subunits unite to support their kinship unit in a conflict with another unit, and those opposing kinship units themselves unite when conflict occurs between larger kinship units. Feuds are least likely to occur within subunits where the parties are bound by ties of kinship and the necessity of daily cooperation; feuds are more common, and more difficult to settle, as the parties become more structurally distant and cooperate less in matters of economics or conflict. Evans-Pritchard (1940, p. 159) proposes that the 'function of the feud ... is, therefore, to maintain the structural equilibrium between opposed tribal segments which are, nevertheless, politically fused in relation to larger units.'

The idea that the feud is the functional equivalent of law in stateless societies qualifies but does not negate the idea that law and feud are opposed. Functional equivalence only applies to stateless societies but feuds and internal wars involving gangs, guerrillas, and other groups may be found in societies with well-established legal systems.

Moreover, only in some stateless societies can feud be the functional equivalent of law. There are stateless societies that have neither law nor feuding, societies in which people employ entirely peaceful methods of settling disputes (see, e.g., Howell and Willis 1989).

Finally, the idea that violence is functional sits better with feuding than with internal war: the indiscriminate nature of war can result in the political and even physical destruction of a society, rather than its continued existence.

3.3 Law and Feud as Conflict Management

What, then, is the relationship between law and feuding? The young discipline of conflict management sheds new light on this issue, revealing both the contrasts and continuities between law and violence. As modes of handling conflict, law and feuding, it is true, are opposed in certain ways. In law, the parties use words; in feuding, they use weapons. Law tends to be hostile to feuding such that in developed or strong states, feuding is met with forceful criminal punishment. Moreover, in law, it is not the adversaries who typically determine the outcome, but neutral third parties, often applying general rules. However, consider some of the ways in which law and feuding are similar:

(a) In both law and feuding the parties confront one another. They dispute through hostile encounters. In so doing, they behave quite differently from disputants who simply avoid their adversary or tolerate the grievance (see Baumgartner 1988).

(b) In both law and feuding the parties seek victory. They do not want or expect to compromise. By contrast, when people negotiate their conflicts or invoke a mediator they normally anticipate that any settlement will require them to make concessions to the other side.

(c) In both law and feuding third-party supporters typically get involved. Legal conflicts draw in lawyers and witnesses; feuds draw in warriors. In either case, supporters are often crucial to the outcome of the case (Black 1993, Chap. 7).

Black's work not only allows the close similarities and the distinct dissimilarities to be described but to be explained as well. Black argues that the explanation of why violence or law or any other type of conflict management is found lies not in the substance of the conflict but in its social structure. The social structure of the conflict consists of the social characteristics of the participants, including their wealth, social integration, reputations for deviance, and relational distance. Black (1995, p. 855, note 130) summarizes the social structure of the classic feud:

- (1) intermediate relational distance between the parties (neither strangers nor close associates), (2) relational segmentation between the parties (divided by a social chasm, without cross links), (3) functional independence of the parties (lack of division of labor), (4) solidarity of each party (intimate and homogeneous), (5) homogeneity between the parties (same ethnicity), and (6) equality between the parties (similar size and resources).

Black adds:

Narrow the distances in the model by reducing the relational separation and independence of the parties, and the reciprocity and continuity of the violence declines. Increase the distances ..., and the violence becomes more indiscriminate and warlike.

Now consider litigation. According to Black's (1976) theory of law (a theory supported by a substantial amount of evidence), the first three characteristics of the social structure of the feud above would also be conducive to extensive litigation. However, the fourth, fifth, and sixth would not: litigation is attracted more to conflicts between unequals than equals, and to people of different ethnicities than the same ethnicity. In other words, conflicts in which the parties fight and those in which they invoke law have social structures that, while not identical, are similar.

3.4 The Fate of Feud-conflicts under Law

The affinity between the social structures of law and of violence provides an answer to another puzzle: how do disputants handle the underlying conflicts when feuding becomes increasingly difficult? What happens to the feud-conflicts that legal authorities successfully prohibit being fought? Cross-cultural evidence suggests that, in the absence of violence, the contending parties generally turn to forms of conflict management similar to violence. Rarely, for example, do the parties simply tolerate the grievance. Nor do they avoid one another or even engage in extensive negotiations. Most commonly, they resort to one of two courses of action. The first is to replace fighting with litigation. Parties who once traded blows now trade legal claims in a kind of sublimated violence. For instance, before the arrival of state authority, the Mae Enga of New Guinea had a substantial amount of interclan fighting, resulting in a comparatively high rate of lethal violence. The colonial administration's efforts to end the fighting were initially unsuccessful, but eventually the Enga began to turn to litigation:

This litigation the Central Enga quickly defined as 'fighting in the courts,' and they regarded the outcomes as equivalent to military victories or losses affecting whole phratries. Thus the men of a growing clan who believed their group required more land would carefully concoct a case, often spurious, against a weaker non-fraternal neighbor. After patiently rehearsing his followers in the statements they were to make, the Big Man [i.e., Enga leader] ... took the matter to the kiap with the realistic expectation that the sheer weight of testimony would persuade the overworked officer, who had neither the time nor the facilities to sift all the evidence. The indignant defendants of course argued strenuously in rebuttal, but, given the absence of written land records and the intrinsic difficulty of determining 'historical facts' ... it is

understandable that resolute lying often carried the day. However the case was decided, the disgruntled losers would soon fabricate a counterclaim (or polish up a valid complaint) against an apparently vulnerable fraternal clan of the victors (Meggitt 1977, p. 155).

The second course of action is to make increased use of indigenous forms of third-party settlement. If, previously, feuding and mediated compensation payments were alternative ways of handling, say, homicides, mediation payments now come to be the dominant method. For instance, after coming under colonial rule, the Nuer began, with the encouragement of the authorities, to bring all homicides to the Leopard-Skin Chief to be resolved through compensation (though the killer was also prosecuted and punished separately). Thus, by settling homicide cases between lineages that once might have resulted in reprisals, the role of feud contracted while that of mediation expanded (Howell 1954, p. 61).

Whichever option—using judges or mediators—is pursued, both are possible because of the similarity in the underlying social structure of violence and litigation and, more generally, third-party settlement. The arrival of law into a setting previously stateless provides a new outlet for disputes but it does not, at least in the short term, fundamentally alter the underlying relationship between the parties. Hence, when law forbids feuding, former feudists are usually attracted more to litigation, mediation, or arbitration than to forms of conflict management bearing fewer resemblances to violence. Law and feuding, then, are neither opposites nor complements, neither strangers nor siblings. Perhaps they are best thought of as cousins.

M. Cooney

Feudalism

Definitions of feudalism ‘vary widely in their degree of comprehensiveness’ (Max Weber). Historians and social scientists of the nineteenth and twentieth centuries thus do not agree on a standard definition of the term. There is a great deal of controversy about the scope and the explanatory value of the term feudalism. Characteristic of this debate is a plurality of concepts of feudalism. The diversity of definitions and concepts is attributable to differences in both the epistemological interests and in the historical and social theories that inform the approaches of each particular scholar, school of thought, and orientation.

1. Etymology

Etymologically, the adjective ‘feudal’ and the noun ‘feudalism’ are derived from the Germanic *feod* and the Latin *feudum*, which originally meant ‘cattle, money, property.’ During the course of the eleventh century, *feudum* became a technical legal term for the fief with which the lord invests a vassal under specific conditions. Being provided with this fief obliged the vassal to serve his lord militarily. Feudal law, the sum of all recorded feudal legal norms, was known as *ius*

feudale in medieval and early modern legal terminology and as 'féodalité' beginning in the seventeenth century. During the course of the eighteenth century, structural changes of a social and political nature brought about a fundamental shift in the meaning of the term 'féodalité.' Since then, the words 'féodal' and 'féodalité' have been used to designate not only the legally vested relationship of dependence between a lord and his vassal, but also an entire societal condition: the political and social condition of the *ancien régime*. A legal term was thus transformed into a kind of political catchword in order to call into question the legitimacy of a traditional political and social order. Thus associated with socio-critical connotations, 'feudalism' entered into the languages of Europe as both a word and a concept.

2. Historical Controversies about Feudalism

In his *Esprit des Lois* (1748) Montesquieu equates the '*lois féodales*' with the breakdown of public power and the disintegration of the central authority of the French state into territorial centres of power. Voltaire (1694–1778) denounces the '*system féodale*' as a system of sovereignty in which public power was divided among 'countless little tyrants.' In *Qu'est-ce le tiers état*, a text appearing in 1789, Abbé Sieyès attacks the nobility and the church as 'agents of feudality' whose privileges were incompatible with the ideal of equality under the law. In his view, freeing France from the 'ruins of feudality' was the most important task at hand. Influenced by persistent and widespread unrest among the peasants, the national assembly decreed the 'abolition of feudalism' (*abolition de la féodalité/du régime féodal*) on August 11, 1789. In the writings of Karl Theodor Welcker (1790–1869), one of the leading thinkers of Southern German liberalism, the feudal system is a glaring counterpart to the liberal order of the early Germanic period with its public cooperations. In keeping with the polemical use of the word '*féodalité*' in revolutionary France, Welcker employs phrases like 'feudal despotism' (*tyrannie féodale*) and 'feudal anarchy' (*anarchie féodale*) in order to characterize feudalism as a form of domination which, based on the violent usurpation of power, was blatantly inconsistent with the early Germanic ideal of popular self-determination ('*Volksfreiheit*').

3. 'Feudal Rule' and 'Feudal Mode of Production' in the Work of Georg Wilhelm Friedrich Hegel and Karl Marx

In Hegel's philosophy of history, the 'feudal system' constitutes a step in the historical process which brought about the 'progress from feudal government to monarchy.' Hegel defines feudal government as a

'system of private dependence and private commitment' in which 'the general injustice' and 'the general rightlessness' assumed an institutionalized form. Under the conditions of feudal rule, the lawful power of the state was superseded by a more personalized form of power which individuals held on the basis of their 'private property.' According to Hegel, 'the wilful brutality of particularistic law' prevented the formation of an administrative and controlling authority that could act for the common good to protect the freedom and equality under the law of its civil subjects. In Hegel's view, only the legal government of a monarch can adequately guarantee freedom. 'Feudal rule is a polyarchy; it consists of nothing but masters and slaves. In a monarchy, on the other hand, there is only one master and no slaves because under a monarch, the bonds of slavery are broken and justice and law prevail. True freedom issues from a monarchy.'

In Marx's view of history, 'feudal society' with its typical 'feudal relations of property' and its 'feudal mode of production' constituted a 'progressive economic form of society that produced a new class, the bourgeoisie, which broke down the 'feudal barriers to production.' Marx does not, however, work out an explicit theory of the origins, structure, and transformation of feudalism in detail; he never systematically treats the dynamics of the feudal mode of production. For him, terms like the Middle Ages, feudalism, and feudality are interchangeable. Marx links the Middle Ages and feudalism to the idea of a premodern society that created the necessary conditions for the rise of a capitalistic society which eventually overcame and dissolved feudalism itself. In the 'Communist Manifesto,' he writes that 'the means of production and exchange on whose foundation the bourgeoisie built itself, were generated in feudal society.' 'Modern bourgeois society that has sprouted from the ruins of feudal society has not done away with class antagonisms. It has but established new classes, new conditions of oppression, new forms of struggle in place of the old ones.' Marx is interested in the Middle Ages as the epoch that preceded the 'epoch of the bourgeoisie.' He is concerned more with the political state of medieval society than with an analysis of the feudal mode of production. Like the liberal critics of prerevolutionary corporate society, Marx assumes that in the feudal society of the Middle Ages, 'the supreme command in war and justice is based on landed property.' In his opinion, past and present share common structures with regard to this connection between power and property, for in both feudal society and a bourgeois society, the form of ownership determines the form of rule. The 'supreme command in industry is based on the ownership of capital,' while rule in feudal society was based on the control of land. However, the difference between feudal and bourgeois power relations was that in the Middle Ages, control of landed property determined

both social standing and legal rights to rule; the 'constitution of private property' was also the 'political constitution.' In feudal society, 'property or membership to a privileged family or the nature of one's occupation ... were essential elements of political life in the form of landlordism, class, and corporation.' Control over land formed the basis for rule over people. Noble birth was a kind of guarantee for the privileges of a lord. Private corporations such as guilds administered justice over their members, a right which the modern constitutional state reserves exclusively for itself. Narrow 'personalized relations of dependence' characterized the 'social conditions of material production.' Bond men were personally dependent on a small class of landholding nobles; as serfs, they were obliged to pay dues to their feudal lord and provide him with certain services.

Interpreting history from a Eurocentric perspective, Marx equates classical antiquity with a slave-holding society, the Middle Ages with feudalism, and the present times with capitalism. This classification of history reflects Enlightenment philosophy's belief in progress and combines it with the view of history held by postrevolutionary historians and social scientists. In their view, '*féodalité*' is a term to describe both an epoch and a society: in the linear, evolutionary course of world history, '*féodalité*' or more exactly the '*système théologique et féodal*' was a link between the society of ancient slaveholders and the '*système industriel et scientifique*' that produced the French Revolution.

4. Feudalism as Conceived by Historians and Social Scientists: Max Weber, Otto Hintze, and Marc Bloch

Weber's concept of feudalism has nothing in common with revolutionary and liberal authors' view of feudalism as a system of anarchy, injustice, and violence. Weber integrates socio-political, legal, economic, and spiritual-religious structural elements into a single model. Weber defines feudalism as a traditional system of governance that combines economic, social, and cultural factors. The idea that a feudal society is determined exclusively by socioeconomic characteristics—its 'feudal mode of production'—is quite alien to him. In his view, feudalism is not a type of economic management, but rather a type of domination that requires an economic basis. Weber argues that as a form of organizing and exercising domination, feudalism is a political phenomenon. The structural principle of feudal power relations is the fief. Feudal relations determine the structure and form of the political order, a hierarchically graded feudal pyramid that consists of feudal lords, vassals, and their subvassals. Weber defines *enfeoffment* as 'any investment of rights, especially the right to use land or to exercise territorial domination in exchange for military or

administrative services.' The polity was not held together by—to his mind—the integrative forces of a bureaucratically controlled state, but drew on the personal relationship of loyalty between lord and vassal for stability and duration. During investiture this relationship took on the character of a legally binding contract in a symbolic act which included commendation (*homagium*) and an oath of fealty (*fides*). In the absence of a centralized bureaucracy, 'the personal feudal bond of allegiance and the feudal code of honor serve as the glue of political cohesion.' Charlemagne's reform of the army led to a feudalization of military affairs. Knights were provided with economically useful fiefs which obliged them to provide military service. A cavalry composed of heavily armed feudatories replaced an army that once consisted of freeborn peasants. The feudalization of administrative structures transformed the early and high medieval realm into a system of ruled territories (duchies, ecclesiastical and secular principalities, margravates, earldoms) whose bearers were bound to the king by feudal law as tenants in chief. The feudal system was of fundamental significance for the political-legal organization of the kingdom. As a political principle of organization that divided the power of lords, feudalism laid the foundations for a decentralization of political power. Contractually stipulated division of power caused rivalries and conflicts between the central authority of the king and local vassals. By banding together to form corporations, feudatories transformed the feudal union into a corporative state.

Weber also points out that the manor constituted the economic basis of feudalism. The manor was 'the standard object of feudal tenure.' The power of nobles and princes was founded on ownership of land, human beings, and livestock. The conditions under which feudalism emerged and its function as a system of rule lent it a social character. The social differentiation between peasants and trained warriors grew out of the emergence of an armored cavalry. Membership to the noble class of lords was necessary in order to exercise power in the feudal system. Ownership of a manor which yielded rent entitled one to a 'lordly mode of existence' and enabled one to live according to one's social standing. Honor was the most important norm influencing conduct. Work-free rental income was indispensable for a life 'from which the social forms of prince and nobleman originate.' 'Feudalism, especially in the form of free vassalage and, more importantly, in the feudal system appeals to "honour" and personal, freely rendered and sustained "allegiance" as constitutive motives of conduct.' Honor and allegiance, the embodiment of the 'feudal ethics' which are characteristic of Western feudalism, constitute the 'extreme opposite of all objective business relations.' Feudalism produced and cultivated an ethics of the nobility in the form of heroic asceticism, heroic honor, and hero-worship; these ethics contradict the objectiveness of business relations and operations. The idea of the fief

determined the various forms of 'feudal incorporation,' 'all sorts of social relations: from one's relationship to the Saviour to that to his lover.'

To continue with Weber's concept of feudalism, in the long term, 'feudal structures of power with their clearly defined rights and duties' contributed to the 'stability of the economy.' The 'constancy of the legal system' contributed to the 'emergence of a rational capitalistic system and fostered its penetration into the gaps and seams of the feudal system.' According to Weber, the feudal system also had the rationalizing effect of molding society into 'an at least relatively constitutional formation.' The feudal relationship between lord and vassal created a 'constitutional state' which did not arise on the basis of a legal system, but rather on the basis of subjective rights agreed upon by free partners. By strengthening the personal rights of the individual feudatory, a system of social relations emerged in which contract and consensus constituted the predominant forms of societal integration.

In *Character and Spread of Feudalism* (1929) Hintze follows in the steps of Weber's methodology to 'describe the ideal type that underlies the concept of feudalism.' In his effort to precisely define feudalism as a socio-historic category, Hintze follows the rules of modeling ideal types to go beyond the hermeneutical interpretation of historical texts and concepts. Hintze argues that feudalism is more than 'a self-contained and coherent system of institutions' that constitute the 'feudal state.' His concept of feudalism is thus intended to understand and include other phenomena that are not a part of the feudal system in a strict sense. He therefore tries to link political, military, and socio-economic structural elements in his definition of feudalism. He understands feudalism not only as a principle of political organization, but also as 'a principle of military, economic, and social constitution.' According to Hintze, feudal structures had an effect on the development of sovereignty and social stratification in three ways: first, in the 'selection of a highly trained and loyal class of warriors who, bound by private contract, assumed a privileged position; second, 'in the development of a manorial, rural economic form which provided for the privileged class of warriors'; and third, in the 'elevation of this military nobility to the status of local lords who exercised considerable influence or who, because of their arbitrary way of ruling, assumed a privileged position' within the loosely structured feudal state.

Hintze distinguishes between three main phases in the development of feudalism in the history of the Romance-Germanic peoples: 'first, the era of early feudalism in which the military factor predominated—it extends roughly until the end of the twelfth century; second, the era of high feudalism in which the military nobility attained the height of its political influence, either by attaining relative independence from their feudal overlord as was the case under the arbitrary rule of princes in Germany, or in the form of

a corporative federation within a more solid feudal monarchy as it occurred in England when barons joined together in parliament against the crown—it extends roughly up to the sixteenth or seventeenth century; and third, the era of late feudalism in which the main interest of the nobility was in preserving and exploiting its socio-economic position as lords of manors and estate owners—it extends up until the era of the French revolution and up until the dissolution of traditional relationships in rural areas in the nineteenth century.' Hintze sets up guidelines for applying the term feudalism to non-European states, societies, and cultures. In his view, the term feudalism is, strictly speaking, only applicable to a society in which 'military, socio-economic and political feudalism are fully developed.' Working under this premise, Hintze argues that 'feudalism in its fullest sense can only be found—albeit with considerable deviations and particularities—in Russia, the Islamic nations and Japan.' Egypt, the ancient Orient, the Roman Empire, India, and China only exhibit initial signs of a feudalism that extended equally over the political order, the manorial, agricultural economic form and a military nobility which, supported by work-free income, was bound in allegiance to the ruler. In view of the poorly developed possibilities for communication, large kingdoms required a decentralized administration and court system which were meant to function on the basis of the feudal bond of allegiance between ruler and noble vassals.

Like Otto Hintze, Marc Bloch also views feudalism as a social type. His book *La société féodale* is considered to be 'a model of analysis of social structure,' a 'paradigm of a *histoire totale*.' Bloch does not limit himself to describing an ideal type which other scholars can use as a starting point for their own research. He also analyzes and describes European social history from the mid-ninth to the mid-thirteenth centuries, never losing sight of feudal society as the main connecting thread throughout this era. He sees vassalage and the manorial system as 'leading characteristics' of feudalism as a type of society. He designates the manor as 'the fundamental unit of the feudal regime.' According to Bloch's understanding, feudalism encompasses more than just those forms of social interaction that result from vassalage and the feudal and manorial system. He sees feudalism as a society that should be reconstructed as a complete interactive system. He therefore examines the basic structural conditions—including transportation, trade, population, the system of communication, and the monetary system—that constitute the environment of society. He is concerned with describing the '*atmosphère mentale*,' the 'culture of the feudal period' that influenced the social behavior and societal life of the people by means of its 'forms of feeling and thinking' including its literature (heroic song and epic), its education and scholarship, its attitudes toward nature, time and history, and its matters of

faith and religious practices. Bloch identifies 'fear of punishment in hell' as 'one of the strongest social powers of this time.' The 'kingdom of the feudal period' had a 'holy character.'

Personal ties and relationships of dependence had a great influence on the societal interactions which Bloch designates as feudalism. 'A network of bonds of dependence that ran through all levels of human society from top to bottom gave the culture and society of European feudalism its distinctive character.' Forms of personal dependence that existed within families and clans were based on blood ties. Under vassalage and the feudal system, personal bonds were forged through freely made agreements, thus initiating a relationship in which services and duties were interchanged. Legal tradition, voluntary devotion, or involuntary coercion produced legal, economic, and social inequality on manorial estates between noble lords, serfs, and tenant farmers. Central elements of Bloch's concept of feudalism include vassalic dependence, which bound vassals to perform military services for a lord, and manorial dependence, under which villeins and serfs (*coloni, villani, mancipia, servi*) were made to pay their landlords dues and tributes and perform statute labor. Like Max Weber, Bloch sees vassalage as patterns of behavior and relations which shaped relationships within the family, between lovers, and between the believer and God.

Because the members of societies generally designated as 'feudal' were subdivided into groups which were stratified according to profession, prestige, wealth, and power, Bloch examines social divisions as well as legal and economic inequality between the nobility, burghers and peasants, high and low clerics. He views bearers of 'public power' in the 'feudal epoch' (emperors and kings, princes and prince bishops, dukes and earls) not as representatives of the so-called 'feudal state,' a system of public rule distinct from society, but rather as bearers of 'traditional powers' in terms of their social bonds, limitations, and functions. It was, after all, their duty in a legally and socially 'divided society to maintain certain principles of order and unity.'

5. History and the Concept of Feudalism: Marxist, Historical, and Social Science Perspectives

Marx and Lenin are only interested in feudalism as a societal formation that constituted a preliminary stage of capitalism. Influenced by Marx, Lenin, and Stalin, socialist historians and social scientists have developed a theory of feudal society that not only explains its origins and characteristics, but also takes the change in conditions of production as a starting point to develop a criteria for the division of history into epochs. According to the prevailing theory of Marxism, feudal conditions of productions and feudal

social conditions gradually evolved between the end of the fifth and the middle of the ninth centuries. The 'epoch of developed feudalism' lasted from the middle of the eleventh until the end of the fifteenth century. 'It was a time in which feudal conditions of production and exploitation in Western and Central Europe prevailed and influenced the economy and society, politics and class struggle, culture and ideology in spite of critical disturbances during the late medieval centuries and variations in the degree reached by capitalistic conditions of production in the most advanced European regions.' Feudalism was able to endure over a span of several epochs because the 'early bourgeois revolution' (peasants' war, Reformation) miscarried. As a 'late feudal order' characterized by 'unrestricted rule of the nobility,' 'absolute feudal monarchy,' 'fragmentation of the feudal state,' the continuation of feudal conditions of production, and the 'development of capitalistic forms of production,' feudalism continued until the end of the eighteenth century, when it was overcome and dissolved during the French Revolution by 'bourgeois emancipation.'

The question of the 'essence' and 'genesis of feudalism' grew out of an interest in the structures of the precapitalistic form of society. The following characteristics of premodern feudal society arise out of a comparison between the two systems feudalism and capitalism: low level of technique, dominance of a barter economy, and feudal and hence divided ownership of land. Strictly speaking, the owner of the land was the feudal lord. He had the absolute ownership (*dominium directum*) of the parcels of land which were lent to the peasant. The peasant was granted the right to use the land by way of a loan (*dominium utile*). The instruments of production necessary to work the land belonged to him. The villein and serf owed their lord 'surplus work' (*corvée*) and 'surplus products' (payment in kind, dues) for the use of the land. The 'extra-economic compulsion' which issued from the lord lent the exploitative feudal conditions duration and stability. Extra-economic compulsion refers to the connection between property and sovereign rights. Because the lord of the manor also had the right of jurisdiction over the peasants to whom he granted use of his land, control of jurisdiction was a constitutive element of the exploitative conditions of production.

The majority of non-Marxist historians exclude forms of manorial dependence from their concept of feudalism. They use feudalism and feudality as synonyms for the feudal system and feudal law. In their view, a definition of feudalism that includes all forms of dependence including that of the peasant on the manor is an imprecise and thus unsuitable term for ordering and explaining this historical phenomenon. They reject a definition of feudalism that is more broadly conceived to include all areas of political and social life because they say that it cannot be verified by the sources themselves. They argue that the term feudalism loses its heuristic value if the clear-cut

reference to the fief of a vassal who is obliged to perform military service is lost; in their view, extending the term further is linguistically and objectively ungrounded. Faced with the dilemma of defining feudalism either as a form of society or as the feudal system, François Louis Ganshof chooses the latter. His justification for this choice is symptomatic for all historians who, by means of an exact interpretation of the sources, claim to be able to determine 'how it actually was.'

Ganshof defines 'the feudal system as a collection of institutions,' 'that create and regulate two kinds of bonds between one free-born man, called vassal and another, called lord or seignior: the 'vassal' is obliged to obey and serve—chiefly militarily—the 'lord', and the 'lord' is obliged to provide the 'vassal' with protection and a livelihood. The lord normally fulfilled his obligation to provide the latter by granting the use of land known as the 'fief.'

It has often been pointed out that conceiving of the feudal state as a counterpart to a bureaucracy leads to a 'one-sided exaggeration of domination' and does not adequately take 'the communal, co-operative, and corporative elements in the village, the city, and in the country' into account (Otto Brunner). Research in social and constitutional history that focuses on the role of the community in towns and in the country confirms this skepticism. It is argued that there is 'no logical connection' between 'feudalism,' which over-emphasizes the rule of the nobility, and 'communalism,' which sees the community as an organ of civic and peasant self-determination (Peter Blickle). Hence by seeing the peasant as a mere object of domination and exploitation, the 'feudal' point of view ignores historical records and documents to overlook the fact that the peasants themselves were also active subjects in the long development from serfdom into freedom.

Historians who examine changes in social structures in order to explain the development of modern capitalism (Perry Anderson, Rodney Hilton, Maurice Dobb, Eric Hobsbawm, Hans Ulrich Wehler) use feudalism as a term of demarcation. Free of dogmatic fixation, the work of Ludolf Kuchenbuch, Guy Bois, and Rodney Hilton examines the sources closely and focuses directly on its subject in order to empirically substantiate and better clarify the term 'feudal mode of production.' *Feudalism and History* (1956), an anthology edited by Rushton Coulborn, attempts to turn the definition of feudalism as a 'territorial system of governance' into a category of world history that could be used for international comparisons. Drawing on this definition of feudalism, the volume comes to the conclusion that only Western Europe, Japan, and early Chou-China display evidence for the existence of a feudal social system. English and French historians make little attempt to justify their use of the terms feudalism, '*féodalité*,' and '*féodalisme*' to describe structures of medieval and early modern agrarian

societies. This usage is part of the established terminology of the field. The intense debate about feudalism in the former GDR ended after the unification of Germany. The *Jahrbuch für die Geschichte des Feudalismus* (*Annual for the History of Feudalism*) ceased publication in 1990. German historians avoid the term feudalism as an ideologically loaded construct. They consider the term manor ('*Grundherrschaft*') on the other hand, as indispensable. However, the term manor also originated as a politically tendentious term; at the end of the eighteenth and beginning of the nineteenth centuries, enlightened and liberal authors who saw the manor as an illegitimate form of aristocratic despotism used the term to stigmatize the connection between domination and ownership of property which made the peasant dependent on noble lords and removed land from circulation on the free market.

6. Feudalism as a Type of Society

Adherents of a liberal concept of the town which originated in the nineteenth and early twentieth centuries object to usage of the term 'feudalism' or 'feudality' to label medieval society as a whole because, they argue, the political order and the socioeconomic life of the town—municipalized since the twelfth century—can hardly be characterized as 'feudal.' As Otto von Gierke argues in *Rechtsgeschichte der deutschen Genossenschaft* (1868), 'free union,' a new form of incorporation that formed the basis for the medieval town, was destined to 'break the feudal system.' Max Weber recognizes the medieval town as one of the factors that 'broke the restraints of the outer and inner authorities of the feudal era.' According to Marc Bloch, social relations within the town were inconsistent with the 'feudal type.' Because of its 'liberties,' its 'economic expansion,' and 'collective independence,' medieval towns remained 'foreign bodies in feudal society.' As a community in which personally free citizens with equal rights vowed their mutual solidarity by oath, the upward bound aspiring citizens became a 'destructive element for the feudal system.' Experts in the fields of law and the social sciences have recently emphasized that assuming the form of a commune, the medieval town developed a 'principle contrary to the hierarchically structured forms of domination in feudal society' (Gerhard Dilcher). Further, the medieval town proved itself to be 'a point of crystallisation for an alternative principle of legitimacy,' for a 'legitimacy by virtue of statute, not tradition and piety,' and for a 'republican, not a feudal or estate-based model of governance' (Wolfgang Schluchter). Otto Brunner, on the other hand, contends that the medieval municipality developed into 'a special configuration in the world of European feudalism.' He argues that the bond of fealty that was characteristic for the European system of governance,

'so-called feudalism,' also determined the relationship between the town lord and the municipality. In the Marxist interpretation of history, which defines the Middle Ages as 'age of feudalism,' medieval and early modern towns are referred to as 'economic and social units of feudal society.'

In order to compare and distinguish societies with different formations and structures, it is useful to have a relatively wide range of general definitions. The term feudalism is just this kind of general definition: it is a tool of historical study in the attempt to understand and describe premodern society in its entirety. This conclusion cannot be called into question or disproved by the fact that the medieval town had its own special political, social, and economic character, and therefore contributed to the transformation of the so-called feudal society into a civil society. The towns of Old Europe were not sovereign polities; they were bound up in the constitution of kingdoms and principalities. Max Weber refers to the 'feudal town lords' to whom the town council had to pledge loyalty and obedience each time the crown changed hands or new lords came to power. Weber also points out the 'feudal character' that marked the lives of urban patricians and oligarchs and makes reference to the existence of 'feudal unions' within the towns of Northern Italy and the development of a clientele at the hands of the nobility in the towns of Southern Europe. Patrician families claimed to possess the qualities of the nobility and therefore wanted to be regarded as nobility and receive the same status. The councils of late medieval and early modern towns often saw themselves as an authority appointed by God and worthy of the loyalty and obedience of the citizens. The council saw its rule as a system of command and obedience and derived its position not from a mandate of the citizens but rather from its *summa potestas*. When towns tried to increase their power by setting up territories of their own, they acted as feudal lords themselves by exercising dominion over territory and people. The different quality of the medieval and early modern town did not preclude structural elements of a feudal provenance and character. Because empirical evidence indicates that the borders between systems are permeable, it is probably justified to include the town as a special configuration in a more open concept of feudalism.

The concept of feudalism is useful as a kind of comprehensive model which draws connections between the various constituent areas of reality in a given society (politics, economics, law, social behavior, religion, and culture) in order to show and explain how these areas function independently as well as how they interplay with each other as elements in a complete social system. If the concept of feudalism is to be used in this way, then it is necessary to expand on the meaning it has acquired during its genesis with new contents. Only by formulating the concept of feudalism anew is it possible to free it from the ideological burdens of the eighteenth and nineteenth centuries

and make it useful for our current understanding of the past.

The following features can be considered as typical structural characteristics of a feudal society: (a) Understood as political feudalism, the feudal system—in view of the limited communication possibilities—provides regions in the process of expansion which are difficult to organize politically: access to the dispensation of justice, administrative services, and military protection. Organized according to feudal law, land, administrative posts, and legal rights can be equally invested and bequeathed; the result is a system of governance determined by the interplay between manorial and cooperative powers at the level of both the kingdom and the regions. (b) Political feudalism also refers to fragmentation of executive and judicial powers. During the medieval and early modern eras, a monopoly on state power in the hands of a king was—in most cases—unknown. The monarchy and the nobility divided public power among themselves. Noble lords ruled over land and people by virtue of both their own right and royal investment. Competition for power, a consequence of divided and fragmented executive power, allowed for the development of a cooperative social structure that, in the long run, contributed to the disintegration of feudal power and social conditions. The medieval town emerged only because feudalism did not represent a fully realized structural principle with regard to politics and society. Processes of social differentiation could therefore take hold in the seams and gaps of the system, thus forming a basis for the development of the town as a new kind of settlement and social form. (c) In the chiefly agrarian structured societies of early and high medieval Central and Western Europe, the territorial sovereignty practiced by kings, noble lords, and municipal cooperatives was not one of many principles structuring society, but rather the fundamental way of ordering life and was of importance for the whole of society. (d) Decisive for the organization of social life were relations of personal dependence: the vassal was dependent on his feudal lord, the client on his patron, the serf and tenant on their ecclesiastical and secular landlord, the apprentice on this master, the craftsman, homemaker, and wage earner on his manufacturer. (e) The exercise of dominion as well as the extent and range of political participation were closely connected with one's social position. The distribution of political power and social organization were closely linked. This relationship was not only an expression of legal and social inequality, but also of the absence of the division between public and private law. The medieval *societas civilis* was constituted neither as a system of social and economic needs which was separate from the state nor as a society of citizens with equal rights. (f) Medieval and early modern societies were devoid of the inherent laws of secular orders and institutions. Christianity constituted an interpretative and formative power which encom-

passed the whole of society and pervaded and regulated all realms of life. The connective and binding power of the political order was rooted in ideas and principles of the Christian religion which attribute justice and power to God. Not only did manifestations of social inequality require legitimacy in religion, but also justice, the economy, science and art, war, and peace. The social character of religion encompassed more than just works of Christian *caritas*; it also constituted a *vinculum societatis*, a kind of bond that integrated groups and unions through common convictions concerning right and wrong.

Defining feudalism involves the difficult task of comprehending and describing both the unifying and the differentiating aspects of the premodern *societas civilis*, which became thinkable as a social unity through the medieval reception of Aristotle. However, because the urban and rural societies of the Middle Ages and the Early Modern underwent various structural changes, it is crucial from a methodological standpoint to use the term feudalism in a way that makes the difference between ideal-typical model and concrete historical reality clear.

K. Schreiner

Fiducial and Structural Statistical Inference

Fiducial inference is a statistical approach to interval estimation first advocated by R. A. Fisher as an alternative to the then dominant method of inverse probability, i.e., using Bayes' Theorem. Considerable effort has gone into formalizing Fisher's notions using such concepts as statistical invariance and pivotal quantities. This entry describes elements of the fiducial approach and relates them to other currently more widely used statistical approaches to inference. Section 1 introduces some basic inferential ideas via a simple example.

1. A Simple Example

Consider a variable y that is directly available or has arisen by some preliminary reduction process and suppose that y measures θ in an unbiased manner and has error that is normal with known variance σ_0^2 . Then we can say for example that $P(y \leq \theta + 1.64\sigma_0; \theta) = 95$ percent.

Parenthetically, we note that the preliminary reduction could have occurred as part of the underlying investigation or as part of some subsequent simplification of the statistical model by one of the common statistical reduction methods, sufficiency or conditionality. If the reduction is to a sufficient statistic, then the conditional distribution describing possible antecedent data has no dependence on the parameter and the model for the sufficient statistic is used in place of the original model. If the reduction is by conditionality then there is typically an ancillary variable with a distribution free of the parameter and the given model for the possible original data is replaced by the conditional model given the ancillary (supportive) variable; see also *Statistical Sufficiency*.

With a data value y^0 the fiducial methodology would take the above probability expression and substitute the value y^0 and then treat θ as the variable for the probability statement, thus giving a 95 percent fiducial probability statement $P(\theta \geq y^0 - 1.64\sigma_0; y^0) = 95$ percent. The structural approach would consider the normal $(0; \sigma_0^2)$ distribution for the error $e = y - \theta$ and might record for example the probability $P(e \leq 1.64\sigma_0) = 95$ percent; then with data value y^0 the probability statement would be applied to the error $e = y^0 - \theta$ giving the structural probability $P(y^0 - \theta \leq 1.64\sigma_0; y^0) = 95$ percent or equivalently $P(\theta \geq y^0 - 1.64\sigma_0; y^0) = 95$ percent. In a somewhat related manner the Bayesian methodology might use a uniform prior $cd\theta$ and obtain a posterior distribution for θ that would have $P(\theta \geq y^0 - 1.64\sigma_0; y^0) = 95$ percent. For this simple example the three methods give the same result at the 95 percent level and also at other levels, thus saying essentially that with data value y^0 the probability distribution describing the unknown θ is normal $(y^0; \sigma_0^2)$.

With more complicated models the results from the three methodologies can differ and philosophical arguments concerning substance and relative merits arise. However, for one straightforward generalization the methods remain in agreement: the normal distribution can be replaced by some alternative distribution form; this is discussed in some detail in Sect. 2.

2. Fiducial Probability

Fisher (1922, 1925; see also *Fisher, Ronald A (1890–1962)*) had already introduced most of the

fundamental concepts of statistical theory, such as sufficiency, likelihood, efficiency, exhaustiveness (minimal sufficiency), when he chose (Fisher 1930) to address directly the aspiration mentioned above. He took Laplace and Gauss to task for ‘fall(ing) into error on a question of prime theoretical importance’ by adopting the Bayesian approach that ‘Bayes (had) tentatively wished to postulate in a special case’ and which was published posthumously (Bayes, *ibid*). He then proposed in a restricted context the fiducial method, as discussed.

Neyman and Pearson (1933) then gave a mathematical formulation of fiducial probability that became known as confidence intervals. Fisher (1956) however treated Neyman and Pearson’s formulation as a ‘misconception having some troubling consequences ...’; logical and philosophical arguments between the two sides were intense for many years. In particular the slight to Laplace and Gauss may well have affected the views of the more mathematical participants.

Fisher (1930) entitled his paper ‘Inverse Probability’ and examined a statistic $t(y)$ whose distribution depended on a single parameter θ . Let $P = F(t; \theta)$ be the distribution function of t , and let P itself be what we might now call a p -value for assessing θ ; of course in the usual continuous case P has the uniform distribution on $(0, 1)$. ‘If now we give P any particular value such as 0.95, we have ... the perfectly objective fact that in 5 percent of samples’ t ‘will exceed the 95 percent value corresponding to the actual value of θ ...’. Then to ‘any value of’ t ‘there will moreover be usually a particular value of θ to which it bears this relationship; we may call this the ‘fiducial 5 percent value of θ ’ corresponding to’ the given t . This led to Neyman and Pearson’s (*ibid*) confidence methodology but Fisher treated this as a misconception and he followed different directions and interpretations for the fiducial methodology; for a view on related approaches see *Estimation: Point and Interval*. For this present simple case with scalar t and scalar θ , there seems little difference between the fiducial and the confidence approaches and interpretations.

This discussion effectively ascribes a distribution to θ based on an observed t ; this is called the fiducial distribution for θ . Just as the density of t for given θ is obtained as $(\partial/\partial t)F(t; \theta)$ so also the fiducial density is obtained as $(-\partial/\partial \theta)F(t; \theta)$; the negative sign is inconsequential and is merely the result of $F(t; \theta)$ being examined typically for the case that is increasing with θ . The fiducial distribution for cases like the present can also be called the confidence distribution, which recently has a variety of uses in statistical inference. This alternative name emphasizes its more conventional role and attempts to avoid the inappropriate stigma that surrounds the fiducial concept.

For the fiducial approach in more general contexts, Fisher (1935) recommended a maximum reduction to a statistic $t(y)$ by the use of sufficiency. For example,

with a sample $y_1, \dots, y_n$ from the normal $(\mu; \sigma^2)$ distribution, the reduction would be to $t(y) = (\bar{y}, s_y^2)$. The methodology then suggests the use of a pivotal quantity $p = p(t; \theta)$ with a fixed distribution and a one-one relationship between any two of p, t, θ ; recall more generally that a pivotal quantity is a function of the variable and parameter that provides a measure of departure of variable value from parameter value, and has a fixed distribution which allows an assessment of an observed departure. Thus for the example a natural pivotal is

$$\left\{ z = \frac{\bar{y} - \mu}{\sigma/\sqrt{n}}, \quad \chi_{n-1}^2 = \frac{(n-1)s_y^2}{\sigma^2} \right\}$$

which has independent components, normal $(0, 1)$ and chi-square with $n-1$ degrees of freedom. Fisher (1956, p. 172), however, rather deviously rejected this as a legitimate part of the fiducial methodology, but he was somewhat less explicit about what would be legitimate. This pivotal reduction procedure is now however a rather familiar component of standard inference theory and in particular of confidence theory.

The final step is to invert the pivotal quantity, that is, to insert the observed values for the variables and then transform the distribution of the pivotal quantity to the parameter. For the example this gives

$$\mu = \bar{y} - \{z/(n-1)^{-1/2}\chi_{n-1}^2\}s_y/\sqrt{n}$$

$$\sigma^2 = (n-1)s_y^2/\chi_{n-1}^2$$

where the $\bar{y}, s_y^2$ have their observed values. We can then write

$$\mu = \bar{y} - ts_y/\sqrt{n}$$

where t is Student with $n-1$ degrees of freedom. This fiducial calculation closely parallels that for the confidence approach, except that the limits here are calculated from the Student distribution for μ rather than from the Student distribution of the pivotal t . In quite wide generality fiducial regions can correspond to confidence regions; it is just a matter of whether the limits are calculated before or after the data are observed, a non-issue from the Bayesian viewpoint.

There are however cases where routinely obtained confidence and fiducial regions can differ. For example, consider a sample $(y_{11}, y_{12}), \dots, (y_{n1}, y_{n2})$ from a bivariate normal distribution with means μ_1, μ_2 , variances σ_1^2, σ_2^2 , and correlation ρ , and suppose primary interest centers on the regression coefficient $\beta = \rho\sigma_2/\sigma_1$ of the second variable on the first variable. Standard regression analysis of the second variable on the first variable can produce an interval that differs

from that obtained from the joint fiducial or structural distribution for all the parameters by integrating out the unwanted parameters; see for example, Fraser (1979, pp. 189, 204, 280, and 293). Also there are other familiar cases where fiducial, structural and Bayesian methods can differ; see for example, the Behrens-Fisher and the Fieller-Creasy problems, and for some discussion see Wallace (1980).

Now suppose we generalize and examine a sample $y_1, \dots, y_n$ from some distribution with location μ and scale σ . For example the basic form $f(z)$ of the distribution might be, say, the longer-tailed logistic, or the Student with 6 degrees of freedom often cited as a realistic error pattern. The distribution for the underlying errors is then $f(z_1) \cdots f(z_n)$ and for the sample is

$$\sigma^{-n} \prod f\{\sigma^{-1}(y_i - \mu)\}$$

With a typical general error shape we do not have a simple minimal sufficient statistic as with the normal error pattern above. Fisher (1934) then recommended conditioning on an ancillary statistic and suggested the statistic

$$d_1 = \frac{y_1 - \hat{\mu}}{\hat{\sigma}}, \dots, d_n = \frac{y_n - \hat{\mu}}{\hat{\sigma}}$$

called the configuration statistic, whose coordinates are standardized residuals, standardized here with respect to maximum likelihood values. The conditional distribution of $(\hat{\mu}, \hat{\sigma})$ is fairly easily expressed in terms of likelihood. Let

$$L^0(\mu, \sigma) = c\sigma^{-n} \prod f\{\sigma^{-1}(y_i^0 - \mu)\}$$

be the observed likelihood function from data $(y_1^0, \dots, y_n^0)$, and $(\hat{\mu}^0, \hat{\sigma}^0)$ be the observed maximum likelihood values. Then the conditional distribution given the observed configuration statistic $(d_1^0, \dots, d_n^0)$ is

$$g(\hat{\mu}, \hat{\sigma} | d^0; \mu, \sigma) \frac{d\hat{\mu}d\hat{\sigma}}{\hat{\sigma}^2} = cL^0(\hat{\mu}^0 + (\mu - \hat{\mu})\hat{\sigma}^0/\hat{\sigma}, \sigma\hat{\sigma}^0/\hat{\sigma}) \frac{d\hat{\mu}d\hat{\sigma}}{\hat{\sigma}^2}$$

which can be used to give confidence intervals; also a straightforward fiducial argument following that for the normal case gives

$$L^0(\mu, \sigma) \frac{d\mu d\sigma}{\sigma}$$

for the fiducial distribution. If f is replaced by the standard normal we get the result discussed earlier and

we get it without any reference to sufficiency. This with some other results suggests (Fraser and Reid 2000) that the primary concept sufficiency can be replaced quite widely by appropriate conditioning, and with a major gain in generality of viewpoint.

Fisher (1935) did not use maximum likelihood notation for this location scale model. The notation here adapts to more general contexts (Fraser 1968, 1979) but needs to be modified if the error distribution involves a shape parameter which would then make the maximum likelihood estimates parameter-dependent.

For more general problems the fiducial can have non-uniqueness difficulties, and these tend to arise from the choice of what pivotal to use. For example with the bivariate normal discussed, different pivots can produce different fiducial distributions (Fisher 1956, p. 172, where he elusively denigrates the pivotal approach).

There are also issues connected with finding a marginal fiducial for a component parameter. For a general discussion of marginalization paradoxes connected with methodologies concerning distributions for parameters, including the Bayesian methodology, see David et al. (1973).

For a mathematical analysis that avoids some of the difficulties with the fiducial methodology, see the transformation group framework in Fraser (1961a, 1961b); this mathematical analysis led to the development of the structural approach described below. The marginalization issues still remain, however, and this is related to the common assessment technique of examining a procedure with many repetitions from the same distribution with fixed parameter value. Alternatives to this are suggested in Fraser and Reid (2000).

3. Structural Probability

In many applied problems it is possible to ascribe an underlying error distribution to the model. For example with measurements that are normal with unknown error scaling we might write

$$y_i = \mu + \sigma z_i \quad i = 1, \dots, n$$

where the $z_1, \dots, z_n$, are independent standard normal variables. If we then examine (Fraser 1966) these expressions with observed data we can note rather easily that many characteristics of the underlying realized errors can be numerically evaluated. Specifically, let

$$d_1 = \frac{y_1 - \bar{y}}{s_y}, \dots, d_n = \frac{y_n - \bar{y}}{s_y}$$

be standardized residuals; then the observed $y_1, \dots, y_n$ and the underlying realized $(z_1, \dots, z_n)$ have the same standardized residuals. In fact, $n-2$ characteristics as presented by the residuals are available concerning the

underlying errors. Most theory concerning applications of probability would then say the analysis should be conditional on these observed characteristics, that is, on what you know concerning the realized error (Fraser 1976, Chap. 4, pp. 161–2 and Chap. 11, pp. 456–66). This for quite general problems automatically gives the conditioning used by Fisher and avoids the need to invoke a conditioning principle and seek an ancillary such as the configuration statistic.

This present type of analysis carries through equally (Fraser 1966) if the normal distribution is replaced by some other error pattern. The conditional error distribution can be viewed from an invariance argument as being valid after the full data are observed. This distribution then gives the structural distribution for μ and σ . The mechanics follow closely what is presented for the fiducial case and the resulting structural distribution agrees with the fiducial distribution, $L^0(\mu, \sigma)d\mu d\sigma/\sigma$. The difference here is that a rather strict invariance structure is assumed as part of the argument. This is summarized in general notation.

The structural approach is possible in cases where the underlying error can be directly modeled and the observed response is obtained as some transformation of this. Let Z designate a general error variable with known density $f(Z)$ on say R^n . Let Y designate the response as obtained by a transformation or re-expression θ in some space Ω . Then we have

$$Y = \theta Z, \quad f(Z)dZ,$$

For the invariance we assume that a transformation θ carries R^n into R^n and that the collection Ω of such transformations is closed under composition and inversion. Also for details here we assume that the transformations are smooth and at most one transformation carries a point Z into a point Y . For some general background on transformations and invariance, see *Causal Inference and Statistical Fallacies*.

If we consider all the transformation Ω and apply them to a data point Y^0 we obtain a set ΩY^0 of images, of possible antecedent error values. If Z^0 is the unknown realization of error that produced Y^0 then we have $\Omega Z^0 = \Omega Y^0$ or equivalently we have that Z^0 lies in the set ΩY_0 . This means that a probability assessment should be made conditional on the observed set ΩY^0 . Let $D(Z)$ be a reference point in the set ΩZ and let $[Z]$ in Ω be the transformation in Ω that carries $D(Z)$ to Z . Then we have that the model $Y = \theta Z$ with data Y^0 can be rewritten as

$$[Y] = \theta[Z], \quad D(Y) = D^0,$$

giving the conditioning $D(Y) = D(Y^0) = D^0$ that appears as an observed ancillary in the fiducial framework. The conditional distribution of $[Z]$ given

$D(Z) = D^0$ then describes the reduced model $[Y] = \theta[Z]$ with data $[Y^0]$. The structural distribution of θ is then given as $\theta = [Y^0][Z]^{-1}$ using the conditional distribution $[Z]$ just described.

In most contexts the support measure dZ can be replaced by an invariant measure $dM(Z)$

$$dM(Z) = \frac{dZ}{J(Z)}$$

where $J(Z)$ is an appropriate Jacobian (Fraser 1979). Expressions are simpler if we use density $\bar{f}(Z)$ with respect to the measure $dM(Z)$: $\bar{f}(Z) = f(Z)J(Z)$.

The distributions of $[Y]$ and $[Z]$ conditional on $D(Y) = D(Z) = D^0$ are

$$c\bar{f}(\theta^{-1}[Y]D^0)d\mu[Y], \quad c\bar{f}([Z]D^0)d\mu[Z]$$

where $d\mu[Z]$ is the corresponding invariant measure on the group Ω . The inverted distribution, called the structural distribution for θ , is

$$c\bar{f}(\theta^{-1}[Y^0]D^0)dv(\theta) = cL^0(\theta)dv(\theta)$$

using the right invariant measure ν on the group Ω . In the Bayesian context the typically preferred noninformative prior is the right invariant measure $dv(\theta)$. Thus the structural distribution coincides with this preferred Bayesian posterior.

This group type model covers a wide range of regression multivariate and spherical distribution models but not in the simplified notation used here; for further details see Fraser (1968, 1979).

Recent likelihood asymptotics has been able to obtain many aspects of these results in a general asymptotic context; see Fraser et al. (1999) and Fraser et al. (1999).

4. Comment

Fiducial inference led to confidence intervals, with both having evolved from the Bayesian procedures initiated in the eighteenth century. In terms of freedom of usage, we have Bayesian inference as the more liberal. The foundational issues center on validity and interpretation of the probabilities for the parameters. Here the conditions are strictest for the structural and minimal for the Bayesian. In the nice cases they agree; and in the less standard cases they pressure the proponents to clarify their assumptions.

For some recent discussion of confidence and fiducial interconnections plus references see Barnard (1995), with complementing views in Fraser (1996). Also see Fraser and Reid (2000) for a discussion of the interplay with objective Bayesian methods.

Field Observational Research in Anthropology and Sociology

Field observational research in anthropology and sociology—or the process of doing ethnography—brings the social science investigator directly to the

scene of the human behavior she or he describes. It involves ‘being there,’ or ‘I-witnessing.’ So also, of course, do other forms of documentation: journalism, film, travel writing, explorer or missionary’s report, even background research by a novelist. What makes ethnography distinctive as a research practice is that it forms one point of a triangular process of knowledge construction which also includes comparative social theory and documentary contextualization.

The fieldnotes that result from ethnographic discovery procedures are not merely ‘written up,’ but are filtered and interpreted against theoretical propositions and the comparative record of other field observational studies; they are also grounded and enhanced by historical, ecological, demographic, economic, and other documentary sources that provide background and context. As the products of this mode of research are read—monographs and articles also referred to as ethnography—they stimulate new comparative theoretical thinking, which in turn suggests further problems and interpretations to be resolved through more field observational research. Ethnographies also regularly lead to new demands and rising standards for documentary contextualization—more history, more ecological or demographic backgrounding, more attention to state policy, economic trends or the world system. This triangle of ethnography, comparison, and contextualization is, in essence, the process by which field observational research in anthropology and sociology is utilized to explain and interpret human cultures and social life.

1. History and Scope in Anthropology and Sociology

In 1851 Morgan published his *League of the Ho-de-no-sau-nee, or Iroquois*; combining fieldwork and comparative and theoretical interests in political organization, this book was the first anthropological ethnography. It depicted the structure and operation of Iroquois society, detailing matrilineal kinship, political and ceremonial life, material culture and religion. After formation of the US government Bureau of American Ethnology in 1879, a stream of ethnographic accounts of native American societies began, including landmark field observational studies of the Zuni by Cushing, the Baffin Island Inuit by Boas, and, after 1900, ethnographies of Plains, Eastern Woodland, and California groups by Boas’ students trained at Columbia University. During the 1930s the scope broadened to include rural and urban studies in Latin America, the Caribbean, Africa, and Europe, and also in contemporary US settings.

In Great Britain’s colonies, local government official or missionary fieldworkers followed the topical guidebook *Notes and Queries on Anthropology*, drafted by Oxford University theorist Tylor and others, and first published in 1874. This armchair scholar/man-on-the-

spot division of labor ended two decades later when Oxford-trained Spencer collaborated in field observational study with local expert Gillen, producing their *Central Tribes of Native Australia* in 1899, and providing detailed coverage of cosmology, ritual, and social organization which revealed unheralded complexity, and which sparked theoretical work by Durkheim and Freud. In 1898 a team from Cambridge University conducted fieldwork in Torres Strait north of Australia, and member Rivers used genealogical data to probe community history, migration trajectories, marriage patterns, demography, and inheritance. Rivers and his students conducted further ethnographic studies in India and the Pacific, but their work was eclipsed by the more thorough Trobriand Islands field observational research of Malinowski, resulting in *Argonauts of the Western Pacific* in 1922 and its famous first chapter on method. Malinowskian ethnography dominated British social anthropology thereafter, and by the 1940s reshaped American cultural anthropology as well.

In sociology, there is less agreement about the disciplinary origin of field observational research methods. Conventionally, the monographs of the University of Chicago department during the 1920s and 1930s are cited (Madge 1962): studies of itinerant 'hobo' workers, youth gangs, dancehall employees and patrons; Italians, Poles, Jews, French Canadians, Mexicans, and Chinese; and central city 'gold coast' apartment, artist colony, and rooming house dwellers. Two decades before this research, however, Du Bois used similar methods (both he and the Chicago school were inspired by British and American urban survey and settlement house movements) to produce *The Philadelphia Negro* (1899), which depicted life in an inner city neighborhood comprised of southern migrant and northern-born African-Americans. Even earlier, Engels in 1844 studied new classes, Irish labor migration, urban spatial arrangements, symbolic attachments, and modes of observable behavior in Manchester and other rapidly industrializing British cities, although his *Condition of the Working Class in England* was not published in English until 1892.

Since the 1920s there has been much cross-fertilization between anthropological and sociological ethnography. A few of the Chicago studies were conducted by researchers identifiable as anthropologists, and the Lynds, authors of *Middletown* (1929) which credits anthropologists Rivers and Wissler for methodological inspiration, and Whyte, author of *Street Corner Society* (1955 [1943]) and influenced by Harvard anthropologists, are presented as major figures in the development of American sociology (Madge 1962). Gluckman, a Manchester social anthropologist whose fieldwork was conducted in Africa, was influential in the development of ethnographic fieldwork by British sociologists working in schools, gangs, and factories during the 1950s and later (Burgess 1984). In recent decades, both anthropol-

ogists and sociologists have undertaken field observational research in a wide range of overlapping settings, at home and abroad; so increasingly do scholars from folklore, education, environmental psychology, political science, and other disciplines. Ethnography, however, remains central to credentialing, teaching, publishing, and theory-construction in anthropology, while it occupies a more marginal position in contemporary sociology, or in other fields.

2. Selection, Access, Rapport

The selection of a particular population or site for field observational research is ordinarily related to some unanswered question or outstanding problem in social theory. Personal connections or predilections of researchers also shape this selection, but the fieldworker must justify his or her choice in terms of some significant theory to which the project is addressed. Usually this is made explicit in a written proposal for funds to underwrite the fieldwork.

While ethnography is thus lodged from conception in social theory, a comparative viewpoint also molds the fieldwork process. First, investigators acquire a cross-cultural or cross-site perspective by training and reading; when addressing any aspect of social life—marriage, leadership, ethnicity, etc.—field observational researchers recall examples of similarities and differences elsewhere. Second, the comparative perspective focuses attention on trends and transitions, not just on similarities and differences at random (which are infinite). Rather than treating each fieldwork case as unique, ethnographers place the social phenomena they study within comparative frames (foraging, horticultural, agricultural, pastoral, industrial, colonial, neocolonial economies; cooperative, competitive, individualistic societies; gender subordination, complementarity or equality; etc.) Ethnographic results in turn provoke debate, revision, and innovation in such theorizing.

While significant theories bring fieldworkers to particular locations, actors, and activities, once they arrive they begin to observe and listen. Often they must learn to listen—by learning the language, the local vocabulary, and current verbal conventions. Field observational research now turns away from theoretical discourse to the viewpoints and concepts of the people (informants, subjects, actors, consultants) themselves. Ethnographers aim to document how the people see and talk about their everyday social activities and groupings, and about the wider worlds they live in. It is their normal scenes of activity, topics of conversation, and standards of evaluation that are the objects of field observational research.

This does not begin by announcing: 'I'm your ethnographer; when can I interview you?' Investigators must be honest about their role and sponsorship (covert field observational research remains contro-

versal and rare), but their paramount aim is to listen and to move as quickly as possible into the natural settings of social life, the places people would be, doing what they would be doing, if the ethnographer was not there. This involves a continuing process of requesting and obtaining access to the many locations, activities, and groups that comprise the overall fieldwork arena. As ethnographers observe and listen in a wide-ranging manner, within parameters set by the significant theories that bring them there, they begin to understand culturally meaningful behavioral conventions, and to formulate culturally appropriate utterances. This indexes a second continuing process of building interpersonal rapport with informants, a topic that preoccupies many autobiographical accounts of field observational research—one of the most instructive being Whyte's 1955 [1943] Appendix to *Street Corner Society*.

As the ethnographic process unfolds, the fieldworker must constantly make decisions about where to be, whom to listen to, what events to follow, and what to safely ignore and leave out. These decisions are guided both by the significant theories prefiguring fieldwork, and by new theories of significance that arise in the field. These latter theories—hunches, hypotheses, ideas about connections and relationships—emerge as listening and observation proceed. They suggest which persons and activities to focus upon, what places and events to attend to, and which objects and their circulation to follow. As this occurs, the fieldwork 'funnel' narrows, to use Agar's (1980) apt metaphor. The early phase of securing access and building rapport is wide, open, and nearly all-encompassing; as theories of significance emerge, pan out, or are discarded, the funnel of informants, events, and activities narrows. Goals crystallize. Research design sharpens.

3. *Discovery Procedures: Listening*

Ethnography's greatest strength is situated listening. Interviews become useful at later stages of fieldwork, but field observational research begins by listening to what British anthropologist Richards (1939) called 'speech in action.' Here the actors control topicality—talking to each other about what they usually do—and the researcher secures access to their turf—the locations they usually occupy. Early on, as rapport begins to be established, fieldworkers deliberately place themselves in a wide sampling of such situations. Then, as the research funnel narrows and other methods are deployed, the ethnographer becomes more selective about where to listen.

The importance of situated listening was emphasized memorably by Whyte. After he asked an intrusive question during illicit gambling activities, and stopping the ongoing flow of behavior, Whyte's key

informant Doc told him, 'Go easy on that "who," "what," "why," "when," "where" stuff, Bill. You ask those questions and people will clam up on you. If people accept you, you can just hang around, and you'll learn the answers in the long run without even having to ask the questions.' 'I found that this was true. As I sat and listened, I learned the answers to question that I would not even have had the sense to ask if I had been getting my information solely on an interview basis' (1955 [1943], p. 303).

Situated listening becomes the basis for understanding both what can be talked about in later conversations and interviews, and what categories and evaluations the actors use to observe and interpret ongoing behavior.

4. *Discovery Procedures: Observing*

Many veteran field observational researchers bristle when they are told that their methods are not quantitative. Using both emic categories articulated by the actors, and etic categories formulated by the community of social science observers, ethnographers count, sample, and calculate ratios, proportions, and probabilities as part of their fieldwork activities (Johnson 1978). These countable quantities include numbers of people in events, their positions, their comings and goings; objects, inventories; and exchanges, movements, orderings, sequences, associations, assemblages, and arrangements of many sorts.

Malinowski's classic *Argonauts of the Western Pacific* (1922) incorporated his numerous observations of the interisland *kula* exchange of seashell valuables—necklaces traded for armlets—as canoes from one community arrived at another, exchanges were conducted, and then additional exchanges of items including foodstuffs, timber, greenstone, and pottery followed. Who exchanged what, the order, etiquette, volume, frequency, and other variables were all counted and analyzed. In Whyte's *Street Corner Society* (1955 [1943]) the size, composition, duration of activity, and initiation of interaction were recorded and analyzed for numerous group events; Whyte even demonstrated quantitatively a relationship between hierarchical group leadership structure and bowling scores.

Harris (1964) furnishes field observational researchers with an etic model of 'the great stream of uninterrupted behavior' that extends backward in time and unfolds continuously. He provides a technical vocabulary to operationalize recording of isolatable events and linked segments of the behavior stream—from individual body movements and their environmental effects at the most basic level, through sequences of multiactor scenes connected by actor, place, or object. Sanjek (1978) applied this approach in a multiethnic Ghanaian urban neighborhood to

collect (through interviews) sequences of multiactor scenes for 40 adults, each over four-day periods, in order to test whether their social networks were structured more by common ethnicity or by class position, and in which behavioral settings ethnicity and class were stronger or weaker.

Johnson (1975, 1978) developed an observational fieldwork approach to formulate statistically valid time allocation patterns in his research among the Machiguenga of Peru. By randomly selecting actors and times for observation at their most likely location, and recording their ongoing behavior at the time of each random visit, a powerful quantitative record of how a given population allocates its activities among production, reproduction, leisure, and other categories resulted. This and similar methods have been employed in a wide range of fieldwork settings (Gross 1984).

5. Discovery Procedures: Interviewing

Barth recounts of his highland New Guinea research, 'My field procedure was ... to rely very heavily on observation of spontaneous, unelicited word and act. I paid particular attention to this in Baktaman questions and explanations *to each other*—in men's houses, in the fellowship of hunting and working, during initiations and other rites. Only secondarily, and with much reticence, did I ask my own questions, and then only when they seemed cast in a native pattern and received easy and natural response' (1975, p. 226).

Interviewing is problematic (Briggs 1986). Human beings are apt to reinterpret or reformulate the past to make it conform with their ongoing sense of the present. Moreover, the ever present danger of an observer effect in fieldwork—that the presence of the observer affects and reshapes an actor's behavior and response—is especially difficult to control in an artificial one-to-one interview situation where normal social activity is suspended. Still, interviews are essential to field observational research. They are best left for later stages of the ethnographic encounter when, to use Agar's funnel metaphor, the speech events of fieldwork move from wide and open to narrow and more focused.

After the investigator has become at ease with the language and local codes and references, and has successfully gained access to natural conversations and amassed a stock of cultural knowledge via situated listening, deliberate intervention into speech events may begin. These steps may be graded from least to most intrusive and controlled.

(a) Still on the informants' turf, and still in the accustomed activities of daily life, the field observational researcher begins to enter natural conversations as a speaker, and begins to shift topicality to

her or his own interests. This process starts gently, by moving appropriately into rounds of chatting, gossiping, and ordinary comment. As cultural competence increases, and as theories of significance emerge, the fieldworker attempts to direct conversations by introducing questions and suggesting topics for responses from informants.

(b) After an initial period of fieldwork—a few months perhaps—arranged interviews may begin. This class of speech events is disruptive—the informant is removed from her or his turf, either to the ethnographer's household or office, or by transforming an everyday location into a scene of ethnographer–informant dialogue—an activity that would otherwise not be occurring there. Typically the earliest of these deliberate breaks in time–place behavioral flow reserve topicality for the actor. In such open-ended or discovery interviews, the informant is encouraged to move the conversation according to his or her own interests.

(c) In later and more productive interviews, the ethnographer begins to assert control. General topics are introduced, allowing informants to expand freely upon their own points of view and knowledge. In more structured ethnographic interviews, topicality is more firmly shaped and directed by the fieldworker; informant responses now move away from orations and free commentaries and to more specific responses to questions.

(d) In the most focused forms of interviewing, the ethnographer controls both turf and topicality as fully as possible. Questionnaires and interview schedules may be used, and the objective is to obtain particular types and pieces of data. These may include household interviews, psychological tests, or reports of disputes, or may encompass repeated interview sessions to secure lengthy life histories, with the fieldworker now guiding the subject according to preset standards of scope and comprehensiveness.

(e) Though not a major part of ethnographic practice, in some instances, and when still on the informants' turf, the fieldworker may ask direct and pointed questions, and attempt to secure precise pieces of data for his or her records. Interventions of this sort are especially dangerous—the inappropriateness of such seizures of topicality in everyday settings may be jarring to the actors. Typically speech events of this sort occur in the final days of fieldwork, when local rapport is at its peak, research goals are most pressing, and the fieldwork funnel approaches its vanishing point.

6. Notes and Records

The production of notes and records (Sanjek 1990) begins to move the field observational research process toward its ultimate written products. Focused in-

interview sessions with seated informants often permit direct transcription of verbal statements, but in open-ended and ethnographic interviews, brief written notes—what Ottenberg (in Sanjek 1990) terms scratch notes—are taken during the session, and these form the basis for the construction later of fuller written fieldnotes. Fieldworkers often go through this two-step process even when interviews are tape recorded, both as a backup to and index of the taped session, and because of the analytic gains many ethnographers note in transforming their scratch notes into fuller descriptive fieldnotes.

In field observational research in natural behavior stream settings, similar brief jottings may be inscribed, but major attention is directed to the event in progress. Often it is not even possible to record scratch notes, and both they and fuller fieldnote description occur later. Mead (1977) wrote about the nagging pressure to type up fieldnotes from scratch notes, and about the danger of scratch notes growing 'cold' when this was delayed, even by one day. But she also wrote of the satisfaction of being caught up with this work, and of the importance for later ethnographic writing of the insights gained in moving from scratch notes to descriptive fieldnotes.

Ottenberg sees this process as the interaction of scratch notes and headnotes—the stored memories and interpretations that arise from direct participant observation as filtered by the ethnographer's overall theoretical stance. Headnotes form an essential complement to fieldnotes (and to more formal fieldwork datasets or records). Headnotes are employed to make sense of one's fieldnotes when they are re-read later for ethnographic writing projects. The importance of headnotes is particularly evident when one ethnographer attempts to use another's fieldnotes, and quickly realizes how difficult it is to understand them without headnotes of one's own (Sanjek 1990).

Fieldnotes typically are kept in running chronological order, and may minimally be indexed separately by actor and topic. Additionally, field observational researchers often generate records, or well-defined sets of data organized by topic, person, or other category. These may include records of household composition, land holdings, ritual performances, life histories, folktales, etc. Sometimes decisions to collect sets of records are part of the initial research design, and preset forms to enter such data may be brought with the investigator to the field setting. In other cases, a decision to collect a systematic body of records develops during fieldwork, often emerging within general running fieldnotes and then being separated out in new record files.

Fieldnotes and records present ethnographers with great masses of information—hundreds, even thousands of pages—that while being accumulated may be arranged only by chronological order or by topic. Malinowski (1922) urged that ethnographers constantly re-read and begin to organize and analyze their

notes while still conducting field research, but commonly the more focused work of indexing them occurs when fieldwork is over. As ethnographers then turn to ethnographic writing, they readdress the theoretical discourse they turned away from in fieldwork. Fieldnotes and records must now be related directly to the comparative and contextual points of the knowledge-construction triangle.

7. *Canons of Validity*

Field observational research aims to maximize validity—'the degree to which scientific observations actually measure or record what they purport to measure'—rather than reliability—'the repeatability, including interpersonal replicability, of scientific observations' (Pelto and Pelto 1978, p. 33). Reliability is valued in survey, medical, and product safety research. In ethnography, restudies to assess change may be conducted, but independent investigation of the same locale or population is unlikely or impossible.

Validity depends on the intensity and depth of field observational research, but it always remains a goal rather than a property that can be independently measured (Wolcott 1995, pp. 167–70). A quantitative, and highly reliable, randomized sample study that investigates the gender, ethnicity, class, and other characteristics of the five best friends of members of a given population would be less valid than one in which cultural meanings and categories of friendship were first discovered through listening to natural conversations or eliciting such information in interviews. In the case of Indian immigrants in New York City, for example, the 'five best friends' study might miss entirely the category of *rakhi* ritual friendships between adult males and females which are affirmed in an annual festival where the man ties a flower bracelet on the woman's wrist.

If validity remains important, but elusive, how can it be assessed in field observational research results? Sanjek (1990, pp. 393–404) proposed three canons of validity by which ethnographic writing may be evaluated. The first is theoretical candor, the openness with which the ethnographer addresses the significant theories, and even more, the local theories of significance that structured the fieldwork process. A second canon calls for explicit depiction of the ethnographer's fieldwork path—the number of informants from whom information was obtained, in what ways, and their relationship both to the wider population the field observational study concerns and to each other. A third canon concerns information about the fieldnote evidence itself: not simply 'how much' and its basis in listening, observing, or interviewing, but more significantly the precise relationship of notes and records to the written ethnography. Some ethnographies utilize fieldnotes directly, even masses of them; others, for rhetorical or narrative purposes, do

not, and need not. What matters in the end is that readers of field observational research have a clear picture of what the ethnographer did and why, who they talked to and learned from, and what they brought back to document it.

Field observational research produces results that can be obtained in no other way. This ethnographic tradition entails that 'the description of people's activities, their interactions with each other, [and] their verbal behavior' be 'copious and detailed'; 'cumulative development ... consists above all in the fact that such data, provided they are adequate, never become obsolete and can be used by analysts ... in researching questions not visualized by the researchers who collected them' (Anglin 1979, p. 49).

Fieldwork: Ethical Aspects

Fieldwork involves a range of methodologies including ethnographic participant observation, in-depth interviews, direct observation of individual or group behavior, or a combination of both qualitative and quantitative approaches (Denzin and Lincoln 1998). Social scientists conducting fieldwork confront unique ethical dilemmas in the course of implementing their investigations, particularly when researchers are actively engaged with participants in their natural environments. Ethical dilemmas occur when there are conflicts about what is considered to be an appropriate response to a situation involving the investigators, research participants, or the production and use of research materials. A full treatment of these issues is beyond the scope of this paper. This article briefly explores ethical issues associated with informed consent, the protection of confidentiality, the development of personal relationships with research participants, involvement in illegal activities, and intervention in on-going social activities. Finally, a framework for resolving ethical dilemmas in fieldwork is outlined.

1. Informed Consent

National and international guidelines for ethical conduct in research with human subjects identify specific requirements for informed consent: the provision of information, comprehension of information, and voluntary participation (Faden and Beauchamp 1986, Weissstub 1998). Voluntary participation in research depends upon the individual's ability to understand not just the meaning of the research, but the impact it may have on his or her life. Excessive financial compensation or unrealistic promises may constitute coercion, especially if someone is vulnerable because of social factors such as poverty or ethnic background. Voluntary participation may be inhibited when there are social status and social class differences between fieldworkers and research participants—differences based on gender, age, education, income level, religious affiliation, and ethnic identity. The institutional affiliation of the field researcher may also pose a threat to participants. Additionally, the fluid and unbounded nature of many social science field studies complicates

the straightforward approach to informed consent associated with other forms of social science methodologies.

A number of factors influence informed consent in fieldwork—the specific goals of the research, the cultural context of the research project, and communication issues that influence comprehension of information. In international settings, the challenges associated with implementing informed consent in fieldwork are heightened because of language barriers that may inhibit effective communication, particularly regarding the translation of scientific concepts. Misunderstandings and miscommunication about social science research are more likely to occur when fieldworkers and participants speak different languages. Language barriers may be reduced through the use of an interpreter. However, translators must negotiate not only language, but also cultural and contextual factors. Some of the problems associated with interpretation in social science fieldwork include: the inability to translate equivalent expressions easily across languages; paraphrasing that results in omissions or erroneous substitutions of terms; varying levels of comprehension; and the influence of conflicting cultural beliefs and values concerning the meaning and purpose of research.

Differences in beliefs about who has the authority to give permission to participate in research also influence the consent process. Beliefs about personhood, individual autonomy, and decisional capacity are embedded within the social and cultural patterns of family ties and community obligations. In Western industrialized nations, where personal autonomy is emphasized, research participants are expected to make decisions for themselves or through designated surrogates. However, in many non-Western settings, religious or tribal leaders or a person's extended family may play a significant role in decisions concerning research participation. Cultural differences in beliefs about the nature of personhood and the location of decisional authority for consent have been problematic for social science investigators conducting fieldwork in international settings (Levine 1991). Negotiating informed consent with designated authorities in non-Western populations requires fieldworkers to move beyond narrow definitions of personhood, autonomy and self-determination. While respect for persons demands cultural sensitivity to local customs, social scientists conducting fieldwork are never authorized to conduct research without regard to potential harm and without attempts to be informative throughout the duration of the study (Levine 1996). Moreover, although a tribal chief, village elder, or community leader may express approval of a research agenda, sensitivity to cultural customs is secondary to honoring individual choice regarding participation (World Health Organization and the Council for International Organizations of Medical Sciences 1993).

1.1 Informed Consent in Observations of Group Interactions

In fieldwork involving direct observation of group activities, arrangements usually are made prior to initiating the study to inform group members that the fieldworker will be present in the course of routine activities. In closed systems such as a hospital unit, a community center, or other institutional setting, informed consent should be obtained from all those who are at the facility on a regular basis. Individuals who are not present on a regular basis but whose behavior may be observed in public group activities should be alerted to the presence of the fieldworker if it is feasible to do so. In some group observations conducted in the course of fieldwork, it may not be possible or necessary to obtain informed consent from every person present. For example, at informal gatherings such as family or community events, or in public places where individuals interact informally, it would be intrusive for the fieldworker to explain the study to everyone present.

2. Protection of Confidentiality

Protection of confidentiality and privacy for research participants is an important aspect of fieldwork (Cassell and Jacobs 1987). Fieldwork in social science investigations often involves the collection of sensitive information concerning an individual's personal life, including information on physical conditions, mental illness, or behavior regarding illegal activities. Individuals or communities could be harmed if information was inadvertently or purposely disclosed. In some cases, information could be used to ostracize or marginalize research participants, particularly if research participants suffer from a stigmatizing illness such as HIV/AIDS, or if they are involved in activities that may be viewed as socially deviant.

Data collection strategies associated with fieldwork require careful attention to the representation of individuals and communities in written transcripts derived from interviews and observations (Fluehr-Lobban 1991). Descriptive data recorded in field notes, daily logs, or diaries should be entered using a coding system that protects the confidentiality of the research participants. Additionally, field data should also be secured outside of the research setting in order to safeguard the identity of participants. Pseudonyms, rather than the names of participants, must be used in published manuscripts that include case narratives. This gesture, however, will not necessarily protect confidentiality because it may be possible to identify the individuals involved based on the details of the case and the research setting. Nevertheless, at each stage of the research—data collection, data analysis, and data reporting—every effort should be made to protect the privacy of the study participants. In

obtaining informed consent, investigators are obliged to advise participants in fieldwork about the methods designed to protect their privacy.

3. Relationships with Research Participants

Social scientists involved in fieldwork have the opportunity to form close personal relationships with research participants because of the collaborative nature of ethnographic approaches such as participant observation. The development of trust between fieldworkers and the individuals involved in the research enhances the potential for collecting important information relevant to the study. However, in some circumstances, investigators may find themselves in compromising situations because of their personal relationships in the field.

3.1 Intimate Relationships

Although it is rarely addressed in the literature (for an exception, see Kulick and Willson 1995), fieldworkers may become intimately involved with research participants. Sexual relationships with field participants are more likely to occur in the context of extended fieldwork. Traditional anthropological fieldwork—where the investigator may spend months or years in an environment far removed from familiar social networks (often in a different country)—represents the type of setting that contributes to the development of intimate personal relationships with research participants. Despite what some might view as the natural inclination to form a sexual attachment with a close companion, the prevailing opinion among social and behavioral scientists is that sex with participants in the field should be avoided. Sexual relationships between researchers and study participants may diminish the relative objectivity of the investigator.

More problematic is the potential for coercion of socially vulnerable individuals. Moreover, attitudes concerning sexual behavior are socially constructed and the meanings attached to sexual intimacy may vary significantly between the fieldworker's home community and the research setting (Singer et al. 1999). The social complications that can result from a sexual relationship (e.g., jealousy, accusations of infidelity, gossip) jeopardize the integrity of the research and place the investigator at risk for problematic interactions with the broader community.

3.2 Illegal Activities

Investigators conducting fieldwork with populations such as illegal immigrants, or with individuals involved

in activities such as drug use or the sex trade, may be asked to participate in behavior that is legally questionable. For example, fieldworkers investigating the use of illegal drugs may be asked to share drugs with study participants or to assist in procuring or holding drugs or drug paraphernalia. While some researchers may believe that participation in these types of activities strengthens the bonds of trust between a fieldworker and research participants and thus increases the likelihood of securing information that is meaningful and necessary to achieve the study goals, there are strong reasons for avoiding participation in illicit or illegal behavior. As with sexual involvement with study participants, engaging in illegal activities seriously threatens the integrity of study findings and places the researcher at risk socially, professionally, and in some cases, physically. Fieldworkers may find themselves targeted for blackmail or other forms of coercion. Additionally, fieldworkers who participate in illegal behavior diminish the potential to secure funding for future research. A full consideration of the ethical dimensions of involvement in illegal activities cannot be explored in this essay.

4. Fieldworker Intervention in Ongoing Social Activities

Questions concerning the intervention of a fieldworker in problematic situations that occur in the course of conducting research are challenging. The fieldworker's decision should be a judgment based on the purpose of the study, the context, and the specific event that occurs. When investigators continually intervene in field situations that are directly related to the issue being investigated, the possibility that their research will have an impact is jeopardized since they would be unable to document the events being studied. For example, fieldwork with injection drug users to investigate HIV risk behavior would be inconclusive if researchers attempted to stop practices known to facilitate the transmission of the virus. The fundamental problem is one of advocacy—when to be an advocate for research participants and when to maintain the more circumscribed role of the investigator (Bosk 1985). In general, non-intervention is the accepted mode for fieldwork.

5. Recommendations for Resolving Ethical Dilemmas

Investigators who confront moral dilemmas in the course of conducting fieldwork must consider carefully the full range of issues involved in the problem. A systematic approach to ethical decision-making begins with a robust description of the research dilemma.

This would include details about the purpose of the study, the research design, the sponsors of the study, and the individual participants and community involved in the research. The researcher then must consider the cultural and social values represented in the ethical problem. The relevant values of the study participants, the study community, the professional community, and the study sponsors should be outlined. The researcher must determine the principal value conflict. At this point in the process of decision-making, the fieldworker should consider whose values are threatened and who are the most vulnerable to potential harms. This process of reflection facilitates the identification of the key issues involved in the ethical dilemma. When the primary ethical issues are determined, the investigator should outline a full range of strategies and consider the potential risks and benefits associated with each solution. The decision regarding a course of action should maximize respect for the individual and group values identified. The vulnerability of research participants and the communities within which they live should be of paramount importance in resolving the ethical dilemma encountered.

Fieldwork in Social and Cultural Anthropology

1. Origins of a Method

Fieldwork is a term which has been employed for nearly a century by social/cultural anthropologists, for their major methodological tool and a profound professional experience that leaves its mark on their lives throughout their careers. It designates a complete concentration on observations in their chosen site of research, for a considerable period of time, usually of no less than six months and up to a few years. Originally, that engagement involved a total separation from the researcher's ordinary life, and his/her immersion into a remote and alien social environment. Anthropological fieldwork is known also as the 'ethnographic method.'

The idea of fieldwork owes its origin to the interests of scientists at the turn of the nineteenth century concerning the evolution of the human species, as much as to the expansion of European colonialism that brought under its rule vast territories inhabited by unknown 'exotic' peoples. But no less, that movement coincided with a growing awareness in the United States about the vanishing cultures of native Americans. The new science of anthropology that intended to satisfy these interests was at its first stages mostly speculative, based on secondary sources of data, collected by missionaries, traders, colonial administrators, travelers, adventurers, etc. The practice of pre-fieldwork anthropology was nicknamed 'arm-chair anthropology.' Its most celebrated, as well as discredited representative, remains James Frazer whose monumental work was all based on library material.

The invention of fieldwork as the characteristic method of anthropology, as well as of its corollary aspect of 'participant observations,' has often been attributed to Bronislaw Malinowski, the British–Polish scholar, who is also considered among the founders of the school of functionalism in anthropology. His claim to fame as fieldworker is based on his long stay, of more than two years, during World

War I, among the Trobriand Islanders. Although he was not the first to employ the method engaging participant observation, nevertheless, his linguistic skills, the meticulous ethnographies he produced, and the introductory chapter on his method of inquiry that opened his most famous work (*Argonauts of the Western Pacific* 1922) have become the hallmark and quintessential model of fieldwork for almost half a century.

The fieldwork projects carried out by Malinowski, his colleagues, and the later generations of younger anthropologists entailed observations of the minutiae of everyday life in the various domains of social behavior and cultural traditions. In sum, it was supposed to record the totality of the social experience in the studied society. The essence of fieldwork was encapsulated, for example, in the following statements by representatives of three generations in British anthropology:

This goal is, briefly, to grasp the native's point of view, his relation to life, to realize *his* vision of *his* world (Malinowski 1922, p. 25).

First, in my estimation, is the point that fieldwork in the empirical mode remains the *sine qua non* both for the testing of theory and, what is more important, for making new discoveries (Fortes 1978, p. 24).

'Good' fieldworkers are those who are prepared to have good 'trips,' that is, suspend as far as possible their own social conditioning in order to have sensory and mental knowledge of what is really happening around and to them (Turner 1985, pp. 205–6).

In the United States, the method of ethnographic fieldwork was initiated by Franz Boas and his students most of whom had until World War II concentrated their work in the not too far away reservations of Indian tribes. Their trips to the fields of research had rarely involved a long departure from their ordinary life and work. They were also far more dependent on key informants who provided them with data on specific subjects. Consequently, they were not as deeply engaged in the routine of everyday life of the people they studied. The ethnographies by Ruth Benedict are good examples of the achievements and deficiencies of the tradition of short fieldwork trips and reliance on informants. Margaret Mead, probably the most celebrated among Boas' students, who went to Samoa in a style of research closer to the British tradition (1928), was later seriously criticized for her poor work as fieldworker. It was mostly since the mid-1940s that American anthropologists have been equally engaged in intensive fieldwork projects away from home. Compared with the British tradition, American anthropologists, since the early stages, have developed a distinctive orientation in their fieldwork projects, more broadly directed toward inquiries of culture and personality (represented in later years, for example, in the works by Clifford Geertz and his colleagues).

The method of fieldwork was adopted in most Western European countries, though in France the interests of leading anthropologists (Lévi-Strauss in particular) were far more concentrated in oral and textual traditions such as tribal myths of creation. They attributed little importance to the ethnographer's experiences *in vivo*. The ethnographic tradition was also adopted outside Europe and the United States.

2. The Practice of Fieldwork

As a first step in their project, fieldworkers in the Malinowskian tradition have always been acutely aware they must develop *rapport* and friendly relationships with the people in their chosen field. They are expected to listen attentively, and witness whatever happens around them in the field, without disturbing the natural flow of events. As they consolidate their position with locals, they usually add information through more active modes of communication (such as initiating conversations, interviews, collecting statistical data, taking photographs, etc.), but they are careful not to instigate a flow of information into preconceived patterns of their own making. They invest much of their time recording this material in their notebooks or computers. The bulk of that store accumulates into their most treasured fieldwork product—'fieldnotes' (to be later transformed into an ethnography). The hallmark of anthropology, fieldwork had also come to differentiate anthropology from sociology. That major difference became more prominent a few decades later when anthropologists were no longer confined to the study of remote Third World societies.

The practice of fieldwork has raised many, as yet not fully resolved, problems of methodology and ethics. Considered a 'method,' it is assumed to maintain a standardized guide for professional behavior, as well as technical rules concerning the collection and recording of data. But throughout the history of anthropology, the craft of fieldwork was practiced, mostly by individuals, who went on their own to explore new research sites where they confronted conditions and constraints not envisioned by their teachers and colleagues. For many years, the teaching of anthropology in many universities did not include specific courses in methodology. The apprenticeship in anthropology was gained through more informal methods such as a close familiarity with the relevant corpus of ethnographies (and particularly those associated with the candidates' departments, for example, 'The Manchester School'), attending presentations and seminars by colleagues who returned from the field, communication with those who had already gone through the experience, and finally, through the good or bad fortunes of the novice on his arrival in the field and his success in establishing rapport with his native hosts. No surprise, fieldwork had been often described

as the major *rite de passage* for students of anthropology. Many anthropologists have been engaged in one major fieldwork project only. But it seems that more ethnographers have gradually become involved in a few fieldwork ventures throughout their career.

Ethnographic work in the various sites of fieldwork, in the early days and today, has been based on an ethos of trust. Anthropologists, mostly engaged in a lone journey, have never been able to implement a procedure of testing the accuracy and truthfulness of fieldnotes reported by colleagues and students. Rarely did fieldworkers choose to return to a field studied already by another ethnographer. The few cases of contested reports have gained much attention, in particular, the controversy between Oscar Lewis and Robert Redfield who studied the same community of Tepotzlan, and Derek Freeman's refutation of Margaret Mead's observations in Samoa. But long-term research, carried out by anthropologists whose continuing interest and commitment to a particular field has been supported by sufficient funds or easy access, also offered a strategy of verification of observations made at earlier trips.

Although anthropologists have been expected to master the language of the society they studied, that prerequisite was rarely fully achieved. Constraints of time and linguistic skills often impelled them to rely on 'informants' as interpreters until they gained a better command of communication in the native languages. The length of stay in the field was usually determined by budgetary as much as by personal circumstances. But an informal norm of one year seems to have dominated fieldwork projects.

How fieldworkers present their role, and to what extent their subjects comprehend the purpose and consequences of their work, remains an unsolved ethical problem. However, some norms that pertain to a universal code of behavior have been institutionalized at an early stage, such as the disguise of the community studied. More rigorously maintained is the tradition of disguising the identity of individual participants. But no regulations were designed in regard to the rights of privacy in recording and disclosing of intimate information collected during fieldwork. Anthropologists were left to make their own decisions concerning ethical issues under the assumption of a deeply felt responsibility toward 'his/her people.' This dilemma was addressed, for example, by Geertz (1968, p. 157): 'A professional commitment to view human affairs analytically is not in opposition to a personal commitment to view them in terms of a particular moral perspective.' In any case, fieldworkers were expected to record in their fieldnotes, without censoring, as much as they could remember from their daily observations and conversations.

During many years of practice, however, anthropologists informed their colleagues, also in a more public fashion, about the circumstances they en-

countered during fieldwork. The early publications had mostly revealed the personal tribulations of individuals in their respective fields (e.g., Powdermaker 1966, Freilich 1970). But certain specific subjects of methodology had engaged a more rigorous professional treatment. For example, 'the extended case-method' (Gluckman 1958), though mostly a method of ethnographic presentation, suggested a follow-up strategy that stimulated the fieldworker to concentrate his/her observations, thereby revealing the hidden connection between disjointed events. Another theme that gained much attention concerned the various types of informants one might meet at entrance to a new field, and the strategies and precautions one might consider working with them (e.g., Casagrande 1960, Shokeid 1988). Detailed manuals and reference materials for the various aspects of fieldwork have gradually developed into books of methodology so long absent (e.g., Epstein 1967, Wax 1971, Agar 1996, Ellen 1984, Shaffir and Stebbins 1991). A more meticulous approach came to the fore examining the methods of recording and safekeeping of fieldnotes, the most valuable product of fieldwork (Sanjek 1990). Also, conferences dedicated to specific methodological issues have become frequent events (such as 'fieldwork at home').

3. *Transformations in Fieldwork Research*

The idea of fieldwork had gone through immense changes since the days of Malinowski and the generations that established the ethnographic tradition of participant observations in remote, apparently homogeneous societies, clearly identified within territorial and cultural boundaries. The consequences of World War II, the decline of colonialism on the one hand, but the expansion of anthropology in academia on the other, made both the entry and the budgeting of long trips to remote continents an impractical goal for the growing number of students. Instead, many candidates turned their interest to various attractive fields within the borders of their own societies. No doubt, there had been previous successful projects in the United States and Europe of ethnographic studies in fields 'at home' (for example the most celebrated work in an Italian lower class Boston neighborhood by Whyte 1970). But these few research endeavors were unusual cases, in a tradition that was directed to confront 'other cultures' away from home.

The new search for fields close to home seemed at first to involve only a transfer of sites, such as the study of the apparently clearly defined urban ethnic neighborhoods in the United States (e.g., Lewis 1966, Hannerz 1969). However, that novelty demanded a change in the style and intensity of participant observation (Plotnicov 1973). But of more profound consequence, the next change of spatial sites of fieldwork came to also include institutions that offered

specific services to permanent or transient populations (for example, Myerhoff's (1978) work in a community center for aged people). That transformation opened the door to a choice of fields that, hitherto, have not been considered suitable for observation (for example, fieldwork in the scene of gay life, such as by Newton 1972, Read 1980, Shokeid 1995). In these fields, the fieldworker is often unable to observe the participants throughout a wide spectrum of daily activities. Moreover, in the fields of anonymous participants, the observer's ability to record behavior and communicate with his subjects of research had been very limited in scope. These new fields were instrumental in the development of the method and theory of *symbolic interaction*.

The transformation of methods could also be identified in the choice of problem-oriented ethnographic projects. Even when the relevant site was actually a bounded territorial unit, it engaged a modified strategy of fieldwork (e.g., Ginsburg 1989). But another major change of sites entailed a complete eradication of the bounded spatial characteristics of fieldwork. These unbounded sites included observations of participants in particular occupations (e.g., Agar 1986, Hannerz 1998), observing cultural performances (e.g., Heilman 1983), as well as observing the members of dispersed social categories (e.g., Ortner 1997). These fields, no longer designed to record the totality of personal and communal life experiences, have been variously defined: *delocalized*, *multisited*, *postcommunity*, *focus groups*, and *transnational spaces*.

The ongoing change of the spatial research entities have not necessarily transformed some of the major characteristics of fieldwork. Anthropologists in the new fields continue to initiate their observations mostly as individuals, men or women, engaged in their lone projects. It seems, however, there are less couples involved in these projects, compared with the tendency of married anthropologists to take along their families to the more remote field sites.

In recent years, however, some issues not considered before, concerning the fieldworker's feelings and demeanor, have been openly raised in conferences and edited volumes. Anthropologists preparing for a fieldwork project have never been requested to consult about their personality traits and social capabilities to accommodate what might become stressful field circumstances. But since Malinowski's widow published his personal diaries (1967), revealing the prejudices and the emotional stress experienced in the field by the mythical founder of fieldwork, a more relaxed attitude was gaining place in the professional discourse about fieldworkers' personal problems. This attitude has been closely related to the genre of reflexivity that since the late 1970s gained popularity in ethnographic text (e.g., Rabinow 1977). The lone fieldworker was no longer perceived through the image of the infallible man or woman, expected to withstand successfully all obstacles in a valiant test of personality that proves

he/she are capable of penetrating the social codes of alien cultures in far away territories.

The new fieldwork sites in Western urban societies contributed to that growing awareness and doubts about some long established taboos that separated the fieldworker from the subjects of his observations (e.g., Kulick and Willson 1995, Lewin and Leap 1996). The border between the observer and the observed that was naturally upheld in the old fields, where the alien researcher had been conspicuously distinguished (by race and other visible marks of personal characteristics), are no longer easily maintained in many of the new sites of fieldwork. The photographs displayed in many ethnographies of the founding generation, showing them in a landscape of exotic trees and simple huts, posing in the company of minimally clothed natives, have become a symbolic emblem for the changing circumstances of fieldwork.

It is probably an irony that by the end of the twentieth century, a century that gave rise to modern anthropology, fieldwork, its most inventive method and major signifier of professional identity, seems to have lost its incontestable paramount position. Critical views of the validity of positivist methodology, as well as the growing influence of postmodernist currents in cultural studies, are challenging the authority of ethnographic texts based on participant observations (e.g., Marcus and Fisher 1986). These intellectual movements, popular in recent years, inspire and legitimize anthropological projects that are based on other types of data (such as textual and mass media creations) which can be collected without the need for fieldwork. It is too early to predict whether the new genre of arm-chair anthropology will have a more lasting impact on the role of fieldwork and its practitioners.

Figurative Thought and Figurative Language, Cognitive Psychology of

1. A Definition

Different types of linguistic expressions (metaphors, idioms, proverbs, etc.) form figurative language. Since the seminal work of Lakoff and Johnson (1980 but see Black 1979), the term 'figurative' is also used to denote conceptual entities that contribute to shaping our understanding of the world. Figurative language in general, and metaphor in particular, plays a central role not only in everyday discourse and in linguistic change but also in reflecting and shaping how people think in a broad range of domains (Cacciari 1998).

1.1 Literal vs. Figurative Language

When a speaker/reader encounters a sentence, she/he is generally able to judge whether it is intended literally or not. The ease with which people deal with this distinction in everyday discourse belies the difficulty and complexity of the distinction between literal and figurative language in the linguistic and psycholinguistic literature. No universally accepted criteria for discriminating between literal and nonliteral expressions have yet been devised. Many researchers expressed serious doubt as to whether a sharp distinction can (or should) be drawn between these two varieties of language use and proposed to substitute it with the notion of levels of conventionalization of meanings and sentence uses.

Despite the pervasiveness of figurative language, many language researchers still assume that it represents a peripheral issue that language comprehension and production models can easily ignore. For instance, current psycholinguistic models of production are almost silent as to why a speaker would select a figurative expression instead of a 'corresponding' literal expression (if any). Likewise, standard semantic theories still assign a rather peripheral and theoretically uninteresting role to figurative language (with the important exception of cognitive linguistics). Two long-standing assumptions contribute to this error.

(a) Figurative expressions can always be paraphrased literally since they only represent a 'stroke of style' reflecting, as Black (1979, p. 27) ironically stated, the 'incidental pleasure of stating figuratively what might just as well have been said literally.'

(b) The opposition between literal language as the realm of clear shared meanings, and figurative language as the realm of idiosyncratic, obscure meanings.

The cognitive psychology of figurative language does not consider figurative language as an ornament added to everyday straightforward literal language but it views it as a powerful communicative and

conceptual tool. This shift in the view of figurative language, and particularly of metaphor, from a strictly linguistic entity to a conceptual structure has opened a new wave of studies on the mental representation and the comprehension of figurative language. The main stance of this new viewpoint consists of treating metaphor as a bridge that forces the human mind to construct higher-order linkages between the entities referred to in metaphorical assertions. This bridging function is very widespread since metaphors can be used to connect a variety of different domains: abstract entities; abstract concepts to sensory-perceptual experiences and to concrete objects; perceptual experiences belonging to different sensory modalities (as in synaesthetic metaphors).

2. *The Comprehension of Figurative Language*

Contemporary cognitive research on figurative language comprehension began in the 1970s with a predominant focus on metaphor only recently extended to other linguistic expressions, particularly to idioms. Despite the fact that a vast family of expressions form figurative language, not all tropes have been investigated with a theoretical and experimental effort similar to that employed for metaphors and idioms. For instance, proverb comprehension has been scarcely investigated (see Honeck 1997); analogies have almost always been treated as a separate problem generally studied independently from metaphor, even though the two tropes are often confused and sometimes actually difficult to differentiate (see Gentner and Jerzierski 1993). The privilege accorded to metaphor is not surprising if one considers that, since Aristotle, it has been considered the trope *par excellence* often even serving as a collective label for any and all rhetorical figures.

3. *Metaphors as Comparisons*

Metaphor, according to the still most influential definition that comes from Aristotle, is said to be a form of transfer of a name from one object to another. The 'ground' of a metaphor (i.e., its content) can be the set of properties that two concepts share (e.g., in 'Dew is a veil' both are transparent, covering, shimmering). In some cases, it can be a superordinate category that subsumes both concepts (e.g., as in 'the tooth of the mountain' where the mountain peak and the tooth partake of the category 'sharpened forms'). In other cases, it may be necessary to reconstruct the underlying analogy involving both concepts (e.g., as in Virginia Woolf's 'She allowed life to waste as a tap left running').

The comparison view of metaphor has generated a class of comprehension models that can be characterized as feature- or attribute-matching models (for a review, see Cacciari and Glucksberg 1994). Matching

models adopt the assumption that in attributive metaphor, of the form 'An A is a B,' the A and B concepts are represented either as sets of features or as positions in an n -dimensional semantic space. Regardless of the specific representational assumptions, matching models assume that metaphors are first transformed into comparison statements, and then the features of the vehicle are compared to, or mapped onto, those of the topic.

The two basic assumptions – that metaphors are implicit comparison and that the comparison is derived from a sharing of features – are each problematic, for different reasons, and have been extensively criticized insofar as they do not contribute to definitively clarify what metaphors are and how they are understood. These assumptions are in fact unable to account for several factors: first, that metaphorical comparisons, unlike literal ones, are nonreversible or asymmetrical, that is, they change their meaning if the order of the topic and the vehicle is modified. Second, they do not provide any explicit mechanism for distinguishing between relevant and irrelevant features or properties nor for introducing new features into the mental representation of metaphor's topic. In processing terms, then, they posit that in order to understand a metaphorical assertion, one should first transform it into an explicit comparison. Hence this process should take longer than with a comparable literal expression. On the contrary, a consistent body of evidence suggests that attributive metaphors are understood as quickly as literal sentences when embedded in appropriate contexts, a result which confirms that identical comprehension processes are involved irrespective of language use. More importantly, the feature-matching process may be too limited to capture the full range and impact of metaphors.

Metaphors may have more to do, as Levinson (1983, p. 150) noted, with 'the contingent, factual (real-world) attributes of the referents of the metaphorical focus than with the semantic features that can be claimed to express its meaning.' Metaphor does something more than simply calling our attention to pre-existing similarities between the semantic features of the topic and the vehicle. Whether similarity is pre-existing or is created by the metaphor depends of course on the nature and quality of the metaphorical assertion. In many cases, good metaphors certainly made us perceive resemblances previously unperceived.

4. *Metaphors as Categorizations*

A metaphor can imply a comparison, but it is not in itself merely a comparison. Provided that it is not an implicit comparison, how can we characterize a metaphorical statement? Two theoretical answers have contributed to radically change the cognitive studies on metaphor representation and comprehension: the

Conceptual model (Lakoff and Johnson 1980, Lakoff 1993, Gibbs 1994) and the Property Attribution model (Glucksberg and Keysar 1990, 1993).

These models share the idea that metaphor's use and understanding involves not only linguistic or discourse processes but also reasoning and conceptual processes. Metaphor is based at the same time on the use of acquired categories and conceptual schema and on the creation of new categories and conceptual schemas. These models differ in important respects: first of which the locus of metaphoricity. According to the Property Attribution model proposed by Glucksberg and Keysar, metaphors belong to language use since they are linguistic entities expressing assertions of categorization similar to those expressed with literal language. They are used not simply to call the reader's attention to superficial similarity between concepts but to label categories that have no conventional names of their own. Metaphors create new categories employing the predicate to name the class of things that it exemplifies. When one says, 'My job is a jail,' she/he wants to suggest that his/her job is part of the metaphorical category of situations that are involuntary, unpleasant, and so forth, and to attribute specific properties to the metaphor topic 'job.'

In nominal metaphors, the metaphor topic and the vehicle play distinctive roles in that the topic provides constraints on what is likely to be attributed, while the vehicle provides properties to be attributed to the topic. Metaphorical vehicles are located at two different levels of category abstraction: the literal concrete level (the subordinate level), where they are members of a class of entities, and the more general, superordinate, attributive category level. A metaphor vehicle such as 'jail' can refer simultaneously to a concrete physical structure, and to the metaphorical category of situations that are involuntary, unpleasant, confining, and so forth. The literal 'jail' contains all the properties of the superordinate category 'jail' plus the properties that are specific to a jail *per se* (e.g., having painted walls, being made of concrete, etc.).

According to the Conceptual model proposed by Lakoff and colleagues, the locus of metaphor is not in language, but in the way in which people conceptualize one mental domain in terms of another. 'The general theory of metaphor is given by characterizing such cross-domain mappings' (Lakoff 1993, p. 203). The linguistic expression of metaphor is a simple epiphenomenon of a more general feature, i.e., that we think in metaphorical ways. Lakoff contends that everyday metaphor is characterized by a huge system of thousands of cross-domain mappings that motivates the idea that metaphor is primarily conceptual. It is not just 'a matter of language, but of thought and reason. The language is secondary. The mapping is primary, in that it sanctions the use of source domain language and inference pattern for target domain concepts. The mapping is conventional, that is, it is a fixed part of our conceptual system' (Lakoff 1993, p.

208). People use figures of speech in everyday conversation because they conceptualize much of their experience through the figurative schemes of metaphor, idioms, metonymy, and so forth.

These two models also differ in their theoretical scope: whereas Glucksberg and Keysar want to provide a psycholinguistic model of how people use and comprehend metaphors in discourse, Lakoff's aim is to single out a general account of human thought independently from any processing validity (but see Gibbs 1994).

5. Idioms: What They are and How They are Comprehended

The task of defining what an idiom is, how it is acquired and understood is still rather controversial although enough evidence has been cumulated to formulate satisfying models of the comprehension processes (for a review see Cacciari and Tabossi 1993, Gibbs 1994). One of the problems in defining idioms is that idiomatization is a process: a given structure is not idiomatic once and for all, but gradually acquires its idiomaticity. A very general definition is that idioms are composed of freely occurring units whose global meaning cannot be reduced simply to the meanings of these units.

Idioms behave at the same time as words and as larger-than-words chunks. From a processing viewpoint, this has been taken to imply that they were multiword lexical units accessed as such from the mental lexicon. The 'Lexical look up' models of idiom comprehension share the idea that idiom meanings are apprehended by direct memory retrieval, not by linguistic processing. They differ in terms of representational assumptions: according to Bobrow and Bell (1973), idioms are stored in a separate mental idiom list that is accessed and scanned when the literal analysis of a given string fails. This assumption has been rejected on the basis of the robust finding that idioms are understood as quickly as (if not more quickly than) comparable literal expressions. According to Swinney and Cutler (1979), idioms are represented as long words together with all ordinary words of the mental lexicon.

The received view is that idioms are noncompositional strings of words. Despite this, it has been noted that even in the most frozen of idioms (e.g., 'kick the bucket'), the semantic of the single constituent words is still available even though these idioms behave much as words, with their meaning acquired and stored in memory, as for other memorized strings of words (lines of poetry, snatches of songs, etc.) one cannot 'slowly kick the bucket' due to the semantics of 'to kick' that implies an abrupt action (Nunberg 1978, Glucksberg 1993). On more general grounds, this reflects the fact that language comprehension is nonoptional: in spoken language, the

meanings of the words are activated and discarded all the time since understanding occurs automatically without conscious control by the subject.

The recent psycholinguistic literature has shown that during the comprehension of idioms there is activation of the literal meaning of the words forming them, despite what is predicted by the direct look up models. According to the Configuration model (Cacciari and Tabossi 1988, Tabossi and Zardon 1993), idioms are no different from any other type of familiar, memorized string of words. When during a conversation a listener encounters one of such strings (e.g. 'being in seventh heaven'), the word meanings are activated up to the point (and even sometime later) in which the string itself is recognized as an idiomatic configuration. A configuration is made up of the same lexical units that need to be activated during the comprehension of literal discourse. This implies that there is only one processing of an idiomatic string up to the point in which, after the 'keyword' of the idiom is activated, the configuration can emerge. In some idioms, the keyword can appear very early, for instance, immediately after the main verb (e.g., as in 'spilling the beans' or 'breaking the ice'); in other cases it can be located at the end of the idiomatic configuration (as in 'being in seventh heaven' or 'looking for a needle in a haystack'), changing the time course of the comprehension process.

6. The Role of Semantic Transparency

The role of syntactic and semantic factors in idioms' interpretation has emerged in the last few decades corresponding to a new wave of studies that has concerned two main areas. The first one concerns the interplay between lexical and syntactic information, that is, the syntactic flexibility of idioms. A consistent body of evidence suggested that the number of syntactic variations an idiom can undergo still retaining its idiomatic meaning may be predicted on semantic grounds: the more the idiomatic meaning can be analyzed, the more flexible the idiom is. The second area has to do with the interplay between lexical and semantic/conceptual systems, that is, with the problem of semantic transparency of idiom meanings. The semantic transparency of an idiom's meaning has been defined as the extent to which the meanings of the words forming an idiom contribute to its overall figurative interpretation. Enough evidence already exists to reject the received view that idioms are semantically empty strings, suggesting that semantically transparent idioms (e.g., 'spill the beans', 'skate on thin ice') are easier to comprehend and to acquire for both children and adults.

These studies argued that adults and children could reliably differentiate among types of idioms (for a review, see Cacciari and Tabossi 1993), for instance among:

(a) Analyzable-opaque: the relation between an idiom's elements and the idiom meaning may be opaque, but the meaning of the individual words can nevertheless constrain both interpretation and use (e.g., 'kick the bucket,' 'by and large,' 'speak one's mind').

(b) Analyzable-transparent: there is a clear semantic relation between the elements of the idiom and the components of the idiom's meaning usually because of metaphorical correspondence between the idiom's elements and the components of the idiom's meaning. The elements of an idiom map onto the components of the idiom's meaning (e.g., in 'spill the beans,' 'spill' corresponds to the act of revealing or letting out, and 'beans' to the materials that had been heretofore concealed or otherwise unknown).

(c) Quasi-metaphorical idioms: here the literal referent of the idiom is itself an instance of the idiomatic meaning. A particularly relevant case or instance is used to name all possible other situations that one might want to describe using the semantic characteristics epitomized by the idiom referent. For instance, 'carrying coals to Newcastle' is simultaneously an ideal or prototypical instance of a useless transfer of something and also a phrase that can refer to any instance of bringing something to a place that has a surfeit of that something (as in 'Selling rice to Japan is like carrying coals to Newcastle'). The literal referents of this type of idiom are relevant and appropriate to their idiomatic meanings.

Quasi-metaphorical idioms may serve the same communicative function of metaphor vehicles in expressions such as 'My lawyer is a snake' or 'My job is a jail.' In these metaphors, vehicles such as 'snake' or 'jail' serve as exemplars of their metaphoric categories—vicious people and confining, unpleasant situations, respectively—and simultaneously as names for those categories (Glucksberg and Keysar 1990). Consider a metaphorically intended term such as 'snake.' It provides a set of candidate properties (many and different) that can be plausibly attributed to a person. Usually, mutual knowledge among the speakers and/or the discourse context provide the relevant knowledge about the person to which such a vehicle ('snake') refers so that only a subset of properties will be attributed to him/her. Metaphorically speaking, a person can be a 'snake' in several respects: she/he can be vicious, dangerous, hit you unexpectedly, and so on. Topics such a lawyer or a supposedly good friend would require, for instance, the instantiation of a different set of attributive properties (or values) insofar as each of these two topics put constraints on what is more likely to be attributed to them.

Linguistic processing and idiom look-up can occur in parallel. Ordinarily, people understand idioms following the basic principles of language comprehension to court. Language is full of noncompositional units that are not idiomatic at all. Consider, for

instance, nominal compounds such as 'carpet sweeper' or 'vacuum cleaner': a carpet sweeper sweeps carpets but a vacuum cleaner does not clean vacuums. As a processing default, people retrieve an idiom as a configuration from the lexicon. Still, the meanings of the words forming it and its underlying structure (be it metaphorical, analogical, metonymical, etc.) are available and might play a role if necessary for discourse purposes. In these cases, people can use their intuitions on the structure of an idiom as well as on the conceptual templates underlying it to elaborate on an idiom's meaning.

7. Sense Creation and Extension

The notion that semantic properties of the constituent words of an idiom play an important role in the comprehension and production of idioms has been extended to also account for the problem of meaning extension, i.e., polysemy (Glucksberg 1993). The words forming familiar idioms might become polysemous in that they have at least two meanings: their default context-free literal meanings, and the meanings that are induced by the idiom context. With repeated use, familiar idioms might become able to induce polysemy adding the idiomatic meaning to each word's set of possible meanings. The verb 'spilling,' for instance, might acquire as a secondary meaning that of 'revealing.'

Figurative language is arguably the most powerful source for meaning creation and sense extension. Words evolve additional meanings through it. When such an evolution is consistent and stable enough within a speech community, then a new lexical entry can be added to the list of possible meanings of a word. At that point, lexicographers will officially confirm a new sense by adding it to the dictionary.

Words as well as idioms do not acquire new senses randomly. Most often idioms derive their meaning from metaphors that for some reason emerge in language. According to many authors, this process is not at all arbitrary (for a review, see Cacciari 1998). As Quinn (1991, p. 79) noted, 'the invention of new metaphorical expressions is constrained...by the necessity of finding metaphors that make sense in terms of the cultural models and by preference for metaphors that do a particular good job of this.' Hence, metaphors that become conventionalized (the first step toward idiomatization) presumably represent 'satisfying instantiations' of culturally shared models.

Language comprehension may always involve a mixture of sense selection and sense creation. As Clark and Gerrig (1983) noted, in general speakers consider the information they share with the addressee, evaluate the salience and coherence of potential interpretation against this common ground, and select or create specific interpretations, 'all with deceptive ease' (1983, p. 607). This 'deceptive ease' reflects human's ability to simultaneously process information coming from

different domains: lexical, syntactic, semantic, pragmatic, and so forth. Figurative language, as an old tree, extends its roots across these domains, taking its nourishment where it springs. That's why it is such a crucial hinge among different language systems.

Film and Video Industry

The production, and distribution of cinema occurs throughout the world but since the 1920s has been dominated by eight or less giant Hollywood studios. These vast multinational enterprises create films that are presented in virtually every country in the world, frequently capturing a major share of the business despite competition from locally made and distributed motion pictures. Almost continuous technological change—led by the Hollywood oligopolists—did not lessen Hollywood's industrial power, and so all other film industries sought to ape Hollywood's continuous success. The coming of sound and color, and the innovations of pay-TV and home video (played on VCRs) simply extended Hollywood's influence, and increased its profits. Analysis of the Hollywood studio system has led to praise or damnation of this omnipresent, inescapable, and highly influential industry.

1. The Film and Video Industry

A handful of companies have defined the Hollywood film industry, dominating the US and world markets. They have weathered a world war, and a Great Depression, innovated wide screen and color technologies, made peace with television, learned to exploit home video, and were more powerful at the end of the twentieth century than ever before.

The coming of sound solidified control by five studios over the world cinema market: Paramount Pictures, MGM, Twentieth Century Fox, Warner Bros., and RKO. During the 1930s and 1940s by controlling the key cinemas in the downtowns of nearly all major US cities, the 'Big Five' took in nearly all box-office take. Only after they granted their own theaters first-runs, did they then permit smaller,

independently owned theaters to scramble for the remaining bookings months, or even years, after a film's premiere.

Paramount represented the most profitable, powerful, and traditional business-like Hollywood company. More than any other member of the Big Five, Paramount relied on its chain of more than 1,000 theaters to maintain its corporate might. Not surprisingly, a former theater operator, Barney Balaban, stood at the top of this corporate colossus, hiring more lawyers and MBAs than movie stars.

Metro-Goldwyn-Mayer (MGM) technically functioned as a successful unit of Loew's, a theater chain concentrated in the Eastern USA. MGM, more than any other studio, relied on the star system, producing films from its massive Culver City, California-based 'factory' of 27 sound stages (for interior shots), and a 168-acre back lot (for outdoor scenes).

Twentieth Century Fox ranked behind Paramount and MGM with neither as large a theater chain or studio facility. Studio boss Darryl F. Zanuck used what he had to authoritatively produce films for world distribution. His decisions were final, frequently belittling to all subordinates: 'Don't say yes until I've finished talking!'

Warner Bros. represented the only family-run operation among the major movie studios, with eldest brother Harry as President, middle brother Abe supervising worldwide distribution, and baby brother Jack heading studio production. The innovation of sound pushed Warners into the Big Five, yet financially the company struggled through the 1930s and 1940s.

Radio-Keith-Orpheum (RKO) was formed so that radio's RCA could sell its sound equipment to Keith-Orpheum theaters. While the studio created many memorable films—such as *Citizen Kane* and the Astaire-Rogers musicals—RKO's only regular profitability came from the distribution of Disney animation. TV killed RKO.

The Big Five tolerated some competition—from Universal Pictures, Columbia Pictures, and United Artists—as the 'Little Three' depended on the Big Five for access to the top theaters in the USA. The suburbanization of the US, and the coming of television allowed Universal, Columbia, and United Artists to prosper because the advantage of owning theaters disappeared because of antitrust action by the US government. The former Big Five, save RKO, tried to re-invent themselves.

Warner Bros. began its transition into what became Time Warner when in 1956 the founding brothers sold out, and a series of new owners embraced television production. In 1969, Kinney National Services, a New York conglomerate, purchased Warners, and Steven Ross, son-in-law of Kinney's founder, began to fashion the modern Hollywood-based prototypical multinational media conglomerate. In 1989 Ross merged Warner with Time, and the largest media

company in the world was created. A decade later AOL took control.

Paramount stubbornly hung on until 1966 when Charles Bluhdorn's Gulf + Western Industries conglomerate, after a 2-year battle, took over. Through the 1970s and 1980s the 'new' Paramount thrived as part of a classic conglomerate, but in another 2-year struggle, was taken over in 1993 by another media conglomerate, Sumner Redstone's Viacom, Inc.

Twentieth Century Fox began its reinvention in 1956 when longtime studio boss Darryl F. Zanuck resigned. His replacements struggled, but did lead the way to licensing feature films to major television networks. NBC's 'Saturday Night at the Movies' began TV's showcasing of feature films. The surprise hit *Star Wars* (1977) moved Fox to the top of the Hollywood studio hierarchy, and within a decade led to the studio's purchase by Australian media mogul Rupert Murdoch. From the Fox studio base, Murdoch created the Fox TV network.

MGM never was able to reinvent itself, even with its merger with United Artists. The two other members of the Little Three did far better. Columbia went through several ownership changes (including during the 1980s when Coca-Cola owned it), but it was not until 1989 that stability came when Japanese electronics giant Sony purchased Columbia. During the 1990s Sony never was able to exploit its Hollywood studio to sell more VCRs, but did learn to create vast profits.

Universal also struggled until 1962 when the MCA talent agency acquired it. Thereafter, under Lew Wasserman, Universal ascended to the top of Hollywood movie and television studio hierarchy as Wasserman innovated the made-for-TV movie, and the modern film blockbuster—*Jaws* (1975). Wasserman retired in the early 1990s, and in 1995 Canadian liquor giant Seagram took control.

Disney joined Warners, Paramount, Fox, Sony, and Universal to form the 'Big Six' of the 1990s. Beginning in 1984, Michael Eisner leveraged Disney's weak position into major studio status, a significant change in an industry with so much long-term stability. Indeed, how had this small number of companies survived and thrived for so long—with no real newcomers joining their ranks?

First, even with all the social technological and industrial changes, the major companies alone continued to be able to distribute films around the world. At considerable expense, all maintained offices not only in the USA, but in every region of the world. In most countries around the world, owners of theater chains knew the Hollywood majors alone could continuously deliver popular films, and so even theater owners outside the USA preferred Hollywood films to native productions. The Hollywood studios' record at the box office satisfied theater owners—a conservative lot with most of their assets invested in real estate. Economies of scale prevented rivals from building and maintaining equal world distribution networks.

Second, modern Hollywood fashioned the blockbuster strategy to turn television into a friend, not a foe. Through the final quarter of the twentieth century, the Hollywood oligopoly learned to generate profits from creations that premiered with blitz TV advertising, which in turn was married to a multirevenue generating machine to sell musical sound tracks, novelizations of the stories, 'action figures' from movie characters, and endless sales on video. Each movie aspired theatrically to become a smash hit because if it succeeded then the feature turned into a 'product line,' designed to fill all entertainment needs and desires from toys to theme park rides to campaigns to sell more McDonald hamburgers.

The blockbuster strategy in turn led to ever escalating costs of production so it became more difficult for rivals to join the exclusive Hollywood club. By the close of the twentieth century the average Hollywood feature cost in excess of \$50 million to produce, and half again that amount to publicize. *Titanic* doubled those average cost figures, but then earned in excess of \$2 billion in revenues. Potential filmmakers knew that if they ever aspired to have a world audience see their creation and to attain undreamed of wealth, they needed to be 'green lighted' by one of the Hollywood major studios.

Alone, Hollywood could keep the revenues flowing year after year—particularly from home video. While theaters still premiered new films, it was 'downstream' on video where the bulk of the monies were generated. The theater functioned as the 'voting booth' where hits were made, and necessary publicity generated. But once the film had fully milked the box-office it went into release on pay-TV and home video that created more than two-thirds—in the long run—of the average film's revenues. Hollywood executives carefully planned—in classic price discrimination fashion—to drain all possible revenues from each of these release venues, only releasing it to home video when they reasoned all the revenues from theatrical and then pay-TV had been procured. Each window in this sequence was an exclusive; a new window opened only when all value of the previous window had been captured. This exploitation of video represented Hollywood's newest advantage in the film industry.

2. *The Rest of the World*

While the Hollywood majors maintained their economic power and influence, filmmakers outside Hollywood long struggled to find their place in their national cinemas, often requiring the assistance of their governments. Only sporadically have large nation-states—France, Italy, Japan, and India in particular—been able to mount a studio system as an alternative and serious rival to Hollywood in their own countries, let alone elsewhere.

Globally, only in the rare nation does Hollywood not capture more than half the business. The Hollywood majors maintain offices around the globe, where their representatives maintain constant contact with the heads of the dominant theater chains, pay-TV outlets, and home video retailers. Hollywood's regular production of hit films provides a strong incentive for foreign theater, pay TV, and home video companies to consistently deal with them rather than take a flyer with some new company—even a native company.

But other nations did try. During the 1920s European nation-states—led by the United Kingdom, France, and Germany—sought to build their own studio systems, and were successful for short periods of time, until their leading filmmakers left for Hollywood. During the 1920s, the new Soviet Union tried to build an alternative national cinema industry under Communism. The 1930s ended these experiments. At the close of World War II, the focus shifted to state sponsored television, but still in Japan and India studio systems did succeed, even while conceding Hollywood a vast share of the monies paid for cinema attendance.

After the advent of the blockbuster, it became harder for foreign governments to subsidize a native cinema industry. Most chose to focus on television instead. But Germany and Australia, for example, did for a time in the 1980s create enough different types of popular productions long enough to be discovered as the latest 'new wave.' Japan had long had a studio system, but the coming of television and the takeover of Hollywood studios by Sony, and temporarily, Matsushita, ended the importance of that native industry. But India, for example, was still able to maintain native popular cinema, complete with a star system and defined genres like Hollywood. But these films were intended for domestic consumption, with minimal export possibilities. Community viewing in cities and poor areas alike still flourished.

Hollywood has long maintained an influential trade association—the Motion Picture Association of America noted for its ratings of films, but far more influential around the world for lobbying to smooth the way for international distribution. The MPPA lobbied the US State Department to keep cinema trade 'free' to permit the Hollywood oligopoly to continue pulling billions in revenue from the foreign [read: non-US] market. Foreign governments, on the other hand, resented US pressure, and formally and informally sought to protect the national film industries, and their cultural integrity and identity.

3. Industrial Analysis

The common thread of Hollywood power and influence, and its growing presence around the world, have led to much analysis of the Hollywood film industry. Three different interpretations have dominated.

3.1 Marxist Industry Analysis

Marxist critics have long seen this influential cultural industry as a classic example of monopoly capitalism, focusing on how these long lived corporations colluded to devise ways to maintain their power and cultural imperialism. While Wall Street celebrated Twentieth Century Fox and Paramount's co-financing of *Titanic*, Marxist critics would see this as yet another example of studios working together—not competing—to maximize profit. Since there were at most eight players, they did not have to worry about going out of business, but simply seeking how much their exploit and keep in profits.

The long-term propensity toward concentration of ownership, endemic to monopoly capitalism, was simply exemplified by the Hollywood motion picture industry. That is what history should teach us, and that is how Hollywood has behaved even in the face of new technologies. Marxists focus on the expansion of giant corporations and the spread of their influence to television, music, toys, theme parks, and other entertainments. Market concentration and anticompetitive behavior describe the operation and ownership of the Hollywood movie industry.

Marxist industry analysis usually focuses on international distribution, seeing the trend toward globalization as evidence of cultural and economic imperialism. While Hollywood publicity focuses on the production of films—its stars, stories, and special effects—international distribution has always been a key to corporate longevity. No other national film industry has been ever been so far-reaching, endangering indigenous, nonprofit seeking culture. They correctly emphasize that Hollywood taught the mass culture businesses to focus on and exploit the advantages of globalizing as seen in the work of Wasko (1994) and Guback (1969).

3.2 Neoclassical Industry Analysis

Neoclassical economists emphasize that movies face competition from all forms of mass culture. While there are and have been a few very powerful studios, consumer sovereignty means that no Hollywood company can ever force a customer to pay to see a film—even *Titanic*. These analysts focus on the forces and interplay of supply and demand, seeing the movie theater as a classic voting booth, where top grossers win and unpopular films are pulled almost immediately. They stress that there is a great deal of product diversity that permeates the entire landscape of the mass media. This is why genres—from science fiction to westerns, from dramas to comedies—ebb and flow in relative popularity. With the rise of the VCR, for example, the choice of titles to rent or buy needs to be measured in the thousands. Like the Marxists who come to their analysis with a predetermined

anticapitalist assumption, these neoclassical analysts enter the debate with a procapitalism assumption as seen in the work of Litman (1998).

3.3 Industrial Organization Analysis

Industrial organization economists start with neither pro- or anticapitalistic assumptions, and instead seek first to define 'who owns the media,' then analyze what economic conduct emerges from that industrial structure, then detail how the industry performs given specified criteria, and finally recommend possible public policy corrections to make the industry do 'better.' Industrial organization economists have long recognized the host of advantages that enabled them to maintain their considerable economic power and keep out the competition.

For example, cross-subsidization enabled a Hollywood corporation—with interests in a number of media markets—to extract profits from a thriving area to prop up another less financially successful area. Single-line corporations do not have this luxury and so aspiring single-line Hollywood operations invariably fail as Gomery (1986) discusses.

Or, to take another example, reciprocity enables a diversified member of the Hollywood major studios to choose to whom they will sell and then only deal with those companies that cooperate with other units of the media conglomerate. For example, Universal Pictures might not sell movies to Time Warner's HBO unless Time Warner's cable franchises book Universal's (partially owned) USA television network.

Horizontally, year after year, the Hollywood oligopoly has generated considerable profits from a wide spectrum of mass-media enterprises, including theme parks, music, and television production. There is no such thing as a single-line major movie company. The major Hollywood companies also control the process of production and distribution—as they long have—but also more and more of the increasing avenues of presentation, from pay-per-view channels to home video to digital home viewings.

Film: Genres and Genre Theory

Genre, a term notoriously difficult to pin down, refers to a type of film or other art object where instances of the type share similarities in form and style, theme and content, as well as communicative function. A film genre is thus based on a set of conventions that influence both the production of individual works within that genre and audience expectations and experiences.

1. The Study of Film Genres

The concept of genre has been important since the beginning of the history of film, as a category for the industry and thus for the production, marketing, and distribution of films; for film critics and the academic, esthetic, historical, and theoretical analysis of film; and for audiences as a framework for the selection and experience of films. The study of film genres is therefore placed in a triangular structure relating to the institutional, social, and cultural context of films; to the esthetic, formal, thematic, and stylistic dimensions; and to audiences and reception understood both in an empirical social and psychological sense.

The development of studies of film genre from classical to modern film theory have shifted between focus on different aspects of this triangular structure. Studies of particular film genres, e.g., the Western or the family melodrama, may stress the social and cultural aspects of genre, as ideological or ritual expressions of American history, values, and mythology, or as part of the Hollywood studio system and the institutional development of production norms. Or studies may stress the formal, narrative, visual, iconographic, and thematic structure of particular groups of films in order to find similarities and variations and historical changes and developments.

But studies of genre have also focused on psychological aspects of genre such as gender and the imaginary, using Freudian, Lacanian, and feminist terminology or, as it has been the case in recent thinking about genre, from a cognitive and emotional theory of basic prototypes of film genres. But many theories of genre do not stress just one part of the triangle but clearly indicate that genres are unstable and fuzzy categories. Rather than defining film genres as sharp, distinctive, and essential categories, modern genre theory tends to define genres as prototypes, and to see the establishing of genres as processes related to institution, text, and audience, and historical changes.

1.1 Auteur and Genre

Although film genres are found as categories from the beginning of film history, used by both production companies and film critics, the systematic theoretical and historical reflections on film genres were developed in the 1950s as European auteur theory met US genre films. The early theories of film were often very strongly tied to a more individualized and esthetic understanding of film as art, and therefore often viewed mainstream cinema and genres as commercially dominated formulas, that did not allow artistic freedom and innovation for the auteur. But although this discussion is often repeated even today, film genre theory in general has explicitly questioned this normative division between an industrialized product and mainstream cinema on the one hand and film art and the auteur concept on the other.

In the 1950s French critics centered around *Cahiers du Cinéma* and the New Wave stressed the variations and auteurism of classical genre films in their writings on classical Hollywood cinema. Bazin, despite his central role in the formulating of a realist film theory and an auteur theory, was also engaged in describing the special qualities of classical US genre-films, such as the Western. In his two seminal articles (Bazin 1971a, 1971b) published in French in 1953 and 1954, he discussed the Western, and especially John Ford's Westerns as US film art *par excellence*. In these articles, Bazin saw the Western as a visual and narrative embodiment of American history and myths, and in his definition of what constitutes a genre, he focused on both thematic elements and elements of cinematic technique and style, narrative structure, and *mise-en-scène*. He also initiated later discussions on the historical transformation of the Western, defining both its pure classical forms and newer forms, which he called 'superwesterns' and 'novelistic Westerns.'

Bazin's articles mark a transition from a normative esthetic notion of genre films as just degraded, commercialized, and industrialized art. He combined auteur perspectives and genre perspectives into a more general esthetic and cultural perspective on all forms of film. This was also the intention behind a number of

later US contributions to the general understanding and re-evaluation of US film genres. Braudy (1976) not only explicitly criticized the division between film as art and film genres, but also claimed that mainstream genres can express broader cultural, social, and esthetic values than classical works of art can. Buscombe ([1970] 1995) takes a broad discussion of literary genre theory as his starting point, and specifically uses Wellek and Warren's distinction in *Theory of Literature* ([1949] 1956) between 'outer form' and 'inner form' and their cinematic equivalents, thus opening a more structural and esthetic specification of genre definition.

1.2 Semiotics and the Ritual and Ideological Turn

The move from auteur to genre from the late 1960s was sustained and further developed through the influence of semiotics, structural anthropology, and literary genre theory to a broader ritual and ideological approach to the study of film and film genres. The ritual approach involved both a more systematic analysis of cinematic texts and a form of institutionalized practice expressing and negotiating fundamental cultural values. The ideological perspective involved a critical study of cinema and cinematic genres and the reproduction of dominant forms of ideology from sociological, Marxist, Freudian, and feminist perspectives. The two approaches do not necessarily exclude each other but in the ritual approach there is a tendency to see the relation between genre and audience as one of negotiation and exchange, whereas the ideological perspective more often stresses the principle of dominance.

In Cawelti's broad ritual study of popular literature and film (Cawelti 1976) and in Wright's classical ritual and structural analysis of the Western (Wright 1975), genres are seen as fundamental story types that represent and embody cultural images and myths with both universal and historical elements, and which are recognized by the audience. Genres and the act of genre reading balance between mimesis and escapism. Cawelti's idea is that genre formulas work because they are able to express and negotiate historical conflicts and mental and cultural oppositions and contradictions in a way that is accepted, understood, and appreciated by a large audience, not just dominated by ideology. He rejects deterministic theories in favor of symbolic or reflective theories, where assimilation, negotiation, and change take place but without denying that formula stories reflect and affirm dominant forms of thought and attitudes.

Cawelti defines five universal story types that can be used and combined in different ways: adventure, romance, mystery, melodrama, and stories of alien beings and states. In Schatz's (1981) study of classical Hollywood genres he talks about genres in a fundamental semiotic way in which he sees 'film genre as

a specific grammar or system of rules of expression and construction and the individual genre film as a manifestation of these rules' (Shatz 1981, p.19). Basic film genres form the *langue* and individual genre films form the *parole* of genre filmmaking and film language, and he defines the grammar in terms of a genre's iconography, characters, settings, and plot structure. Shatz's analysis is a study of some of the most stable film genres in the classical Hollywood system, the individual films, and the directors, but he also points to two very basic types of supergenres: genres of order (Western, gangster, detective) and genres of integration (musical, screwball comedy, family melodrama) with two very different narrative strategies, settings, types of hero, and solution models of conflicts that either express violent elimination and male dominance or emotional, familial integration and couple or female orientation.

Shatz's approach points to problematics also addressed in the more ideological and feminist genre theories developed at the same time, but with a background in French film semiotics or the influential UK journal *Screen*. One of the seminal articles articulating the ideological approach is Comolli and Narboni's ([1969] 1992) article, printed originally in *Cahiers du Cinema* and in English in *Screen* (1972). Every film is political and ideological, they state, in so far as no film or filmmaker can escape the commodity form and the capitalist economy. According to Comolli and Narboni, filmmaking at large is nothing but an expression of the prevailing ideology, which is working behind the back of both the filmmaker and the audience. But the article also defines a kind of ideological genre taxonomy, in which films are defined in relation to whether and how they try to oppose the dominant ideology. Among the seven genres defined are: the majority of films, which are just unconscious instruments of ideology; films that have an explicit critical content and or/form; films that have an ambiguous secret message and form; and films like documentary films, that are seen as only illusionary breaks with the dominant ideology.

Ideological genre analysis found dominance of ideology disguised behind classical realism or inscribed in the apparatus of cinema, and therefore viewed the audience as rather passive. However, ideological analysis did look for both a countercinema and counterstrategies to the dominance of ideology in genre film and mainstream cinema. But whereas the ritual approach saw qualities in the mainstream film and its relation to the audience on a more direct level, the ideological approach often investigated ambiguities and contradictions in genre films dominated by ideology. Writers belonging to the ideological and semiotic project (e.g., Wood [1977] 1995 and Klinger [1984] 1995) therefore also found elements of artistic personality still visible in genre films and often described subversion of the dominant tendencies in mainstream film.

1.3 Gender and Genre

The story of genre theory and gender starts with the feminist project based on the ideological and Freudian-Lacanian-inspired genre theory that sought to find the dominant. Mulvey's ([1975] 1992) much quoted essay combined elements from all aspects of the ideological genre theory, but with the aim of demonstrating the male dominance of the feminine in mainstream Hollywood. She pointed to the male gaze and the feminine characters as the looked-upon object, and she also described the asymmetric relation of active/passive roles. But Mulvey's article did not just open the feminist critique of male dominance, but also the demand for another esthetic, a feminist countercinema. Eventually it also led to the investigation of subversive female readings of classical genre films, most notably 'women's films,' e.g., melodrama or film noir as it is very broadly demonstrated in Gledhill's (1987) anthology on melodrama and women's films and Kaplan's ([1978] 1998) on women and film noir, in which prominent feminist film genre critics, e.g., Mary Ann Doane, Tania Modleski, and Annette Kuhn, figure. Later feminist writers have directly entered more action-oriented and excessive 'body genres,' such as Williams studying pornography, horror, and melodrama (Williams 1989) or Clover's (1992) thorough study of the horror genre. And just as feminist criticism has opened towards seemingly more 'masculine genres', gender studies of film genres have also included studies of gay and lesbian films or gay and lesbian aspects of mainstream genre films.

1.4 Genre, Reception, and History

In literary genre theory (Todorov [1970] 1975) the distinction between theoretical genres is defined in more general terms by criticism and theory, and historical genres are defined as genres actively used and recognized by critics and readers. This distinction in a way is a starting point for Neale's (1980, [1990] 1995) and Altman's ([1984] 1995, 1999) contributions to a genre theory. Neale (1980) represents screen theory as combining ideological and semiotic-esthetic aspects. But he expands the concept of genre to a very multifaceted process. Genres are both social and textual institutions and, according to Neale, they work to create a coherence and narrative closure, which positions the viewer safely inside a well-known structure: 'a genre is, simultaneously, a coherent and systematic body of film texts, and a coherent and systematic set of expectations' (Neale 1980, p.37). Altman ([1984] 1995) also clearly continues the semiotic project of genre definition, but at the same time seeks a merging of the ritual and ideological approach and the more general description of genres as a grammar and language. His suggestion in the article is

thus to combine the semantic approach to genres, defining its 'building blocks', and a syntactic approach defining the actual structures in which the semantic elements are placed. But at the same time he argues for a stronger historical complexity in the study of genres, and for a stronger emphasis on the study of genres in historical contexts and to actual interpretative communities.

This line of argument focusing on reception and the historical process of 'genrification,' and genre as a kind of 'game' between critics, producers, and audiences in a concrete historical process, is strongly underlined in Neale ([1990] 1995) and Altman (1999). Taking some historical examples of how different early film genres were defined in industrial and critical terms and how long it took for well-established genres to stabilize as both institutional and audience categories, Neale argues for genre studies with more real historical integrity, actually studying the discourses on genre used in a historical context, rather than only constituting general, theoretical genre concepts. Along the same lines, Altman focuses very much on the unstable and fuzzy nature of genres and the differences in audiences' readings of individual genres and individual films. He adds a pragmatic dimension to his earlier semantic-syntactic dimensions to include the user-contexts aspect. So key terms in this reception-oriented historicizing of film genre theory are different readings, multiple users, and conflicting understandings of genres, instead of genres understood as relatively stable categories based on both general textual similarities and a social and cultural contract or common understanding.

1.5 Cognition, Emotion, and Genre

A move in the opposite direction back to a more general definition of genres can be found in the strong new trend toward cognitive and pragmatic studies of genres in the 1990s. The earlier semiotic and ritual sociocultural approach to genres defined dominant structures based on more general patterns of mental, generic procedures, that partly explain why mainstream genres are so strong and dominant. This point of view was based on structural arguments that were not very firmly anchored in a psychological dimension. Cognitive-pragmatic genre studies also define very basic patterns and schemata in our active construction of narrative forms and basic generic formulas. But the cognitive-emotional theories focus on more internal psychological dimensions, but do not exclude a pragmatic-historical dimension, since all such mental aspects of communication are situated and embodied in a specific historical and communicative situation. The cognitive-emotional genre theory also opposes the dominant Freudian, Lacanian, or Jungian-inspired psychology in the screen tradition of genre studies. Important contributions to this new cognitive-emo-

tional genre theory is Bordwell's (1985) description of different narrative prototypes and the way they cue the spectator and Carroll's studies of horror (1990) and his later article on emotion and genre (Carroll 1999), in which melodrama, horror, and suspense are described from a cognitive-emotional perspective.

But the most ambitious attempt to formulate a cognitive and emotional theory of genre is that of Grodal (1997). Grodal defines a new typology of very basic genres based on the viewer's active-passive relation with the film, the kind of distanciation or identification involved, and the typical moods and emotional responses activated during viewing: associative lyricism, canonical narratives of action, obsessional paratelic fictions, melodramas, horror, schizoid fictions, comedy, and metafiction. Behind these basic forms we then find a number of more concrete, historical subgenres. The basic assumption of the book is that genres of visual fiction are mental structures that to a large degree are modeled on the basis of a simulated reality of actions and emotions to which we react with much the same experiences and capacities as in real life experiences. In his book Grodal describes both the typical embodied flow, during the experience of visual fiction with reference to cognitive-emotional psychology, and the reason for the strength and popularity of the prototypical genres of visual fiction and their relation to different mental and emotional activities and experiences. Grodal's book is, of course, not strongly oriented toward the cultural and historical aspects of moving images, but there is no essential opposition between a cultural, historical, and stylistic approach to visual fictions and Grodal's position, as long as one realizes that certain aspects of the experience and processing of moving images cannot be described as culturally constructed in any short-term sense.

2. Film and Genres

How many film genres are there, and how do we define them and distinguish one genre from another? This is the basic question raised by film genre theory, and this is also the question raised in more concrete, historical analysis of particular film genres and their development. Theoretically there are at one end theories that try to define genres as relatively stable and accepted narrative, stylistic, and thematic structures that transcend individual films and clearly influence and determine both production and audience response; at the other there are theories that stress the unstable and processual nature of genres and the fuzziness of genre. Some theories argue for few and very basic generic prototypes with a variety of possible subgenres, that may vary and change historically, whereas practical criticism and the history of film genre categories often show that you can construct genres on the basis of many criteria, for instance on content and dominant

type of narrative action (war films, porno films), on specific stylistic features (film noir, musicals, animated films), on the basis of the expected audience (women's films, children's films), on the basis of emotional response (comedy, melodrama), etc.

Although genres are often related very clearly to the dominance of US cinema worldwide, national variations of genres are also very important and often have more universal influence, e.g., the Asian martial arts films or the British heritage film or costume drama. But although historical, national, and other variations are very common and the number of actual genres defined in some critical context is probably very large, then some basic narrative modes and generic formulas are stronger and more permanent and universal than others.

2.1 Basic Film Forms and Universal Formulas

Kracauer (1960) defined two basic types of film: narrative films (story films), and nonnarrative films (nonstory films) which he divided into 'films of fact' and experimental/avant garde films. He considered narrative film to be the most important and basic form. In a similar way Williams (1984) has suggested that before we talk about specific subgenres, we should perhaps talk about only three, very basic or principal film forms: narrative film, avantgarde/experimental film, and documentary film. This division is also supported by Bordwell's (1985) division of films belonging to the more canonical, classical narration which dominates both Hollywood mainstream formats and national European mainstream films; art cinema narration with its more fragmented and less linear models of narration found in, for instance, European neorealism, New Wave cinema, and modernist and postmodern films; and finally nonnarrative forms such as documentary. All three forms have very distinct institutional backgrounds and are normally very easily recognized by the general audience, because distribution and indexing of art cinema, for example, is linked to special cinemas, festivals, and a special critical discourse, and documentary films have a totally separate distribution and are indexed much more for their special reference to reality.

2.2 Classical Hollywood and Beyond

Very often the classical Hollywood genres form the basis of what is generally understood as the fundamental genres, and these would most typically include melodrama, comedy, action-adventure, science fiction, horror, Western, film noir, crime genres, and musical. But each of these categories has subcategories, such as the crime genre, which is often further divided into gangster films, thrillers, hardboiled detective films, spy films, police films, etc. A popular

Internet site like the Internet movie database lists 11 general genre categories: action and adventure, art house and international, classics, comedy, drama, horror and suspense, kids and family, musicals, science fiction and fantasy, special interests and studio specials, and documentary. But each of these categories again has a large number of subcategories. Action and adventure, for instance, includes war films, Westerns, and disaster films. Neither the historical, critical, nor the popular taxonomy of genres are defined in very rigid and stable forms, although some basic forms are clearly present. As indicated in the ritual approach, the cognitive approach, and in most studies of the classical Hollywood system, it is however possible to define a number of more general generic forms and prototypes, which then often have different subforms and furthermore can change and vary historically.

Several models of typical historical developments of genres have been suggested in film genre theory. Neale ([1990] 1995), for instance, discusses the evolutionary model, used by Schatz (1981). In this model genres move from an experimental stage to a classical stage and to stages of more opaque, baroque, ironic, or even metatextual modes in which the basic formula elements are so familiar that directors and audiences have a more playful and reflexive relation with them. Neale points to another model in which genres occupy shifting positions as dominant, and run through phases of canonization, automation, and reshuffling. In recent theories on genre mixing and intertextuality it is furthermore often indicated that it is an increasingly common strategy by both the producer and the director to try to mix genres, to have maximum audience effect, and that furthermore the general audience today is much more used to genre mixing and intertextual and metatextual elements even in mainstream films.

2.3 Nonfiction Films and Genre

Many theories and discussions of film genres relate mainly to fictional film; however, both nonfiction film genres and the distinction between fiction and nonfiction are very important for the understanding of the fundamental film genres. Historically the term documentary was defined by John Grierson in 1926 as 'creative treatment of actuality.' This definition points to the fact that documentary films, like all nonfiction genres, have a special and more direct reference to reality than even the most realistic fictional film, but that on the other hand all documentary films are also a product of rhetorical and esthetic choices. Plantinga (1997) gives a pragmatic definition of the distinction between nonfiction and fiction: Nonfiction is related to those discourses that make explicit claims about reality and fiction to discourses that do not, a distinction between an assertive and a fictional mode, in which the

spectator treats the reference from text to reality in two fundamentally different ways.

Historically, esthetically, and rhetorically the documentary film has developed many different ways of representing and talking about reality. Barnouw (1993) uses different communicative roles to define different rhetorical purposes in documentary: explorer, reporter, advocate, poet, promoter, and observer. Renov (1993) in his theorizing about documentary forms makes a distinction between four fundamental functions of documentary films: to record, reveal, and preserve; to persuade or promote; to analyze and interrogate; and to express. Combinations of each of these communicative roles or purposes of course result in different subgenres of documentary.

Documentary genre theory offers several ways of defining the basic genres, but one of the most widely cited is Nichols's (1991) definition of four fundamental modes of representation: *the expository documentary* (with direct address to the viewer, often through authoritative voice-over and based on explicit arguments); *the observational documentary* (often based on simply edited visual observation and people expressing views in their observed reality, but without explicit commentary); *the interactive documentary* (based on a more active intervention and interviewing into reality, but still without an authoritative voice and comment); and *the reflexive documentary* (with a dominance of more self-reflexive and poetic strategies foregrounding the film's own strategy and relation to reality). If these modes can be taken as basic prototypes, then of course different subgenres can mix these modes and rhetorical strategies and it should also be added that mixing of fictional forms and documentary forms also has a long history. Docudrama and drama documentary or even more more complicated fact-fiction formats have developed strongly in recent film and TV culture adding to the esthetic and rhetorical variations of documentary forms or 'faked' documentary forms (Rosenthal 1999).

I. Bondebjerg

Film: History

As the art of film enters its second century, film historians not only encounter a longer and more heterogeneous film-historical past, but do so from within contexts unimaginable during the 1930s, when an important wave of book-length film histories appeared. Most notably, film history is now a field of study within higher education, with specialized journals, professional organizations, and conferences. An indication of film history's evolved condition is the extent to which film-historical research today proceeds through explicit revision of the findings and assumptions of established film histories.

Contemporary film historiography's self-critical orientation, together with the discovery and restoration of lost films, has enabled a fundamental rethinking of key periods of film history. Examples include recent studies of silent-era cinemas that had preceded or outsurvived the formation of Hollywood's so-called classical cinema. In attending to silent cinema's differences from later Hollywood practice, the new historiography has complicated established interpretations of film history as a progressive movement toward worldwide adoption of classicism. New interpretations of other periods in film history are certain to occur as films continue to be found, identified, reconstructed, and made available to scholars, especially films produced outside of film history's familiar research domains of Western Europe and the USA. Indeed, as new case studies accumulate, it is questionable whether world cinema can be said to have a history, if the term history is understood to imply a single narrative that might encompass the heterogeneity of the world's films and film practices.

1. *Film as Art and Industry*

Critics have often distinguished film from traditional arts, such as painting, music, and literature, by insisting that film is simultaneously an art and an industry. This familiar claim points to differences between the industrialized processes of filmmaking and the craft-based traditional arts that have differentiated the historiography of film from that of the other arts. Here three basic points can be made. First, as products of an industrial system, films lend themselves to a variety of forms of analysis, ranging from traditional art-historical approaches, centered on issues of esthetics and filmmakers' biographies, to

diverse economic, technological, sociopolitical, and quasi-anthropological investigations (see Allen and Gomery 1985, Lagny 1992). Indeed, film history's object of study is rarely defined exclusively in esthetic terms, as is evident in the use of nonesthetic events, such as the end of World War II, to demarcate periods in film history. Even film histories concerned mainly with esthetic questions typically also situate films in economic, technological, and social contexts. In fact, certain film histories conceptualize film primarily as a technological, economic, and/or social phenomenon, to the point of excluding esthetic considerations altogether. Such has been the case, for instance, in studies of the economics of national film industries.

Second, the evidently industrial nature of film production has encouraged modernist conceptions of historical change, according to which film history moves forward, in a single direction, with new films necessarily counting as a technical advance over old films. The histories of the established fine arts tradition have been interpreted in terms of cyclical patterns of change, according to which artistic movements rise, fall, and emerge again, in the manner of the life cycle of a natural organism. In contrast, filmmaking, so evidently a function of technological, industrial, and commercial conditions and forces, also invites conceptualization as an ongoing, forward-moving process, forever open to additional improvement. This conception of historical change as a modernizing process underlies both the film industry's celebration of the latest advances in film technique and critics' nostalgia for the lost artistry of the filmmaking of earlier periods.

Third, film history's progressivist outlook has been supported by the relatively short duration of the cinema's history. The histories of painting, poetry, and music have typically been studied irrespective of present-day artistic developments. Film history, however, has been concerned with an art whose past coincides with a recent and relatively short span of historical time. Thus, film historians have often examined the cinema's past in light of its latest trends. Indeed, on occasion, current developments in film practice have enabled new directions in film-historical inquiry. For instance, during the 1930s, the conversion to sound cinema had made it seem as if 'silent' films belonged to the historical past, thereby providing justification for the creation of film archives in Germany, the UK, the USA, France, and elsewhere.

2. *Beyond Classical Cinema*

Film history often displays a retrospective orientation in which the cinema's past comes up as a prelude to the cinema of the historian's present. Examples can be found in film histories that understand world cinema as having evolved toward the adoption of the so-called classical film style associated with studio-era Holly-

wood. Such adoption is generally taken to have occurred by the late 1930s, when filmmakers, in film-producing countries throughout the world, began making sound movies in imitation of Hollywood's films and filmmaking methods. Popular throughout the world, Hollywood films appear to have met transcultural expectations concerning story structure; moreover, it has been argued that the style of Hollywood films conforms to universal perceptual dispositions (see Bordwell et al. 1985). For instance, in a classical film, the duration of a shot is never too short or too long, but instead just long enough for the viewers, regardless of their cultural experience, to register the shot's significance to the unfolding of the film's narration.

Although Hollywood's studio system had collapsed by 1960, classicism continues to provide the context for inquiries into recent narrative cinema, as if classicism's apparent conformity to naturalized perceptual and cognitive habits has made it difficult to see how mainstream film practice might evolve beyond it. Yet since the 1970s, such evolution appears to have been happening, as the contemporary commercial cinema, with its emphasis on spectacular effects and tendency toward episodic narration, increasingly exhibits nonclassical attributes. Thus, following the pattern whereby today's film trends prompt reconsideration of the cinema's past, the nonclassical salience of current mainstream cinema has served to cast new light on established areas of film-historical inquiry. Such areas have begun to include studio-era Hollywood itself, as is evident in recent critical studies of the nonclassical aspects of Hollywood genres such as the musical, film noir, melodrama, and comedy (see Altman 1999).

3. A Revised Chronology

Since the 1970s, film historians, working in various research fields, have attempted to understand past films and film movements as if classicism's status as the pre-given *telos* or goal for world cinema can no longer be taken for granted. An indication of this development can be seen in a basic shift in historical method. Film historiography has traditionally displayed what might be called a 'vertical' interest in the position of a film, or a film-historical period, within a developmental sequence. In contrast, the new historiography can be said to be defined by 'horizontal' approaches, in which films are analyzed as embedded within contemporaneous contexts of production, exhibition, and reception.

3.1 Early Cinema, 1895–1906

Recent research on the early cinema of the period from 1895 to about 1906 provides a prototypical example of

contemporary film historiography's horizontal orientation. The period of early cinema begins in the mid-1890s with the first screenings of films by inventors of motion picture cameras and projectors. Canonical examples include screenings by the Lumière brothers in France and the Skladonowsky brothers in Germany in late 1895, and, in early 1896, by Birt Acres in London and Thomas Edison in the USA. The period continues until roughly 1906, when the sites of film exhibition were no longer mainly fairgrounds, vaudeville houses, and rented theatres, but came also to include nickelodeons and other permanent venues intended specifically for film screenings.

Accounts of early cinema typically center on the development of techniques of fiction filmmaking, especially devices of film editing. The films of inventors such as Edison and the Lumières were made up of only a single shot, usually lasting the length of a standard reel of film. But by 1899, in response to a greatly increased demand for films, film companies in France, the UK, and the USA began producing relatively lengthy narrative films made up of multiple shots. Historians have analyzed these films as attempts to solve the problem of how separate shots might be staged and connected together so as to create the impression of a continuous story. In established accounts, early multiple-shot films such as *The Great Train Robbery* (made by Edwin S. Porter in 1903) mark important moments in the development of the system of stylistic conventions associated with studio-era Hollywood (see Jacobs 1939).

Since the late 1970s, however, a very different history of the cinema of 1895–1906 has been written (see Elsaesser and Barker 1990). Instead of examining early cinema as a forerunner of the commercial narrative cinema of the late 1910s, the new historiography has analyzed early films in the context of their function within vaudeville routines, illustrated song slides, public lectures, and other forms of popular spectacle and fairground-like attraction. Examining how live music, spoken narration, and other exhibition practices affected the viewing experience, recent studies of early cinema bring forth dimensions of early films occluded within traditional developmental accounts. An example is the theatrical or presentational aspect of early cinema, which became a focus of historical study in the 1980s. Investigating early cinema's practices of direct address, adapted from vaudeville, the fairground, and other forms of popular theater, historians have come to understand early films less as primitive attempts at classical storytelling and more as performances within the context of live, spectacle entertainment at the turn of the century.

3.2 The Transition to Classicism

The cinema of the period 1906–1917 has traditionally been conceptualized as a transition from early cinema

to classicism. Key industrial developments include: a shift in editorial control away from exhibitors and toward producers; the creation of exchanges which rented film prints to exhibitors rather than sold them outright; the organization of film production according to a hierarchical division of labor that gave producers authority over directors and camera operators; the establishment of Hollywood as a production center; and the cinema's further expansion worldwide, marked, for instance, by the emergence of Denmark and Italy as major film-producing countries. Basic stylistic changes include: the dominance of the fiction film over the travelogs and documentary 'actualities' that had been an important part of early cinema; a new emphasis on celebrity performers or 'stars'; and a continuing increase in film length, leading, by 1914, to the establishment of the feature-length film as the norm for commercial movie-making.

As with other silent-era periods, established histories of the 1910s have emphasized the development of devices of film editing. Since the 1910s, critics noted that editing enabled forms of acting unique to cinema, in which actors' performances were constructed through a planned assembly of numerous shots rather than captured in a lengthy, uninterrupted run of the camera. During the 1920s, film theorists in France and the USSR argued that editing, in differentiating film from theater, had served to establish film as a singular art.

Accounts of the cinema of the 1910s have long centered on the work of the director D. W. Griffith. Dubbed the father of narrative cinema, Griffith has been credited with having conceived of the scene as a composite of shots, staged, filmed, and assembled so as to construct a unified dramatic world. In some 500 short one- and two-reel films, directed by Griffith between 1908 and 1912, devices such as the closeup, cross-cutting, and the eyeline match are employed as elements within what film theorists have described as a storytelling 'language' unique to cinema. Films such as *The Lonely Villa*, made by Griffith in 1909, feature elaborate last-minute rescues, made up of dozens of shots. Such sequences include events occurring in as many as three separate locales, cut together in rhythms that accelerate or slow down in relation to the intensity of the dramatic action. Innovations associated with Griffith became essential to US film practice, thus providing the basis for the classical style that would take form in Hollywood circa 1917.

During the 1990s, some historians have challenged the traditional emphasis on editing practices, arguing that proper appreciation of the cinema of the 1910s requires attention to techniques of *mise-en-scène*, i.e., the staging of dramatic action, through arrangement of actors, settings, and props within the camera's visual field (see Brewster and Jacobs 1997). Such attention seems especially warranted in the case of films made outside the USA, where innovations in film technique often were prominent in areas other than

editing. For instance, recent archival discoveries have shown that the film industries of Italy, Russia, France, Denmark, Sweden, and Germany produced hundreds of narrative films whose stories, in crucial respects, were told through techniques of staging. With scenes that play out in extended long takes, European films of the 1910s commonly feature far fewer shots than comparable US films, instead presenting story events through careful choreography of multiple actors' movements relative to their positions within the film's frame. The ensemble performances, in which several dramatic actions may occur simultaneously within a single framing, serve to situate character interactions within a shared environment. Thus, the narration of European films of the 1910s might be said to exhibit a psychological or social dimension unavailable to the contemporaneous US cinema's stress on linear, physical action.

3.3 The Decade of National Cinemas

By 1918, with the operation of Europe's film industries having been interrupted by World War I, Hollywood had established itself as the world's foremost film exporter, with distribution branches in South America, Australia, the Far East, and Europe. In response to Hollywood competition, Europe's film industries imposed quotas and other trade restrictions on Hollywood films, and drew inspiration from modernist trends in the arts to invent distinctive national film styles. The major art cinemas of the 1920s have long been a focus of film historiography. Such cinemas include expressionism and the *Neue Sachlichkeit* ('new objectivity') in Germany, impressionism and surrealism in France, and constructivism in the USSR. In France, where there was no clear industrial division between commercial cinema and art cinema, avant-garde techniques were integral to many mainstream films.

The experimental film movements evolved within a new international film culture, organized around specialized journals, film clubs, and art-cinema theaters. An unprecedented intellectual interest in film became manifest in a proliferation of theoretical writings and manifestos. Theorists stressed the need to overcome the apparent theatricality of established film styles, while numerous filmmakers, in Europe and elsewhere, undertook radical explorations of film's artistic potential. Thus, the films of the major European film movements of the 1920s frequently exhibit far more editing technique than had earlier European films. The new art films also often featured experimental cinematographic devices, from filtered lenses to superimposed images, double-exposures, and split-screen compositions.

Certain European film movements explored film's potential for radical alternatives to conventional scenography. Prominent examples include: the mon-

tage films of the USSR, such as Sergei Eisenstein's *The Battleship Potemkin* (1925) and Dziga Vertov's *Man with a Movie Camera* (1929), famous for their radical experiments in film editing; and French Impressionist films, from Louis Delluc's *Fièvre* (1921) to diverse films by directors such as Germaine Dulac, Jean Epstein, and Abel Gance, who employed multiple superimpositions and other optical effects to simulate diverse moods and affective states. Also important were German films such as Robert Wiene's *The Cabinet of Dr. Caligari* (1920) and Fritz Lang's *Metropolis* (1927), acclaimed internationally for their spectacular, studio-created settings. In addition, German films such as F. W. Murnau's *The Last Laugh* (1924) were known for the use of optical effects and elaborate moving-camera shots to suggest a character's embodied or psychological 'point of view.' By the mid-1920s, with increasing numbers of films and filmmakers crossing national borders, an international avant garde had taken form, encompassing filmmakers in Europe, North America, and Japan. 'International' films, such as Teinosuke Kinugasa's *Page of Madness* (1926) and Carl Dreyer's *La passion de Jeanne d'Arc* (1928), confounded national labels with their unusual mix of styles.

Questions remain concerning how new research into national cinemas besides those of France, Germany, the USSR, and the USA might alter the historiography of world cinema during the 1920s. For instance, during this period, Japan and India were among the world's largest film-producing countries. Yet, as with many other national cinemas during the years between the world wars, the films were rarely distributed beyond the national and regional film markets, and few of them have been preserved by distributors and archives. Thus, historical assessments of world cinema during the interwar years remain incomplete and provisional.

3.4 The Conversion from Silent to Sound Cinema

The introduction of recorded sound to cinema has attracted much historical analysis and commentary. Beginning in 1927, the unexpected success of Alan Crosland's *The Jazz Singer* (1927) provoked debate worldwide concerning the future of cinema. By the summer of 1928, as the film industry in the USA began its conversion from silent to sound cinema, observers described it as nothing less than an artistic, technological, and economic revolution. Historical accounts of the conversion period have traditionally emphasized various traumas, such as: the sudden collapse of established actors' careers, the flood of new stage and technical personnel into the film industry, the technical difficulties of sound filmmaking, the esthetic limitations of early sound films, the refinancing of the film industry by large banks, and the curtailment of avant-garde experimentation brought about by the high costs of sound-film production. The

impression of crisis encouraged partisan assessments, whether in the form of Hollywood's celebration of sound cinema as a great technological advance or critics' nostalgia for the vanished art of silent film. In either case, film history had seemed to start over again with the introduction of recorded sound.

Concerning film esthetics, sound conversion is said to have produced two main consequences. First, early sound films appeared to signal an artistic regression from the sophisticated art films of the 1920s. The available technologies had restricted the style of many early sound films to relatively long takes, stationary framings, and immobile actors who recited dialog in styles familiar to the popular stage. For many modernist critics, sound cinema amounted to a return to the allegedly theatrical cinema of the years prior to World War I. Established histories of the early sound years have focused on exceptional films such as Rouben Mamoulian's *Applause* (1929), René Clair's *Sous les toits de Paris* (1930), and Fritz Lang's *M* (1931), whose innovations in multitrack recording, postsynchronization, playback, and other techniques are credited with having restored movement to cinema.

Second, the technical demands of sound filmmaking are said to have pushed filmmakers everywhere toward adoption of film classicism, thereby producing a worldwide homogenization of film style. For critics familiar with the distinctive national film styles and transnational film movements of the 1920s, sound films often seemed to belong to a common family, regardless of where they were made. Even the USSR, famous during the 1920s for its counter-Hollywood film culture, was, by 1934, producing films that looked and sounded much like commercial narrative films made elsewhere.

In assessing sound's impact on film style, it is important to distinguish between filmmaking in Hollywood, which had undergone full industrialization prior to sound conversion, and filmmaking in other countries. One issue concerns the industrial conditions for film style. Whatever the personal, technical, and administrative upheaval, sound conversion did not fundamentally change Hollywood's processes of serial manufacture. Thus, sound conversion occurred in Hollywood under circumstances that enabled a continuation of silent-era practice. Most notably, Hollywood's sound-era editing style remained essentially consistent with established methods, involving many of the same techniques for constructing a unified, linear narrative. After a brief period of experimentation, even the new sound techniques were brought into line with classical precedent (see Crafton 1997). For instance, in 'backstage musicals' such as Harry Beaumont's *The Broadway Melody* (1929), song-and-dance sequences no longer came forward strictly as recordings of self-contained stage performances but instead functioned within narratives concerning the offstage lives of show-business personalities. By the summer of 1931, with

the industry-wide adoption of multitrack recording and mixing, the foregrounding of sound technique as an artistic novelty had been definitively abandoned in favor of the stylistic balance characteristic of Hollywood films of the late silent period.

In many other countries, however, sound conversion had entailed fundamental industrial change, and hence radical consequences for film esthetics. Small countries such as Canada were unable to sustain the industrial production of feature films, and instead came to produce mainly short films, such as documentaries and animated films. In countries such as India and Mexico, where filmmaking had been minimally industrialized, complete restructuring of the industry occurred, and new, sound-era genres, such as musicals that drew on indigenous entertainment traditions, came to define the national film output.

Research into the worldwide conversion to sound remains in its early stages. Relatively little is known about the output of many important film industries of the period. Recent research on Japanese cinema provides a case in point. Although Japan's large film industry dates from the 1920s, research on the history of Japanese cinema began to flourish only in the 1970s, with the rediscovery of the prewar films of Yasujiro Ozu, Kenji Mizoguchi, and other prominent art-cinema directors. Assessments of world cinema during the 1930s are certain to undergo revision pending further research into other important film industries of the period. In this event, the familiar notion that world cinema became homogenized during the 1930s may prove to have been a function of the restricted corpus of films then available to historians.

3.5 Postwar Internationalism

The decade after World War II is known for the emergence of a revived international art cinema. Prominent institutional developments include: the creation of international film festivals in cities such as Cannes, Venice, Berlin, Edinburgh, and Tokyo; increased government funding of film archives, thereby enabling expansion of the International Federation of Film Archives; new film journals devoted to international coverage; and the opening of special art-house movie theaters in cities throughout the world. These developments had prewar antecedents, and observers noted parallels between the new art cinema and the international avant-garde of the 1920s. Nonetheless, the new film culture differed in the extent to which its global network functioned independently from nation-state institutions.

An example can be found in the worldwide reception of Italian neorealism, whose status as the pre-eminent postwar film movement depended crucially on critical acclaim from outside Italy. Films such as Roberto Rossellini's *Rome, Open City* (1945) and Vittorio De

Sica's *Bicycle Thieves* (1948) drew admiration from filmmakers from every continent. Most notably, in evident contrast to the commercial cinema's linear and formulaic plots, the neorealist films emphasized the acts and events of ordinary life, including chance occurrences, routine, nondramatic actions, and inconclusive chains of events. Neorealist films were also acclaimed for the documentary-like 'realism' manifest in the use of nonprofessional actors, improvised performances, actual locations, and natural lighting.

Neorealism has commanded attention from historians as a beginning for prominent subsequent movements and tendencies in world cinema. Indeed, neorealism is said to have affected filmmaking in Asia, Africa, and Latin America more so than any other film movement of the sound era. For many filmmakers, neorealism offered a coherent, low-budget alternative to the style of commercial cinema, with great potential both for naturalistic social representation and for sociopolitical allegory. Filmmakers who have cited Italian neorealism as a personal inspiration include: Fernando Birra and Tomás Gutiérrez Alea, leading directors during the 1960s in the film industries of Argentina and Cuba, respectively; Satyajit Ray, the famous Bengali director from the Indian subcontinent; and Nelson Pereira dos Santos, founder of the *Cinema Novo* movement in Brazil.

The emergence of innovative film movements in Latin America, Asia, and, by the late 1960s, in Africa, with the Senegalese director Ousmane Sembene, had been conditioned by two basic developments. First, in 1947, movie attendance in North America had begun to fall, and would continue to do so through much of the 1960s. The decline became apparent just as Hollywood faced an important 1948 decision by the US Supreme Court, which required that the five major studios sell off their theater chains, and that both major and minor studios cease a variety of other monopolistic practices. In response to the economic and political adversity, the major Hollywood studios produced fewer films throughout the 1950s, targeted now toward specific markets. Second, during this same period, many countries experienced booms in film attendance, especially in the so-called developing world, where television had not yet emerged as an entertainment alternative. Responding to the demand, major film industries emerged in Egypt and Hong Kong, while the new nations of Burma, Pakistan, South Korea, and the Philippines also began producing films on an industrial scale. Also during the 1950s, India became one of the world's largest film producers, making hundreds of films exclusively for the South Asian film market. By the mid-1960s, some 60 percent of all of the world's feature films were made in Asia, Latin America, and Africa.

Coinciding with the worldwide boom in film production, 'new waves' and 'young cinemas' took form in diverse countries, beginning in the late 1950s and continuing through the 1960s. Young filmmakers

worked to distinguish themselves from the established filmmakers of their native countries by emulating new currents in world cinema. Most prominent was the French New Wave, known for films such as François Truffaut's *Les quatre cent coups* (1959) and Jean-Luc Godard's *Breathless* (1960), which featured inventive adaptations of conventions drawn both from Hollywood and European genre films and also from the international art cinema. Important new waves also emerged in Japan, Czechoslovakia, and, indeed, in virtually all countries, in one form or another, during the 1960s. A famous example is the Young German Cinema, whose self-conscious opposition to Germany's established film culture opened the way for the international prominence during the 1970s of directors such as R. W. Fassbinder, Werner Herzog, and Wim Wenders.

3.6 Film Historiography Since the 1970s

The new film culture of the 1960s would have a profound impact on the writing of film history. An example can be found in the notion of the film director as artist or *auteur*. This notion had been formulated in Paris in the 1950s by a group of young film critics, a remarkable number of whom would go on to become key directors of the French New Wave. These critics argued that film directors should be seen as performing the kind of creative role traditionally accorded to novelists, playwrights, painters, and composers. A precedent could be found in certain currents in film critical writing during the 1920s, which had recognized filmmakers such as Charlie Chaplin, F. W. Murnau, and Erich von Stroheim as artists. But the auteur critics extended the sphere of art to encompass a remarkable diversity of films, including, in some cases, even low-budget sound-era genre films. Provocatively comparing movie directors to Mozart and Shakespeare, the auteur critics expanded the canon of great film artists to include current commercial directors such as John Ford, Orson Welles, Alfred Hitchcock, and Howard Hawks.

The 1970s might be said to have opened a new era in film historiography. During the 1970s, the integration of film study into university curricula in Western countries opened up new contexts for film-historical research. For instance, the notion of the director as artist came to inform the academic study of film, leading to the publication of numerous monographs on a wide variety of filmmakers. Moreover, professional approaches to film study, involving the critical re-examination of established film history, also took form. A case in point is the new historiography of silent cinema. Whereas previous film historians had often relied on other historians' accounts, together with personal memories of films, the new generation of archivists and professional scholars studied large collections of film prints, comprised of recognized classics as well as many lesser known or forgotten

works. Additional historical sources included a wide variety of print documents, including film reviews, trade publications, film companies' catalogs, and paper prints of films from the US Library of Congress. The result of this research was a thorough reconceptualization of the early silent period. This work, in turn, is likely to serve as an exemplar for historians working on later periods, such as the period of sound conversion, which, like early cinema, demands both empirical research and historiographical reflection.

As the cinema now enters its second century, new technological changes can be expected to enable new ways of seeing the cinema's past. For instance, as computer-generated digital images come to replace the cinema's photographic image, cartoons and other nonphotographic animated films may come to appear central to film history. In any case, as old films continue to be restored and made available to scholars, significant changes in film historiography continue to occur. At annual silent-film festivals, such as those held in Bologna and Pordenone, large bodies of films, representing the output of diverse directors, actors, studios, film movements, and national cinemas, are made accessible to critics and historians. Each year, new discoveries stimulate revision of established scholarship, while at the same time underscoring the incompleteness of the historical record, and hence the certainty that film history will remain a work in progress.

Finalization in Science

The finalization model addresses the question of how internal (cognitive) and external (social) regulations interact in the dynamics of modern science. It assumes that paradigm building in scientific disciplines will eventually lead to stable theories that solve the fundamental problems in the field and are unlikely to be repealed by a Kuhnian scientific revolution (Kuhn 1962). With the advent of paradigmatic theory, research programs in disciplines become responsive to social and political goals on the level of theory formation. Therefore, cognitive autonomy in the sense of a compelling internal logic of the growth of knowledge is a transient feature and hence more characteristic of an immature science than a mature one. (The finalization model is explicated in Böhme et al. 1983; it has been reassessed in contributions to a symposium for *Social Science Information* Vol. 36, see Leeming 1997.)

1. The Internalism–Externalism Debate

The internalism–externalism debate—a debate that has intrigued historians and sociologists of science since the 1960s—fell into disrepute in the 1980s when mainstream studies of science became preoccupied with the analysis of the social construction and cultural embeddedness of knowledge (see *Laboratory Studies: Historical Perspectives*). These studies have tended to discard any distinction between the cognitive and the social aspects of science (Shapin 1992). However, a (relative) distinction must be upheld if one is to explain not only how science can be shaped by social context, but also how society can be transformed through science (see *Knowledge Societies*).

Modern science emerged from the struggles over cognitive order that waged throughout the seventeenth century, eventually establishing the notion of, and a niche for, the pursuit of natural knowledge which sets empirical facts categorically apart from religious belief, social choice, or political preference (see

Webster 1976). The ‘edge of objectivity’ (Gillespie 1960) is culturally biased: modern science applies an operational (experimental) conception of truth that reflects a social interest in prediction and control. Despite that bias, however, it yields universally valid knowledge. Accordingly, when observations in the laboratory fail to identify any interesting epistemological difference between the pursuit of knowledge and the pursuit of power (Knorr Cetina 1995, p. 151), this tells more about sociology than about science. The finalization model acknowledges the premise of social construction, but still emphasizes the institutional and cognitive differentiation and specificity of modern science as a system of knowledge production. It considers the internal logic of the system—albeit as an emergent property and evolving process.

2. The Rise of Scientific Internalism and its Transition

2.1 Paradigmatic Science

Historically, scientific fields develop through phases in which the mechanisms of internal problem generation prevail. The *locus classicus* of such growth, both in cognitive and institutional terms, are academic disciplines or specialties (e.g., mechanics, electrodynamics, physical chemistry, genetics, biochemistry) that pursue research programs in which the fundamental laws governing the phenomena in their respective object areas are elaborated and confirmed. In this phase of theory formation or paradigm building (Kuhn 1962), frontiers of research are largely determined through explanatory ideals and strategies within science. The flow of problems in understanding the nature and mechanisms of light, electricity, matter, heredity, or cell differentiation regulate the dynamics of the disciplines. The full logic of this internalism is not well understood and remains a matter of ongoing debate among philosophers and sociologists of science (see Hacking 1983, Pickering 1995). The search for more fundamental and more comprehensive theories to explain natural phenomena of increasing complexity seems to be an element of that logic.

2.2 Postparadigmatic Science

The finalization theory adopts Thomas Kuhn’s phase model of disciplinary development (preparadigmatic, paradigmatic, normal science) with one major modification: it assumes that the dynamics of paradigmatic science can lead to mature theories which provide a fundamental and, in a certain sense, conclusive understanding of the phenomena in their domain. To assume that all theories will eventually be falsified or superseded through scientific revolutions, and completely replaced by new paradigms, fails to account for the extraordinary stability of modern theories. For at least

100 years, consolidated theories of motion, heat, light, electricity, matter, or heredity have not been rendered obsolete, despite the Kuhnian revolutions that established new paradigms. Werner Heisenberg (1971) proposed the concept of 'closed theory' to capture the stability of classical mechanics and electrodynamics in the transition to relativity and quantum mechanics (see also Böhme 1980).

To the extent that disciplines achieve theoretical maturity, the core of their dynamics will shift from research that strives for the discovery of new fundamental laws to research that applies these laws to the wealth of phenomena in their domain. Science is a truly 'endless frontier' (Bush 1945) not so much because fundamental problems are multiplied beyond limits and paradigm change is always imminent, but rather because existing paradigms can be extended to an indefinite number of applications. Such applications are termed 'postparadigmatic' science in the finalization model.

2.3 *The Social Direction of Theory Development*

Applying paradigmatic theories is not a simple exercise in deduction. The general principles of hydrodynamics or quantum mechanics or organic chemistry are valid for fluids or solid matter or the processes of plant nutrition, respectively, but they cannot be applied to them without a series of steps of theory specialization through which the principles are extended and adapted to the complexity of real objects. These steps involve such fundamental achievements as the boundary layer concepts in hydrodynamics, or the band concept in solid-state physics or the metabolic cycles in biochemistry. Postparadigmatic science (Kuhnian 'normal science') is not puzzle solving in a trivial sense, it is theory development at the frontiers of basic research. The point the finalization model raises is that internal regulation of science becomes weak at these frontiers. While problem generation may flow from the natural complexity of real phenomena in the domain of general theories, it can also flow from the task of coping with the boundary conditions defined by technical and social tasks. For example, fluid mechanics had been developed into a theory of flow around airplane wings by Prandtl early in the twentieth century; more recent efforts in fusion research extended the theories of magneto-hydrodynamics to the special conditions required for controlled fusion in a reactor: stability and containment of a plasma in toroidal geometry.

3. *Limitations of the Model*

The finalization model is biased on physics as the exemplary scientific discipline and on theory building as the prevalent pattern of scientific internalism. While

the model may cope with the fact that there are other internal frontiers in physics, such as the exploitation of instruments for discovery (Hanson 1965), a critical point is that the meaning of theory may vary among disciplines. Such variation will be reflected in what sociologists describe as the 'epistemic culture' of a field (see Knorr Cetina 1999). Further analysis is needed to determine whether models of scientific growth derived from the case of physics are transferable to genetics or physiology or ecology. The case of agricultural chemistry suggests that theoretical maturity may not be a necessary condition for goal oriented theory development (Krohn and Schäfer 1983).

Finalization is not the only option for the development of disciplines that have reached the paradigmatic stage. 'Normal science' can also pursue the extension of available theories to objects of purely academic interest. In addition, there is also the possibility that the paradigmatic dynamics in the discipline is renewed; non equilibrium theories that go beyond classical mechanics are one example. Such renewal does not challenge the assumptions of finalization as long as new theories do not supersede established paradigms, but indeed provide a more precise understanding of their domain of validity.

Applied science must not wait for finalization to become feasible. To a great extent the mobilization of science for external objectives, today as in the past, does not occur on the level of targeted basic research and theory development; rather, less ambitious strategies are pursued that aim at the quick exploitation of findings and methodologies available in science. Application strategies are pervasive in science. They even intrude disciplines in the paradigmatic phase. However, it seems that the priority and the logic of paradigm building remain unaffected in this case. A study of the relation of early molecular biology to medicine indicates that external orientation can operate as long as it converges with the internal frontiers of the discipline. In addition it is possible to transfer the findings and techniques of basic research to contexts of application (Hohlfeld 1983).

Finalization is a pattern of goal orientation in science that becomes feasible with the growth of knowledge in scientific disciplines. However, critical social and political demands for scientific knowledge often transcend the boundaries and resources of existing disciplines. Ecological prognosis of climate change resulting from the burning of fossil fuels is a case in point. While such demands may be rejected as 'transscientific' from the perspective of traditional disciplines (Weinberg 1972), they do find resonance in what has been called 'post-normal science' (Funtovicz and Ravetz 1993). This is basically a recursive effort to combine scientific analysis with political judgement of how one should responsibly proceed in view of the fact that hypotheses about imminent danger cannot at present be tested by scientific means. See also van den Daele and Krohn (1998) as to how the methodology of

research is translated into a policy design for dealing with the inherent risks of the implementation of new technology.

4. The Science for Society Perspective

Ever since Bacon and Descartes, modern science has been hailed as a ready tool for social and political goals. Historically, however, it took time until the sweeping promises began to materialize. Now, at the beginning of the twenty-first century, the applied mode of science seems to dominate (Gibbons et al. 1994). Pressure to cooperate with various consumers of science, mainly industry, is extended even to academic research. Such pressure does not just reflect a change of political climate or the emergence of a new narrative of the science–society relationship (Elzinga 1997): science itself has become more susceptible to external direction. The finalization model provides an understanding of this susceptibility by analyzing the supply-side of science, so to speak. With theoretical maturity, social and political objectives can be pursued through targeted research at the core of scientific disciplines. Postparadigmatic sciences flourish in many fields of physics (National Academy of Sciences 1972, p. 404); the same would hold for chemistry and considerable parts of molecular genetics. The advancement of science is bound to bring more disciplines to a postparadigmatic stage.

Finalization affects the social relations of scientific disciplines. New issues of responsiveness and accountability arise. Social goals for basic research may be defined by scientists sensitive to social issues, but must ultimately be justified in political, not scientific, terms. The generation of problems in postparadigmatic research can be easily converted to a political process that entangles scientists in negotiations with stakeholders in society over the future development of their fields. Finalization, however, implies a commitment to theory formation. While bound to social objectives, it thus operates at some distance to problem definitions derived from the immediate instrumental needs of companies, governments, or regulatory agencies. Such distance may be needed if the true potential of science for society is to unfold. Theory building provides broader horizons of both explanation and technology, in light of which present definitions of problems and goals may have to be reconsidered.

The finalization model suggests that the distinction between social context and cognitive contents is indispensable for the analysis of the social relations of science. Within a conceptual framework that reduces knowledge to social construction and discards any reference to scientific internalism, one cannot account for the changing patterns of scientific growth and their impact on society. These points deserve more consideration in contemporary sociology of science. To

that end, it is not enough to provide a new language that can be applied equally to natural events, experimental data, and theoretical arguments on the one hand, and to social actors and processes on the other (see Latour 1993). The notion that knowledge is categorically separate from power, interest, and social relations must be rehabilitated. This will not jeopardize the social studies of science: it will only eliminate some of the misleading epistemological claims from sociologists who observe science, and perhaps spare us more ‘science wars’ (Gross and Levitt 1997) from researchers who do science.

W. van den Daele

Finance, Geography of

1. Money and Finance

The geography of money and finance is an important part of what money and finance actually are: the spatial pattern of automated teller machines and bank branches, the passions aroused by currency zones and credit ratings, the flow of financial information through fiber-optic cable networks and satellites, the hierarchy of international and offshore financial centers—all attest to this fact. Yet it is remarkable how little understanding of these different geographies existed until comparatively recently. With a few honorable exceptions, the geography of money and finance was neglected until the 1980s. Since then, however, geography has become a major element of the study of money and finance, for three main reasons.

First, the 1980s were a period of major changes in cultural perceptions of money and finance. Whereas previously finance had been seen as the preserve of stolid accountants, solid bank managers, and squalid dealers, in the 1980s, through the offices of film portrayals, television series, and print journalism, it became recast as a dynamic, even sexy, area of the economy.

Second, money and finance had become such a central element of the geography of modern economies that it was impossible to ignore. The ‘financialization’ of the economy, especially the tendency of economies to run to essentially short-term financial criteria such as shareholder value, had become so noticeable that it was no longer possible to envisage money and finance as a subsidiary activity whose role was simply to oil the wheels of production.

Third, geographers produced a series of works on money and finance which has proved the value of a distinctive geographic perspective that emphasizes how space creates money, as well as how money creates space. Foremost among these works were David Harvey’s *The Limits to Capital* (1982), a Marxian analysis of capitalism which included a seminal chapter on money; subsequent books by Leyshon and Thrift (1997a), McDowell (1997), and Clark (2000); and edited collections from Corbridge et al. (1994) and Martin (1999). In turn, this literature has been paralleled by work in politics, sociology, and even economics. In this article, each of four different but related geographies of money and finance is examined in turn.

2. International Finance

Geography first approached money and finance through the lens of *international finance*. Events like the developing-country debt crisis of the 1980s, the developed-country debt crisis of the early 1990s, and the establishment of the euro zone in the late 1990s demonstrated both the power of international finance and its essentially geographical nature. Geographers gravitated to four main areas of work. Not surprisingly, the first of these was the link between international finance and urbanization implicit in the hierarchy of world cities. Work taking place at a number of levels attempted to show the mechanics of this relationship; for example, specific financial markets were related to the success of particular cities. A further, natural extension of this work consisted of investigations into the global hierarchy of offshore financial centers, which, though smaller in scope, are also key features of the international financial system.

The second area of work concerned new financial instruments. In particular, the geography of new forms of options have proved of interest, not least because they have had direct impacts on the urban and regional fabric through various market imperfections and financial scandals (Tickell 1996, 2000, Pryke and Allen 2000).

One more area of research has been international debt. The debt crises of the 1980s galvanized geographers, and led to a continuing stream of work on finance and development. Then, finally, wrapping all of these areas of work together has been the issue of

governance. The shifting balance of power between the national state and financial markets, the growth of supranational regulatory institutions, and the status of world cities as centers of global governance in their own right are topics that underline just what an important area of work this has become (Thrift and Leyshon 1994, Gilbert and Helleiner 1999), one which overlaps, in particular, with the concerns of international political economy.

3. Retail Finance

Geographers gradually became interested in the national- and regional-scale financial systems through the issue of *consumer finance*. That interest has taken a number of different forms. To begin with, there was a general interest in the changing geographies of retail finance: for example, variations in employment in the industry between states in the USA, the hierarchy of domestic financial centers in the UK, the variable gender and ethnic composition of financial services labor forces, and so on. This work has produced a base from which it has been possible to inquire into the dramatic restructuring of financial services, covering subjects as diverse as the rise of call centers (and their urban and regional consequences) and the diffusion of new financial management ideas. In turn, it has also become possible to intervene in a number of policy domains. The most dramatic intervention has been in policies towards financial exclusion, through careful study of the large numbers of poorer people who do not have access to the formal domestic financial system and who are often further disadvantaged as a result (Leyshon and Thrift 1995, 1997b). While the number of those excluded has fallen in many Western economies, the fact remains that this is a pressing problem only made worse by some of the effects of restructuring, such as the closure of bank branches in poorer areas. The result has been both an interest in changing government policy to force the financial system to acknowledge its civic role and a widespread interest in financial institutions able to be used to construct alternatives: credit unions, micro-credit, alternative currencies (e.g., time dollars), small-firm financial schemes, local exchange trading schemes (LETS), and the like.

4. Electronic Finance

The impact of electronic telecommunications on money and finance has been critical. Historically, finance has always been one of the industries most likely to feel the impact of changes in telecommunications, given its emphasis on speed. However, of late, this impact seems to be so great that it is actually redefining what money is by producing new spatial and temporal frames, in rather the same way as in the

changeover from coin to paper money (Leyshon and Thrift 1997a, Pryke and Allen 2000). International finance has been in a process of change since at least the 1960s as a result of continual advances in telecommunications which are leading to nearly instantaneous 24-hour financial markets, trading globally. In turn, these developments are producing changes to the current hierarchy of world cities (e.g., Thrift 2000). An important finding made by geographers has been that the increasing amount of electronic information is not necessarily leading to a decline in face-to-face interaction. Especially in the larger international financial centers, which receive very large amounts of electronic information, face-to-face interaction in tightly defined social networks is vitally necessary to lessen the interpretive load in many markets, as well as to allow new stories about what is happening to be created and put into general circulation. Retail finance is also being changed by electronic telecommunications, and, in the long run, the changes here may be even more dramatic than in international finance. Currently a transition is under way from intermediate technologies such as call centers—which still include human elements—to much more heavily automated systems (for example, employing automated voice recognition to replace call center agents). In turn, this transition may well produce a new geography of web-based banking in which consumers will use intelligent agents to undertake much of their financial business (Leyshon and Thrift 1999, Thrift 2000).

Perhaps the most important outcome of electronic money and finance will turn out to be the growth of a combination of software and databases. The effect of the rise of automated decision systems, combined with large synthetic data sets, on the economic circumstances of most individuals has serious connotations, which are now being explored. For example, the concentration of data in the hands of a few private-sector firms raises obvious issues concerning civil liberties and regulation. Geographers specializing in geographical information systems have been intimately involved in the construction of many of these systems and must shoulder some of the responsibilities for the outcome.

In turn, the advent of this new electronic monetary space has contributed to financial exclusion. It seems likely that cities will 'splinter' even further, with serious consequences for social equality. In particular, a large minority of people will not only be excluded electronically but, given the changing status of money, financially as well.

5. Social and Cultural Issues

Finally, the social and cultural elements of the geography of money and finance have increasingly become visible. As an electronic site of exchange, money has increasingly become an evacuated signifier,

a kind of cultural degree zero. In such a situation, social and cultural aspects become more rather than less important, since they become the crucial identifiers of what counts as money in the absence of money as a tangible object. So, in certain senses, money has proliferated; all kinds of different monies, labeled according to their social and cultural usage, have sprung up.

Such developments have produced considerable geographical interest. To begin with, there has been a large amount of work on the historical iconography of money and finance, and especially the role of money in establishing national identity (see Gilbert and Helleiner 1999). Then there has been work on how money is read through a growing discursive apparatus of television programs, newspaper articles, and the like, which demands 'financial literacy' as a ticket of entry (Leyshon et al. 1998). And there are the social and cultural fault-lines created by money, both within its labor force (as, for example, in the matter of gender and sexuality; see McDowell 1997) and in its ability to produce social and cultural capital for certain elite segments of that labor force, which has enormous spread effects in cities like London and New York (Leyshon and Thrift 1997a).

6. Further Directions of Research

Further directions of research on money and finance are clear. The first of these is the increasing privatization of welfare, with welfare functions that were often produced or guaranteed by the state being run down, leading to a situation in which individuals increasingly have to make their own private arrangements for health and old age. Thus we are seeing the birth of what Clark (2000) has called '*pension fund capitalism*,' which, especially given the general aging of populations in many countries of the world, is becoming a pressing economic issue with profound consequences for the distribution of income, and for life chances. The second direction is *software*. Increasingly, the financial system will be run by machine codes, yet remarkably little is known about the agency of code or how to regulate its production. Here is a pressing theoretical and practical issue. The third direction is *speed*. Increasingly, electronic money is producing instantaneous exchange. There is much hyperbole about this state of affairs but precious little research informing us on how social skills and practices are adjusting and thereby changing what money is. Then, finally, there is the matter of financial exclusion. As already noted, this is a pressing issue which demands the design of different kinds of financial institutions. Geographers have been very active in this area and have been able to demonstrate the full range of competencies that they now have concerning money and finance, competencies that

as recently as the 1980s would perhaps have been regarded as surprising.

Financial Accounting and Auditing

After situating accounting and audit as social practices, this article examines research objectives and methodology in these fields.

Accounting and audit are closely linked social practices. By means of the information it produces, accounting assumes two principal functions: the ren-

dering of accounts and the taking of financial decisions. Standardization and audit then come into play, since accounting information must necessarily be a reliable and believable reflection of the events and conditions it portrays. The initial role of auditing is to assess the reliability and credibility of the accounting portrayal. Taken together and in their complementary roles, accounting and audit are major elements of social regulation.

The resulting importance of accounting and audit in contemporary societies, for better or for worse, has made them the object of active research. Depending on the research methodology employed, research may be conducted from a historical, sociological, or economic perspective.

1. Accounting and Auditing as Social Practices

The origins of accounting have been lost in the mists of time, predating even figures themselves. Indeed, we have been counting for a very long time (and continue, moreover, to do so) without the help of figures. However, generally it is agreed that modern accounting was born at the end of the Middle Ages in Northern Italy with the 'invention' of double-entry book-keeping. A chapter of the Franciscan monk Luca Pacioli's work on mathematics (the *Summa de Arithmetica, Geometria, Proportion e Proportionalita*), published for the first time in 1494, introduces this invention which was to enable accounting to fulfill its present-day functions.

1.1 The Functions of Accounting

In short, let us say that accounting fulfills, and has probably always fulfilled, two main functions: on the one hand, a rendering and control function, and on the other, an aid to decision-making function.

Its first function may be related to the old master-servant relationship. When a servant is given any sort of task or assignment by his master, he must, sooner or later, give a narrative or numerical account of the manner in which he has carried it out. Accounting is precisely one of the instruments which enables a servant to give an account to his master, and the master to check his work.

In the light of this, it is not surprising that modern accounting was 'invented' at the end of the Middle Ages in the big towns of northern Italy: Florence, Genoa, and Venice. Their bankers and merchants, at the head of veritable multinationals, operated all over the Mediterranean and northern Europe. To carry out business activities that were often far away from their home-towns successfully, they were obliged inevitably to rely on agents and representatives that their invention of double-entry records enabled them to control more effectively.

Similarly, it is easy to understand the importance accounting assumed in the nineteenth century when joint-stock companies mushroomed and the split between partner-capital contributors and directors appeared. Partners removed themselves, or were removed, from the running of companies, and directors were obliged legally to provide them with information on their administration at regular intervals by the production of balance sheets and income statements. What financial theory terms an 'agency relationship,' therefore, became a legal requirement. To use agency theory vocabulary, one might say that the partners played the role of principals, and the directors that of agents. Accounting is, therefore, the instrument that enables the principal to control what his agent has done, and the agent to give an account of what he has done. In this relationship, the accountant occupies a somewhat unusual position since he draws up the accounts—destined for the principal—of the agent who must give an account. English expresses this triangle very well since it has three words, to designate respectively he who has an account to give (the accountant), he to whom the account must be given (the accountee), and finally, he who does the accounts (accountant).

This 'accounting game' is obviously a complex social game to the extent that the person giving the account possesses more information than the person to whom the account must be given, and to the extent also that he may be tempted to manipulate the accounts and present them in a way favorable to himself. The accountant, who draws up the accounts, occupies, despite himself, the position of mediator, and so it is a good idea for him to belong to an organized profession with a strong sense of ethics.

Accounting's aid to decision-making function is as old as the preceding one and linked closely to it, moreover. The bankers and merchants of northern Italy, mentioned above, had to join forces to amass the capital needed to finance their businesses. They obviously had to share the profits, and to do so, they needed an instrument which would enable them to calculate what these were. The new double-entry accounting was also capable of responding to this need and naturally still exists in today's big companies. A company's annual accounts allow shareholders not only to keep track of the activities of their directors, but also to take the decision which is, as it were, the high point of their annual general meeting, the decision concerning the allocation of profits.

The two main functions of accounting have taken on a dimension that matches the responsibilities of today's companies. Today, companies must give an account not only to those who have entrusted them with their capital, but also to many other partners such as the Government, their suppliers, customers, employees, and in more general terms, the public. So their accounts (and in particular their balance sheet and income statement) have to satisfy various needs for

information which correspond to very different models and control and decision-making rationales. More specifically, they should, for example, allow:

(a) investors, as previously mentioned, to assess the way the directors administer the business and to take into account their decisions regarding purchasing, and the retention or sale of stocks and shares;

(b) banks and financial establishments to judge the financial solidarity and reimbursement capacity of the company;

(c) employees to analyze its social effectiveness and its durability;

(d) suppliers to understand its capacity to honor its debts;

(e) customers to measure its capacity to fulfill the orders it receives; and

(f) the Government to control its taxable profit.

At this stage, one might say that this type of accounting is the system of information through which a company, or any other organization (including nonprofit-making organizations), gives an account to its economic and social partners, and, in doing so, submits itself to their control and allows them to take decisions. It is because the information it produces is, for the most part, of a financial nature that it is described in this way. Moreover, financial accounting which responds to the need of third parties for information can be distinguished from the type of accounting known as management accounting which responds more specifically to a company director's need for information. If it is to assume its vocation of providing information for third parties effectively, financial accounting must obey recognized rules and the application of these rules must be controlled. This is the role of the audit.

1.2 Standardization and Auditing

In all major developed countries, accounting obeys standards fixed by the accounting profession and/or public authorities. In addition to purely national standards, there are now international standards produced by the *International Accounting Standards Committee* (IASC). The aim of standardizing corporate accounting is to make the financial information it produces intelligible and credible. However, to the extent that it is the companies themselves who do their own accounting, standardization is not an adequate condition for the credibility of their accounts. The accounts must be audited.

Auditing a company's accounts consists of checking that they have been drawn up in accordance with current procedures and standards and that they give a true and fair view of the company's financial situation. Obviously, the audit cannot consist of redoing the company's accounts. The auditor proceeds essentially by means of investigation and cross-checking in order

to identify anomalies likely to call into question the reliability and credibility of the accounts on which they must give an opinion. This opinion, which is the result of these investigations, serves to certify the accounts. Certification can be positive or negative, and accompanied by observations and reservations of varying degrees of importance. It should allow the recipients of the accounts, and in particular investors, to assess their validity.

In the course of the twentieth century, the accounting audit received legal consecration in very many countries. Joint-stock companies must have their accounts audited by independent professionals. In Anglo-Saxon countries, the audit assignment is undertaken by certified (US) or chartered (GB) accountants. These providers of credibility form what the sociologists call a 'profession' in the sense that they take on a task which is in the general interest and are, for this reason, subject to requirements regarding their competence and professional code of ethics. Auditors' codes of ethics place great emphasis on their independence.

The audit has expanded considerably its initial accounting vocation and in the second half of the twentieth century has undergone considerable, protean development, generating a major economic sector dominated at world level by several large consultancies such as Arthur Andersen, Price Waterhouse Coopers, Deloitte Touche Tohmatsu, Ernst and Young, KPMG, (known as the 'Big Five'). In the widest sense of the term, the audit now covers all 'listening' activities ('audit' comes from the Latin 'audire,' to hear), evaluation, supervision, and external control of organizations. To the accounting audit previously mentioned has been added the management audit, the quality audit, the environmental audit, etc. Moreover, all organizations, and not simply companies, make use of the audit.

Together, therefore, accounting and auditing form one of the mechanisms which contribute to maintaining links of collaboration and confidence between the various economic and social players, whether these be individuals or organizations. The multiplication and increasing complexity of the relationships between social players has created an enormous demand for accounting and auditing. One might even say that modern society is an 'audit society' (Power 1997).

2. Accounting and Auditing as Research Subjects

Accounting has never been a fixed, immobile technique. For five centuries at least, if one traces its modern origins back to the Middle Ages, it has adapted constantly to developments in companies and their environment. This adaptation is, in a sense, the expression of a form of applied research that one might qualify as spontaneous, carried out by the

practitioners themselves, heads of companies, and accountants. But it was not until the twentieth century that accounting and audit became objects of research for the social sciences, of interest in particular to historians, sociologists, and economists.

2.1 Accounting History

During the twentieth century, accounting has been the subject of very many historic investigations. All the major academic accounting reviews (*Abacus*, *Accounting and Business Research*, *Accounting-Organization and Society*, *The Accounting Review*) publish articles on the history of accounting. Entire reviews are even dedicated to it such as *The Accounting Historian's Journal* and *Accounting Business and Financial History*. Through these many publications, it would seem that the history of accounting can be approached in several different ways.

Certain historians are interested in accounting as a recording technique and pay particular attention to the genesis and evolution of the double-entry system that still is the most striking aspect of accounting. Other historians wish to see accounting as something more than pure technique and consider it to be an instrument of social and economic regulation. From this point of view, its history is not an autonomous history and is part of several histories: the history of the economic system, the history of companies, the history of techniques, and the general history of ideas.

One of the first to adopt this point of view was the economist Werner Sombart who postulated that there was a very strong link between the development of the capitalist system and that of accounting, going so far as to claim that one was not conceivable without the other, that double-entry accounting allowed the company to be set up as a place of economic calculation, to give a numerical expression to the profit objective, and thence to rationalize the allocation of resources. Although contested, Sombart's thesis has contributed to reviving the history of accounting.

2.2 Accounting Sociology

Since the past 1970s, and above all in Great Britain, the sociology of accounting has undergone major developments. These developments are sufficiently differentiated for two distinct schools of thought to be identifiable within this field of research: an interpretative, and a radical school.

The interpretative school, represented by authors such as Giddens, Morgan and Foucault, aims to interpret accounting practices, in particular national standardization practices, through reference to their technical, economic, social, cultural, and political

context. This type of research tries to highlight the various conditions which influence accounting and which mean that it cannot be considered as an isolated technique. Although it relies mainly on sociological methods, in particular the monograph, it also uses the historical method. Its main organ is the review *Accounting Organizations and Society*.

The radical school, which is Marxist or neo-Marxist in inspiration (with references to Habermas and Marcuse) considers that accounting and auditing are mechanisms designed and implemented by the dominant social groups to defend their interests and strengthen their domination. It is, therefore, a question of dispelling the mystery surrounding the neutrality and objectivity often attributed to them and of highlighting their ideological function. Researchers who position themselves within this trend willingly support the oppressed (poor countries, women, and in the United States, blacks) and lend them their expertise. From a methodological point of view, they make highly eclectic use of social science approaches. Intentionally provocative, and with a leaning towards intellectualism, they go so far as to call upon poetry to illustrate and defend their theses. Their main organ is *Critical Perspectives on Accounting*.

2.3 Accounting Economics

Economic research has given birth to what is commonly known as positive accounting theory. According to Jensen (1983), this is a theory capable of explaining '... why accounting is what it is, and what consequences accounting figures have on people and on the allocation of resources.' At the end of the 1970s, the theory was promoted by two professors from the University of Rochester, Ross L. Watts and Jerold L. Zimmerman.

The research conducted in the wake of these two pioneers was inspired principally by the agency theory and aimed to highlight the determinants of choices of accounting methods made by company directors, where standardization authorizes such choices. In agency theory, the company is a 'nexus' of contracts, formal and informal, concluded mainly between the directors and the stockholders. To the extent that accounting produces information that serves to draw up and control the execution of these contracts, company directors are said to pursue their personal interests and choose methods that give them an advantage.

Within the context of this problem, it is possible to formulate many hypotheses on the accounting behavior of company directors. One might suppose, for example, that directors linked to their company by a profit-sharing contract would choose accounting methods that tend to increase present profits at the expense of future profits. One might also suppose that

company directors whose debt ratios are bordering on the thresholds tolerated by the lenders would once again choose accounting methods that increase the profits and diminish the debt ratios. Such hypotheses may be subjected to the statistical tests common in economic research.

Finally, positive accounting explains the choices of accounting methods made by company directors by reference to various economic and financial characteristics of the companies: their size, level of debt, Stock Exchange listing, etc.

This research trend has been the subject of very many methodological and epistemological criticisms (see, e.g., Christenson 1983), but it remains the mainstream of accounting research in the United States. The resulting research papers are published mainly in the *Journal of Accounting Research* and in the review specially created by Watts and Zimmerman, the *Journal of Accounting and Economics*.

To these various types of research (historic, sociological, and economic), that are cognitive in nature, may be added applied research, the object of which is to define accounting concepts, principles, and procedures. Research aims to define a theoretical framework for accounting practice and is, to a greater or lesser extent, linked to the work of the standardization bodies. In contrast to the preceding types of research, it is described as normative.

Financial Institutions in Economic Development

The financial system can be considered as a composite of financial activities and the institutions that implement and regulate these activities. Financing of firms is one activity of the system, and capital (securities) markets and banks are their principal financing sources. The sociology of financing economic development examines the institutions that shape the development of firms and nations—particularly in emerging markets.

There have been several sociological analyses of development, including firm, industry, and country studies; but what remains largely unexplored is the role of banks and other financial institutions in this process, and how this relation is influenced by national and international contexts and events, to say nothing of local populations and their initiatives (cf. Evans 1995, Gereffi and Korzeniewicz 1993). After reviewing some theoretical approaches to financing growth and economic development (development) this entry focuses on banks, the principal institution in financing development in most emerging countries. It will identify studies that are rooted in social structure and that focus on such questions as how banks emerge, the sociopolitical reasons for their involvement, which forms are prevalent, and how development is financed. To conclude, some policy-related research challenges will be posed.

1. The Financial Context

Financing of households, businesses, and the government are the three main financial activities in any country. Financing is mainly achieved through capital

markets and/or banks as well as own savings by economic units. A firm can draw upon its savings to finance its production, it can issue stocks, bonds, or it can borrow from banks. Households usually borrow from banks, while governments issue bonds and/or borrow from banks. Cross-nationally and cross-temporally, there are significant differences in these activities. Businesses in the United States and the United Kingdom use capital markets (securities issues), while those in France, Germany, and Japan mainly use bank loans. Among these countries there are differences in bank-industry relations. German banks are inclined to intervene in industry because, in addition to being important shareholders, they control access to all sources of finance. In France, on the other hand, businesses have access to a wider array of public and private institutions whose lending terms are shaped by the government (Zysman 1983).

There is little consensus over which system contributes most to the overall development of an economy. Evidence indicates that having a robust banking and capital market is correlated with economic development (Demirguc-Kunt and Levine 1999). Levine (1997) reminds us of one classic controversy, i.e., whether Germany's development in the latter half of the nineteenth century was more rapid than Great Britain's because its economic structure was based on banks with close links to industry, whereas Great Britain's was more securities market-based and ties between banks and industry were less intimate. As countries mature and evolve into service-oriented economies, there is a growing belief that capital markets are increasingly more effective at intermediation than banks, as Ness (1974) and Haber (1997) illustrate for Brazilian development. Nonetheless, banks are essential to small and medium sized firms as they are less able to tap capital markets for funding. Similarly in emerging countries where there tends to be a lack of a tradition of investing, where capital markets are absent, or are only beginning to mature, banks are the principal financial intermediaries and have been the primary engines for financing economic development. They are heavily linked through equity and management to industry. In these countries the state may own a good portion of the banks, and share the market with foreign or large domestically owned banks. In China nearly 100 percent of the banks belong to the state; in India 70 percent are state owned. In contrast, in the United Kingdom more than 50 percent of the banks are foreign owned (*Economist* 1997). For an open-banking country in which foreign banks are treated the same as domestic banks, the United States has relatively little foreign ownership (less than 10 percent) of separately chartered banks (Barth et al. 2000). And as the twenty-first century begins, throughout the global economy banks are growing in size and becoming more multifaceted in their operations, often as a result of huge mergers and acquisitions which themselves are fueled by the advent

of new regional markets (Makler 1999). Bank growth is in response to an increasing and rapid demand for huge, often multilateral, financing coupled with banks' desire to provide all or one-stop financial services.

1.1 Banks in Emerging Economies: Some Anomalies

Economists view banks as the principal financial intermediary between savers and investors. Banks obtain deposits from the public and invest what they receive in loans and securities. But their role is broader. They are important centers in the formation of wealth, the distribution of economic power, and they influence the way societies change. Political scientists see banks as a powerful interest group attempting to influence public policy or elections. Anthropologists see banks as 'unorganized,' informal institutions that provide capital to small rural or urban businesses.

Sociologists have focused mainly on bank power and have elaborated Berle and Means' analysis of corporate ownership and control. Few have studied banks as institutions or have explored the meaning of their wide array of relations. Few have related form to performance. Even fewer have focused on emerging countries where banks have played a significant role in change and development, as Mizuchi and Stearns (1994) recognized. This would require comparisons among a diverse selection of countries in addition to those that have a similar standard of living such as Germany, Japan, the United Kingdom, and the United States (Levine 1997).

2. Development and Banks in the Social Sciences

While few studies of the role of banks in growth and development are found in sociology, a number of distinctive theoretical approaches have emerged in the general study of financial institutions that illuminate the conditions under which one or another type of bank will appear and explain what differences this makes for economic development.

In economics, one debate has to do with supply and demand. Some have characterized banks as demand-following, or as passive, permissive intermediaries that merely provide services or loans to creditworthy borrowers. Economists such as Goldsmith (1969), Gurley and Shaw (1967), and Patrick (1966) saw banks as supplying capital, encouraging efficient credit allocation, increasing accumulation, and sometimes assisting in the founding of new enterprises or in promoting mergers, but only upon the demands of their clients. Others viewed banks as supply leading. Among these was Schumpeter (1961), who brought credit creation by banks to the fore, identifying them as supply-leading and growth-inducing agents of development. In creating new sources of credit, banking systems were ranked slightly behind those of

entrepreneurship and innovation. For Schumpeter, well-managed banks fuel technological innovation by identifying and funding entrepreneurs who were identified as most likely to introduce and implement new products and production processes successfully. But in his discussion of commercial banks he simply mentioned the ability of banks to create purchasing power, without analyzing their method of capital accumulation or their relations with entrepreneurs.

It was Gerschenkron (1962) who introduced the importance of context and institutional form. In an often-cited explanation of the role of banks in development, he observed that the historical timing of a nation's industrialization determines which economic actors and social institutions will be involved. One of his principal hypotheses was that the more backward an economy relative to others in the same period, the greater the likelihood that financial institutions would be created to supply capital in advance of demand. In the transformation of once backward countries to industrialization, the role of the state, and the emergence of specialized private and state banks designed to increase the supply of capital and provide better-informed entrepreneurial guidance to nascent industries were also emphasized as important to development. As for form, he saw the pressure for industrialization in latecomers resulting in larger industries and banks. And because of the magnitude of bank lending to industry Gerschenkron predicted that banks would acquire 'a formidable degree of ascendancy over industrial enterprises which extended beyond the sphere of financial control and into that of entrepreneurial and managerial decisions' (Gerschenkron 1962, p. 14). Thus institutional dominance was introduced into his analysis.

Classical Marxist theorists also viewed banks as dominant. Lenin saw banking as concentrating into a 'single collective capitalism,' as predatory, and as controlling industry, causing capital concentration and conglomeration. To Hilferding (1981), finance capital (or that capital supplied to industrialists and controlled by financial intermediaries) was the means by which big banks forged concentration among non-financial corporations and created a new class 'under the direction of high finance.' And through investment in more and more basic sectors, banks propelled the state as their agent into the world market (Hilferding 1981, Harvey 1982). In applying parts of this theory to the United States, sociologists Mintz and Schwartz (1985) and Fennema (1982) found in some periods extensive interlocking between the directorates of major US corporations and banks, that industry was dependent on banks because of bank control over financial resources, capital flows and knowledge of money markets, and that American banks interlocked with important foreign banks to form a discrete consortium in world finance. But like Gerschenkron, neither Hilferding, Lenin, nor more recent scholars have demonstrated successfully that such a strategy

will result in finance capital's economic or political hegemony. To the contrary, in studying bank transformation in Brazil, Garman and his colleagues (1998) illustrate that while banking concentration resulted during privatization there was little evidence of finance capital's domination of the process.

The typical institutional form that emerged in Europe in the nineteenth century was the financial conglomerate or multi-sector company, transacting in different markets owned and controlled by a family-owned bank. In their quest for growth and development, governments have been bankers, have recruited domestic and foreign banks, and encouraged financial conglomeration and financial concentration. The classical cases in financing development are Germany and Japan where, in preparation for World War II, military governments nurtured large banks and encouraged their spread into and control of non-financial sectors in order to develop these sectors (Hadley 1970, Roe 1994). In Japan, the conglomerates were known as *zaibatsus* and today they are referred to as *keiretsus*. In South Korea they are *chaebols* and in Latin America they are usually known as *grupos* (Leff 1978, Granovetter 1994). In most emerging countries where the state is a formidable economic actor, state-owned banks share the market with large family-owned and foreign banks. These banks were recruited by the state, which provided subsidies to encourage the development of basic, agro-industrial, and export industries. As a result, the families achieved economic security and upward mobility, and the foreign investors became more embedded in the economy. The bank, usually at the core of the conglomerate, served primarily as a direct source of capital for member firms that were faced with increased capital requirements posed by industrialization and export markets. It also served as a source of employment for family members and close friends (cf. Gerlach 1992, Lamoreaux 1994). In exchange for the promise of investment, foreign banks also received 'benefices' such as authorization to open branches or to purchase domestic banks. During Brazil's industrialization in the 1970s foreign capital formed alliances with prominent family-owned firms in order to access local markets. In exchange these firms and their controllers were provided with technology, capital, and access to international markets (Evans 1979, Cardoso and Faletto 1979). What soon became known as Brazil's economic miracle was largely fostered by the banking sector, its conglomerates, and its alliances (Makler 2000). The state-banking sector relation in Brazil and other emerging countries is thus more symbiotic than in some advanced economies (cf. Hall 1991, Weber 1968).

Interlocking boards of directors and the resulting exclusivity favor large business growth over small. But this pattern seems to be tempering. Davis and Mizuchi (1999) found that the interlocking between the boards of American banks and major industrial

corporations declined significantly from 1982 to 1994, reflecting a strategic shift by banks away from lending to major corporations. While corporations are turning more to capital markets for their financing, interlocking and, as a consequence, lending is likely to be increasing between banks and smaller firms that are less able to secure funds from capital markets (cf. Barth et al. 2000). In relations between banks and smaller firms, commercial transactions are more likely to be embedded in social attachments that improve loan acquisition, offer favorable credit terms, and motivate smaller firms to achieve, as Uzzi (1999) has shown.

Another topic that has intrigued sociologists is the impact of foreign capital on social structure in emerging nations. Some nations, in their quest for rapid economic development, have encouraged foreign direct investment, including banks, because of the promise of technological and industrial growth that they represent. Foreign banks have been cast as stimulating competition in their sector, better able to withstand macroeconomic shocks because of their geographic diversity, and as relieving scarce regulatory resources because they are regulated by their home country (World Bank 2000). Yet some development economists as well as some sociologists have been dubious about foreign capital's contribution, while others have viewed it more favorably. In studying late nineteenth-century Chile, Zeitlin (1984) found that important family groups that had merged with foreign capital to develop the nitrate industry at first flourished but later were economically and politically weakened when the government, in an attempt to curb an export crisis, threatened nationalization and limitations on further foreign capital participation. However, other studies suggest that associations with foreign capital can foster development, local entrepreneurship, and provide mobility opportunities for local businesses. In comparing Brazil, India, and South Korea, Evans (1995) demonstrates that foreign capital and national governments can perform a nurturing or a midwifery role in the development of certain economies. In an earlier study of Brazil, Evans (1979) found that foreign capital formed alliances with prominent family-owned firms in order to access local markets. In exchange, these firms were promised technology and access to international markets.

There are few sociological studies of foreign banks in emerging countries, and those that exist are inconclusive as to whether banks contribute to development. In the 1990s foreign banks proliferated in Latin America. Guillén and Tschoegl (2000) have documented the dramatic rise of Spanish banks but advocate further research to understand their investment strategies. In Brazil, foreign banks have spread but it is unknown whether their lending, like many of the leading domestic banks, is mostly directed toward larger foreign or state-owned corporations, or whether it is becoming more widespread to include small and

medium sized businesses. In that country, banking secrecy provisions preclude detailed analysis of size and regional distribution of loans, and for their part banks resist studies of their lending, presumably fearful that such information will be used by their competitors (Ness 2000).

Values, politics, and laws underlie this proclivity to conglomerate, to concentrate finance capital, and to allow foreign or outside banks to practice in national markets. In some societies, centralization and concentration of economic and political power are tolerated while in others they are not. Because of their feudal heritage, a populist, anti-big-bank ethos has historically been absent in Japan and South Korea while instead large enterprises are celebrated (cf. Roe 1994, Orru et al. 1991). In several Latin American countries centralized power and large private and public institutions are also preferred. In Brazil, because of its patrimonial heritage, large financial conglomerates flourish, and Brazilian federalism leads development-prone administrations to decentralize financial power to them in exchange for their economic and political tribute (Makler 2000). In contrast, American ideology has distrusted large monopolies and banks and has favored smaller, encapsulated, locally accessible, and locally embedded institutions. Since the early nineteenth century the American banking system has been fragmented, consisting of numerous small banks without extensive branching and a few large banks that have been hampered legally from capitalizing in other financial services (Roe 1994). The mixing of banking and commerce is prohibited, and although banks can now engage in securities and insurance their spread into real estate activities is restricted. The state 'recruits' banks to invest in nonfinancial sectors such as community housing and urban development programs, not through continuing subsidies and dispensations as in patrimonial systems but through regulation.

This ideology is rooted in American federalism that fostered fragmented, decentralized, and 'separate but equal' banking where each state chartered and protected its own banks while excluding those from other states or foreign countries. National legislation echoes this ideology. The National Bank Acts of 1863 and 1864, and the Glass-Steagall Act of 1933 restricted banks from spreading geographically and sectorally into other financial and non-financial sectors, thus leading Roe (1994) to predict that the United States might have achieved greater growth earlier with stronger, less fragmented, money centered banks. Yet eleven Southeastern states closed their markets to outside banks. This gave resident banks a monopoly within the region (known as the Southeast Compact). As a result these banks registered greater profitability, made proportionately more property loans, and for a decade (1980–90) more economic growth occurred in this region than elsewhere in the country (Barth and Jahera 1994). Southeastern growth subsided with the

debut of national banking deregulation and banking liberalization in the 1990s. This legislation repealed six decades of constraining legislation and resulted in nationwide banking, mergers, acquisitions, and the spread of banks into securities, insurance, and other sectors. Concentration is increasing and the multi-sector financial conglomerate is likely to become the dominant organizational form, as in many European countries, Latin America, and other emerging countries. With the advent of electronic banking and nationwide conglomeration, the relation between local deposits and local financing will become increasingly tenuous.

3. Challenges

A growing apprehension with globalization and its effects on the development of national markets is casting an important challenge for sociologists as it did for economists who were concerned with post-World War II recovery half a century ago. Moving from studies of financial structure and power, sociological research at the beginning of the twenty-first century should focus on outcomes of financial intermediation, and these should be analyzed in ways that could inform public policy.

First, the ways that economic units, be they regional markets, nations, or large or small businesses, finance their starts and their growth should be clarified. For mature, more service-oriented economies, capital markets (securities) are viewed as more efficient but for emerging economies and for new businesses banks (loans) are the principal form. Is this the case, or will there be increasing multi-sourcing as access to financial markets is widened through deregulation, technological innovation, and new financial institutions?

Second, monitoring whether major changes in local and national economies are accompanied by changes in financing enables identification of new forms of financial intermediation that finance development. Granovetter (2001) and other scholars (cf. Kaplan 1999, Kenney and Florida 2000), for example, found that the rapid growth of California's Silicon Valley information technology industry depended upon the creation of a new form of financial intermediation: venture capital. Early venture capitalists were mainly successful engineers who invested their profits and often took equity and managerial positions, unlike most financiers who hardly associated with their investments.

Third, in studying emerging countries, recognition of the embeddedness of market segmentation or the duality of the financial market is challenging. Paralleling the two forms of financial intermediation (banks and securities) is informal financing. This is particularly prevalent in emerging markets among poorer populations that have little, if any, access to (or

knowledge of) formal financial institutions that serve large businesses (World Bank 1989, Carstens 1995). Biggart (2001) studied micro credit programs such as rotating savings and credit associations that lend modest amounts of money for entrepreneurial business activities to poor women who are organized in solidarity groups. By starting with the demand side, with credit seekers, pertinent financial institutions can best be identified and from there related to performance. Answering these two questions is a promising start: What is the relevance of one financial institution compared to another for development; and how, in turn, does development change and evolve to affect that institution and its organization? But more challenging is understanding the relation between financial development and social organization. Capital markets create dispersed savers (investors) who are interested primarily in financial return and risk, while banks have been more locally embedded and attentive to the special needs of their borrowers. Capital market development might well result in a depersonalized form of capitalism. The banking industry is becoming more concentrated in nationwide conglomerates rather than in locally oriented institutions, and globalization has brought foreign banks to many nations. For emerging economies these banks represent financial efficiency and economic stability, yet for all nations the sovereignty of their regulatory institutions and their economic development has been challenged.

Fine Arts

Whereas the arts and other forms of creation may be the results of qualities inherent to the human species, the fine arts constitute a particular subset of this broad domain. For the most part a specifically European phenomenon, a social construction embedded in his-

torical, socioeconomic, and political developments in the context of the late Middle Ages, they reached their apogee with the rise of the nation state. Sustained by the development of a discourse that singled out certain art forms as unique and superior to other forms of creation, their high standing was achieved through association with prestigious supporters, penetrating esteemed milieus, and the establishment of selective procedures that became institutionalized over several centuries. Having become a well-entrenched cultural structure, even with the decline of the conditions and institutions that had sustained them, they continue to exert influence over other genres, some of which came into existence only much later.

1. Introduction

Neither timeless nor abstract, like all categories of thought, the fine arts came into being over time through a process of construction and subsequent reconstructions (Zolberg 1990). The term as used today cannot be assumed to possess the same connotations as when it first appeared. Moreover, although functional equivalents of the fine arts have been found in several geopolitical regions and at different historical moments (Alsop 1982), the fine arts represent a complex of meanings which were until relatively recently associated with European civilization. From a social scientific standpoint the fine arts need to be understood in relation to the arts and cultural creation more generally. The first part of this article deals, therefore, with the standing of the fine arts as a subset of aesthetic creation in relation to other forms.

Three developments supported the emergence and subsequent durability of the cultural structure of the fine arts:

(a) The constitution of its intellectual roots as an integral part of European discourse within the changing socioeconomic and political context of the Middle Ages and the Renaissance.

(b) Somewhat independently, professionalization of artistic creation in which individual achievements came to be favored over the communalism of the previously pre-eminent institution of creation, the guild system.

(c) Intersecting these trends, in the place of the previously dominant forms of patronage by the church, the nobility, and fairly autonomous cities, the emergence of new support structures in whose constitution creative artists played an active part: first, official patronage through academies; next, the dealer–critic system.

In the final section, this article analyzes processes of cultural change that, moving beyond anti-academicism, itself a part of the modernist movement, takes the far more radical stance of postmodernism.

Whereas modernism accepted the position of fine art as a hierarchically superior domain of creation, postmodernism contests the very idea of such a hierarchy. It disregards barriers between the fine arts and commercial art forms, professional artists and self-taught creators, art world members and outsiders to it. It rejects the separation of art from politics, science, nature, and even life itself. In trying to clarify the conditions under which certain forms, old and new, gain legitimacy as fine art, this article explores the possible consequences that expanding this construct to encompass existing fine art worlds, cultural politics, and commercial entertainments may have for the idea of fine art in the future.

2. The Making of the Fine Arts Core

2.1 Structuring Aesthetic Culture

Distinguished by a set of artistic categories that made up what has been authoritatively designated ‘the modern system of the arts,’ the fine arts owe their uniqueness to a particular cultural development. It encompasses the transformation of a body of ideas, largely derived from classical thought, thence reformulated in late medieval scholasticism and filtered through Renaissance conceptions. Culminating in the intellectual innovations of the Enlightenment, the fine arts became the established aesthetic structure with which all later arts and scholarship had to contend. Fully constituted by the eighteenth century, as Paul Kristeller noted in his classic formulation, it consisted of a core of five fine arts—painting, sculpture, architecture, music, along with the *belles lettres*—poetry and eloquence (Kristeller 1951, p. 497). While other forms migrated into and out of this cultural structure—dance and garden design, for example—these five became the core of what was meant by Art.

Kant, the first major philosopher to integrate aesthetics into his intellectual system, posited the enduring qualities of art, its universalism, the pleasure it gave, yet insisted that art should not provide too much ease of enjoyment. In this way Kant’s analysis attributed to fine art a seriousness equal to his theory of truth (epistemology or metaphysics) and his theory of goodness (ethics) (Kristeller 1952, p. 42). As later critics have noted, an important criterion in Kant’s formulation was to be art’s gratuitousness, its freedom from social necessity and usefulness. A striking consequence of this construction is that it can be seen as a bulwark for ideologies justifying social inequality (Bourdieu 1984, pp. 494–5).

Although it served as a foundation for philosophical writing throughout the nineteenth century, the system of the arts has been challenged by, among other things, ideas associated with the Romantic movement and by

new technologies. As Kristeller noted, aesthetic analysis based on the modern system of the arts is hard pressed to be appropriate to new mediums and art forms such as the modern concert grand piano and motion pictures (Kristeller 1952, p. 46). Thus, knowing the intellectual roots of the concept is insufficient for understanding the social significance of the fine arts. Without reducing one to the other, the orientations of intellectual and art history with their focus on autonomous genres and their structure, and influences emanating from within their particular domain need to be situated within the social, political, and economic changes with which they intersect. With aesthetic analysis and history of art as the intellectual foundation, the social history of the arts has provided an important perspective by emphasizing the changing social context within which the arts developed and with which they interacted (Hauser 1951)

2.2 Patronage of the Fine Arts: A Contribution of Social History

In their studies of artistic transformations, social historians of the arts stress the effects of changing patterns of patronage: shifts in support structures from the patronage; of the classical city states, imperial courts, churches, secular cities, and states to individual aristocrats, royal courts, or magnates (Hauser 1951, Castelnovo and Guinzburg 1981, Kempers 1992). They have observed that the social standing of art forms and artists is frequently commensurate with the status of their patronage source. Most social historians contend that patrons—those who ‘pay the piper’—call the tune. Further careful examination suggests that the nature of their influence is highly complex. The idea that art is a mere ‘reflection’ of its support system has been shown to be oversimplified (Balfe 1993, p. 4). Instead, it is important to recognize the diversity of intermediate institutions of culture and the expansion of varieties of possible sources of patronage, especially since the middle of the nineteenth century. While social historians provide insight into the impact of major social structural changes on the arts, much social history neglects the agency of artists, individually or in groups, to act on their own behalf. Recent studies indicate that artists played an active role, for example, in establishing the Royal Academy of Fine Arts in France (Heinich 1993) and, in the process, constituting what for over a century was considered ‘the canon.’

For painters who sought to gain the support of royalty and the nobility, the uncertainty of their social position appears to have been the main incentive underlying their strategies. With the establishment of the Academy in the seventeenth century (Heinich 1993), recognition by the highest status groups in society went a long way to providing that standing, at least for a lucky few. In conjunction with subsequent

developments, the fine arts (*beaux-arts*) came to be treated as inhabiting a separate sphere with its own intellectual legitimacy and, under certain conditions, a degree of autonomy from mundane social constraints. This new autonomy is implied in Max Weber’s observation that ‘art becomes a cosmos of more and more consciously grasped independent values which exist in their own right. Art takes over the function of a this-worldly salvation.’ Although Weber goes on to caution that ‘the refusal of modern men to assume responsibility for moral judgments tends to transform judgments of moral intent into judgments of taste (‘in poor taste’ instead of ‘reprehensible’)’ (Gerth and Mills 1946, pp. 941–2), he correctly notes that many Western artists since the late Middle Ages aspired to that autonomy. In that regard, the most durable supporting institution became the academic system (Pevsner 1940).

2.3 The French Academy: Institutional Support for Official Creativity

As an administrative structure encompassing educational institutions, competition, and rewards for talent, the French Academy became the principal gatekeeper in commissioning art for official public purposes. Following a rationale derived from the prestigious humanistic classical scholarship, with the purpose of symbolizing the glory of the monarch and (not very differentiated from him) the State, academicians selected aspirants, rigorously educated them in a certain kind of creativity, established and maintained standards of quality, and legitimated art forms. With the ruler’s accord, this entailed institutionalizing certain art forms and genres based on subject matter, materials, and style, elevating some hierarchically over others. In the process they established the ‘great culture’ that redefined Art (Corvisier 1978, Heinich 1993). The French academic system was widely admired, envied, and imitated in many nations. With variations in accord with local conditions, traditions, and diverse contingent factors (Pelles 1963), it became the successful rival to the previous leading patronage structure, the Church, and overwhelmed the provincial nobility.

Academic dominance of art careers had both symbolic and material consequences. Sustained by an aura of the sacred derived from the King himself, enjoying the acclaim of scholars and amateurs of high standing, fine art was at times treated as a quasi-religion of high culture. But the very fact of attaining high standing contributed to the ambiguity of the position of fine art. Intricately connected to leading institutions of religion, politics, education, and finance, its sacrality was constantly threatened by contamination from the worldliness associated with those domains. The penalty for artists who too obviously were concerned with financial success rather

than high-minded disinterestedness might be condemnation to separate development as part of a provincial 'little culture' to a weakened, marginalized position as a client of the Church (Corvisier 1978), or—worse yet—to the mercies of market forces.

Artists whose works were refused in official *Salons* where they could be viewed by high-status private collectors or clients and public officials with authority to commission and purchase art for public buildings, cathedrals, or churches with elite parishioners, had little recourse but to sell their paintings from their own studios or, worse, at public markets and open air fairs, to an indiscriminate clientele of lesser standing and with considerably lower financial rewards.

At the height of their pre-eminence as gatekeepers, academies and the choices they made were confronted by challenges emanating from artists and other art world participants, including dealers, critics, scholars, and collectors, who were outsiders to the official art world. In the context of eighteenth and nineteenth century shifts in political power away from an aristocracy that had been allied with a narrow stratum of wealthy financiers, an expanded and heterogeneous middle class came to prominence. It provided a diverse market that was no longer coterminous with the taste promoted by the official milieu. Instead, its members seemed to share an elective affinity with the entrepreneurship of the new dealer and critic system. This combination created conditions favorable to aesthetic innovations that were to challenge the officially recognized fine arts even more profoundly (White and White 1965, Boime 1971, Zolberg 1983).

2.4 From the Academy to Anti-academic Movements

Whereas under the Old Régime, fine art was what the monarch preferred, through much of the nineteenth century it was largely economic elites whose tastes, whether conventional or audacious, came to dominate (Boime 1971). Its demise as a result of the Great Revolution had left a void in the aesthetics that it had imposed on French cultural life. Remade after its virtual abolition and modified several times, the academic system flourished for the better part of the nineteenth century. Its eventual re-establishment as a set of state institutions was welcomed by many aspiring artists, who found that career avenues reopened to them (Boime 1971). But its success was soon diluted, overwhelmed by increasing numbers of aspirants (White and White 1965).

Through administrative control of admissions, the assignment by their juries to better or worse locations for art works on its walls, the prestigious biennial *Salons* might become opportunities for artists to be rewarded with prizes, government or private commissions, and future sales or, on the contrary, be quite unnoticed. Alienated from the traditional or official

artistic values of their time, convinced of its favoritism toward the most timid conformity, many artists became disenchanted with the academic institution that earlier artists had helped to launch. Highly innovative at its beginnings, the official academy, as is the case of many formal organizations, was accused of becoming increasingly rigid and oligarchic for excluding innovative ideas and creators. By the middle of the nineteenth century, academic administrators were being charged with behaving like crude bureaucrats, unreflectively enforcing old ideas, favoring the predictable and the safe over the new and audacious.

These accusations were sometimes exaggerated by critics and disgruntled aspirants. In fact, its officials were not resistant to change across the board. The hierarchical dominance of history painting, portraits of monarchs, nobles, and very wealthy officials and businessmen with which the century had begun was being overshadowed by the end of the nineteenth century with the elevation of what had previously been classed as lesser genres. They included landscape paintings and nominally allegorical or mythical themes, often in a style accentuating narrative as opposed to timelessness, sweetness rather than nobility (Bouguereau) (Boime 1971). But the ethos of tamedness imposed on art students and members conflicted with the increasingly prevalent conception of the artist as Romantic genius with a singular vision (Bourdieu 1995). The academy became synonymous with the overbearing institutions that trammelled their imaginations.

In trying to account for the eventual demise of academic authority, Harrison and Cynthia White have argued that the very success of the institution made it the goal of too many aspiring artists. Under the onslaught of swelling numbers of applicants, the academy was obliged to introduce increasingly selective mechanisms (White and White 1965). From an ethnographic perspective, the analytic categories developed by Howard Becker provide further insight into the social roles of artists in complex institutional settings or 'Art Worlds.' For Becker, the world of art is made up of several different types of artists. Certain artists are 'certified'—as 'integrated professionals,' or they may be nonconformists—'mavericks' (Becker 1982). In the exceedingly centralized French system especially, mavericks were viewed and often presented themselves as outsiders and innovators who knew the rules and *deliberately* violated them.

As Becker suggests, most were trained in the academic institutional system that rejected them, or studied with academically trained artists. But many were willing to risk exclusion from its sales institution, the official *Salon*, in order to be true to their ideas. Although, as later research indicates, in fact, relatively few of them were very innovative or audacious. This was even the case of the most celebrated event of the Second Empire, the *Salon des Refusés*, when Impressionists' works were displayed, as well as various

later dealer-organized exhibitions. But even the more conventional ones formed alliances and exhibited with independent groups of real mavericks (Huston 1989).

One of the most important results of their refusal to conform is the seemingly unending succession of new style after style. Associated with groups of artists who provided moral support for their efforts, each new stylistic form became a contender for official and public recognition. Its leaders were: Courbet and Naturalism; Corot and Millet and other Barbizon painters who led the movement for revalorizing landscape painting; Manet and numerous painters influenced by him who made up the Impressionist group, rejecting the foundation of classical drawing they had acquired in favor of color experiments that provided a direct relationship to nature; Neoimpressionists such as Signac and Seurat who undertook quasiscientific experimentation with the optics of color in their *pointillisme*; Van Gogh and his deliberate distortions of Expressionism; Gauguin and his combination of gothic line and form with eroticized exoticism; Cézanne and his uniquely difficult-to-characterize works (Rewald 1988). Most of these 'independent' artists found themselves barred from a place in official exhibitions for most of the nineteenth century.

For artists of modest means, the dealer-critic system that expanded and flowered in the nineteenth century was essential for permitting them to survive honorably as painters. As fine artists, they relished the informality of contractual arrangements that made agreements with dealers rest on a gentlemanly handshake (Vollard 1978, Moulin 1987). Even artists who were independently wealthy, such as Manet and Degas, sought to build support among new middle class collectors through the growing dealer system. Unexpected as it may have been to their critics, eventually a number of their aesthetic innovations came to be more highly prized than the more conventional art of their contemporaries. As controversial and willing to risk failure as they were, however, for all their innovations, they continued to work in the basic mediums and genres of art, rather than create entirely new forms of art.

3. How the Core Collapsed—On Artistic Change

3.1 The Tradition of the New

From approximately the middle of the nineteenth through nearly half of the twentieth century it became customary to speak of artistic change as a revolutionary succession of art movements or *avant-gardes* (Poggioli 1971). Most of them challenged stylistic strictures governing artistic form, some challenged the social structures of art worlds, and certain of them used their art to attack political and social arrangements beyond art worlds. Through these independent

artists of *avant-garde* or secession movements that challenged the academy's legitimacy, the academic fine arts fell into disrepute. Several of the new styles gained ascendancy, but even as anti-academic artists, they did not eradicate the idea of fine art itself, nor their aspiration to aesthetic autonomy.

The story of the apparently inexorable march of new styles encompassed elements that contributed to the 'tradition of the new,' as Harold Rosenberg termed it (1965). Its pattern of innovation, rejection, and acceptance has become familiar and conventional in the fine arts, and is acknowledged as part and parcel of the flow of modernism. In the post-World War II period, the United States produced what was then considered the most innovative artistic movement. Referred to variously as Abstract Expressionism, Action Painting, or simply the New York School, its members aspired to replace the figurative content and narrative of art, largely hegemonic at the time, by abstract representations of the artist's feelings and impulses. Viewed by many as incomprehensible or self-indulgent, as it gained acceptance among a few collectors and a place in adventurous museums, in line with the century-long pattern of the challenge by the new, it too was faced by rivals: even without an institution such as the academic system, *avant-gardism* itself had become institutionalized. Soon, they too found themselves and the aesthetics they had constructed challenged (Crane 1987).

As unexpected as they were, the new genres and styles—Pop Art, Minimalism, Pattern, Photo-Realism—could claim as much legitimacy as had previous newcomers. There was little basis for holding them off except through assertions of bad faith on the part of artists, decline of standards, lack of discrimination. On the one hand, these resemble the reproaches that have been invoked for a century and a half. On the other, the Pop Artists had crossed the barrier separating naked commercialism from disinterested art. Their popularity assailed what might be called the dominant canon of abstractionist modernity, leading the way to what has been termed the postmodern condition.

3.2 Postmodernism and Challenge from the Margins

Despite their confrontational stance, few artists of anti-academic movements actually repudiated 'the modern system of the fine arts' until well into the twentieth century (Danto 1986). Instead, the idea of 'fine art' has until very recently retained its lofty status. What has changed is that it may be freely attached to new genres, many of them nonexistent at the height of academic dominance, and most unrecognizable to nineteenth century observers. Whereas modernism accepted the position of fine art as a hierarchically superior domain of creation, postmodernism contests the very idea of such a hierarchy. It disregards barriers between the fine arts and commercial art forms,

professional artists and self-taught creators, art world members and outsiders to it. It rejects the separation of art from politics, science, nature, entertainment, and even life itself.

Maverick professionals have attempted to overthrow the existing canon that has been the foundation of their training (Becker 1982). Excluded groups on the fringes of established art worlds are a constantly renewed source of aesthetic change, whether through challenging aesthetic ideas or simply to gain entry without changing prevailing aesthetic forms or hierarchies. Most prominent are women, racial or ethnic minorities, or disadvantaged people more generally, who attempt, either on their own behalf or through the mediation of influential gatekeepers, to penetrate to the center (Lang and Lang 1990).

But over the years the margins of the art world have come to defy easy categorization. As has become startlingly evident, the barriers between high and low art, art and politics, art and religious rite, art and emotional expression have been repeatedly blurred and breached. One outcome of these assaults on conventions, in which the periphery has come to be valorized beyond all predictions, is that it is virtually impossible to find an aesthetic center. These developments have had their critics, many of them simply conservative either politically or aesthetically, or sometimes both.

How certain artists and art forms gained ascendancy has often involved political and social contexts that are intertwined with aesthetics. They may involve the construction of institutional support favoring particular stylistic forms while excluding others. Under authoritarian political regimes in modern times this has led to fierce repression of artists and their works (Nazi Germany, Stalinist Soviet Union, Maoist China, among others). Even in liberal regimes, artists may be restricted in the free expression of their creation. Whereas in the past the most important sources of support came from absolutist monarchs who were attempting to centralize their nation states at the expense of competing institutions and what they constructed as peripheral cultures, today the ground is shifting. This is indicated by growing interest in the construction of social identities that are not as co-extensive with a nation's boundaries as was the ideal expectation of the past. The survival or revival of cultural conflict around language, ethnicity, and religion provide a fertile ground for jockeying for pre-eminence by winners at the expense of dominated groups.

A familiar cliché has become that of imagining the artist facing a philistine world that misunderstands him, struggling for inspiration, and gaining recognition only belatedly. Applied to nineteenth-century composers such as Beethoven and Schubert; painters such as Gauguin and Van Gogh, in the twentieth century this model was moved to the lives of Jazz 'greats'—Scott Joplin, Billy Holliday, Thelonius

Monk, and many others. The insertion of Jazz and other popular music into the domain of the fine arts is far removed from academies and official legitimacy. But by now almost the entire body of popular commercialized culture and the constitution of stardom could be included in this analysis of forms that are outside of fine art canons.

Supposedly born as low-life brothel music, Jazz grew in the late 1910s and 1920s into a wickedly exciting, commercially powerful form of popular music. Taken up as an art form by European intellectuals, who incorporated it into ideas of an essentialist primitivism that were popular among artists and writers, and appealed to many amateurs, their attention provided the cachet that ordinary commercial musical forms lacked. Eventually, certain American intellectuals were drawn into defining Jazz as an expression of revolt against the conventional lives they were expected to live. By the 1940s, with the advent of be-bop and the regular forays of composers such as Duke Ellington into concert halls, Jazz began to take on the trappings and pretensions of Art, moves supported by patrons, official government bodies, foundations, while commercial entrepreneurs became less important. Its legitimacy functioned at two levels, one aesthetic and the other political. Rather than being content with the entry of the new musical forms into common usage through appropriation by industry agents, even at increased financial returns, African Americans became active in asserting the importance of their identity through its innovations.

The rise of Jazz to respectability and fine art standing is based, by now, on a long history reconstructed (or constructed). It includes a cataloged repertory and a body of admirers and practitioners. It has a closely perceived linkage with black cultural identity and hence has the support of related interest groups who advocate funding for minority cultural and political projects. Jazz (or 'black classical music' as some call it) is firmly embedded in the curricula of institutions of higher education and conservatories. It is deemed worthy of support by governmental agencies such as the National Endowment for the Arts and State Arts Councils. By now, Jazz has attained a level of respectability that would have been difficult to predict less than a century ago.

The very nature of art in the late twentieth century entails a constant process of absorbing, sampling, appropriating, amalgamating new and unusual forms, and incorporating a changing body of personnel. Currently, the field is much larger and the number of contenders has multiplied, as has the core itself. The line between classical and commercial entertainment has been crossed repeatedly. Beyond professionals and mavericks, creative work by folk and naïve artists has penetrated the museums and galleries that had been host to creators formed in the attachment to autonomous fine art of whatever form. No longer a single canon, the centralized academy and its in-

stitutional descendants have given way to competing groups who promote a broad range of genres or forms (Huyssen 1986, p. 218). It may be that, as Andreas Huyssen has suggested, the previous domination of the fringes by the West may be replaced by a healthy resistance of the dominated in the form of a productive tension between the political and the aesthetic (Huyssen 1986, p. 221).

V. L. Zolberg

Fire, Human Use, and Consequences

1. Introduction

The ability to handle fire is, like language and the use of tools, a universal human attainment: no human society in historical times is known to have lived without it. The ability to handle fire is also exclusively human; while other animals have developed rudimentary signals and tools, only humans have learned to handle fire.

Today fire is continuously present in all human societies. It is used in many different guises, some highly visible, others largely hidden from public view and consciousness. Its control has played a far more important part in human history and social evolution than is generally acknowledged in the literature of the social sciences.

2. The Original Domestication of Fire

Fire is, according to dictionary definitions, a process of combustion, manifested by heat and light. It occurs relatively rarely in nature; when it does, it does not last long, with a few exceptions such as the burning coal-fields in Northern China which have been alight for

many centuries. Most natural fires have rapid and drastic effects. They cause a quick disintegration of organic matter, reducing it to ash and smoke in a process of transformation that is almost the prototype of 'destruction.'

During the Paleolithic, human groups have learned to turn this destructive and essentially purposeless natural force into a regularly available asset that could be used for a variety of 'productive' purposes. They 'domesticated' fire, they 'tamed' it and 'incorporated' it into their own societies. They were able to do so thanks to their general capacity for culture—for learning new forms of behavior, sharing those with others, and transmitting them to following generations. Adjusting their behavior in such a way that a fire could be kept burning continuously, they developed a fire regime which enabled them to expand their control over their natural environment, while at the same time affecting their own social arrangements and their personal habits and feelings (cf. Goudsblom 1992, pp. 12–41).

The uses of fire were diverse, ranging from the enjoyment of heat and light to clearing land for hunting and gathering and to cooking. Their overall tendency was to make life in human groups more secure and comfortable, but also more vulnerable and dangerous. *Fire increased at once people's destructive and productive potential.* Its control thus reinforced a basic trend in human history and social evolution: the increasing differentiation in behavior and power between humans and all biologically related species.

3. Fire and Agrarianization

The formation of the fire regime may be regarded as a paradigm for other regimes that were developed at later stages in human history. A paradigm in a double sense: first of all, substantively, the regime by which humans learned to extend their care and control over fire could serve as a model for subsequent forms of care and control over other forces in nonhuman nature such as plants and animals. Second, the domestication of fire may be seen as a model case in a methodological sense, since it exhibits some basic principles which may be observed again and again in human history and social evolution.

Toward the end of the Paleolithic, between 15,000 and 10,000 years ago, some human groups began to extend their care and control over selected plants and animals. This marked the beginning of what is often called 'the First Revolution' but is better viewed as the second great ecological transformation brought about by humans. That transformation could not have taken place without the firmly established control of fire. Once it was under way, it in turn deeply affected the further development of the part played by fire in human society.

The domestication of fire was a precondition for agrarianization first of all because in most areas using fire ('slash and burn') was the most efficient technique of opening up fields for cultivation by removing the existing vegetation. Moreover, most of the crops selected for cultivation needed cooking before consumption as a staple food. As a further, less tangible precondition, the solidly established 'species monopoly' over fire gave humans a dominance over other animals which enabled them not only to bring certain species under direct control but also kept most of the remaining 'wild' animals at a distance from their crops and herds. Finally, the long familiarity with a fire regime probably helped to prepare people for the strains of an agrarian regime demanding self-imposed 'deferred gratification.'

With agriculture and livestock, fire was no longer the only nonhuman source of energy under human control. Gradually it ceased to be the prominent focus of group life that it had been for many thousands of generations, becoming increasingly more dispersed over various sorts of specific 'containers,' such as hearths, ovens, and lamps, beyond which it was not allowed to spread. Its use was subjected to stricter regulation. Whereas during the initial stages of domestication, the main concern had been to keep the one fire burning, the main concern now became to prevent the many fires from causing a conflagration.

As the more advanced agrarian societies grew more populous, the number of fires in use increased proportionally. Those fires were increasingly concentrated within the 'fire-protected zones' of towns and villages, in special containers. The uses of fire became more specialized, with various crafts and professions such as smiths and potters developing their own pyrotechnic skills. With proliferation, concentration, and specialization came new forms of organization, if only to meet the growing need for fuel. Unavoidably, the use of fire also reflected the process of stratification, as some privileged people came to command huge supplies of fuel, and could use fire for impressive displays of power, whereas many others might never call any fire their own.

A common problem in all advanced agrarian societies was the prevention of uncontrolled fire in cities. For the growing urban populations the proliferation of fires increased the risks of blazes, while the accumulation of property meant that people had more to lose.

Of course, it was fire as a natural force with its aimless and self-generating destructiveness that was feared. In case of a military raid people had to reckon with the common practice of 'sack and burn.' But ordinarily they encountered fire only in its domesticated settings where the greatest danger lay in carelessness and where they had to rely on their own and their fellow citizens' incessant caution.

Once a fire did break out in a preindustrial town, there was little one could do. Usually the only way of

stopping it was by creating a 'fire break' and tearing down the buildings towards which the fire was advancing; deliberate destruction by human hands had to put an end to the blind destruction by fire. By far the most effective way of restricting the risk of conflagrations was then, as it still is, prevention.

There is a tendency today to conceive of problems of fire prevention primarily in terms of technology: of building materials and technical equipment. However, the problems have always been at least as much civilizational. The crucial issue was human behavior in its social context of informal and formal controls.

Little is known about the organization of fire brigades in preindustrial cities. The available evidence suggests that their effectiveness, and their very presence or absence, reflected important aspects of the social structure. In ancient Rome, fire brigades at first operated as private bands, and were later brought under imperial military command. A glimpse of the situation in the Roman provinces is shown in a letter from the emperor Trajan, written in 112 CE, in which he refused permission to the governor of Nicomedia to establish a fire brigade of citizens on the grounds that such an organization could easily 'turn into a political club' (Goudsblom 1992, p. 118). One of the social innovations in the towns of medieval Europe was that they had civil fire brigades.

4. Fire in Industrial Society

After the original domestication of fire and the rise of agriculture and animal husbandry, industrialization was the third major ecological transformation set in motion by humans. Again, natural forces originally outside the human realm were brought under human control. These natural forces consisted primarily of large, untapped sources of energy stored up in fossil fuels. Tapping the sources of coal, and later also of oil and gas, enabled people to exploit a great variety of other mineral resources as well, from iron to plutonium.

From the start, industrialization involved an enormous increase in the number, variety, and intensity of man-made fires. Just as the first stages of agrarianization were marked by extensive and conspicuous use of fire in the clearing of land by slash and burn, early industrialization dotted the landscape with smoke stacks and steam locomotives. In agriculture, the extensive use of fire gradually made way to more intensive forms of tillage with less conspicuous use of fire. Similarly, fire and smoke have become far less prominent in the industrial scene, as production and transport were powered increasingly by electricity and other forms of technologically processed energy (cf. Hughes 1983).

Yet modern industry as well as agriculture continue to be highly fuel-intensive. Most of the energy used is still derived from fossil fuels. Combustion processes

continue to play a central role, but they are relegated to special containers so that most people are not confronted with any of the features that can make the presence of a fire annoying and dangerous. The caprices of the flames are fully controlled. Soot, smoke, and risks of burning are reduced to a minimum. The furnaces and combustion chambers in which great heat is concentrated remain cool on the outside.

Typical products of modern fuel-intensive industry are cars, with engines designed to be propelled by finely tuned and minutely controllable combustion processes. Cars are made of steel, plastic, and glass—materials produced and processed at high temperatures. Yet when people get into their vehicle and turn on the electrical ignition to start the engine they are unlikely to be consciously aware of using fire and the products of fire. Nor are they used to stopping and thinking of the unintended contribution they are making to CO₂ emissions and, probably, to global warming (cf. Fleming 1998).

The highly fuel-intensive character of modern technology is matched by the advanced standards of fire prevention. Every branch of industrial production, from the building trade to the manufacture of clothes and furniture, is subject to strict measures with respect to fire. In such branches as the aircraft or the hotel industry, regulation has become international.

Along with productivity the social potential to destroy, or 'destructivity,' has increased greatly. Not only have the means of preventing and fighting fires become more effective, but so have the means of starting fires, while cities as targets for arson have also increased in number and size. Consequently, the hostilities of World War II have caused some of the largest urban fires in history, as in Hamburg, Dresden, Tokyo, Hiroshima, and Nagasaki. Forest fires caused directly or indirectly by human action have also been more numerous and larger than in any previous century (cf. Pyne 1995).

Forms of fire use that were common and relatively inconsequential before the industrial age have become far more consequential under today's socioecological regimes. Thus, in many parts of Asia and Africa the need for firewood is now significantly contributing to deforestation. The high concentrations of wood stoves and ovens in the crowded metropolises in China and elsewhere have detrimental effects on human health.

5. Symbolic and Religious Aspects

From all over the world myths have been collected relating how humanity first came to master fire, often in a feat of cunning and deceit (Frazer 1930). Those myths convey a sense of the preciousness of fire which is represented as a unique possession, separating humanity from the animal world. Many people told that neighboring groups living further away in the

bush did not have fire and were unable to cook their food; those stories have all been proven slanderous.

Fire is generally believed to have purifying effects. The domain of culture is seen as coinciding with the range of domesticated fire. Thus, cooked meat is regarded as edible for humans, raw meat as only fit for beasts. Similarly, land cleared by burning is trusted as belonging to the human domain, whereas uncleared bush and forest are feared as a dangerous hideout for predators, serpents, insects, and evil spirits.

The sense of preciousness has also found expression in rites. The communal fire would be the center of group life, and people would treat it as sacred, surrounding it with ceremony and taking care that it would never cease burning. The Roman cults of the hearth and of Vesta, the fire goddess, show how such ancient rites could persist in an urban setting (cf. Pyne 1997).

Yet, with urbanization, the sense of the preciousness of fire was often superseded by a general anxiety of the dangers it posed. Thus while Hindu and Zoroaster fire cults kept alive the age-old worship of fire, they were surrounded by ceremonial care. In Christianity and Islam, some old fire traditions persist, as in the burning of candles and incense. Fire no longer plays any part in beliefs about the origin of human society, however. Instead, it is strongly associated with evil. Sinners and unbelievers are threatened with a life after death in which they will be tormented by eternal burning.

Fire festivals, such as those held all over Europe on Saint John's day, when things considered impure would be committed to the flames, were occasions of combined joy and horror. Modern literature and art abound with evocations of the terrors of fire. Most novelists who have described a blaze attribute the disaster, quite realistically, not to natural forces such as lightning but to human action—either to personal negligence, madness, or malice, or to collective aggression, in war.

A more dispassionate way of regarding fire, not in terms of its good or bad effects upon human beings but as a natural force in its own right, was first developed by the philosophers of ancient Greece. Out of various antecedents a generally accepted doctrine emerged according to which the universe consisted of four elements: earth, water, air, and fire. In China and India similar systems of thought developed. With some variations the view in which fire constituted one of the major elements remained the dominant cosmology for natural scientists and physicians well into the modern era.

Alchemists and chemists, as the direct successors to the metallurgists and 'fire masters' of a previous age, made the study of fire into their central concern. Just as modern mechanical industry in its initial stages owed a great deal to the steam engine, the rise of modern physical science would have been inconceivable without the laborious efforts of earlier investigators experimenting with, and theorizing about, fire.

6. Conclusions

The control over fire has been a human species monopoly since the Paleolithic. It constitutes an integral part of the apparatus with which humans have established and continue to maintain their dominance over other species.

Ever since the earliest stages of its domestication, the same sequence of events has recurred again and again in human relations with fire: deliberately sought advances in control are followed by unintended increases in dependency, and as the dependency sinks deeper into the social and economic infrastructure, it tends to become increasingly less clearly perceptible. Like agrarianization, industrialization began with conspicuously huge applications of fire. As industrial production became more specialized and highly organized, so did the use of fire. In everyday life in highly industrialized contemporary societies, flames are visibly present only in such highly domesticated guises as cigarette lighters, candles for ceremonial use, or wood fires intended to create a sphere of comfort and relaxation. When, on the other hand, a fire is shown on television or in the newspapers, it almost always spells war and disaster. The regularly controlled combustion processes upon which industrial production largely rests are now mostly relegated away from public view.

In accordance with this apparent eclipse of fire, it has also ceased to be regarded in the natural sciences and philosophy as one of the elements out of which the world is composed. The very concept of fire has disappeared from scientific discourse, to be replaced by the more abstract concept of 'energy'—something that cannot be directly seen, heard, smelled, or felt. Similarly, many a day may pass in the life of the average citizen of a modern industrial state during which he or she does not witness any physically observable fire. In the social sciences, too, fire has become almost completely unnoticed. It can be concluded from the foregoing that this is unwarranted.

Firm Behavior

At the heart of the supply side in the theory of how markets function is the theory of the firm. This article surveys the received economic wisdom on how firms make their decisions as to the types and quantities of products they will supply, the prices at which they sell, and the investments they make toward future operations.

That economists have adopted the convention of talking and writing about the behavior of 'the firm' is semantically curious. Supply decisions are made by entities bearing a host of names—corporations, companies, enterprises, businesses, ventures, farms, factories, establishments, and, of course, firms. The word 'firm' is derived from the Latin verb *firmare*, which evolved over time to describe the confirmation of a transaction by signature. The notion of a 'firm' metamorphosed during the nineteenth century to define houses of business organized through written agreements, notably, partnerships, and in modern lay parlance, it is used most frequently to describe partnerships in such fields as law and accounting.

1. Complex Organizational Forms

Meanwhile, the forms of business organization were changing in legal structure and scope. Corporations replaced partnerships, and multi-unit business enterprises operating both within a nation and multi-nationally came to supply the lion's share of services and (especially) products. Already in the sixteenth century, the Venetian merchant Antonio was said by Shakespeare to have 'an argosy bound to Tripolis, another to the Indies ... a third at Mexico, a fourth for England, and other ventures he hath squandered abroad.' In 1995, US business corporations reported

sales of roughly US\$14 trillion, partnerships US\$0.85 trillion, and non-farm individual proprietorships US\$0.81 trillion. In 1982, 7,030 companies with 500 or more employees surveyed by the US Bureau of the Census (1986) generated 41.3 percent of all business employment. On average, those relatively large enterprises operated 64 separate domestic business establishments or plants each, not including foreign branch units. Thus, much of the industrialized world's business is done by organizations of considerable geographic scope and complexity.

Within this array of organizational forms, the theory of the firm is ambiguous, or one might say flexible, in isolating the locus of supply decision-making. The decisions encompassed under the theory may be made at the individual branch or factory level, at the headquarters level, at some intermediate management level, or across a composite of levels.

Few 'firms,' however they may be bounded, carry out internally all the activities needed to provide the goods or services they ultimately supply. Many intermediate inputs, supplies, machines, and specialized production and marketing services are procured through arms-length market transactions from other entities. The characteristic defining the bounds of a 'firm,' Ronald Coase argued in a seminal article (1937), is 'suppression of the price mechanism.' According to Coase, activities are collected within what we call a firm when transaction costs incurred in using the price mechanism for external purchases or sales exceed the cost of organizing those activities through direct managerial controls. Transaction costs may be high when work specifications are complex or rapidly changing, contract negotiations and renegotiations are burdensome, and /or there is a substantial risk of opportunistic deviations by one or another party once contracts have been fixed. The higher the transaction costs, the more a firm is likely to be vertically integrated to carry out internally the activities needed to implement its ultimate supply objectives.

2. The Goals of the Firm

If an organization is to act purposefully, it must have more or less clearly defined goals. In the standard static theory of the firm, the goal is simple: the firm maximizes profits. On the output side, this entails expanding production until marginal cost rises into equality with marginal revenue (which, for a purely competitive firm, is the product's parametric price). On the input side, profits are maximized by hiring the diverse inputs until the value of their marginal product, or in monopoly cases their marginal revenue product, is equal (when inputs are competitively supplied) to the inputs' prices. In addition, the firm must operate on its production function rather than off it; that is, it must avoid the manifold risks of X-

inefficiency (see, for example, Leibenstein 1966). This will be examined further later in this document.

Matters become more complicated when time and uncertainty enter the picture. On the time dimension, two general problems can be distinguished. For one, firms are faced with a continuing menu of opportunities to invest in longlived production facilities and new products. The standard theory says that they should accept all mutually independent investment projects whose internal rate of return exceeds the firm's marginal cost of investible funds. (Interdependence or mutual exclusivity of projects requires the satisfaction of additional conditions.) Additionally, when a firm has monopoly power and hence a choice of alternative output price levels, setting a price that maximizes current profits encourages the entry and expansion of competitors who erode future profit-earning opportunities. The firm must then make a tradeoff in its pricing between present and future profits. In the most elegant control-theoretic formulation of this problem (Gaskins 1971), the firm holds its price below the short-run profit-maximizing level so as to slow the rate of competitors' expansion and hence the erosion of future profits, appropriately discounted to present value, by the optimal amount.

One crucial variable in these calculations is the marginal cost of investible funds, also known as the firm's discount rate. Standard treatises on corporate finance suggest that the firm's discount rate be measured as the weighted average cost, taking into account income tax implications, of the various external sources of funds, i.e., common stock, long-term debt, and short-term loans; and the extent to which external financing, as compared to the reinvestment of current earnings rather than paying dividends, is utilized. Two complications arise here. First, the optimal mix or portfolio of financing methods must be chosen. There is disagreement in the literature over the extent to which external finance costs should and do vary with those portfolio choices. Second, debt costs vary over time with changes in macroeconomic money market conditions; and common stock financing costs fluctuate with both general macroeconomic conditions and with investors' volatile 'animal spirits,' to use Keynes' (1936, p. 161) metaphor. There is disagreement among scholars over whether firms should accept current market signals unequivocally in setting their investment discount rates or whether, recognizing that investments are for the long term, they should try to see beyond current market trends and 'smooth' anticipated external finance market costs in computing discount rates. If they fail to heed short-run equity market trends, they may be subject to hostile takeover by another enterprise more closely attuned to maximizing current shareholder value. Compare Marris (1963), Jensen (1988), and Scherer (1988).

A related question is how a firm's decision makers should treat the intrinsic uncertainty of investment payoffs. In principle, external financial investors eval-

Figure 1
Marginal efficiency of investment schedule for the firm

uate the overall risks of a firm's investments and, by their reactions, introduce appropriate risk premiums into the firm's cost of capital. Using these, internal decision makers should presumably choose investments so as to maximize the discounted expected value of their investments. Often, however, risk aversion creeps into investment evaluations when decision makers or their staff adjust discount rates upward, shade estimated payoffs downward, or avoid through sensitivity analyses projects with substantial downside risk. Again, the firm that internally introduces more risk aversion than external investors prefer thereby increases its vulnerability to a hostile takeover. A further perplexity has been largely ignored in the relevant literature. Under standard practice, firms array their prospective investment projects in descending order of internal rates of return (IRRs), accepting all projects with IRRs in excess of the cost of external capital. This descending array of projects is the microeconomic analogue of what Keynes (1936, pp. 135–6) called 'the schedule of the marginal efficiency of capital.' It is illustrated by the line ME_1ME_1' in Fig. 1.

Assuming this procedure to be unbiased, all projects but the marginal one (at point Z in Fig. 1) yield a return in excess of the rate O_i required to attract outside capital; that is, they yield a supranormal return. Received theory states that in long-run equilibrium, competitive firms do not realize supranormal returns, although monopoly firms may do so. But if the representative competitive firm faces a schedule of investment opportunities such as ME_1ME_1' , how can it not enjoy supranormal returns, contradicting the predictions of the theory? There are two possible answers.

(a) Competitive firms, unlike monopoly firms, may systematically overestimate the profitability of their investments because they fail to take into account the likelihood that product prices and hence returns on investment will be reduced when many other firms,

each an atom relative to the market, make similar investments. This answer can be defended theoretically, but seems inconsistent with the premise that investors try to factor into their decisions all the expected environmental changes that could affect the returns on their investments. Compare Richardson (1959).

(b) The difference between competitive and monopoly firms may lie as much in the shapes of their marginal efficiency functions as in the expected output and price behavior of rival firms. In particular, the monopoly firm's MEI function may resemble ME_1ME_1 in Fig. 1, whereas the typical competitive firm, faced with competition in exploiting investment opportunities as well as in pricing its output, confronts a function more like the dash-dash schedule ME_cME_c , with much less (and in the limit no) possibility of rationally expecting supranormal returns.

3. Getting Things Done

Even when it is agreed that business firms should maximize either their current profits or the discounted present value of their long-term profits, there is many a slip between cup and lip. Difficulties intrude because complex and difficult decisions must be taken in the midst of what von Clausewitz called the fog of war and because decisions must be implemented within complex organizational frameworks. Organizational complexity in turn engenders communication breakdowns, coordination failures, goal conflicts, and motivational problems.

3.1 Bounded Rationality

Running anything but the most pedestrian business enterprise is difficult. Firms' decision makers seldom have a clear view of how consumers will respond to price changes outside the range of those with which experience has been accumulated; that is, demand curves are imperfectly visualized. In oligopolistic markets, the reactions of rivals are crucial to profitability but difficult to predict. Whether technological innovations will function as hoped is uncertain. Even less certain is how consumers will respond to product design changes, minor or radical. Decisions that might turn out brilliantly if rival firms remain passive could fail if rivals respond with aggressive countervailing strategies.

In a debate that raged during the mid twentieth century, it was asserted that business decision makers were not only subjected to great uncertainty about the environment in which they operated, but didn't understand the basic logic of profit maximization as taught by economists. In a famous reply, Machlup (1946) insisted that the variables used in firm decision making

are only 'subjective estimates, guesses, and hunches' and that, just as automobile drivers can solve the problem of passing another car on a two-lane, two-way road without comprehending the differential equations of acceleration and convergence, so also business decision makers (or at least, the successful ones) intuitively solve the equations of profit maximization. Since that time, hundreds of thousands of young people trained in graduate business administration programs have entered the real world of business. It is surely true, even if it once was not, that business decision makers at least understand what marginal analysis means.

The more serious problem is undoubtedly what Herbert Simon (1959) called 'bounded rationality'—that is, the impossibility of having all the information about present and future conditions needed to formulate and solve decision problems with the rigor economic theorists might desire. Seeking to explain how business decision makers function under these conditions, scholars have proposed and extended a 'behavioral theory of the firm' that recognizes real-world information availability and processing limitations (see, for example, Cyert and March 1963). Rather than assuming profit maximization as a well-focused objective, the behavioral theory of the firm postulates that decision makers adopt more limited proximate goals—e.g., setting plausible short-term sales and profit targets—and then 'satisfice' in striving to attain them. The targets may then be ratcheted upward over time to converge, at least under favorable conditions, toward a true profit maximum. Similarly, decision-making processes are simplified to emphasize 'rules of thumb' and 'routines' whose pursuit leads in the general direction of profit maximization and whose modification, under the stress of adverse outcomes or the recognition that environmental variables have changed, tends in a rough way to emulate the outcomes that would emerge from a perfectly rational but informationally unattainable profit maximization exercise (see, for example, Nelson and Winter 1982).

3.2 Decentralization in Complex Organizations

Some suppliers of goods and services such as traditional family farms and 'Mom and Pop' retail outlets have only primitive organizational structures. However, much of the world's business is done by geographically dispersed multi-unit, multi-product enterprises. For them, complex organizational problems cannot be avoided. Hardly anything could be achieved by a large organization, whether it be a business enterprise, a church, or an army, without resort to decentralization. In the simplest models, goals and means are chosen by the organization's head, called the 'principal,' and the work is carried out by lower-level employees, called the 'agents' in the large body of

literature on principal-agent relationships. In more realistic multi-unit enterprises, strategic decisions on the markets to be served, the units responsible for serving them, and the financial and physical means at those units' disposal are set by top management; more detailed decisions on product specifications, prices, outputs, and marketing methods are made by unit managers; and the work is done by individuals within the various subordinate organizational layers. The paradigm for such decentralization, surveyed historically by Chandler (1962) and said by Williamson (1970, p. 175) to be 'American capitalism's most important single innovation in the twentieth century' is the so-called multidivisional or M-form organization. Under it, corporate leaders supported by a small central staff provide broad strategic direction and assign goals to virtually autonomous operating division heads, whose performance in meeting their goals is monitored by the corporate staff, with rewards and punishments being dealt out by the corporate leadership in proportion to the divisions' goal attainment. Or in still more complex variants, the corporate office sets overall policy and strategy; group executives are responsible for achieving broad product line or geographic region goals; and individual product division heads must operationalize the efforts needed to meet the goals (or bear the consequences if they fail). Although no one-to-one correspondence is possible, it is the individual product division within complex corporate organizations that is most like the 'firm' as it has been traditionally construed in microeconomic theory.

3.3 Information Flow Occlusions

With decentralization come several problems. One is the decentralization of knowledge. Central office executives usually know more than individuals lower in the corporate hierarchy about overall corporate goals (entailing *inter alia* understanding what stockholders want) and sources of finance. Production foremen have the most detailed knowledge of what can and cannot be done in cranking out products. Field sales representatives often know best what kinds of products their customers want and what rival firms are doing. R&D staff members have expertise in determining what product features can be achieved physically—insights that are sometimes sharpened by interaction with customers, but that for more radical product changes lie outside the range of customers' perception. Division managers serve as information collection points and are best positioned to see the 'big picture' in their lines of responsibility. Information on customer needs and production possibilities must flow upward from the shop or field to division managers and corporate officials; information on policies and decisions must flow downward for implementation. But information flows are commonly attenuated and distorted. Lower-level employees are loath to admit

their known shortcomings, problems they anticipate but hope to avoid, and the organizational 'slack' they could turn into higher output if pressed. Through hubris, superiors often speak without listening or hear only what they want to hear. Revolutions in information transmission, processing, and storage technology have mitigated some of these problems, but they have by no means eliminated them. As Andrew Grove, one of the most thoughtful information technology business leaders of the twentieth century, observed (Byrne 2000):

Brains don't speed up. The exchange of ideas doesn't really speed up, only the overhead that slowed down the exchange ... You can reach people around the clock, but they won't think any better or any faster just because you've reached them faster.

3.4 Suboptimization Failures

Decentralization implies pushing decisions down to operating levels at which hands-on knowledge and responsibility for implementation are present. But when this is done, suboptimization failures can occur. Division A may supply a key input to Division B. But to meet its financial performance targets, Division A needs a generous markup of prices above costs which could adversely affect the financial performance of Division B or lead it to substitute a less suitable input for the high-priced input. Timely intervention by higher management, with a possibly adverse impact on the motivation of the sacrificing entity, is required to solve such 'transfer pricing' problems. Or functional group X may have the special skills needed to help functional group Y solve a problem, but the effort required from group X may come at the expense of meeting X's direct performance targets, so the desired cooperation fails. Again, subtle intervention by higher-level management can solve the problem, but only by deviating from the decentralization principle.

3.5 Goal Conflicts

Perhaps the greatest challenge is ensuring that all members of a business organization conform to higher-level goals. The problem begins at the top. In principle, it was said earlier, firms maximize profits, long-run or short-run, to serve the interests of their owners—in the case of corporations, the equity shareholders. But there are many reasons why this may not happen. A pathbreaking book by Berle and Means (1932) observed that as the ownership of modern business corporations became dispersed away from founder-owners toward increasing numbers of shareholders, each with too small a stake to warrant intervening actively in their investment target's management, the ownership function became separated

from the control function. Top managers, Berle and Means continued, exercised effective control over their organizations and enjoyed within broad limits discretion as to the objectives they would seek to advance. They might opt to maximize the value of shareholders' ownership interests, but they might equally well pursue alternative and conflicting goals—for example, maximizing the size of the business empires they control by acquiring other companies on terms that reduce original shareholders' stock values; paying themselves lavish salaries; enjoying perquisites such as richly furnished offices and trips in corporate jets to posh golf and skiing locales; contributing enthusiastically to local community cultural establishments; or simply seeking a 'quiet life' devoid of entrepreneurial risk-taking.

Corporate boards of directors are—in principle—supposed to represent stockholder interests. Reality is more complex. During much of the twentieth century, directors of American business corporations were chosen and appointed by company managers, owed their continuing presence on the board to the managers, and adopted codes of behavior that discouraged sharp questioning and opposition to management positions except in times of crisis (see Mace 1971). As a result, they provided at best a weak check against managerial actions that reduced shareholder value. In other nations, widely differing board of directors structures exist, but again, board members have often served as less than diligent stewards of common shareholder interests.

Gradually, this has changed. During the last two decades of the twentieth century there were pressures from institutional investors (such as pension funds), government regulators, and the stock exchanges throughout much of the world to improve 'corporate governance,' rendering corporate directors less beholden to inside management and more dedicated to defending stockholder interests. In the USA, for example, corporations have been induced to restructure their boards so that 'outside' members comprise a majority, to create board member nomination committees dominated by 'outside' directors, and to form compensation committees in which only outsiders determine the salaries and bonuses of inside managers. Much more emphasis has been placed on bonuses and stock options rather than straight pay as means of motivating top managers to perform well on behalf of stockholders. As a result, boards have come to intervene more aggressively in company decision-making and, when performance has been less than satisfactory, to fire the responsible top executives.

Nevertheless, problems remain. The compensation of top corporate managers in the USA during the 1990s rose to unprecedentedly high multiples of average company salaries. One reason was a booming stock market that enhanced the value of stock options without requiring extraordinary performance on the part of managers. Also, with superior information on

company prospects, inside managers could 'game' the timing of stock option awards and bonus target-setting to maximize the chances of a favorable outcome. And to help them in the task of top manager compensation-setting, board committees hired outside management compensation consultants who instigated emulatory competition among companies to reward their executives—few of them leadership superstars—at least as liberally as peers and in the process raised the average for all.

At the end of the day, leadership and the ability to create effectively functioning teams are crucial to organizational success. Even among those who have reached the top ranks in business organizations, the quality of leadership varies widely. Graduate schools of management have found it much harder to teach leadership than any of the other requisite arts and skills (but see Heifetz 1994). Economists have few qualifications for saying anything sensible about how superior leadership emerges, so the subject is left to other disciplines contributing to this *Encyclopedia*.

The goal conflicts observed between shareholders and top managers are replicated manyfold at the lower levels of corporate organizations. Operating unit managers 'game' against their corporate superiors to set performance targets and bonus schemes that are biased on the side of yielding generous compensation. Knowing that personnel turnover is high and corporate staff memories short, operating unit managers take actions that sacrifice durable profitability for the sake of higher short-run profits and bonuses. Production and sales force supervisors recognize that their tasks could be carried out with smaller staffs, but refrain from profit-enhancing cutbacks to hold reserves against future contingencies and to maintain a 'nice guy' reputation. These incentive conflicts might be reduced in companies with 'superincentive' compensation schemes; for example, in high-technology startup companies that award potentially lucrative stock options to all employees in responsible positions. The phenomenon is a relatively new one on which clarifying research is needed.

4. Natural Selection

Achieving good economic performance at the operating levels of complex organizations is not easy. Communication and incentive failures abound. There is considerable X-inefficiency. But goods and services do get delivered at levels that on average are nothing short of remarkable. One reason is that in national economies with firmly implanted capitalist institutions, most business firms must strive to improve their internal incentive systems and hew to something approximating a profit maximization line lest they be displaced by competitors who do a better job of satisfying consumer wants. In vigorously competitive

industries, firms that stray too far from the path of profit maximization are unlikely to withstand the forces of natural selection (see Alchian 1950, Nelson and Winter 1982). When competitive pressures are weak, however, product market forces may be insufficient to jeopardize non-maximizers' survival. In such cases—more the exception than the rule in well-functioning economies—the disciplinary job is left to the still-imperfect instruments of corporate governance.

First Language Acquisition: Cross-linguistic

In this article, motivations for cross-linguistic research into children's acquisition of their first language(s) are noted with a brief historical outline of the field (Sect. 1). This is followed by a review of trends which appear to be universally shared across children acquiring different languages (Sect. 2), compared with the impact of typological properties of particular target languages on processes of acquisition (Sect. 3). The article concludes with a note on desiderata (Sect. 4).

1. Approaches to the Field

The major motivation for the cross-linguistic study of language acquisition, as of cross-linguistic research in general, is to compare what is universally shared across children irrespective of the specific target language or speech community to which they belong, on the one hand, with interlanguage variation and the impact of properties peculiar to a particular language or language type on the other (Slobin 1997b). A related, psycholinguistically motivated question is how the specifics of target-language typology interact with acquisitional principles and strategies deriving from more general extralinguistic factors of perception, cognition, and social interaction (Slobin 1985b).

The first studies of children's acquisition of their native language(s) which can be characterized as cross-linguistic in orientation date from the nineteenth and early twentieth centuries. These were generally diary studies of childhood bilingualism, among children raised in more than one language, mainly in Europe. Such studies provided potentially rich data for cross-linguistic comparisons, as did a range of studies of children acquiring languages other than English (Ferguson and Slobin 1973). However, these were by and large not systematically directed to the testing of psycholinguistically motivated hypotheses, and they tended to focus on phonology, inflectional morphology, and the lexicon, with little concern for syntax or semantics.

The rise of developmental psycholinguistics in the USA in the 1960s created a field of inquiry which aimed to integrate insights from linguistic theory and description with developmental patternings in first language acquisition. Such studies tended to be anglo-centric, but provided a basis for research in other

languages. For example, the general developmental stages delineated in Brown (1973) for the early years of grammatical development appear to apply across languages (see Sect. 2 below).

This anglocentricism was countered by the Berkeley project on four typologically distinct languages (Slobin 1982). Since then, data have been collected from a wide range of languages, both across and outside Europe. These include surveys of several dozen typologically distinct languages in the five volumes edited by Slobin (1985–1997). Other collections focus on particular domains including: early clause structure (Bowerman and Perdue 1990), the lexicon–syntax interface in verb acquisition (Lieven 1998), and narrative construction (Berman and Slobin 1994, Hickmann et al. 1996). Generative grammars gave rise to a parameter-based analysis of acquisition in different languages and domains, for example, Hyams (1986) and Weissenborn (1992) on null subjects, Meisel (1992) on functional categories and the ordering of constituents (see *Generative Grammar*).

Research in child language since the 1980s has thus yielded a large body of data on acquisition of numerous languages, including ones with non-European typology. Many of the latter studies are anchored in ethnographic-type fieldwork, for example, for Inuktitut by Shanley Allen, for Mayan Quiché by Clifton Pye, and for Sesotho by Katherine Demuth; or in research conducted by native speakers, as in Soonja Choi's work on Korean. This work combines to demonstrate that (a) children early on adapt to the particular constraints of their native-language typology, as verb-initial or verb-final, accusative or ergative, as synthetic or agglutinating; (b) they do so on the basis of the particular cultural norms for caretaker–child interaction in their speech community; (c) they do so with equal rapidity and ease across languages; and (d) within languages, the acquisition of certain subsystems may be delayed for language particular reasons of relative structural and/or semantic complexity, on the one hand, and because they belong to restricted registers of usage not accessible to young children, on the other.

2. Universal Trends in Language Development

Different points of departure underlie claims about universals in language acquisition. A nativist, Chomskyan-based view will specify these in terms of the formal principles characterizing a generative model of Universal Grammar (UG) with cross-linguistic variation accounted for by differential setting of structural parameters according to the target language. A Piagetian orientation will explain them in terms of general cognitive principles and shared conceptual underpinnings which provide a universal epistemological basis for acquisition of linguistic

knowledge (Slobin 1985). The view espoused by this author is that children start out the task of acquisition equipped with categorial and semantic distinctions of the type termed by Chomsky 'substantive' as against formal universals, akin to Keenan's (1979) idea of 'naive' or primitive universals (Berman 1993b). For example, children do not need to learn that there are two main kinds of sound segments, consonants and vowels; that propositions distinguish between predicates and arguments; or that there are intransitive and transitive clauses, with one-, two-, or three-place predicates.

Whatever the explanation they propose, researchers agree that there is a clear biological underpinning to the overall developmental stages manifested by children in command of language production irrespective of mother tongue. Just as children sit before they stand, and walk before they run, so children across the world babble before they produce single words, rely on single words before they start combining words, and produce isolated clauses before they join these together by increasingly specific lexical means and complex syntactic devices.

Overall progression thus involves an evolution in construction types. Language production typically starts out with utterances, as behavioral elements which provide the initial basis for expressing relations between semantic content and phonetic form. These typically take the form of isolated lexical items or unanalyzed strings of words, starting around the end of the first year of life. Structure dependence emerges when these lexical units are combined in simple-clause structure, realized by morphosyntactic markings of verb–argument relations. Next, adjacent clauses are combined, first by coordination, subsequently by various kinds of subordinate constructions—initially mainly finite and subsequently nonfinite—leading up to complex clause-linkage by derived nominalizations (Berman 1993a). This needs to be qualified for a verb-final language like Turkish, where the unmarked means of clause linkage is by nonfinite, nominalized constructions. These emerge relatively early in Turkish compared with European or Semitic languages.

With respect to acquisition of morphology, the domain in which languages tend to differ most, children generally acquire the bulk of the inflectional system of their language before they master its derivational morphology. This is understandable since inflection is more regular, productive, and grammatically obligatory than derivation. Besides, derivational processes depend on a level of vocabulary expansion not achieved by young preschool age. In fact, in some instances, like derived nominals or the high-register Latinate lexicon of English, children will master derivational processes only well into school age. In contrast, they by and large command the inflectional systems of their language by the age of three, irrespective of how morphologically opaque or synthetic these happen to be. Cross-linguistic differences affect

acquisition of inflection along two main dimensions. Psychological processing principles like perceptual saliency coupled with regularity and transparency of form-meaning mappings account for the fact that, for example, Turkish-speaking children gain command of the bulk of their rich system of agglutinating, inflectional suffixes by a much earlier age than children acquiring languages with more synthetic or syncretic morphologies like Hebrew or Icelandic. And experiential factors of frequency of use in the everyday colloquial speech that constitutes the linguistic input and output of young children explain why certain grammatical categories are acquired relatively late in languages where they constitute high-register or literate constructions.

In the domain of syntax, children typically gain command of simple clause structure in their language between ages two to three years. Basic word order emerges very early indeed, first between phrasal constituents, only later within phrases. Constituent ordering is followed by grammatical marking of verb-argument relations, around the same time or somewhat before inflectional marking of grammatical agreement. The overall progression is thus much as Brown (1973) defined for English: from single words to early word combinations, thence to simple clause structure, followed by a range of devices for clause linkage.

Another commonality is the general development observed across children from rote-learning of unanalyzed items to partial productivity followed by command of structure-dependent rules and generalizations, which are subsequently constrained by conventions of lexical and discourse usage. This has been demonstrated, for example, for how children acquire the semantics, morphology, and syntax of causative verbs in three typologically distinct languages: English at the more analytic or syntactic end of the scale, Hebrew with relatively synthetic bound morphology, and Inuktitut as a polysynthetic language which marks causativity by both morphological and lexical means (Allen, in Lieven 1998).

General language development thus proceeds across different phases, from pregrammatical to structure-dependent to appropriate use. And it becomes both more elaborated and varied in structure and use, on the one hand, and more restricted or constrained by target-language specifics, on the other. Thus, in acquiring the sound system, babies proceed from universal crying to uttering a range of speech sounds, followed by babbling, which is increasingly restricted to elements of the native language to a point where eventually the system will be so constrained as to impose a non-native pronunciation in other languages. Similarly, in morphology, across languages children proceed from nonalternation between forms to immature strategies for initial markings of grammatical categories, thence to 'creative errors' of over-regularization, until eventually the system becomes fully

constrained by lexical convention. And in the acquisition of the lexicon, again across languages, children move from a restricted vocabulary of nursery terms and over or underextensions of conventional items to a period of creative innovation; eventually the conventional lexicon takes over, while at the same time vocabulary growth is both constrained and elaborated by socially and culturally appropriate distinctions of register and usage, lasting into adolescence.

3. Impact of Target-language Properties

As against these cross-language commonalities and claims for universal constraints, whether formal-linguistic or perceptual-cognitive, current research reveals a marked effect of target-language typology from a very early age. Such more language-specific claims have been explained in cross-linguistic perspective as reflecting a modified, neo-Whorfian characterization of the relation between language and thought (Slobin 1996) and as demonstrating the critical impact of caretaker input from the very start (Bowerman 1995). This very early sensitivity to target-language properties has been observed in a variety of linguistic domains. For example, language-specific effects exert an influence on speech perception and babbling during the first year of life (Juczyk 1997). And well before they have command of grammatical inflection, children will adjust their speech output to the prosodic character of their language, as intonation or tone-based (Demuth 1993), and they will show rapid command of vowel-harmony where required, as in Turkish (Aksu-Koç and Slobin 1985).

Children's encoding of the semantics of space and which distinctions they mark linguistically (e.g., in shape or location of figure and ground respectively) is also markedly influenced by target-language specifics. Thus, the universality of the early preference among children acquiring European languages (and also Hebrew) for the prepositions *in*, *on*, and then *under*, which was convincingly explained in terms of perceptual properties of space and shared cognitive preferences, has now been queried, since it turns out that quite different factors govern the encoding of spatial distinctions in languages like Korean or Tzeltal compared with English and Dutch (Bowerman 1995). Children appear to relate to the categories relevant to their own native language without initially manifesting universal patternings in the expression of spatial distinctions.

Null subjects are another domain in which universalist claims have been made. Thus, Hyams (1986) suggested that children first set the prodrop parameter to the unmarked value of plus, irrespective of target language, since English-speaking children in the early stage of grammar acquisition produce numerous

subjectless sentences, as do their Italian peers. Weissenborn (1992) showed, however, that target language input has a marked influence from very early on in this respect, since children acquiring French produce fewer subjectless sentences than those acquiring German, and the latter do so less than children acquiring strongly pro-drop languages like Italian and Spanish.

The very early impact of target language is evident not only in which categories are distinguished, but also how. This is clearly shown in Clark's (1993) cross-linguistic comparisons in the domain of word formation. When young children express the notion of 'undoing' or reversal of actions, they do so from early on in ways peculiar to their native tongue: by the prefixes *un-* in English and French *dé-*, and by particles like *ab* and *aus* in German, *af* and *uit* in Dutch. Hebrew-speaking children, in contrast, must do this lexically or periphrastically, since their language lacks the morphological means for this semantic category. Similarly, in order to express causativity, children will start by using syntactic means with verbs like *make* in English and *faire* in French, a construction type used only rarely by Hebrew-speaking children for this purpose. Subsequently, English-speaking children will overextend verbs like *fall* or *sing* to transitive contexts; in Inuktitut, children will first use morphological and then lexical means of causativity while in Hebrew, they will first neutralize and then alternate morphological patterns to mark verb transitivity (Allen in Lieven 1998, Berman 1993b).

This research converges to suggest that apparently universal acquisitional principles of structural simplicity and semantic transparency in form-meaning mappings are affected and perhaps even superseded by typologically pervasive properties of the target language. For example, it has been argued that children will find it easier to juxtapose words than to affix bound elements to a stem or root, and that these processes are perceptually more salient and so more accessible to young children than stem-internal vowel alternation. However, in a language like Hebrew, which uses vowel alternation to express basic grammatical distinctions such as verb-tense, children mark past vs. present tense at much the same time as their counterparts acquiring languages which use more linear morphological means. Moreover, although their language allows both noun compounding and external, linear affixation to a stem for new word formation, Hebrew-speaking children typically innovate nouns, verbs, and adjectives by the more typically Semitic device of attaching syllabic affixes to a consonantal root: and they rarely use the option favored by English-speaking children for creating novel verbs by zero derivation or syntactic conversion (Berman 1999).

Children's acquisition of word classes and the composition of their early lexicon are other areas which suggest that claims for universal underpinnings

of acquisition may need to be modified. Prior research on children's lexical repertoire at the one-word stage in several languages showed that more nouns were acquired earlier than verbs, while the vocabulary spurt in the period before early word combinations also consisted mainly of noun like terms. Gentner (1982) explained this in terms of general cognitive principles, since verbs as relational terms are holistic rather than coherently packaged entities, while nouns (at least those in the input and output of one- to two-year-olds) tend to encode semantically 'natural' categories that refer to concrete objects which are perceptually identifiable. Recent research has shown, however, that this noun bias may be an artifact of the nature of the lexicon and lexical input in the target languages, and that in some cases, verbs may be acquired earlier and in greater quantities than nouns (for example, the studies by Brown and by Choi in Lieven 1998).

At more advanced stages, developments in form-meaning mappings in extended discourse provide further evidence for the impact of 'typological imperatives.' A five-language cross-linguistic sample of picturebook narratives produced by children aged three to five and nine-year-olds compared with adults (Berman and Slobin 1994) showed that the expression of textual temporality was critically affected by native-language tense/aspect systems even among our youngest subjects. In Hebrew, children marked only grammatical tense, in Spanish they distinguished both simple from progressive and perfective from imperfective aspect, while in Turkish they gave grammatical expression to modality. Moreover, there was no evidence for 'compensation' in the sense that children attempted to give lexical expression to notions not grammatically encoded in their language (e.g., by using periphrastic adverbs to mark aspectual distinctions in languages like German or Hebrew). On the contrary, not only 'do speakers tend to limit their attention to those semantic distinctions marked in the grammar, they may even overattend to such distinctions in early phases of development' (Berman and Slobin 1994, p. 619). Slobin (1996a, 1996b, 1985-97) has since extended these observations to the expression of locative trajectories. Proceeding from Talmy's (1985) distinction between verb-framed languages (Hebrew, Spanish, and Turkish in our sample) and satellite-framed languages like English and German that rely heavily on locative particles, he shows that the way young children—like adult speakers of the same language—talk about motion, paths, and directionality depends critically on how these notions are grammatically and lexically encoded in their language. Here, too, the underpinnings of such distinctions are evident very early: at the one-word stage, Germanic-speaking children use particles like *off* or *aus* to express direction of motion in ways encoded by verb-stems by children acquiring French, Spanish, or Hebrew. For example, at the age of 18 months, my Hebrew-English bilingual daughter would say either English *down* or a

truncated stem form of the Hebrew verb *la-redet* 'to get/go down,' when she wanted to be taken out of her high chair.

In another cross-linguistic project comparing children's narrative texts produced by children aged from five to 15 years on the basis of two picture-series, Hickmann et al. (1996, p. 391) focused on the devices for introducing, maintaining, and shifting reference to characters in a story. They found that the English, French, German, and Chinese 'rely differentially on local vs. global devices to mark newness: postverbal position is obligatory in Chinese ..., indefinite determiners in the other languages; across languages: newness markings emerge late (age seven), local markings emerge before global, and local and global markings are strongly related.' Their findings point to an important interaction between shared developmental trends and linguistic specificity. Relatedly, in the Berman and Slobin (1994) study, across languages, three-year-olds tended to relate to each picture in isolation, four- and five-year-olds were able to encode linearly expressed local relations between events in terms of local temporal relations of sequentiality and subsequently of causality, school-age children constructed a globally organized hierarchical narrative, and adults tended to adopt individual rhetorical styles with rich interpretation and a personal narrative stance.

Ongoing cross-linguistic research on the production of narrative and expository texts by schoolchildren and adults reaffirms such interaction between generally shared developmental trends and typologically determined expression of semantic distinctions and selection of rhetorical options. Nine-year-olds can all construct wellformed personal experience narratives, but are unable to produce coherent expository texts. Further, only from high-school age will one find consistent, deliberate, and appropriate differentiation between language usage across spoken and written texts, marking highly language-particular register distinctions. In contrast, overall genre distinctions appear similar across languages. For example, narrative texts are couched in past tense and mainly perfective aspect, and they have light subjects (mainly pronominal in English and French or null subjects in Hebrew and Spanish), while expository texts rely more on generic or extended present tense and have more lexical and heavier, more noun-phrase subjects and objects. This, too, interacts with target-language options and preferences. For example, in order to express a detached, impersonal perspective in English, passive is quite widely used even by grade-school children, increasingly by adults; and passive is also quite common in the Icelandic texts. In contrast, passive is used far less in other languages, even though it occurs as a structural option: Swedish subjects rely heavily on the impersonal pronominal *man* corresponding to the very common use of *on* in French; Spanish and Hebrew achieve the same rhetorical effect by means of sub-

jectless or second person impersonal constructions. Similar patterns emerged for differential use of pronominal compared with null subjects and also for relative clauses as devices for syntactic packaging in the picturebook narratives.

Discourse-based cross-linguistic comparisons thus suggest that reliance on certain linguistic forms may depend not only on structural factors of relative morpho-syntactic complexity or productivity, but also on the extent to which a given rhetorical option is favored for specific discourse purposes in current language usage.

4. Conclusion

In sum, on the basis of shared cognitive and linguistic universals, even very young children are attentive to key typological properties of their language. From an early age, they recognize 'where the action is at' in the input language, not only which categories are formally distinguished, but also how. *When* this type of sensitivity finds expression will depend on general developmental, largely extralinguistic factors. For example, the spatial distinctions studied by Bowerman (1995) and her colleagues will precede command of derivational marking of linguistic subcategories, and these will emerge earlier than rhetorical mastery of linguistic forms in the context of extended narratives. But in each case, the specific ways in which children encode form-meaning relations accord with how this is done by adult speakers of the same target language rather than by children of the same age in other languages.

As noted in the introduction, a large body of data is currently available for acquisition of different domains in a rich range of languages from Europe and elsewhere. What now seems necessary is to extend systematic and deliberately comparable research designs across a range of languages and linguistic domains—along lines conducted for morpho-syntax by Slobin (1982), for word formation and derivational morphology by the structured elicitation and diary studies reported in Clark (1993), for semantic encoding of space by Bowerman (1995), for temporality by Weist and co-workers (Weist et al. 1993), as well as for narratives by Hickmann (1996) and by Berman and Slobin (1994). Such studies might profitably focus on two contrasting directions of cross-linguistic comparison: (a) languages which are typologically very distinct, for example, ergative or accusative, verb-initial or verb-final, analytic versus synthetic or agglutinating; and (b) languages which are typologically close, like Dutch and German, or Arabic and Hebrew, but which differ along certain restricted dimensions. Such work should aid in specifying the relative weight of the various factors touched on here. It would help to delineate the interaction between language-universal and language-particular, between intralinguistic,

cross-linguistic, and extralinguistic factors in acquisition. And it could provide psycholinguistic motivation for the distinction between language-specific, typologically shared, and cross-linguistic or universal features of language structure and use in developmental perspective.

R. A. Berman

First Past the Post, in Politics

1. First Past the Post, in Politics

First past the post (FPTP) is the name given to the simplest possible system of electing persons to office. Also known as *single member plurality* system, FPTP refers to contests where the candidate with the most votes, and only that candidate, is elected from a given electoral district. FPTP is used in legislative elections in 68 of the 211 independent states and related territories identified in the *International IDEA Handbook of Electoral System Design* (1997, p. 20). Even though FPTP is used in about a third of the states and territories, countries with FPTP constitute nearly half of the populations included in these units, because

they include populous countries such as Bangladesh, India, Nigeria, Pakistan, the UK, and the USA. Many of the countries with FPTP are former British colonies.

Two features distinguish FPTP from other electoral systems: the number of elected seats per district (one) and the rules by which those seats are allocated among candidates (simple plurality). Because both of these factors contribute to the unique character of FPTP, it is worth considering them in sequence.

1.1 Single-member Districts

Under FPTP, only one person is elected per district. In the US House of Representatives, for instance, although there are 435 districts, each district is represented by a single person (hence the term 'single-member district'). The same is true for the British House of Commons. In contrast to FPTP, in many national legislatures, the top two, three, or n vote-getters are elected to represent the district. In the extreme case, the entire country is a single multi-member district, and all legislators can be said to represent the same district. The Israeli Knesset, for example, has a solitary district comprising the entire country, and all 120 members of Knesset represent it. The same is true of the Dutch legislature, which has 150 members from a single national district.

In the systematic comparison of types of electoral systems, the number of elected seats within a district is termed the *district magnitude*. In FPTP, where the district magnitude is one, voters usually vote directly for candidates. If a party's candidate wins in a district, that party has won essentially 100 percent of the representation for that district, despite receiving only a portion, and not necessarily more than half of the total votes. For example, suppose that there are three parties evenly distributed over a hundred districts. If the vote in each district is 40 percent for party A and 30 percent each for parties B and C, party A will have 100 percent of the seats with 40 percent of the votes. This pattern (with more realistic numbers) often gives the largest single party a proportion of seats in the legislature that is higher than its proportion of votes in the electorate. Thus, leading or majority parties in FPTP tend to be over represented.

This exaggeration of the seat shares of the parties that are largest in votes is not unique to FPTP. Virtually all electoral systems do so, but FPTP does so more than proportional representation systems (Rae 1971). However, it is also possible in FPTP systems for a party to receive a majority of votes, but only a minority of seats, for example, when such a party's supporters are heavily concentrated in a few districts.

In systems where the district magnitude is high (and therefore, by definition, not FPTP), voters typically cast their ballots for parties who are then allotted legislative seats more or less in proportion to their

share of the electorate's vote. In general, higher district magnitudes imply some kind of proportional representation (see *Proportional Representation*).

1.2 Plurality Rule

Within single-member district systems, a winner can be picked via one of several alternative rules. Plurality, the simplest rule, implies that the one with the most votes wins. Other options include absolute (more than 50 percent) majority requirements, with runoff elections between the top two finishers if necessary; approval voting, wherein voters give one vote to each candidate they approve of; the Condorcet procedure, in which the winner of a series of paired comparisons (if there is one) is designated the winner; and the Borda count, wherein points are assigned by voters to candidates in order of their preference.

When there are only two candidates, simple plurality rule is equivalent to majority rule and has four desirable properties: decisiveness, anonymity, neutrality, and positive responsiveness (May 1952). When there are more than two candidates, neither plurality rule nor any other system fulfils another (weaker) handful of simple desiderata: universal admissibility of preference orderings, the Pareto criterion, independence of irrelevant alternatives, and nondictatorship (Arrow 1963).

1.3 Consequences of FPTP

The great virtue of FPTP is its simplicity. Voters make a single choice and the candidate with the most votes wins. However, FPTP has fewer desirable properties than many other methods in multicandidate elections. Compared to other rules, plurality is the least likely to pick a Condorcet winner, i.e. a candidate who is able to beat all other candidates in pairwise contests. Also, simulations show that the plurality rule results in average social utilities that are lower than those under other rules (Merrill 1988). Such drawbacks may not be very consequential when there are only two candidates. Furthermore, when there are only two options, as in a two-party system, there is no need for more complex electoral systems.

When three or more candidates compete in a FPTP election, some of the candidates may divide the votes of some segment that might otherwise agree on a winning candidate. This could result in a victorious candidate who is less preferred by the electorate than one of the losers. If voters are aware of this eventuality they may be able to coordinate in order to elect a more preferred candidate. FPTP encourages voters to cast their ballots strategically and consider the behavior of other voters. If a voter's first-choice candidate has little chance of getting a plurality of votes, the voter

may find it advantageous to vote for a less preferred but more viable candidate instead of 'wasting' his or her vote on a candidate with little chance. In contrast, multi-member districts and even single-member districts with decision rules other than plurality may reduce the incentives for voters to deviate from their first choice.

Strategic behavior and an aversion to wasting one's vote means that FPTP elections are typified by contests between two major candidates, whereas alternative systems often exhibit several viable candidates. Extending this result to parties, FPTP systems routinely have only two major parties, a phenomenon that has been coined *Duverger's law*, named after the French scholar who extensively described the relationship (Duverger 1954). Proportional representation systems, however, usually have more than two parties, a result that has come to be known as *Duverger's hypothesis* (Riker 1982, Cox 1997).

When there are only two viable candidates in an FPTP election, no abstentions, and the candidates are choosing their positions to maximize their electoral support, the candidate ideologically closest to the median voter is advantaged (Downs 1957). FPTP systems thus tend to produce more moderate outcomes than alternative systems. The incentive for candidates to take moderate positions can produce candidates who are only minimally differentiated, leading some to conclude that the choices in FPTP are often of little consequence. One potential advantage to such a system, however, is that the outcomes from one election to the next tend to be more ideologically consistent, resulting in small, incremental policy changes over time.

First World War, The

1. Causes

The outbreak of the First World War in the summer of 1914 has been attributed to accident, design and confusion. The first position suggests that no one intended that armed conflict would break out in 1914; the second, that German and Austrian military elites planned the conversion of a Balkan diplomatic crisis into an armed confrontation; the third, that political and military leaders throughout Europe began to maneuver with some notion that war was possible, but found that they could not resist the momentum of confrontation (Joll 1992).

What was the sequence of events subject to these interpretations, and which has commanded the support of most historians who have addressed the issue of the descent into war in 1914? On 28 June 1914, the Archduke Franz-Ferdinand of Austria–Hungary, heir to the throne, was assassinated in Sarajevo. The crime was carried out by a group of Serb student patriots in neighboring Bosnia, then a province of the Austro–Hungarian empire. Their aim was to demonstrate the force of Slavic nationalism, and to challenge the domination of these south Slavic lands by imperialists in Vienna and Budapest.

In this aim, they succeeded completely. The government in Vienna decided to make this crime a matter of state, and to lay the blame for this political murder on the independent Kingdom of Serbia, and its intelligence services. On 5–6 July, Austrian officials went to Germany to seek support for their policy of making Serbia 'pay' for the assassination. German officials gave their approval, offering a 'blank check' to their Austrian allies. With this backing, on 23 July the Austrians presented Serbia with a list of demands which constituted a challenge to the status quo in the Balkans.

This is where Russia entered the conflict. A humiliation for Serbia would humiliate her Slavic ally, Russia. With Russian backing, Serbia met most of the Austrian demands, but refused to capitulate completely. In support of Serbia, Russia ordered partial mobilization of her armies on 29 July. In support of Austria, and in response to the numerical superiority of Russian forces, the German army mobilized too.

Once German mobilization was in progress, then the crucial link appears between a conflict in the Balkans and an all-European war. German military

planning had for years established a set of priorities to safeguard the security of the German empire. The primary point here was the need to avoid fighting a two-front war. Thus, it was necessary for Germany to eliminate a western threat on the part of Russia's ally, France, before facing the huge armies Russia could put in the field. To do so, a military plan—the Schlieffen plan—was developed through which German forces could move in a huge arc from Cologne in southwestern Germany westward through Belgium and then southward through France. The destination, after 42 days, was in the vicinity of Paris, where the French army would be destroyed, just as had occurred in 1870.

The Schlieffen plan was thus a German response to the threat of a two-front war. That threat had materialized out of the confrontation of Germany's ally Austria-Hungary with Russia's ally Serbia. But the German plan to destroy the French army by an arcing move through Belgium threatened to bring in the UK, guarantor of Belgian independence (Ritter 1958).

And that is precisely what happened. The German invasion of Belgium precipitated a state of war among the five great powers: Germany and Austria-Hungary on one side, and France, Russia and the UK on the other. By 4 August 1914, the First World War had begun.

Had anyone intended this moment to occur? Probably not. While the chief catalyst of the war crisis was the decision by Austria and Germany to press Serbia to pay a political price for the assassination, the outbreak of war was less a conspiracy than a complex mixture of arrogance, a sense of national 'honor,' ignorance, and confusion. All the actors in this drama misjudged the other side. Each move forward in the crisis was followed by a further heightening of tension. First Austrian honor was at stake; then Russian honor; then German fears of encirclement led her to respond to a perceived threat from Russia by threatening Russia's ally, France; and when confronted by a likely invasion of France, the UK hesitated, and then in defense of her honor, she declared war on Germany.

Two elements in the crisis were crucial in the prevention of a diplomatic solution. The first was temporal; the second, structural. First, timing. The war crisis lasted for one month. But a closer view of these events presents us with an even shorter timetable in the slide towards war. One week separated the Austrian ultimatum to Serbia—on 23 July—from Russian and German mobilization—29–31 July. In that time period, it was simply impossible for alternatives to be explored, or for the weight of antiwar and pacifist opinion, by no means negligible, to be brought to bear on political leaders. The crisis moved too fast to be stopped.

The second determinant of a general European war was, broadly speaking, structural. That is, the chronic instability of southeastern Europe was insufficient in

and of itself to bring the Great Powers to war. What turned a minor conflict into a major crisis was the linkage between the Balkan conflict and the longer-term balance of power between Germany and the UK. Once the UK and Germany were aligned on opposite sides, then the crisis of 1914 became a contest for control over northwestern Europe. Should Germany defeat France in 1914, as she had done in 1870, the German navy would occupy the Channel ports. British shipping lanes, necessary to feed her home population, would be open at the pleasure of the German navy. No British government could accept that prospect (Kennedy 1980).

It is true that the British Foreign Secretary, Lord Grey, did not make this issue clear in his diplomatic handling of the war crisis. The German Chancellor, Bethmann-Hollweg hoped that the UK would stay out of the war. But geographical and strategic imperatives overshadowed diplomatic miscalculations. An invasion of Belgium and France posed a real and present danger to British vital interests. And when the UK entered the war, so did the British empire. What had started in Sarajevo, echoed in Sydney, Capetown and Calcutta. By 4 August 1914, the world was indeed at war.

2. *Conduct*

The 1914–18 war spanned the globe, but its outcome was determined by what happened on the battlefields of Western Europe. This article therefore offers an outline of the major military encounters of the war, encounters which left lasting traces both on the landscape of Europe and on the contours of the rest of the twentieth century.

The battlefield in 1914 was Victorian in character. Artillery provided more fire power than ever before, but most of it was horse-drawn. Four years later, the battlefield was transformed. By the end of the war, it took on contours recognizable to most soldiers who would come to fight in later conflicts. Infantry, artillery, tanks, and air power were all coordinated through communications systems and supply systems of great complexity and sophistication. Supplying animal power meant relatively little; supplying machines meant everything (van Creveld 1977). The 'storm of steel' in the words of the German infantryman Ernst Jünger, had come to stay (Jünger 1929).

2.1 1914

The two major military encounters of 1914 produced very different outcomes. In Belgium and France, the German army, one million strong, pushed forward in a swing westward and then southward. It met stiff resistance from Belgian forts, and then was harried by stubborn French and British defensive action. As the

German army moved west into Belgium, the French army moved east towards Alsace and Lorraine, provinces lost to Germany in 1871. German defenses held and inflicted massive casualties on the French. On one day, 24 August 1914, over 24,000 French soldiers died in action. This 'Battle of the Frontiers' was a massive defeat for the French. But the strength of their east-west rail links enabled the bulk of French forces to move west to meet the real threat of the German advance towards Paris. There on the river Marne, the German thrust was stopped. The German army retreated northward and dug in on the river Aisne. When French and British forces pursuing the German army reached the Aisne, they were unable to move the invaders. There the 'Western Front' was born. It soon stretched from Belgium to Switzerland.

There is little doubt that the Battle of the Marne was a German catastrophe. The whole purpose of German strategy had failed. There would be a two-front war. By the end of 1914 the chief of staff of the German army, von Moltke, had been replaced by Erich von Falkenhayn. But what redressed the strategic balance was a massive German military victory on the Eastern front. Two columns of Russian troops advanced into East Prussia at the same time as the German army moved through Belgium and France. These columns were separated by a string of lakes. A German staff officer, Max Hoffmann, took advantage of the geography and of the existence of a north-south rail link. Under the cover of darkness, the German army in the north moved south. The Russian column in the north had no idea they were facing an empty landscape; the Russian column in the south had no idea they were facing a numerically superior force, that is, until they were annihilated at the Battle of Tannenberg. The commander of Russian forces in the south, Samsonov, committed suicide. The two commanders of the German forces, who had not planned the operation, but who reaped its rewards, became national heroes. They were Paul von Hindenburg and Eric Ludendorff (Showalter 1991).

2.2 1915

The war spread in 1915, but the rough stalemate of 1914 remained unbroken. One major attempt to break it was in Turkey, then an ally of Germany. To 'stop our troops from chewing on barbed wire' on the Western front, as Winston Churchill, Britain's First Lord of the Admiralty, put it, a plan was hatched to knock Turkey out of the war by a naval operation. The aim was to use British naval power to force the straits that connected the Mediterranean Sea to the Black Sea. Once done, then the Turkish capital of Constantinople would be indefensible. The defeat of Germany's ally Turkey would serve many purposes. It would open supply lines to Russia; it would convince all and sundry, especially in the Islamic world, of the error of siding with Germany in the world war; it

might even convince Germany to withdraw from France and Belgium.

Nothing of the sort happened. Here too, a mixture of arrogance, ignorance and confusion ruled. The enemy was Oriental, and all the distortions attending Western attitudes towards the Orient flourished. The enemy was underestimated. Attempts to push a naval force through the Dardanelles failed in March 1915. The Allies decide to mount a joint land-sea operation, but no one had a clear idea of the terrain on which soldiers would land. When they went ashore on 24-25 April, they faced steep cliffs and stiff Turkish resistance. They never got off the beaches. A six-month stalemate ensued, after which Allied forces withdrew.

2.3 1916

Two further attempts were made to shift the balance of power on the Western front. The first was at Verdun, in eastern France. There on 21 February 1916, more than one million shells fell on French positions in the hills north of the garrison city of Verdun. The idea was to force the French into total defense of this relatively unimportant position. The French, Falkenhayn reasoned, valued Verdun as a symbol of French freedom and power (Afflerbach 1994). He was right. The French committed 259 out of its full complement of 330 infantry regiments to the struggle for Verdun. They moved into Verdun along a vast conveyor belt, which the French called *la voie sacrée*, the sacred way. It certainly was a field of sacrifice. Falkenhayn succeeded in bleeding the French army white, but he did so at a massive cost to his own troops. Perhaps half a million men died at Verdun, where, by November, the French army had recaptured all the ground lost in the early days of the battle. Lasting ten months, the Battle of Verdun was the longest battle in history. The front remained about where it had been before the bloodbath (Horne 1962).

The same failure to break the stalemate occurred further to the north, where the British and French armies opened a major offensive on 1 July 1916. Here the fault lay in an underestimate of the enemy's fortifications and an overestimate of the power of artillery to destroy them. A one-week barrage by British guns was supposed to obliterate German defenses between Amiens and St Quentin in the lowlands of the Somme. But the deep dugouts under the German lines withstood the barrage, and when British forces moved out early in the morning of 1 July, they were mown down by German machine guns. Of the 100,000 men who went over the top, 60,000 were casualties, of whom 20,000 died in that single day. Thereafter, British and German forces regrouped. A further advance on 14 July was somewhat more successful, but by September, it was apparent that no breakthrough would take place. German lines held, but at a high price. German casualties numbered approximately 450,000; together

French and British casualties surpassed 600,000. One million men fell, and the lines remained roughly where they had been at the beginning of 1916 (Keegan 1976).

Stalemate was also the rule at sea, where the British fleet kept the German fleet penned up to the east of Denmark. One attempt to shift the war to the west at Jutland resulted in mixed fortunes for both navies. But the ultimate result was that the German high seas fleet was kept away from Britain.

2.4 1917

In 1917, the balance of power remained unchanged on the Western front. But in the east and in Italy, Germany and Austria were in the ascendant. First came the crisis in Russia. After the February revolution which toppled the Czar and put a provisional government in power, a provisional government vowed to carry on the war. This was its worst mistake, made evident by a catastrophic offensive launched on 1 July 1917. When the Russian offensive failed, a counter-offensive produced a massive Russian retreat which effectively destroyed the Russian army as a fighting force. When the Bolsheviks came to power in October, they saw what had to be done. They sued for peace, and signed an armistice on 3 December 1917. Germany and her allies had won the war on the Eastern front.

In Italy, the Allied cause suffered a series of alarming reverses. At Caporetto, the Italian army collapsed, and fled westward 100 km where a new defensive line was hastily formed. In France, a spring attempt to pierce German lines at the Chemin des Dames failed, and when the French commander Nivelle persisted in trying to do the 'un-doable,' his army mutinied (Smith 1994). Nivelle was replaced by Pétain; the offensive was called off; the anger of frontline troops abated. British attempts to shift the balance of power in Flanders were also unsuccessful, in part through the unhappy coincidence of their attack at Ypres occurring in the wettest summer on record. The British offensive, which ended in the rubble of the village of Passchendaele on 10 November 1917, literally drowned in mud (Prior and Wilson 1996).

The German navy attempted to shift the balance of power by launching unrestricted submarine warfare in February 1917. This was a colossal miscalculation. It did not starve the UK into negotiating an armistice. Despite massive losses to British shipping, domestic food supplies remained adequate (Offer 1991). What was worse from the German point of view, was the provocation posed by naval attacks to the USA, which entered the war in April 1917.

2.5 1918

In January 1918, it would have been difficult for a neutral observer to predict Allied victory by the end of

that year. How did it happen? First, the political and economic balance of power shifted with US entry into the war in 1917. Given the time needed to raise and then move an army of two million men across the Atlantic, it was apparent that US troops and US supplies would directly enter the balance of power only in 1918. This gave the Allies a new and deep reservoir of men and materiel which the Central Powers could not match. Thus, it was not US firepower that turned the tide, but US reserves.

This became apparent after German army launched its last major military gamble of the war. On 21 March, 47 divisions of the German army broke through at the point where British and French forces met on the Western front. Finally, the Western front moved. Within a week, German forces had moved 40 miles (65 km) to the west. In April they attacked at Ypres; in May and June to the south, reaching the Marne. But there the offensive broke down. The gamble had failed. The German army had lost one million men in a last, desperate and futile effort to win the war (Keegan 1999).

When German forces saw that they could not win, the balance of power shifted radically towards the Allies. Starting in early August, German troops began to surrender en masse. High Command was getting reports of low morale among troops, who were convinced that further sacrifices were in vain. At this point, unrest on the home front merged with despair over the military situation. The High Command saw that the game was up (Deist 1991). At the same time, Austrian and Bulgarian positions crumbled. Ludendorff urged the Kaiser to turn to the US President, Woodrow Wilson, to broker an Armistice. Ludendorff resigned. The Kaiser fled to the Netherlands, leaving it to others to face a disaster he and his military had engineered. The Armistice came on 11 November 1918. The Great War was over.

3. Consequences

3.1 Demographic

Total casualties and losses as a proportion of those who served passed a threshold beyond previous experience. Wherever the threshold is, the total of roughly nine million dead soldiers (according to varying estimates) is beyond it: this constitutes roughly one in eight of the men who served. Adding statistics on other casualties, it is apparent that roughly 50 percent of the men who served were either prisoners of war, wounded or killed.

The most murderous theatre of operations was the Eastern front, where disease and enemy action described the course of a nineteenth century war waged with twentieth century weapons. Of all Serbs who served in the war, 37 percent were killed; roughly one in four Rumanians, Turks and Bulgarians also perished. On the Western Front, where the war was won and

lost, combat was about half as lethal: German and French losses were about one in six of those who served; British losses were one in eight.

Initially casualties among social elites were higher than among the rest of the population. The longer the war lasted, the greater was the democratization of loss. The reason is that officer casualties were higher than those in the ranks, and the social selection of the officer corps mirrored inequalities in prewar life. Consequently in its initial phases, the higher up in the social scale a man was, the greater were his chances of becoming a casualty of war. By 1917, elites were sufficiently decimated to require the armies to draw junior officers from wider social groups which in their turn suffered disproportionately higher casualties in the last two years of the war.

Among the poor and the underprivileged, the story is different. Prewar deprivation saved the lives of millions of working class men and poor peasants, whose stunted stature and diseases made it impossible for them to pass even the rudimentary standards of medical fitness for military service during the war. In the British case, roughly 35 percent of the men

examined for military service were either unfit for combat or unfit to wear a uniform at all (Winter 1985).

Numerically, workers and peasants formed the vast majority of the army of the dead. The same was true of disabled men, visible reminders of the war on street corners and in farming villages throughout the world.

More lethal than combat was a visitation of epidemic influenza, colloquially known as 'the Spanish flu.' In 1918 and 1919 this mutant virus killed young, healthy adults throughout the world. The war may have helped spread the disease, though it did not cause it.

3.2 Political

The Treaty of Paris, the peace settlement ending the Great War, was signed on 28 June 1919, five years to the day after the assassination of Franz Ferdinand in Sarajevo. Its major effects were to ratify the break-up of the Austro-Hungarian and Turkish empires, and to establish a new state system in Europe, wherein Germany was stripped of Alsace and Lorraine in the west and much of East Prussia in the east. Primary

Table 1

Some estimates of military losses among combatant countries in the 1914–18 war

	Total killed or died	Total mobilized	Prewar male population (aged 15–49)	Total prewar population	Total killed

responsibility for the war, and for making material reparations for it, were laid at the feet of the new German Republic.

Through a League of Nations, international conflict would be regulated, if not resolved. An International Labour Organization was established to help address problems of working class life, a clear response to the Bolshevik revolution. The new Soviet Union was not a party to the peace negotiations or to the settlement. Instead a kind of quarantine was applied to the Soviet Union, and tacit support was given by the victorious powers to modest military intervention in Russia on the side of the anti-Bolshevik forces. This intervention was a total failure.

While the principle of self-determination for all was established, colonial and imperial issues were resolved through bilateral talks among imperial powers. Thus spheres of influence in the Middle East were divided between France and the UK, and contradictory promises were given to Arabs and Jews as to the future postcolonial disposition of the area.

In short, the Great War set the terms of the international order for the rest of the twentieth century (Boemeke et al. 1998). Domestically, the political consequences of war were mixed. Socialist and labor parties had participated in government. Right wing nationalist groups also grew. Among them were fascist parties, whose elevation of the virtues of armed struggle was mixed with a hatred of the political left. The center of politics weakened, evidenced by the waning of support for Liberal parties. The polarized left-right divide took on violent form in Italy, Germany, and throughout Eastern Europe, mixing ideological and territorial conflicts in such a way as to ensure the outbreak of a new and more lethal world war in just 20 years.

The war opened a phase of domestic strife in which the upheaval of war was mixed with revolutionary struggles. Civil war in Russia lasted for three years after the Armistice; armed conflict continued in the new states of Poland and Hungary. The victorious Allies quarantined the new Soviet Union, and began a phase of cold warfare which lasted for 70 years. For this reason alone, some historians see the war as inaugurating the 'short twentieth century,' from 1914-91 (Hobsbawm 1995).

3.3 Economic and Social

The Great War was both the apogee and the beginning of the end of European domination of the world economy. The big loser was the UK, whose export economy suffered from import substitution in countries throughout the world who developed finished goods during the conflict, when British exports were unavailable. Chronic financial instability weakened London as a banking center. The era of free trade was over (Milward 1984).

The losers paid for the war in a host of ways.

Reparations were forced on Germany, though she managed to avoid paying most of the bill. Worse was the continuation and acceleration of wartime inflation into the postwar years, wiping out savings and deepening domestic social and political conflict in Germany and Austria (Feldman 1993). This drastic reduction in the value of money had serious effects on the social structure and political outlook of middle class groups, threatened by proletarianization (Kocka 1984).

Domestically, economies of scale were introduced during the war which proved important after it. Hence military conflict helped accelerate the movement away from the small, family firm towards corporate economic life. State interest in and intervention in scientific research and education also expanded during and after war, in the light of evident strategic considerations (Hardach 1987).

After the war, the state continued to play a greater role in economic life than ever before. This was not through the ownership of industry, but through the management of debt. In most industrialized countries, taxation levels doubled over the war decade, and much of it was spent servicing war debt. The USA was the exception here, turning because of the war from a debtor to a creditor nation, though the chronic weakness of countries indebted to it after the war, like the UK, helped turn the Wall Street crash of 1929 into the world depression.

3.4 Cultural

Every combatant country mourned its war dead in public. The outcome is a vast array of war cemeteries near the fields of battle and of war memorials dotted in villages and towns throughout Europe, North America, Africa, Asia and the Antipodes. Annual commemorative ceremonies were (and still are) held on 11 November (Winter 1995) (Table 1).

The monumental character of the war has indelibly marked the literature, poetry, and visual arts of the twentieth century (Cork 1994, Fussell 1977, Hynes 1991). The Great War is the point of reference for much subsequent writing about catastrophe, and has introduced terminology—like shell shock—which has entered colloquial language. In many countries, though not in the former Soviet Union or the USA, its shadow is longer than that of the Second World War.

J. Winter

Fisher, Irving (1867–1947)

Irving Fisher is widely recognized as one of the greatest American scientific economists. He has been credited

with being a primary architect of the ‘pillars and arches’ of modern economics—to borrow a phrase from J. A. Schumpeter—through his contributions to the theory of capital and interest, to monetary theory, and to the construction of index numbers. He was also an activist in the promotion of economic and social reforms. His reputation suffered in the 1930s when his approach to the discipline was eclipsed by Keynesianism. His accomplishments were then neglected and had to be rediscovered.

1. Beginnings

Irving Fisher was born on February 27, 1867 in Saugerties, New York and was the elder son of a Congregational clergyman. His was a home grown talent, nurtured in a single American institution: Yale University. Thus, unlike most American economists reaching professional maturity in the last decades of the nineteenth century, he had no direct exposure to the teachings of the German historical school. His intellectual development was shaped by two forceful members of Yale's faculty: Willard Gibbs, a mathematical physicist, and William Graham Sumner, a political economist who was also a champion of Social Darwinism. Their joint influence was observable in his choice of topic for a Ph.D. dissertation—*Mathematical Investigations in the Theory of Value and Prices*. With the publication of this exercise in general equilibrium theorizing in 1892, Fisher was hailed as a path breaker in mathematical economics. Fisher joined the Yale faculty in 1892 as an instructor in mathematics. In the following year, he married Margaret Hazard, a daughter of a wealthy Rhode Island textile manufacturer; their union was to produce two daughters and a son. In 1895, his appointment at Yale was shifted to the Department of Political Economy, an affiliation he retained until retirement in 1935. In 1898, he was promoted to full professor, but was soon diagnosed thereafter with a potentially fatal case of tuberculosis that idled him for the next three years. Upon recovery, he decided that the life of an ivory-tower academician was no longer sufficient to satisfy him. Indeed he was convinced that scientific professionals had an obligation to engage with the world by promoting economic and social uplift.

2. Contributions to the Theory of Capital, Income, and Interest

Fisher had undertaken preliminary inquiries into the nature of capital before the interruption occasioned by illness. He returned to this theme in 1904 when his energies approached full restoration. Results emerged quickly in two major treatises.

In *The Nature of Capital and Income* (1906), Fisher set out a rigorous formulation of key concepts that had formerly been clouded by confusion. Capital (including human capital) was identified as the stock of assets that yield services, whereas income referred to the flow of services that generated satisfactions. He further demonstrated that the value of capital was determined by discounting the future income stream. This finding marked a distinct analytic advance. Though now generally accepted, Fisher's insistence that asset values were oriented toward the future, rather than to historical cost, was controversial when first presented. One feature of the book's argument has continued to be controversial, i.e., his claim that the correct concept of income should identify it with consumption spending and should exclude saving. *The Rate of Interest* (1907) was a logical sequel to *The Nature of Capital and Income*.

The earlier book had established the pivotal role of the interest rate in capitalizing the value of an anticipated income stream. It thus remained to demonstrate how the rate of interest was itself determined. When Fisher first addressed this issue, debate was polarized between two rival positions: one explanation of interest focused on increments in output arising from the use of capital (the technological school); a second emphasized the necessity to reward savers for deferring consumption (the psychological school). Fisher's initial analysis was centered on 'impatience'—or an unwillingness to forgo today's consumption without the prospect of greater consumption possibilities tomorrow—as the principal explanatory factor. When he returned to this topic in *The Theory of Interest* (1930), he argued that the technological and the psychological arguments were complementary, that is, that the interest rate was determined by the interaction between 'impatience to spend income and the opportunity to invest it.' The real interest rate was thus unambiguously a real phenomenon, not a monetary one. This line of analysis would stand in sharp contrast to the monetary theory of interest that Keynes was to offer in his *General Theory of Employment, Interest and Money* (1936). For Fisher, money still mattered because of its impact on the price level. It could thus affect the nominal interest rate, which Fisher treated as the real interest rate plus the inflation rate.

3. Early Work in Monetary Theory

The Purchasing Power of Money (1911) was conceived as an exercise in establishing the validity and usefulness of the quantity theory of money, a doctrine that had been politically contaminated in the polemics over 'free silver' in the 1890s. In Fisher's formulation, 'the equation of exchange' was written as $MV + M'V' = PT$. (In this expression, M represented the quantity of cash and V the velocity of its circulation; M' stood

for total deposits subject to check and V' for the average velocity of their circulation; P was defined as an average price and T as the volume of trade.) This book was a vigorously monetarist document in which Fisher maintained that changes in the general price level were linked to proportionate changes in the money supply. This was true in the 'normal period,' defined as a state of equilibrium in which the values of T and the V 's were constant. His choice of terminology on this point bred misunderstandings: he recognized readily that economic reality was typified by 'transition periods'—when adjustments to disturbances were being worked out—in which the constancies did not hold.

Fisher was not content to offer solely an analytic explanation for variations in the purchasing power of money. Convinced as he was that monetary instability produced distributive injustices by distorting the relative positions of creditors and debtors, he felt obliged to suggest a corrective. His proposed remedy prescribed that changes in the general price level should be offset by variations in the gold content of the dollar (i.e., the 'compensated dollar' plan). But this policy recommendation did not mesh with the analysis presented in *The Purchasing Power of Money*. The 'compensated dollar' scheme rested essentially on a 'commodity theory of money' in which the real value of money was determined by the value of its gold equivalent. This conclusion did not follow from the 'equation of exchange' that Fisher had set out as the basis for his 'quantity theory of money.' Schumpeter (1948) and Patinkin (1993) have suggested that this oddity can be explained because Fisher, the reformer, got the better of Fisher, the scholar.

4. Analytic Innovations in the 1920s

Given Fisher's concern for stabilization of the general price level, his interest in perfecting the instrument for measuring its behavior—namely, the index number—was readily comprehensible. He addressed this in *The Making of Index Numbers* (1922), a work which has continued to be influential. Shortly thereafter, he created an Index Number Institute (INI) that provided weekly reports on leading economic indicators, along with commentary on current events. These analyses were distributed nationally via a syndicated news service. At its peak, Fisher's INI column had a potential to reach about seven million readers.

By the mid-1920s, Fisher's studies had convinced him that the stakes in price level instability were higher than he had earlier thought them to be. When writing *The Purchasing Power of Money*, he regarded distributive injustices as the major evil associated with unstable prices. His later analyses indicated that instability of the general price level was responsible for another major problem—fluctuation in the volume of

trade and, with it, variations in aggregate income and employment. This conclusion, he maintained, was supported by statistical evidence indicating that the rate of change in the general price level was highly correlated with variation in the volume of trade. This relationship, however, was not instantaneous.

His empirical investigations suggested a lag of approximately seven months between the turning point in the rate of change in prices and change in aggregate economic activity. In this research, Fisher introduced a novel statistical technique—the distributed lag—which has become a standard tool in econometrics. With its aid, his results appeared to show conclusively that a rising price level stimulated trade, while a falling price level depressed it. It thus followed that the way to eliminate macroeconomic fluctuations was to maintain a stable price level. In that spirit, the Fisher of the mid-1920s wrote that the ‘so-called business cycle’ was really ‘a dance of the dollar’ and that there was no reason why such disturbances should be tolerated.

5. *Crusading for Causes*

Fisher, the recovered TB patient, was an indefatigable champion of causes. This was evident in his tireless promotion of monetary reforms: in the first instance, in lobbying for a ‘compensated dollar’ that promised to stabilize the dollar’s purchasing power. In the 1920s, he lobbied vigorously for legislation that would compel the Federal Reserve to maintain price level stability. His views by then had changed on how this should be accomplished. In 1923, with the discovery of the potency of ‘open market operations’—a technique for altering commercial bank reserves through the purchase or sale of government securities by the Federal Reserve system—Fisher readily embraced this procedure as the major instrument for central bank control of the money supply. He was a frequent visitor to Washington as a star witness before Congressional committees with jurisdiction over monetary affairs. He also poured considerable energy into mobilizing public opinion behind reform proposals through the creation of organizations such as the Stable Money League.

Fisher’s reformist agenda was not restricted to matters directly linked to his expertise as an economist. He was an enthusiast for measures to improve the health and longevity of the population. On his initiative, a group of leading citizens was organized in 1907 to lobby—unsuccessfully as it turned out—for the creation of a Federal Department of Health that would establish national standards for public health practices and monitor their enforcement. He enjoyed greater success in the promotion of a Life Extension Institute to persuade life insurance companies that it would be profitable to require and pay for annual

physical examinations for policy holders. To reinforce its activities, he co-authored a first-of-its-kind manual of good health practices, entitled *How to Live*, that went through some 21 editions.

Fisher was one of the nation’s staunchest advocates of national prohibition of the consumption and sale of alcoholic beverages. Once the 18th amendment to the Constitution (1920) had been enacted for that purpose, he was a leading voice in arguing against its repeal. Even though enforcement of prohibition left much to be desired, he maintained that this legal ban had still contributed positively to American economic expansion in the ‘new era’ of the 1920s through its effect on improved worker efficiency and on reduced workplace absenteeism. This line of thinking was responsible, in part, for his disastrous misreading of economic conditions in the autumn of 1929 when he predicted that the American economy was on the threshold of permanent prosperity. In the 1920s, he was also an inveterate campaigner for an international organization to promote world peace and for membership of the US in the League of Nations. He was a prominent figure as well in the eugenics movement that he hoped would encourage state governments to enact legislation permitting sterilization of the mentally defective and the criminally insane.

Fisher contributed significantly from his own pocket to support these causes. His ability to do so was enhanced by the sale of one of his inventions—an Index Visible filing system—to Rand–Kardex (shortly to become Remington Rand) for a handsome block of stock and for a position on the board of directors. When informing his son about this turn of fortune, he wrote: ‘This added income will enable me to further the four chief causes which we have at heart, the abolition of war, disease, degeneracy, and instability of money (Fisher to Irving Norton Fisher, June 17, 1925).

6. *Coping with the Disaster of Depression in the 1930s*

Fisher was totally caught off-guard by the collapse of the stock market in the autumn of 1929 and by the events that followed. His personal financial circumstances were left in shambles: he managed to avert personal bankruptcy only by borrowing heavily from his wife’s unmarried sister. The Great Depression was also a professional embarrassment. It did stimulate him to rethink where his earlier line of analysis had failed him. The result—reported in *Booms and Depressions* (1932)—was the debt-deflation theory of Great Depressions. The problem, as he then saw it, stemmed from a situation of overindebtedness in the late 1920s. Once a break in the price level had occurred, the real burden of debt increased. This led to distress selling, to contraction in deposit currency, and to slackening in

the velocity of monetary circulation. Deflation—far from being self-correcting—simply bred more deflation. The remedy was implicit in the diagnosis: ‘reflation’ of the price level to its elevation at the time when most outstanding debts were contracted. When that point had been reached, the general price level should be stabilized.

To accomplish this, Fisher urged a number of proposals on the Roosevelt administration. For example, he endorsed ‘stamped scrip’—a scheme which called for a special currency issue that would lose 2 percent of its value each week unless a two-cent stamp were affixed to it. This device (which he had borrowed from Gesell) was intended to accelerate the velocity of monetary circulation. Though the idea was not original with him, he later put his full weight behind advocacy of a plan that would require commercial banks to hold ‘100 percent reserves’ against demand deposits, thereby eliminating their capacity to create (or destroy) check-book money by extending (or calling) loans. The money supply would instead be controlled by a public authority (e.g., a Currency Commission) that would expand the money supply as needed to achieve a prescribed ‘reflation’ target and thereafter to stabilize. Fisher’s conception of a ‘monetary rule’ was tied to outcomes, as opposed to the ‘rule’ recommended in Milton Friedman’s brand of monetarism that stipulates a fixed rate of growth in the money supply.

Fisher’s thinking about recovery from the Great Depression always had a monetary orientation. He was unsympathetic toward fiscal stimulants—such as Keynesian-style programs of public works—and he made no secret about that. He was also unsympathetic to the analytic message of Keynes’s *General Theory*. Even so, he and Keynes came close to convergence in their recommendations for tax policy in wartime: both championed a tax targeting consumption. The analytic props to their conclusions, however, had nothing in common. Fisher’s views—which he spelled out in his final book, *Constructive Income Taxation* (1942)—rested on the analysis he had worked out in 1906 in *The Nature of Capital and Income*. This argument maintained that income should properly be defined as expenditure on consumption: thus, a sound tax system, in all circumstances, should take aim at consumption spending. Keynes’s position, on the other hand, was informed by his conception of the management of the components of aggregate demand, as formulated in *The General Theory*.

Despite the fact that the Roosevelt administration took little heed of his unsolicited advice, Fisher still believed that something hopeful could be salvaged from the wreckage of depression in the form of lasting improvement in scientific investigation in economics. It had long been his aspiration to build an international organization to bring economists interested in linking economic theory with mathematics and statistics into closer collaboration. Circumstances of

the early 1930s permitted this dream to become a reality. The presence at Yale in 1930 of Ragnar Frisch of the University of Oslo made it easier for three who shared the dream—Fisher, Frisch, and C. F. Roos—to lay the groundwork for the Econometric Society. The obvious shortcomings of economic forecasting in the early depression years—and an apparent need for improvement—convinced a well-to-do businessman to underwrite this new organization.

7. A Word about the Legacy

Fisher was accorded numerous honors by professional colleagues: among them, election to the presidencies of the American Economic Association, the American Statistical Association, the Econometric Society, the American Association for Labor Legislation. But he lacked a committed cadre of disciples: there was no ‘Yale circus’ to match Keynes’s ‘Cambridge circus.’ In the last decade of his life, his approach was largely overshadowed by Keynesianism. To younger members of the profession, he appeared to be out-of-step with the times, with the consequence that his work tended to be ignored.

With the waning of the Keynesian ascendancy, Fisher’s achievements have been revisited. His pioneering analyses of capital and interest have now approached the status of an orthodoxy in the graduate training of prospective professionals. A ‘rediscovery’ in the 1970s documented that an article he wrote in 1926—entitled *A Statistical Relation between Unemployment and Price Changes*—anticipated the essential insight of the Phillips Curve by more than three decades. It is interesting to speculate on how the principals in an intense controversy that divided the profession in the 1960s and 1970s would have behaved had they known that Fisher had identified the ‘reswitching problem’ in 1907.

In the 1990s, some of Fisher’s practical proposals have enjoyed a renewed lease on life. In 1997, the US Treasury issued a ‘stabilized bond,’ the return on which would be adjusted to maintain constancy in its purchasing power. Fisher had advocated the creation of this type of financial instrument some seven decades earlier. In 1995, the US Department of Commerce resurrected another Fisher conception, dating from 1922, when adopting his formula for an ‘ideal index number’ to calculate the GNP deflator.

Fisher died on April 29, 1947 in New York City.

W. J. Barber

Fisher, Ronald A (1890–1962)

Sir Ronald Fisher, the father of modern statistics, was for most of his working life a professor of genetics, first in London and then at Cambridge. He made lasting contributions to mathematical and evolutionary genetics as well as to statistical theory. In statistics his contributions stand alongside those of his great predecessors Gauss and Laplace, while in evolutionary theory he is acknowledged as the greatest of Darwin's successors.

Fisher was born in London on February 17, 1890, the son of George Fisher, a fine-art auctioneer, and his wife Katie. His twin brother was stillborn. At Harrow School, which he entered in 1904 as a scholar, he distinguished himself in mathematics despite being handicapped by poor eyesight which prevented him working by artificial light. His teachers used to instruct him by ear, and Fisher developed a remarkable capacity for pursuing complex mathematical arguments in his head. This manifested itself later in life in an ability to reach a conclusion whilst forgetting the argument, to handle complex geometrical trains of thought, and to develop and report essentially mathematical arguments in English (only for students to have to reconstruct the mathematics later). Fisher's early interest in natural history was reflected in the books chosen for special school prizes at Harrow, culminating in his last year in the choice of the complete works of Charles Darwin in 13 volumes. Fisher entered Gonville and Caius College, Cambridge, as a scholar in 1909, graduating BA in mathematics in 1912. At college he instigated the formation of a Cambridge University Eugenics Society through which he met Major Leonard Darwin, Charles's fourth son and president of the Eugenics Education Society of London, who was to become his mentor and friend. He spent a postgraduate year in the Cavendish Laboratory, Cambridge, studying the theory of errors under F. J. M. Stratton and statistical mechanics and quantum theory under J. H. Jeans (later Sir James Jeans).

Prevented from entering war service in 1914 by his poor eyesight, Fisher taught physics and mathematics in schools for the duration of the war and in 1919 was appointed Statistician to Rothamsted Experimental

Station, an agricultural station at Harpenden north of London. In 1933 he was elected to succeed Karl Pearson as Galton Professor of Eugenics (i.e., of Human Genetics, as it later became) at University College, London, and in 1943 he was elected Arthur Balfour Professor of Genetics at Cambridge and a Fellow of Gonville and Caius College, succeeding R. C. Punnett. After he retired in 1957, Fisher traveled widely, spending his last few years in Adelaide, Australia, as an honorary research fellow of the C. S. I. R. O. Division of Mathematical Statistics. He died there of a postoperative embolism on July 29, 1962. His ashes lie under a plaque in a side aisle of Adelaide Cathedral.

Fisher married Ruth Eileen Guinness in 1917 and they had two sons and six daughters, and a baby girl who died young. He was elected a Fellow of the Royal Society of London in 1929 (as a mathematician) and was created Knight Bachelor by Queen Elizabeth II in 1952 for services to science. He was the founding President of the Biometric Society (now the International Biometric Society) in 1947, and served as President of the Royal Statistical Society (of the UK), of the International Statistical Institute, of the Genetical Society of Great Britain, and of his Cambridge college, Gonville and Caius. He received many honorary degrees and accepted the honorary membership of many academies at home and abroad, and was awarded all the principal medals of the Royal Society, the Royal (1938), Darwin (1948), and Copley (1956).

Fisher's first publication, whilst still an undergraduate, proposed the method of maximum likelihood for statistical estimation (though not in those words) and before graduating he had already given a paper remarking on the surprisingly good fit of Mendel's data. In 1916, without any academic appointment but encouraged by Leonard Darwin, he completed the founding paper of biometrical genetics 'The correlation between relatives on the supposition of Mendelian inheritance' (1918), eventually published in 1918 after it had been rejected for the *Philosophical Transactions of the Royal Society* on the advice of the referees, Karl Pearson and R. C. Punnett (both of whom he later succeeded, as he was fond of remarking). In this paper, Fisher introduced the word 'variance' and established the basis of the analysis of variance.

From his post of statistician at Rothamsted, Fisher made advances which revolutionized statistics, whilst his advances in genetics and evolution were hardly less pathbreaking. In a single publication in 1922 he proved that heterozygotic advantage gives rise to a stable gene-frequency equilibrium, introduced the first stochastic model into genetics (a branching process), and initiated the study of gene-frequency distributions by means of the diffusion approximation, and in another paper he applied the method of maximum likelihood for the first time, to the estimation of linkage.

Also in 1922, building on his method of maximum likelihood, Fisher published 'On the mathematical

foundations of theoretical statistics' in the *Philosophical Transactions* (1922a), a revolution in statistical thought. This time the Royal Society's referees, A. S. Eddington and G. U. Yule, were more complimentary. Amongst the new words and phrases Fisher introduced in the paper in order to clarify the basis of his approaches to statistical inference are likelihood, consistency, degrees of freedom, efficiency, sufficiency, information, significance level, test of significance, sampling distribution, percentage point, statistic, and others of a more technical nature still. Information in Fisher's statistical sense (1925) antedated Shannon's (1948) use of the word for a somewhat different purpose: Fisher information measures the content of a message, whereas Shannon's measures the ability of a channel to transmit a message, independently of its meaning. In 1930, Fisher published the first satisfactory account of what J. Jerzy Neyman was later to call the 'confidence' property of interval estimation.

In distribution theory Fisher built on his 1915 paper deriving the exact distribution of the correlation coefficient (for whose solution he introduced the concept of a sample-space) and used his considerable mathematical ability to solve many further distributional problems, including that of the multiple correlation coefficient and the variance ratio (which G. W. Snedecor of Iowa State University, where Fisher was visiting professor in 1931 and 1936, called 'F' in his honor). His work at Rothamsted on agricultural statistics soon led to the creation of the science of experimental design with the appreciation of the fundamental role of randomization, the development of the principles of blocking and confounding, and the introduction of Latin squares and factorial analysis and similar designs chosen for their statistical efficiency. The methods which Fisher invented or improved were brought together in 1925 in his book *Statistical Methods for Research Workers* (1925b), which he updated continually over the next 23 years until the thirteenth edition was published in 1958 (a posthumous fourteenth edition was prepared from notes written before his death).

In addition to the statistical work associated with his employment at Rothamsted, Fisher pursued his interest in evolutionary theory, guided and encouraged by Leonard Darwin. Putting his deep knowledge of Mendelian theory and Charles Darwin's writings to good use he built on the success of his earlier investigations of 1918 and 1922 to write *The Genetical Theory of Natural Selection* (1930), published in 1930. This book is now seen as the chief document of the 'Neo-Darwinian revolution,' that revival of Darwinism in the 1930s and 1940s from the neglect it had suffered in the early years of the century following the rediscovery of Mendel's paper in 1900. The book contains a wealth of new evolutionary arguments, from the fundamental theorem of natural selection to ideas about sexual selection, inclusive fitness and parental expenditure. More than any other work *The*

Genetical Theory established a firm basis for the modern view that evolution by natural selection is primarily a within-species phenomenon.

Taking up his appointment as Galton Professor of Eugenics at University College London in 1933, Fisher's pace did not slacken. Now able to pursue experimental work, which previously he had only undertaken in a private capacity, he demonstrated his ability as a natural historian. Experimental organisms included mice, poultry, and the purple loosestrife, and even dogs (under the auspices of the Genetical Society). In a long collaboration with E. B. Ford of Oxford he studied natural populations for the purpose of estimating the power of natural selection, thus contributing to the foundation of a school of ecological genetics. But it is in human genetics that he made his most lasting contribution of this period. In 1935 he secured funds from the Rockefeller Foundation to establish a Blood-Group Serum Unit at the Galton Laboratory with the express purpose of initiating the construction of a linkage map of man, for he had already seen the connection between 'Linkage studies and the prognosis of hereditary ailments' (to use the title of his lecture to the International Congress on Life Assurance Medicine in that year). Here is to be found the intellectual origin of the Human Genome Project. At the same time Fisher, with J. B. S. Haldane and L. S. Penrose, was advancing the special statistical theory required in the estimation of human linkage.

Fisher (1935) also saw the publication of *The Design of Experiments* in which his pioneering work in that subject at Rothamsted was expounded fully for the benefit of workers in agriculture and many other fields. Like *Statistical Methods for Research Workers*, the book was an outstanding success, running to seven editions by 1960 (an eighth was later prepared from notes left by Fisher). It opened with a famous description, often quoted, of an experimental design for the problem of testing the assertion of a lady who maintained that she could tell by tasting a cup of tea whether the milk or the tea had been the first to be poured into the cup. In the course of this discussion Fisher coined the phrase 'null hypothesis' for the hypothesis under test.

In 1936, Fisher subjected Mendel's published data on segregation in the garden pea to close statistical scrutiny, concluding that in some respects the data seemed to follow too closely the expectations on Mendel's genetic hypothesis, a discovery that worried him greatly, and left him speculating that perhaps Mendel's assistant, knowing full well what his master hoped to find, was tempted to adjust some of the counts accordingly.

In 1943, Fisher moved to Cambridge as Arthur Balfour Professor of Genetics, where he was reunited with his colleagues from the Blood-Group Unit which had been evacuated there during the war. An immediate consequence was his brilliant solution of the Rhesus blood-group puzzle, involving three closely

linked loci which between them explained the array of serological reactions which to everyone else had appeared chaotic: Fisher did for Rhesus what Mendel did for round and wrinkled.

After the second world war ended in 1945 Fisher attempted to establish bacterial genetics in his Cambridge department and to retain for Cambridge the Blood-Group Unit, but without success. Work in his small department revolved around linkage in the mouse and studies on purple loosestrife, wood sorrel, and primroses, always with a strong background of mathematics and statistics. His *Theory of Inbreeding* (1949) was published in 1949, and in 1950 he published the first paper applying a computer to a biological problem.

In the subject of statistics, developments in the USA during and after the war had tended to obscure the great advances which Fisher had made in the subject, and he found himself having to defend many of his views against critics brought up in the more mathematical and operational climate then dominant. His repeated insistence that statistical inference was a mode of reasoning separate from, though related to, approaches based on decision theory and other behavioral considerations won him few friends, and his continued (if somewhat puzzled) defense of his troublesome 1930 concept of fiducial probability was cited as evidence that his judgment was fallible. He defended his position in a fourth book, *Statistical Methods and Scientific Inference* (1956), published in 1956 with a second edition in 1959 and a posthumous edition with many additions and clarifications. In this work he particularly emphasized the direct role of likelihood in statistical inference, in addition to the method of maximum likelihood, and continued his life-long criticism of the improper use, as he saw it, of prior probabilities and Bayes's theorem in statistical inference, a methodology previously called 'inverse probability' for which he had himself coined the word 'Bayesian' in 1950.

As well as writing his books, Fisher collaborated with Frank Yates, also of Rothamsted, to produce the most widely-used compilation of statistical tables (before computers rendered such volumes redundant). First published in 1938, *Statistical Tables for Biological, Agricultural and Medical Research* (1938) went through many editions.

In retirement Fisher continued his academic work, but also became embroiled in a controversy as to the extent to which the published data supported the hypothesis, then novel, that cigarette-smoking was a cause of lung cancer. Perhaps not fully appreciating the strong feelings which the issue was to generate, he focused on the finer points of the statistical analysis which interested him, on the need always to disentangle causation and correlation, and on the fact that the evidence did not seem to him to disallow the possibility that genetical variability might be a contributory factor in the observed association.

Fisher's papers number nearly 300, and he also wrote many reviews, particularly in *The Eugenics Review* between 1915 and 1935, and letters to journals. He was an accomplished formal lecturer as may be seen from his many presidential and similar addresses, and an occasional broadcaster on scientific topics. His interests were wide, as may be instanced from two examples from his publications: in 1934 he discovered and published the idea of a randomized or 'mixed' strategy independently of von Neumann, and in 1958 he published the first suggestion that the theory of games might be applied profitably to problems in evolutionary biology, the possibility having been drawn to his attention by Dr. Cavalli (later Professor L. L. Cavalli-Sforza).

Small of stature, with thick glasses and a beard, Fisher did not suffer fools gladly. He was a skilled controversialist in conversation, but his quick temper sometimes rendered further discussion impossible. His contemporaries divided rather cleanly into those who regarded him with awe and affection and gratitude for the generosity with which he offered his ideas to them, and those who found him tetchy, difficult, and remote. Especially as a professor at Cambridge, he showed great interest in the few students who passed through his small department, and he always enjoyed the company of young people. Of the many thumb-nail sketches which his greatness has inspired, perhaps the following comment on Fisher by the Cambridge cosmologist Sir Fred Hoyle contains the closest likeness in the smallest span: 'I am genuinely sorry for scientists of the younger generation who never knew Fisher personally. So long as you avoided a handful of subjects like inverse probability that would turn Fisher in the briefest possible moment from extreme urbanity into a boiling cauldron of wrath, you got by with little worse than a thick head from the port which he, like the Cambridge mathematician J. E. Littlewood, loved to drink in the evening. And on the credit side you gained a cherished memory of English spoken in a Shakespearean style and delivered in the manner of a Spanish grandee' (Hoyle 1999).

Fisher was one of the great intellects of the twentieth century. His contributions to evolutionary theory and mathematical genetics ensure him a place in the Darwinian pantheon whilst he is the undisputed father of modern statistical theory.

The statistical methodology he developed has had a far-reaching impact in every field of science and social science. Whether one considers the mathematical theory of distributions, the design and analysis of experiments, the theory of estimation, the theory of significance testing, or the logic of statistical inference, Fisher's is the primary influence. As a teacher of research workers through his statistical books he had no peer.

In genetics he was the principal architect of the application of statistics, much of his theory having been inspired by practical problems, especially in

human genetics. With J. B. S. Haldane and others he initiated the study of linkage in man specifically for the purpose of throwing light on hereditary disease risks, thus foreshadowing the human genome project, and he encouraged the study of associations between blood groups and disease. His studies on natural and artificial populations of both plants and animals would alone have given him an honored place in the development of genetics in the twentieth century. His '1918 paper' is accepted as the starting point for the entire development of biometrical genetics, with its ramifications in plant and animal breeding.

In evolutionary biology, his book *The Genetical Theory of Natural Selection* (1930) hides a brilliant series of evolutionary insights behind a density of writing that requires more concentration than most readers have been prepared to give it, but is now acclaimed as the cornerstone of the neo-Darwinian revival of the mid-twentieth century.

Fishing Societies

The theme of this article is the place of fishing activities and coastal economies in social scientific thought and some of the major issues developed in the relevant literature; the category of fishing, natural and social models of fishing activities and coastal communities, gender relations, ecological knowledge, and resource management.

1. The Category of 'Fishing'

According to some of the evolutionary theories of the nineteenth century, fishing represented a separate and early stage in the history of humans. Such an idea was underlined in many contemporary accounts of particular groups of people largely dependent on fish. The evidence on the role of early fishing, however, is fairly limited. Some scholars suggest that, from the point of view of early humans, aquatic environments must have been both hostile and an inadequate source of food. Others suggest that coastal zones must have been quite attractive, providing a worthwhile challenge, and that people may have exploited them for a long time without leaving modern groundlings any evidence. While the archaeological evidence does not indicate that fishing predated the hunting of terrestrial animals, nonetheless among hunter-gatherers fishing may have played quite an important role. The abundance of resources in coastal zones may, indeed, have provided an opportunity for the development of complex civilizations. There is evidence for a transformation of hunter-gatherer social relations in coastal regimes although many of the important issues involved are far from settled (see *Hunting and Gathering Societies in Anthropology*). Rather than seeing aquatic resources themselves as determinants of complexity, however, one should regard coastal niches as just one possible avenue for intensification (Kelly 1992). With the advent of fieldwork and participant observation, evolutionary speculations tended to be replaced by descriptive accounts. The category of 'fishing' became much less visible than before—sometimes being subsumed under the label 'hunting and gathering.'

While the category of fishing may seem straightforward, it need not be taken for granted. The distinctiveness of fishing activities, it has been argued (Hewes 1948), has two aspects. First, objects behave in a particular manner while in an aquatic substance, due to special conditions of buoyancy, turbulence, solubility, and refraction of light. Second, fishers and their prey occupy different media. An emphasis on differ-

ences in habitat yields a definition of fishing as 'that category of human activity which is connected with the capture or gathering, of animals (or plants) which regularly dwell in the water' (Hewes 1948). The concept of fishing as a particular kind of hunting which happens to yield fish is one element of a common anthropological scheme for classifying types of subsistence: gathering, collecting, hunting (including trapping), husbandry (including fish farming), and plant cultivation. Much like medieval Europeans often distinguished between fishing, fowling, and hunting, modern anthropology tends to operate with three concepts of foraging—fishing, gathering, and hunting. For some scholars, fishing is a broad category that includes shell fishing and the pursuit of large aquatic animals. Others have argued to the contrary that the pursuit of large aquatic animals more properly is classified as hunting and that shell fishing should be classified as gathering.

While some linguistic evidence suggests that fishing and hunting are perceived as similar strategies, differing only with respect to the focus of subsistence efforts, indigenous terminologies do not distinguish necessarily between hunting and other subsistence activities, including trapping, collecting, and gathering. Also, the classification of aquatic organisms, including 'fish,' varies from one society to another. Although in many societies, fish are classified according to an elaborate taxonomy, depending on their shape and usefulness to humans, the category of 'fish' represents one of the largest and most diverse categories found in most environments; at times fish terms are extended to all creatures inhabiting aquatic environments, including turtles, frogs, crocodiles, crustacea, and fish-shaped mammals. In some languages, there is no term for fish; fish are included in a heterogeneous category along with snakes, worms, lizards, and other elongated creatures.

2. Natural and Social Models

Many approaches to fisheries, both of the present and the past, suggest a 'natural' model of fishing, emphasizing material context and ecological relations. Social scientists have often drawn attention to the fact that fishing takes place in a relatively uncertain environment (see Pálsson 1991). People who adapt to earning a living by exploiting marine resources, it is argued, often seem to manage their lives in similar ways. Thus, crew organization tends to be flexible and based more on voluntary ties than kinship obligations, to ensure cooperation and the right combination of skills, to reduce uncertainty, and spread the risks of production. Fishing societies, as a result, seem to have a range of characteristics in common due to the fact that their members have to adapt to corresponding environments and cope with identical problems. Such approaches are reminiscent of the method of cultural

ecology, according to which social life is rather mechanistically adapted to the material world.

In line with the assumptions of the natural model of fishing, there has been a strong tendency to look for parallels between trawling ('industrial hunting') and small-scale fishing on the basis of a common link to water. While focusing on the boundary between land and water is helpful for drawing contrasts between economic and social systems which are organized in similar ways—between, say, aquatic and terrestrial industrial systems—much recent research has emphasized that a unitary category of fishing diverts attention from important issues, in particular the social relations in which production is necessarily to be found. Although there are real empirical differences between fishing and other modes of subsistence, the use of such differences gives misplaced importance to ecology.

One way to understand similarities and differences among fishing systems, to emphasize the social context of production, is to distinguish between societies in terms of mode of circulation—the motivation of the producers and the destination of the products (see *Mode of Production*). Production may be primarily for exchange or primarily for use. Many fisheries conflicts derive from the different rationales of production of the household economy of local small-scale fishing and the market economy of industrial fleets (McGoodwin 1990). Another way to distinguish fishing systems is to underline different forms of managing access to fish. While knowledge of ecology and fishing techniques is important for the understanding of different forms of managing access, one should not ignore the social space in which they occur. The informal exclusion of outsiders by means of secrecy and formal ownership of local territories should not be regarded as functionally equivalent devices. Differences among fishing economies in terms of modes of circulation of products and access to resources insufficiently represent the variety of production systems there is. On the other hand, they help to illustrate the fundamental point that fisheries are embedded in social life. Any study of what happens on board fishing vessels must consider variations in fishing systems and the larger contexts of fisheries and fishing communities.

3. Gender Roles and Identities

In removing 'fishing' from the context of social relations, social scientists have often failed to recognize the importance of the relations of men and women and the significant economic role of women in fishing economies. The issue of gender tends to be suppressed or distorted. Nevertheless, in recent years an extensive literature on the role of gender in fishing and coastal communities has been developed (see, for instance, Nadel-Klein and Davis 1988). In fishing communities, it has sometimes been suggested, one can expect a

sharp division of labor along gender lines in that men do the fishing while women are responsible for the processing of the catch. A rigid sexual division of labor should not, however, be regarded as inevitable. In many cases women's participation in extraction is no less important than that of men. The ethnography of fishing is biased with respect to gender. This observer's bias is partly a reflection of the popular Western image of fishing as a particularly 'manly' activity. Thus, the pursuit of small aquatic animals has sometimes been regarded as mere 'gathering' or 'collecting' if performed by women, but as 'fishing' if performed by men.

Many indigenous accounts of fishing economies are no less gender-specific than observers' accounts, treating women's labor as not only different but also somehow secondary to that of men. While the devaluation of women's work is not restricted to market economies, the change from a subsistence economy to markets often has important implications for the social construction of gender. The 'domestic' labor of women tends to be presented as private labor, on the grounds that it takes place internal to the household and that its consumption products are 'perishable' use values, requiring immediate use. Conversely, only the non-domestic work of men is regarded as socialized since it alone involves cooperation between households, the production of exchange values and durable commodities. Domestic laborers are presented as natural beings outside the social life of the market economy. And women only become social or visible insiders to the extent that they engage in nondomestic production, outside the sphere of reproduction. Women, then, tend to be presented as unproductive (see Cole 1991). But just as extraction is a social activity whether or not it takes place in a group or by isolated individuals, labor is necessarily a social activity whether or not it takes place in a domestic or non-domestic context. The household is not a private place devoid of social content but a social institution constituted by a particular set of relations—the social relations of domestic production involved in the creation of use values, particularly cooking and child care (see *Gender and Feminist Studies in Anthropology*).

4. Ecological Knowledge

Since fish are relatively incapable of coping with human predators, their chances of using evasive tactics are small. The difference in medium, however, has contradictory implications and some observers have emphasized the disadvantages to fishers, pointing out that if humans are invisible to the fish so are fish to humans. Accordingly, it is argued, knowledge of marine organisms is likely to be relatively restricted. Nevertheless, as several ethnographic accounts have shown, in fishing communities people accumulate a

vast amount of knowledge of fish and aquatic habitat. The social distribution and nature of ecological knowledge and its importance for resource management, on the other hand, are matters of some debate.

In fisheries generally, catches vary from one boat to another. Accounts of and interest in such differences vary from one context to another, depending on the nature of the social system involved and the nature of the fishery. Some explanations emphasize differences in luck, others underline personal differences in fishing skill. Some anthropologists have attempted to statistically measure the personal contribution of the leaders of fishing operations, the 'skipper effect' (see Pálsson and Durrenberger 1990). It is difficult, however, to separate the factors involved and recent studies of fishing success have drawn attention to the continuity of the social world to which the skipper belongs, focusing on the importance of the crew for decision-making and, by extension, relative fishing success. In a very real sense, the practical skills of fishing skippers are the result of mutual enskillment, the collective property of a community of practice (Pálsson 1994). Not only has there been a growing theoretical interest in the practical learning of fishers and the general divide between indigenous and scientific knowledge, but fisheries science itself is increasingly seen as an embedded enterprise (Smith 1996). Some scholars argue that learning, whether in science or every-day life, primarily takes place with the internalization of a cognitive scheme (see *Cognitive Anthropology*). Others have emphasized that learning involves the whole person interacting with the social and natural environment (Lave 1990; see *Apprenticeship: Anthropological Aspects*).

In many fishing societies there is little attempt to draw upon the knowledge that practitioners have achieved in the course of their work, for the purpose of marine ecological research. Analyses of human-environmental relations are the privileged task of people formally trained in public institutions. There are important signs of change, however. A greater reliance on practical knowledge, it is sometimes argued, is a practical necessity, given the randomness and complexity of many marine ecosystems. Multispecies marine ecosystems, in particular, are highly unpredictable, with constant fluctuations in interactions among species and between species and their habitat (Acheson and Wilson 1996). This does not mean that governance is impossible; it suggests, however, increasing reliance on a finer spatial and temporal scale of observation and engagement—a scale that only the skilful practitioner is able to apply. There are good grounds, therefore, for exploring how fishers acquire knowledge about the ecosystem within which they operate, how their knowledge differs from that of professional biologists, and to what extent the former could be brought more systematically into the process of management for the purpose of ensuring sustainability.

5. Resource Management

Many fisheries are currently in a state of crisis. Increasingly social scientists are addressing the problems involved, both internationally and in particular ethnographic contexts (McCay and Acheson 1987). Two main positions can be identified, the market approach which gained momentum in the early 1970s and the approach of co-management which has received increased attention since the 1980s. Comparative studies of the implications and consequences of different management regimes represent an important and growing forum for social research.

The market approach assumes that the current crisis in fishing is due to the open-access nature of fisheries; in the absence of both government control and the institution of private property, it is assumed, people will inevitably drive the ecosystem beyond its sustainable limits. The paradigm further suggests that only the 'hidden' forces of the market can ensure efficiency and sustainable use of resources. Finally, the issues of ethics and equity typically are presented as irrelevant theoretical distractions. In several fisheries in different parts of the world, fishing stocks are being turned into private property. First, the resource is appropriated by regional or national authorities and later on the total allowable catch (TAC) for a season is divided into quota holdings and allocated to producers, often the owners of boats. At a still later stage, the temporary privileges of quota holders are turned into a marketable commodity, individual transferable quotas (ITQs).

In some fisheries the crew's contribution and its relevance for quota allocation has been a pressing political issue. Since fishing quotas are often allocated with reference to 'fishing history,' fishers, boat owners, and managers debate on what exactly makes fishing history, focusing on the relative importance of the vessel itself and its technology (favoring the owners of capital) and the crew (favoring labor power, in particular that of the skipper). A related contested issue involves the practical and theoretical merits of effort quotas (number of fishing trips) vis-à-vis catch quotas (size of catch).

The other main approach to fisheries management, co-management (Jentoft 1989), emphasizes democratic decision making and the importance of practical knowledge. A number of anthropological studies have shown that in many fishing societies people have developed indigenous means of regulating access to fishing grounds. In some cases, local groups of users successfully control the reproduction of renewable resources without external intervention, effectively co-managing local resources. In some parts of the world, especially Asia and the Pacific, co-management has a long tradition (Ruddle and Johannes 1985). Recently, such examples have attracted much attention among both researchers and managers, informed by renewed interest in 'indigenous' or 'traditional' ecological

knowledge on the international scene (Dyer and McGoodwin 1994) as well as growing doubts about the modernist concept of 'resource management,' with its assumptions of human mastery, control, and predictability.

Traditionally, anthropologists have focused on isolated communities. Modern anthropology, however, provides useful perspectives on cultural flows and the link between micro and macro levels. Recently, anthropological students of fishing societies have increasingly moved from the narrow context of face-to-face encounters and local communities to the nation state and beyond (LiPuma and Meltzoff 1994). Thus, several anthropological studies have drawn attention to the ways in which local and professional identities are constructed within larger contexts.

Folk, Indigenous, and Customary Law

The term 'customary law' in its most general meaning refers to unwritten legal systems. Though its roots are much older, the theoretical foundations were laid in the eighteenth century by the German historical school of legal theory, which was based on the assumption that all law originated from customs. There, it obtained the meaning of law that does not emanate from the state. The term became fashionable and of eminent practical importance in the nineteenth century, when colonial powers had to determine their relationship to existing legal systems in their colonies. These systems were in the majority of cases unwritten and at best partly written down. With the political demands for self-determination of indigenous peoples, customary law, as one of the fundamental features of their culture and claims for sovereignty, has received renewed interest and political importance. This article will discuss the various terms used for unwritten law and the advantages and disadvantages of each of them. It will then present an overview of the political controversies around the recognition of customary law. Then follows a discussion of the historical developments in the research themes concerning customary law. Finally the debate about the question whether customary law is an invention by colonial powers will be presented.

1. Customary Law, Traditional Law, Indigenous Law, Folk Law, Local Law

The terms 'traditional law,' 'customary law,' 'indigenous law,' 'folk law,' and—for Indonesia—'*adat* law' are often used interchangeably. Each one carries its own connotations and has its specific advantages and disadvantages (van den Bergh 1986). The problem with terms like customary and traditional is that they refer to a presumed unchanged past, though in actual fact each kind of law is subject to continuous change. Sometimes and in some places changes occur rapidly, and at other times law changes slowly and gradually. But there is no legal system that does not change at all. To presume too much continuity poses analytical as

well as political problems. It leads too easily to a fixed and traditionalist representation of local law which has little to do with the social reality of such law. However, when people do not want to comply with proposals or orders from the government, often one of the few legitimate and accepted arguments to oppose government interference is to say government plans go against their traditional law. The real reasons for opposition may be quite different and have to do with distrust of corrupt government officials or differences as to the economic soundness of the proposed plans. This very argument strengthens the perception of government officials that traditional law is indeed an obstacle for development.

The struggle for self-determination of indigenous peoples also suffers from traditionalization of indigenous law. Because reference to long traditions strengthens the claim to self-determination, attention is called away from the flexibility and adjustability of such legal systems. The problem is complicated by the fact that usually there is more than one version of 'traditional' law; the law as it is used and maintained by the local communities themselves, and traditional law as it is interpreted by government institutions.

The Dutch equivalent for indigenous, *inheems*, has had strong colonial connotations and for that reason went out of use. However, in connection with the new discussions about the position of indigenous peoples, it has come into use again. The term 'folk law' (Dutch and German: *Volksrecht*) has been suggested, and in several European languages is a more neutral alternative. In English, it resembles the term 'folklore' too much and is therefore not a good alternative. For these reasons it has been proposed to use the neutral term 'local law' as a generic term for law that is being used and maintained at a local level, from whatever source it is derived.

2. Political Controversies Surrounding the Recognition of Customary Law

Until the nineteenth century colonial governments throughout the world had been mainly interested in controlling trade centers. However, with the change from mercantile to production colonies, colonial administrations had to deal increasingly with local populations at large. In their attempts to gain control they had to determine their relationship towards the existing political and legal systems. In general, they refrained from much interference with family law, but other sectors of law—such as criminal law and land law—pertaining to the political and economic position of colonists and their economic relationships towards the local populations could not simply be left to customary law. Different colonial powers developed very different policies. One extreme was France, with its strong centralistic tradition; it reduced recognition

of existing legal systems as much as it could. England represented the other extreme, with its indirect rule and its concomitant wide recognition of customary law. The Netherlands took a middle position. As in all other colonial countries heated debates took place in The Netherlands about the status and scope of influence of what was called '*adat-law*' of the Dutch East Indies. Issues of both public administration, and material, economic interests were involved in these debates, which touched upon control over large tracts of land. At an abstract level, the question concerned whether colonial law was the exclusive guarantee for economic development, or whether customary law could also support economic growth and development. Ultimately, it was also a debate about the legitimacy of the colonial legal order, the colonial administration, and its monopoly on the legitimate use of force. In a more concrete way, the struggle was about the extent and legitimacy of colonial control over the most important economic assets, i.e., land. See Hooker (1975) for an overview of the legal policies of various colonial powers.

After independence, new states had to reconsider the form and constitution of their legal order. Most countries opted for continuation of the policy of their former colonial motherland and simply took over the former colonial law, including its policy concerning recognition of customary law. Some, among them Malawi, tried to establish a more 'indigenous' legal order. But usually they reverted to the old system after a while. Indonesia, although it claimed to indigenize its legal system, by and large continued the development towards unification that had been initiated by the government of the Dutch East Indies. In most former colonies the issue of recognition is hardly debated any more; there are no serious attempts in countries of the Third World to found a national legal system upon customary law.

However, in countries with indigenous populations—such as Canada, the USA, Latin America, New Zealand, and Australia—the discussion has presented a high political profile since the 1980s. Human rights, in particular the right of self-determination and the protection of cultural rights of indigenous peoples, form the focus of the debate. Many countries negotiate forms of (internal) self-determination and a certain degree of autonomy for indigenous peoples. Debates about minorities in Eastern Europe and the former Soviet Union, and discussions about ethnic minorities in Western Europe, show parallel features with the debates about indigenous peoples (Finkler and K. von Benda-Beckmann 1999). Notions of cultural identity are increasingly used as an argument for autonomy and recognition of group rights. They are also used as an argument to explain and defend 'delinquent' behavior (i.e., the 'cultural defense').

The debate recurs in the context of natural resource management and environmental protection. Indigenous groups and their representatives are trying to

develop 'indigenous' forms of management of tropical forest, land, and water, and call for recognition of local communal rights. Participatory development programmes for natural resource management are also based on the—contested—idea that customary forms of regulation are more adequate than other types of regulation. Notions of participation, self-government, 'good governance,' and sustainability, developed in international law and administration, play an important role in these discussions.

3. Studying Customary Law

The empirical study of customary legal systems began at the end of the nineteenth century. During that century missionaries, travellers, and civil servants had provided a host of widely diverse descriptions of the customs that they encountered. The colonial governments had become particularly interested in land tenure systems, family and inheritance laws. Scholars in the then emerging social sciences developed an interest in customary law as a means to study the evolution of modern society. Thus it was a combination of practical concerns of the colonial government and scholarly interest that elicited a long and rich tradition of the study of customary law.

One problem was how to study unwritten legal systems. The ordinary approach of lawyers to look at legislative and court decisions was inappropriate, because there were virtually no documents. Over the years, different approaches to solve this problem have been developed with different aims. The German legal scholars Post and Kohler were the first to set up a systematic worldwide collection of unwritten legal systems to be used for comparative study. Unlike researchers of the twentieth century, who went out to do extensive field research to learn the ins and outs of particular legal systems, Post and Kohler sent out questionnaires with detailed questions on all aspects of a legal system, to missionaries, travellers, and civil servants. Another German scholar, Bachofen, and his contemporary, the British scholar Sir Henry Maine, each published a comparative study of legal systems in 1861—*Das Mutterrecht* and *Ancient Law* respectively—works firmly rooted in an evolutionary perspective.

From the beginning of the twentieth century a large number of empirical studies began to appear on customary legal systems. Until then the focus had been on a description of the rules of a particular society. But due to scholars like Ehrlich, Malinowski, and Van Vollenhoven (see Holleman 1981), the focus shifted towards a study of the working of law in society. It was their contention that the law could be distilled from ordinary social behaviour. Malinowski's *Crime and Custom in Savage Society* (1926) became one of the most famous examples in this tradition.

From the 1930s on, British, South African, and American scholars doing research in Africa developed

a rich research tradition in the study of customary law with a strong focus on disputes. Standing firmly in the evolutionary tradition, they sought to find the original, authentic customary law, unaffected by modernity and the law of the colonial state. Gluckmann (1965, 1967), Gulliver (1963), and Llewellyn and Hoebel (1967) carefully—sometimes even purposefully—disregarded the colonial state and its representatives. As a consequence, they did not consider it necessary to deal with complex normative structures. Pospišil (1958, 1967) and Bohannan (1965) did write about legal complexity, although they did not deal with the law of the colonial state. The disregard of the state came under vehement attack in the 1970s from critics such as Moore (1978), Spittler, and Von Trotha, who argued that, contrary to what these authors suggested, the state and its law were not at all absent.

Since the 1970s, several important developments have taken place in the study of customary law.

(a) While the earlier studies concentrated on disputes as a source for learning about law, later on the disputing process itself moved into the centre of attention. The 'Berkeley village law project' under Laura Nader led to the classic *Law in Ten Societies* (Nader and Todd 1978). Schott (1978) wrote *Das Recht gegen das Gesetz*. The main objective was no longer the study of customary rules and regulation as such, but the study of modes of dispute management outside courts or court-like institutions (Morse and Woodman 1987); Gulliver's work on negotiation and mediation (1979) is a famous example. These studies have been influential in the movement towards alternative dispute resolution (ADR) in the USA and Europe. ADR is becoming an important export article of the USA to developing countries. For a critical examination of these modern forms of customary law, see Nader (1996); see also K. von Benda-Beckmann (2000).

(b) Customary law is no longer exclusively studied in the context of disputes. Based on the theoretical insight as developed by Ehrlich, Malinowski, and Van Vollenhoven (see Holleman 1981), that law operates primarily in ordinary social life, the role of law in ordinary social relations and social behavior has become a major object of research (F von Benda-Beckmann 1979).

(c) Customary law is nowadays always seen as a part of complex legal systems. It is studied in its relation not only to the law of the state but also to religious law, with which it merged in some societies, while in others the two are considered to be different bodies of law. It embraces, besides the more classical forms of customary law, all kinds of self-regulation within companies and in business branches, ethnic communities, the Mafia, local communities, and organizations of various kinds. In many instances mixed forms of law develop, or unnamed new forms of law (De Sousa Santos 1977). International law, in-

cluding Human Rights of Indigenous Peoples, has provided a new stimulus in the study of customary law in its relation to state law and international law (Merry 1997).

4. The Construction of Customary Law

Many authors have warned that what is often thought to be authentic customary law, in the sense of untouched by Western influence, has in fact been fundamentally influenced by colonial rule. The terms 'invented' or 'fabricated' customary law are proposed to indicate the changed character of customary law as it is usually found today. Some authors maintain that it does not make sense to even speak of customary law as some form of changed or transformed indigenous law, because what has been constructed by the state institutions is an entirely new type of law, invented by the state (Moore 1986, Wiber 1993).

This is not a problem that belongs to the past. In former colonies most courts still apply customary law to many disputes in which the rural population is involved. Parts of customary law are thus incorporated into the law of the state. This is a case of constructed legal pluralism. However, application of customary law regards substantive rules only; procedures of state courts are always designed by the state. Thus 'traditional' substantive law is applied under procedures of state law, as a result of which the substantive rules have undergone important changes. In fact, two kinds of customary law coexist: local law as it is developed and applied by the local population itself; and 'customary law,' or 'traditional law,' as it is applied by government institutions. These two types of law are certainly not fully independent, but stand in complex relationships towards each other and towards the law of the state. Dutch authors writing about colonial law, such as Van Vollenhoven were well aware of what was happening (Holleman 1981). The term *adat* law was designed precisely to indicate the difference from *adat*—the Malay term for local customs in the widest sense of the word, the way of life. Today the term *adat* law is generally used for both the state defined and the local version of customary law.

Courts play a central role in the creation of customary law of the state. Other government institutions (notably land registration offices and extension services) as well as banks adopt the courts' interpretations, enlarging the realm of state-defined customary law. Sometimes these institutions even develop their own version which is slightly different from the courts' version. Thus the influence of international institutions like the World Bank and also internationally operating NGOs and donor agencies has not only renewed the interest in customary law, it also has made the study of customary law more complex.

5. Conclusion

For a long time, customary law was regarded as a vestige of the past that was bound to disappear, but it is clearly far more resilient than was expected. It is subject to change, and it always develops in relationship with, and in response to, other normative orders—of which most important are the state legal system and religious law—but increasingly so in response to international law. In addition, self-regulation and other forms of regulation not emanating from the state or state-like institutions are new twigs on the branch of customary law, giving the concept a far broader scope than it used to have.

Folk Religion

The term 'folk religion' is used rarely today, as it is loosely defined, with the word folk bearing several overtones. It is associated primarily with the English word 'folk-lore,' first used in 1846, and referring to traditional popular beliefs, stories, customs, and superstitions. It relates to the nineteenth century belief that research into 'survivals,' or ancient customs and traditions, as practiced by, e.g., English peasants, and/or 'primitive' peoples, could provide reliable clues to the origins, evolution, or 'progress' of mankind. Folk religion, as part of folklore, is therefore linked to certain European Renaissance, Enlightenment, and post-Enlightenment concepts within psychology and the philosophy of history, concerning the nature of mankind and modes of cultural reasoning. These include human evolution and diversity, comparative religion, and the social functions of religion, including its cultural adaptations.

1. Folk Religion in England

In England and in many other Christian countries, folk religion referred to the survival of pre-Christian and medieval practices. The latter were rooted in the Roman Catholic traditions of pre-Reformation England, when peasants learned through performative ritual rather than intellectual adherence to theological beliefs. The Latin prayers of the medieval Church blurred into charms and superstitions when offered by an illiterate and uncomprehending laity to ward off disaster and disease. Fertility and purification rites, ranging from corn dollies to the churching of women, were customary in rural areas. They became part of folklore, as did continuing beliefs in fairies, portents, ghosts, and witches. Such beliefs often continued well into the twentieth century. In the sixteenth century, the Protestant Reformation brought about the religious use of the vernacular, advances in printing, and increasing literacy. Nevertheless, in the sixteenth and seventeenth centuries, the boundaries of magic, science, and technology overlapped. Dreams were often accepted as supernaturally inspired, on a par with divine judgments and the direct intervention of God in the physical world. From the eighteenth century onwards, such beliefs continued to bridge the divisions between folk and conventional religion.

2. Explorations and Learning in Europe

Throughout Europe, the geographical explorations and new learning of the Renaissance was followed, in the eighteenth and nineteenth centuries, by increasing interest in man's origins and in the natural world. Great interest was shown in the Americas, Asia, the Pacific islands, and in their inhabitants. Writers ranging from Michel de Montaigne to Jean-Jacques Rousseau drew numerous comparisons between these newly discovered peoples and the ancient founders of European civilization, the Greeks and the Romans. At first this took the form of social speculation, of antiquarianism, and of archaeological excavations, such as the eighteenth century excavations of Pompeii and Herculaneum by Johann Winckelmann, which attempted to prove the historical reality of places and events described by the ancient writers. In the nineteenth century, with the expansion of the French and British empires, the interest in antiquity began to include the Middle East. Efforts were made to verify sites mentioned in the Bible. This was partly in response to devastating scientific attacks upon the literal creationism of the Book of Genesis, notably those made by the concepts of geological time, and by evolutionism (as expressed in Charles Darwin's *The Origin of Species on the Basis of Natural Selection* 1859). As well as those interested in establishing the origins of mankind through Biblical truths, others sought the missionisation and Christian conversion of

technologically simple peoples recently encountered in Africa, Australia, and other newly colonized areas. Others saw possible parallels between such people's behavior, customs, and beliefs, and those of early humans.

3. Comparative Religion and Human Origins: Totemism and Evolution

Such beliefs included religion. Under this came polytheism, monotheism, and the concept of a high god; the after-life; theodicy; and divine agency. Opinions were divided as to whether there existed any peoples so 'primitive' as to recognize no god at all. Some commentators, such as John McLennan, and William Robertson-Smith, were preoccupied by sacrifice and cannibalism, sometimes relating these to the origins of Christianity. In *Lectures on the Religion of the Semites* (1889), Robertson-Smith argued that totemism was the earliest form of religion, and that the periodic eating of the totemic animal was both a form of sacrifice and a form of cannibalism, an idea later adopted by Sigmund Freud. Others, such as James Frazer (*The Golden Bough* 1900–22), believed that the answer lay in careful comparative study of all known religious and other rites. Frazer's attempt to elucidate the meaning of divine sacrifice assumed that the comparison of similar customs throughout the world might help to understand the behavior of early humans. This inferred the racial and psychic unity of all mankind. Frazer believed in evolution and the idea of progress, as did his contemporary, Edward Tylor. Tylor, the founder of what is now seen as modern British anthropology, was influenced by Auguste Comte, and became particularly interested in animism and the definition of culture. Frazer and Tylor theorized that the intellectual development of mankind could be described as a movement from magic to religion, and from religion to scientific thinking, an idea later taken up by Bronislaw Malinowski (1925).

4. Folk Religion: Social Functions, Evolution, and Diversity

Folk religion, like folklore, implies the fusion of ancient and modern religious practices, customs, and beliefs. As such it refers to what would today be called multiculturalism, cultural adaptation, and syncretism. These are studied with reference to their social functions, rather than to the theological and philosophical questions which beset man's search for meaning in the universe. As an idea, folk religion belongs both to the Enlightenment and counter-Enlightenment traditions within anthropology. Its most notable representatives include Tylor and Frazer, who tried to present religious beliefs in evolutionary

terms, and Johannes Herder and Max Müller, who insisted on the irreducible diversity of human cultures. Herder argued that cycles of growth and decay affected both man and nature, and that the art and literature of each nation, the 'Volksgeist,' had a unique cultural value that was incompatible with developmental hierarchies. Belief in the Volksgeist was to fuel nineteenth-century nationalism and claims that particular ethnic groups were entitled to their own homelands or nation-states. Müller, a folklorist and noted religious scholar, held that ethnic identity sprang from two human universals, religion and language.

5. *History and Psychology: Society's Impact on the Individual*

The belief that mankind consisted of one species, rather than several racial subspecies, meant that concepts of psychic unity coincided with questions about society's impact on the individual. This was already a well-established theme in the philosophy of history, with the idea that the course of history was ruled by something greater than the influence of individuals who participated in it. The Renaissance historian Giovanni Vico, who developed a cyclical theory of civilisation, attributed this to divine intervention. Georg Hegel saw competing ideas, 'thesis' and 'antithesis,' as determining mankind's behavior. Karl Marx, who had read both Vico and Hegel, claimed ideas were not autonomous but firmly rooted in material conditions which produced an ideological superstructure, a 'false consciousness,' which affected human action. In psychology, William James emphasized the social functions of religious practice. Freud, reworking Christian concepts of original sin, promulgated belief in the unconscious: Carl Jung, that of the collective unconscious. Emile Durkheim's *Les Formes élémentaires de la Vie Religieuse* (1912) (translation *The Elementary Forms of the Religious Life*) held that religious rites were mechanisms for affirming social solidarity, involving collective representations of the group. Durkheim's idea of collective representations influenced Lucien Lévy-Bruhl's concept of prelogical mentalities and discussion of the ways in which the mental capacities and/or, reasoning devices of so-called primitive people were thought to differ from those seen as more civilized and rationalistic. As Evans-Pritchard (1965) pointed out, those who were engaged in the sociological and anthropological study of religion generally regarded it from an Enlightenment, rationalist viewpoint, as a series of superstitions which could only be explained in terms of cognitive variation or social function.

Religion became linked to the study of emotions, to the nature of the self, and to psychological interpretations of social functions, but also to theories of economic exchange, social control, and political legiti-

mization: links which continue today. One effect of this was that religion tended to be seen less as a holistic phenomenon than as the sum of several parts, any of which could be used to support arguments relating to the functions and meanings of other social institutions.

6. *Cultural Groups and Modes of Reasoning*

The ways in which modes of reasoning appear to differ between cultural groups is a perennial theme in anthropology, even though the arguments have long since moved from questions of innate capacities, and from the relationship between magic, science, and religion, to the ways in which particular cultural premises favor different forms of interpretation. Malinowski and Arthur Radcliffe-Brown were the first two European anthropologists to base their arguments upon personal fieldwork rather than armchair speculation. Malinowski held that the religious practices of 'primitive' peoples displayed a rational response to their surroundings, rather than one infused by the mysticism of Lévy-Bruhl. Radcliffe-Brown, influenced by Durkheim, interested himself in the expressive and affective aspects of tribal ceremonies, rather than in their possible origins.

Evans-Pritchard, like his student Mary Douglas, emphasized the logic underlying belief in witchcraft and other quasireligious practices, showing that indigenous interpretations depended on analogies, rational deduction, and the influence of emotions upon a particular line of reasoning.

7. *Folk Religion: Tradition and Adaptation*

Even though the phrase is obsolete, folk religion usually denotes either the traditional beliefs and practices of a particular people, or, more often, remnants from an earlier age. In *Folkways* (1906), the political scientist William Sumner argued that folkways, or the belief in and enactment of folklore, were the result of illiteracy combined with an intellectual closure produced by overwhelming deference to tradition. He pointed out that all beliefs were constantly adapting themselves to the exigencies of everyday life, so that 'pure' customs did not exist. Today, folk religious beliefs and practices may refer to those which have survived attempts to destroy an indigenous culture by colonialism or other means. They are then often described in terms of ethnicity and cultural resistance to forms of oppression. Such oppression may range from the exclusion of certain ethnic groups from formal learning systems to the class exclusion of the illiterate or poorly educated, including those living in rural areas and traditionally defined as peasants. Cultural resistance may encourage the oppressed to cling to beliefs and practices discarded by other social

or ethnic groups, or to create particular meanings and interpretations from their experiences, which are not countered by the interpretations given in formal meaning systems. The result is cultural adaptation, as elements of both the dominant and traditional cultures fuse together. This may give rise to religious syncretism, which may be both formal and informal, encompassing both distinctly new forms of cultural expression (e.g., Brazilian spiritist movements such as Umbanda and Candomblé) and the reworking of the previously discarded beliefs and practices of formal religious systems. Such peasant remnants and reworkings may be ignored by rationalistic and educated believers with higher social status (for a description of this, see Christian 1972). The former may continue to exist without reworking, with few substantial changes, so that they effectively consist of religious survivals, the folk religion of many years ago.

Folklore

'Folklore' has four basic meanings. First, it denotes oral narration, rituals, crafts, and other forms of vernacular expressive culture. Second, folklore, or 'folkloristics,' names an academic discipline devoted to the study of such phenomena. Third, in everyday usage, folklore sometimes describes colorful 'folkloric' phenomena linked to the music, tourist, and fashion industries. Fourth, like myth, folklore can mean

falsehood. While in this text, focus is placed on the first two meanings, the other two are often present, implicitly or explicitly.

1. History

1.1 A Term is Invented

The word folklore was coined by British antiquarian William John Thoms who, in 1846, proposed that this 'good Saxon compound' be used to describe 'the manners, customs, observances, superstitions, ballads, proverbs' and other materials 'of the olden time.' Thoms was inspired by the works of the Brothers Grimm and 'folklore' is apparently a translation of the German 'Volkskunde' introduced in 1806.

Although the word was new, the interest in the phenomena themselves was not. European rulers had long ordered the collecting of traditions that would glorify them, and religious leaders had gathered dangerous beliefs in order to weed them out. However, during the national romantic currents of the late eighteenth and early nineteenth centuries, intellectuals added something new, when they insisted that the customs and arts of illiterate peasants were remnants from a remote human past and should be collected before they were bound to disappear as civilization advanced. Like Johann Gottfried von Herder, many intellectuals also saw a reflection of the true spirit of nations in the traditions of the anonymous folk living close to the national soil.

1.2 A Discipline is Founded

During the nineteenth century, many people were fascinated with folklore, among them scholars with interests in literature, philology, religion, psychology, history, archeology, anthropology, and other fields. In some countries enthusiasts formed societies: the British Folklore Society was founded in 1878, and the American equivalent 10 years later. In other countries, primarily in northern and central Europe, the idea of folklore was directly linked to nation formation. In Finland, which was in the process of freeing itself, first from Swedish and then from Russian domination, Elias Lönnrot pieced together the *Kalevala Epic* from songs collected in oral tradition. Published in 1835, the *Kalevala* became the first example of literature written in Finnish and a national symbol. In addition, the songs formed the core of a national folklore archive and, in 1898, the world's first professorship in folklore was established: the chair in 'Finnish and Comparative Folklore' at the University of Helsinki. Other departments were to follow in other European countries, often in conjunction with the founding of national museums and archives.

However, in many countries, folklore continued to be studied outside formal institutions. In some cases, such as England, separate university departments were never established, whereas in others, notably the United States, they were founded as late as after World War II (see Sect. 3).

1.3 A History of Approaches

On the whole, the ideas employed to explain and interpret folklore coincide with the major schools of thought in anthropology, beginning with evolutionism and diffusionism and moving on toward functionalism, structuralism, and later tendencies. Yet even more than in anthropology as a whole, the study of folklore was long focused on questions of origin; an array of explanations were proposed to account for the origin of such ancient and widely disseminated tales as *'The Dragon Slayer'* and other traditions. The Indianist school championed by Theodor Benfey sought to establish that all European folktales had originated in India and spread from there. The mythological school headed by Max Müller found that all folktales were survivals of ancient nature-myths, while ritualists such as Pierre Saintyves tried to demonstrate that all folktales had originated in rituals.

While these explanations now have mostly antiquarian interest, other early trends of thought remain important. Among these is, first, the diffusionist 'historical-geographical' method developed by Finnish scholars at the end of the nineteenth century. In this cumbersome procedure all recorded versions and variants of a tale type (or a ballad or a riddle) are studied so that the location of the earliest traits (and theoretically also the tale's place of origin) can be determined. The gathering of comparative evidence resulted in massive indexes and catalogues that are still often consulted (Aarne and Thompson 1961). A second intellectual movement that remains important to the understanding of folklore is psychoanalysis. Sigmund Freud, C. G. Jung, Otto Rank, and others came to regard folklore as essential expressions of the individual or collective human unconscious. A third essential strand of thought is the insight that forms of folklore are not only widely spread but also firmly localized and therefore must be studied in their immediate social contexts. Franz Boas' ethnographies of the stories of native peoples on the north west coast of the United States initiated an influential format for the study of folklore in local contexts.

Functionalism, not least Bronislaw Malinowski's analyses of story telling among the Trobrianders, is a fourth development that has had a lasting impact on the study of folklore. Particularly influential is the psycho-functional premise that folklore is 'socially sanctioned' fantasy; as such it permits action that is otherwise not approved (Dundes 1965, p. 277). Finally, structuralist thought has also endured among students of folklore. One structuralist approach deri-

ves from Russian formalism and emphasizes features of plot sequence; in an influential study Vladimir Propp demonstrated that all Russian fairytales share the same plot structure. A second approach derives from the work of Claude Lévi-Strauss and points to the ways in which logical relationships within myths and tales (such as binary oppositions) reflect universal processes of the human mind. Lévi-Strauss' thinking has been central to the analysis of a wide range of traditional forms, not least to Henry Glassie's monumental investigations of vernacular material culture.

2. Key Words

Despite the many decades of inquiry, it remains difficult to define folklore. In one recent attempt it is suggested that folklore embraces 'expressive forms, processes, and behaviors' that are learned, taught, and utilized 'during face-to-face interactions.' It is also suggested that people judge these phenomena to be traditional 'because they serve as evidence of continuities ... through time and space in human ... thought, belief, and feeling' (Georges and Jones 1995, p. 1).

However, many scholars avoid generalized statements and prefer to look at folklore as perspectives and processes that might be illuminated through such keywords as 'folk,' 'tradition,' 'genre,' 'performance,' 'text,' and 'art' (cf. Feintuch 1995).

2.1 Folk

Influenced by the typologies of early social thought and by such conceptualizations as Robert Redfield's 'ideal folk society,' students of folklore long took it for granted that the folk (i.e., the carriers and transmitters of folklore) were illiterate peasants or, to some extent, tribal peoples. However, during the last few decades, the word folk is increasingly regarded as a cumbersome inheritance from earlier thinking and most scholars agree that all human beings in some way or another are involved in folklore processes, as performers, participants, watchers or audiences—sometimes even as indifferent or disdainful audiences (see Sects. 2.4–2.6). But it has been difficult to abolish the word folk. For one thing, it remains important in studies of folklore in feudal systems or other class hierarchies. Second, it remains alive in such compounds as folk art, folk music, and folk dance; attempts to replace 'folk' with 'people,' 'vernacular,' or other words have not been successful (see Sect. 3). Furthermore, despite their conviction that all human beings partake in folklore processes, contemporary students also concentrate on marginal or subaltern peoples. But their reasons for doing so differ from those of nineteenth century predecessors; many students now argue that the role of folklorists today is to assist peoples who lack political power in their quest to gain a public voice.

2.2 Tradition

Used both to name a process of transmission and to name specific cultural elements (i.e., traditions), the concept of tradition is basic to the understanding of folklore and folkloristics. It has long been recognized that tradition not only involves historical continuity but also change. Because folklore forms are often transmitted orally or in other informal ways, they are extremely adaptable to fleeting moments of social interaction. One could even say that it is because of their adaptability that simple string-figures or guessing games have remained in circulation through millennia.

The materials deposited in archives and listed in comparative indexes demonstrate both the adaptability of some themes and their continuity through time and space. For example, comic book hero Superman travels through space in a womblike vessel only to be found and raised by a poor couple in the middle of North America. His story has parallels in the stories of Moses, Cyrus, and other heroes who are similarly found as children floating around in small containers. Furthermore, identity changes are not only characteristic of Superman but also of countless other heroes and heroines in world traditions. The transformation of an orphaned young girl into a rich and beautiful queen is reenacted over and over in oral tales, films, and real life. Folklore themes have a psychological force that makes people recreate them century after century in different communicative modes and media.

During recent decades, students of folklore increasingly utilize the verb 'traditionalize' to name processes in which the past is interpreted or reinvented in a given present. Many students of folklore now emphasize that they do not investigate given sets of traditions but all sorts of practices of traditionalization in social life. Furthermore, by focusing on active traditionalization processes, scholars avoid cementing an opposition between tradition and creativity. They see tradition as a source of creativity, not as a constraint to it (Briggs 1988).

2.3 Genre

Genre means 'kind' and a genre may be seen as a bounded distinguishable form characterized by a specific combination of stylistic traits and elements of content. The classification into genres was for a long time so central that scholars thought that enumerating genres was the easiest way to describe what folklore is (Dundes 1965).

When analyzing genres, students of folklore often find themselves caught in dilemmas familiar to all students of culture. On the one hand, all peoples make local, culture specific, or 'emic' distinctions between genres in their repertoires: coyote tales, superstitions, dirty jokes, little girls' games, gossip, songs while making baskets, and so on. On the other hand,

scholars may observe more overriding features in the same materials and may note how elements of content, style, or structure are shared across cultural boundaries. The extent to which local classifications are emphasized and the extent to which broader ones come into play have to vary with different analytic tasks.

One distinction that was long taken for granted but has proven problematic is that between 'fixed' genres, such as riddles and proverbs, and 'unfixed' genres, such as many narratives. While some genres, magic formulas for example, are fixed in the sense that they must be recited exactly as learned in order to have power, other genres that were long called fixed change too. For example, people often do not cite proverbs in full but merely hint at them through tone of voice. Thanks to performance-centered approaches (see Sect. 2.4), scholars have recently gained new insights into the ways in which oral genres are malleable social phenomena. In social interaction people mix or blur materials so that artful hybrids emerge. At the same time, genres are needed as 'social contracts' that aid memory and establish structure.

2.4 Performance

Since the 1960s, the concept of performance has transformed the study of folklore. Thanks to increasing refinements in recording techniques, scholars have been able to analyze folklore as part of communicative processes in ways that had not been possible before. Two performance-centered approaches will be recognized here; in both, careful ethnographic fieldwork is essential.

One approach is rooted in the ethnography of speaking and other sociolinguistic methods. A basic idea is that verbal art and other forms of folklore emerge in social interaction as aesthetically marked forms. They are recognized as something special thanks to cues made through tone of voice mimicry, gestures, and other devices. Arguing that performance is 'constitutive' of verbal art, Dell Hymes, Richard Bauman, and others have developed ways of studying folklore as artistic communication in everyday life, communication in which, as Hymes says, people shape 'deeply felt values into meaningful, apposite form.' If preachers, story-tellers, weavers, carvers, and carnival participants in the past were seen as transmitters of handed down traditions, they were now regarded as active artists with power to transform social life.

A second performance-centered approach is oral formulaic theory. This was first developed by Albert Lord and others who in studies of South Slavic oral epic poetry show how songs that are many thousands of lines long can live in tradition, although they have not been written down. They are remembered because singers learn to draw on a store of formulae and formulaic expressions and learn to adjust their singing

to different social events. Several scholars have continued along these paths and oral formulaic studies are now enriching the understanding of both ancient (in particular Homeric) epic singing and of contemporary epic performances in India, China, Africa, and Eastern Europe (Finnegan 1992, Honko 1998).

2.5 Text

It has long been recognized that the distinction between oral and written texts is far from firm and that all kinds of texts can be of interest to students of folklore. Some 'folklore texts' have always existed primarily in writing, for instance court records, religious documents, newspaper articles, and xeroxlore. Others have circulated widely as visual representations, for example fables painted inside medieval churches. Furthermore, literary authors have continuously made use of traditional themes and, in a sense, folklore texts can be found in the works of many celebrated writers. For example, contemporary African authors, such as Ayi Kwei Armah, acknowledge their profound debt to oral narrative art and Shakespeare often builds his plays on traditional materials. Actually, a great many art forms can profitably be studied as folklore texts. Classical ballet, for example, shares some of its stylized and repetitive character with the European folktale.

Recently, performance-centered approaches have opened up oral texts in unprecedented ways in that scholars have invented new methods to translate oral performances into writing. In procedures that have sometimes been named 'laying out texts ethnopoetically' students transcribe not only words but also pauses, cadences, gestures, mimicry, and other oral features (Briggs 1988). These procedures have led to many insights. One is that oral narration in many cultures tends to be closer to drama than to prose literature. Another is that repetitions and other features of oral narration (or visual folk art) are not to be dismissed as poor artistry as was often the case in the past. Rather, repetitions can be seen as ways to control complex materials. A repetitive structure simultaneously offers restrictions and creative freedom; it aids memory at the same time as it frees fantasy and improvisation.

During the last few years, the term 'textualization' is increasingly used to describe modes of translating oral performances onto the written page (Honko 1998). Long regarded as routine exercises, textualization processes are now seen as central analytic tasks.

2.6 Art

On some level, scholars always seem to have agreed that folklore has to do with art, creativity, and imagination. Even at times when the study of folklore

was reduced to enumerations of genres and tale types, there was a sense that folklore touches upon the aesthetic dimensions of life. This sense has become heightened during the last few decades, in part due to the interest in folklore as performance. This is particularly the case in the United States, where all kinds of vernacular expressions—from singing to cooking and quilting—are often called the 'the folk arts.'

The focus on art is linked to several perspectives. First, students make a distinction between less articulate folklore performers and artists who are celebrated in their communities and have the power to move others to action. Second, students of folklore have made important discoveries about social life by focusing, not on finished products, but on moments when material objects or community events are being planned or created. Third, the interest in art has led to new analyses of the languages of folklore. Whether verbal, visual, musical, kinesthetic, or tactile, these languages are bold in their use of intense and multi-valent metaphors and other tropes.

It is because of this expressive intensity that folklore, like other forms of art, can be a vehicle through which people can examine or critique the lives they lead. For example, to people who have fled from one part of the world to another, a few songs, stories, or dishes can become embodiments of a precious inheritance which must be preserved and reconstituted in new lands. Conversely folklore can incarnate some of the worst aspects of life: detested symbols of racism and humiliating jokes that outsiders direct at one's own group. Because of its power of presence, folklore can be invoked to hold communities together or to separate them from one another.

3. Folklore and the Politics of Culture

Among contemporary scholars there is both confidence and unease about the future of folklore and folklore study. There is confidence, for example, about the supply of material. The idea that folklore is 'dying out' is no more true today than it was 200 years ago. People shape rituals and tell stories, perhaps more than ever before, but they do so not only in face-to-face interactions but also on the electronic media. There is also confidence in the sense that a great deal of scholarship is being conducted. Indeed, some scholars are convinced that, regardless of discipline, those who study folklore today play a special role as advocates of the artistic expressions and traditions of all those groups and individuals who are caught in the cracks of modern life.

But, on the other hand, scholars are uncertain about the directions of folklore study. There are renewed critical reflections on the discipline's long and euro-centric history and on its often naive, and sometimes disastrous, ideological and political entanglements (Briggs and Shuman 1993). One indication of the

uncertainties are the current controversies surrounding the designation of the field. In Germany, the term 'Volkskunde' is now often avoided, because it is deeply implicated in fascist scholarship and in the creation of symbols for the Third Reich. Here and in some other countries, 'ethnology' is preferred to compounds containing 'folk' (see Sect. 2.1). In other countries, the word folklore is perceived as an inheritance from a colonial era and is being replaced by new coinages, such as the South Indian 'janapada.'

Many critical reflections concern the paradoxical situation that folkloristics regards itself an international field at the same time as it is almost everywhere a construction in the service of nation building and related local endeavors. This was true in the nineteenth century and it is true in the twenty-first. For example, in some newly formed or recently reconstituted nations, folklore and folklore archives play a critical part in efforts to construct visions of homogeneous and exclusive national heritages. In other situations, folklore and folklorists are linked to nation building in other ways. In the United States, for example, they have become important in affirming a vision of the country in which a multitude of diverse cultures can co-exist. This is particularly true of so-called public folklorists. Employed in museums, at the American Folklife Center in Washington DC, or as state folk arts coordinators, these professionals have special skills in collecting, preserving, and presenting the folklore of an immense diversity of groups. But also on a global level folklorists participate in cultural politics. Many work with UNESCO in efforts to safeguard folk traditions around the globe from the onslaughts of modernity.

Whether nationally or globally based, all these endeavors to collect, preserve, and present folklore raise many questions. In whose interest are these efforts being carried out? Whose traditions should be safeguarded and whose should be deleted? What happens to all those traditions that are not beautiful or presentable but offensive, frightening, or incomprehensible? In the view of many scholars, it is the many different kinds of heritage politics and ideological mazes that ought to become an important focus of attention for folklore scholarship in the years to come.

Food in Anthropology

The study of food in anthropology involves simultaneous consideration of both culture and biology. Work spans a wide array of emphases from largely biological to largely cultural, and comprehends a range of topics, methodologies, and theoretical approaches. Food and culture studies emphasize the social and symbolic dimensions of food to gather insights about gender, class, political economy, power, cultural ideology, and cultural identity (Counihan and Van Esterik 1997). Nutritional anthropology gives more weight to biological considerations and examines the interplay of food supply and hunger, nutritional status, breast-feeding, disease, household dynamics, and human evolution (Goodman et al. 1999). The two different approaches overlap and complement each other and reveal the power of anthropological holism to explain the human condition.

1. History and Scope of the Field

Many early ethnographers paid attention to food habits because food is a central focus of the economy in most cultures. In noncapitalist societies, the production, distribution, and consumption of food take up a great deal of people's time, energy, and attention. Marcel Mauss (1923) laid an important foundation of foodways research in anthropology with his pioneering study of exchange in *The Gift* (see also *Exchange in Anthropology*). Mauss directed our attention to the importance of giving, receiving, and repaying in initiating, maintaining, or breaking social and political relationships, and reminded us of how often food is a

key substance in exchanges. Gifts, Mauss pointed out, are 'total social phenomena,' a concept that applies beautifully to food. Mauss used ethnographic and historical literature to explore gifts in a variety of cultural forms, for example the Northwest Coast Indian potlatch and the Maori 'taonga.' He described the meaning of the ancient Hindu food offerings thus: 'The thing given brings a return in this life and the other ... Food given away means that food will return to the donor in this world; it also means food for him in the other world and in his series of reincarnations' (1967, pp. 54–5). Food gifts establish obligations of reciprocity in recipients whether they are gods or humans.

The centrality of food in gifts and economic transactions has ensured its central role in expressing religious beliefs, communicating with others, establishing and breaking relationships, defining social groups and families, and expressing cultural values. Yet few early anthropologists focused explicitly on food, the exception being Audrey Richards who conducted pioneering work on land, labor, diet, and hunger in Southern Africa (1932, 1939). She took a functionalist approach to food and examined the interconnectedness of food-centered production, distribution, consumption, and beliefs (see also *Functionalism in Anthropology*). She consistently examined not only food's important economic and nutritional dimensions, but also its role in constructing social relationships, showing for example how gifts of food declared and enacted the new obligations between families at marriage. Richards was the first anthropologist to do a full fieldwork study centered on food. Although her work was well regarded, it did not inspire followers for several decades.

The current burgeoning of studies in food anthropology began in the 1960s with the stunning work of Claude Lévi-Strauss (1969 [1964]) in France and Mary Douglas (1966) in England. Lévi-Strauss developed his structural theory by applying it to a symbolic analysis of food and other important symbols in hundreds of myths collected from Amazonian Indians. He introduced the idea of the 'gustatory code' (1969, p. 164) which is the most important of the five basic codes (stemming from the five senses) that humans use to transmit cultural messages. The gustatory code refers to the predominance of food symbols and metaphors in human expression which is due to 'the truly essential place of cooking in native thought: not only does cooking mark the transition from nature to culture, but through it and by means of it, the human state can be defined with all its attributes' (1969, p. 164). The study of myths and the consistent patterns that they display on diverse levels of meaning reveals that 'myths signify the mind that evolves them ... there is simultaneous production of myths themselves, by the mind that generates them and, by the myths, of an image of the world which is already inherent in the structure of the mind' (1969, p. 341).

Mary Douglas took a different approach to the symbolic study of foods by focusing on their ability to reveal not the mind's structure but social structure. She demonstrated how foodways revealed concepts of purity and pollution and constructed social boundaries in diverse cultural settings, most prominently in her study of Jewish dietary law. She argued that Jewish rules about food consumption continually reinforced concepts of holiness and renewed the community of the faithful. Together, the work of Douglas and Lévi-Strauss gave an influential demonstration of the role of food as 'good to think' as well as 'good to eat' and overcame the anthropological tendency to take food for granted.

Food studies in anthropology proliferated in the 1970s, 1980s, and 1990s. Researchers have used ethnographic, archaeological, and biocultural fieldwork methods to study foodways—the beliefs and behaviors surrounding the production, distribution, and consumption of food. Douglas and Lévi-Strauss' emphasis on the symbolic role of food did not go unchallenged. Marvin Harris (1985) responded to their work by arguing explicitly that food habits exist for utilitarian purposes. 'Preferred foods (good to eat) are foods that have a more favorable balance of practical benefits over costs than foods that are avoided (bad to eat)' (1985, p. 15). Harris gave priority to material over symbolic concerns in explaining Jewish dietary law. He argued that the pig was an economic competitor with humans in the arid lands of the Middle East where it made much better economic sense to raise ruminants who do not need high-protein foods to flourish as pigs do. Thus, he argued food aversions and preferences evolve primarily to support utilitarian practices based on nutritional and ecological concerns rather than to support religious belief systems.

Douglas and Harris's different explanations for Jewish dietary law show how the study of food provides diverse and complementary insights into human behavior. Anthropologists have examined foodways to gain insights into power in politics, family, gender, class, and race. They have studied human evolution, health, and disease; famine, hunger, and malnutrition; and the relationships between cultural ideology and behavior.

2. Food and Power

Because food is the most insistent and basic daily survival need, it is a central pawn in power struggles in many different settings. In Papua New Guinea, for example, men use food to acquire and demonstrate political leadership. In Kalauna, men 'fight with food' by shaming others through excessive gifts of comestibles (Young 1971). In Wamira, Papua New Guinea (Kahn 1986), men demonstrate their leadership and public renown by accumulating food and giving it away to followers and enemies alike at public feasts.

At the same time, they refrain from eating and thus demonstrate their self-control and prestige through 'the potency of [their] hunger-assuaging magic' and their ability 'to tame the most frightening of uncontrollable behaviors—namely ravenous, rapacious desire—both gustatory and sexual' (Kahn 1986, p. 86).

The attainment of power through giving food away typical of Melanesian and other subsistence cultures contrasts dramatically with the goal of capitalists, who attempt to withhold food and sell it for profit and power, as Mintz (1985) capably demonstrated in his anthropological study of the worldwide commodification of sugar. Sugar production involved Europeans in conquest of Third world countries, seizure of raw materials, and enslavement of Africans to provide land and labor to produce sugar cheaply enough to fuel a vast expansion of sugar consumption and exorbitant profits. The story of sugar provides a case study in how foodways research can uncover the interworkings of political, economic, and cultural systems of power.

Goody (1982) focused explicitly on the role of foodways in constituting class relations by examining the conditions for the emergence of high and low cuisine among some African, European, and Asian cultures. He examined how 'industrial food' can be a form of cultural domination of Third World cultures and explored the socioeconomic structures that enable them to resist. Meillassoux (1975) used a Marxist perspective and economic focus on food production and distribution to examine the persistence of the household economy under the corrosive conditions of colonization and capitalist labor exploitation. Weismantel (1988) showed how specific food behaviors identify class and race in Highland Ecuador. Indians regularly eat potatoes but only on special occasions do they consume the white rice that forms the staple food and symbol of class and race privilege of the whites. In the USA, distinctions between rich and poor, male and female, and white and 'ethnic' Americans are all enacted through foodways (Counihan 1999).

3. Food and Gender

Food is intimately connected with the definition and assertion of gender identity in many cultures (Counihan 1999). Food work ordinarily falls to women and whether this work is revered or denigrated is an important constituent in women's status. Among the Zumbagua of the Ecuadorian Highlands, women use their cooking to express approval or disapproval of their husbands, and they establish hierarchy in the family by their allocation of scarce and valued meat (Weismantel 1988). Among Wamirans of Papua New Guinea, women's roles in producing food and children are likened to each other and valued highly (Kahn 1986). To emulate women's important role in procreation and establish symbolic gender parity,

Wamiran men cultivate taro, which they call their 'children' and which represents their 'personal status and virility' (Kahn 1986, p. 91). Among the Hua of highland Papua New Guinea, men's elaborate system of food rules reveals how they construct gender and overcome their own fears of women's power of procreation (Meigs 1984). They define foods in two categories, *koroko* and *hakeri'a*, female and male. Female foods are wet, cold, fertile, soft, and fast growing; male foods are dry, hot, infertile, hard, and slow growing. Men publicly aver that women and the foods associated with them are polluting and dangerous, yet in rituals they secretly consume the female foods to gain the power, fertility, and vitality of women.

In all cultures, gender relations are clearly expressed through the attitudes of men and women towards eating, feeding, and the body. In contrast to the great majority of cultures, where women aspire to plumpness and pleasure in eating, in the USA, women reproduce their subordination by restricting their eating, reducing their bodies, and loathing their own appetites. As capitalism transforms women from producers into consumers and commodities, they lose social value and power, their bodies become objects, and they lose subjecthood and agency (Counihan 1999).

Anthropologists have shown how cultural practices and attitudes towards breast-feeding vs. formula feeding reveal much about women's power and status. Van Esterik (1989) used fieldwork data and documentary sources on cases in Thailand, Indonesia, Kenya, and Colombia to argue that the adoption of formula-feeding robs women of an important bodily ability, costs them money, and generates profits for multinational corporations at the expense of infant health, especially among the poor in the USA and the world. Empowerment of women depends on creating conditions where they can breast-feed if they choose with dignity and respect so as to ensure the best possible health of children and validation of women's corporeal abilities.

4. Nutritional Anthropology

The relationship between cultural practices, food consumption, health, and disease past and present has been a central focus of nutritional anthropology. Harris and Ross (1987) developed their edited volume *Food and Evolution* to demonstrate the important role in human development of the interplay of biological and behavioral 'repertoires' surrounding food. Goodman et al. (1999, p. 1) defined nutritional anthropology as the study of 'the interrelationships of biological and social forces in shaping human food use and the nutritional status of individuals and populations.' Their volume explored the evolution of human foodways with attention to both fossil and primate studies and the importance of plant and animal domestication

on diet and health. It looked at case studies on lactose tolerance, maize processing technology, and bitter cassava consumption to explore the development and impact of specific diets and food processing techniques and their ecological and health implications. They examined the biocultural causes and effects of hunger, malnutrition, and overeating.

5. Hunger and Malnutrition

Few anthropologists have written books on the causes and effects of hunger, the exception again being the pioneering work of Audrey Richards (1932). Recently there have been a growing number of good articles, some of which have been anthologized (see Counihan and Van Esterik 1997, Goodman et al. 1999, Harris and Ross 1987). Dettwyler (1994) is one of few anthropologists to produce a book-length study of hunger. She focused on feeding practices, health, and disease in Mali by combining ethnographic observations with nutritional methods. She used dietary nutrient assessment, height and weight measurements of children and adults, collection of health beliefs, observations of feeding and breast-feeding practices, and blood, urine, and stool sampling. She was able to assess health status and parasitic invasions and show their relationship to cultural practices and attitudes. For example, Malian beliefs about children's normal appearance being thin and pot-bellied obscured their ability to recognize or end malnutrition in children. Dettwyler's goal was to use her study to develop 'culturally appropriate nutrition education programs, aimed at improving people's understanding of the links between diet and health, and the importance of making sure young children get enough food, of sufficient quality, to meet their needs for growth and health' (1994, p.7). Nutritional anthropology demonstrates the analytic power of combining sensitive social observations with scientific data-gathering to understand the causes and potential cures of hunger, malnutrition, and the diseases of poverty.

6. Future Directions

Future studies of food in anthropology will continue to address links between cultural systems, social inequality, food, and hunger. Studies can do this by examining food in popular culture—particularly the use of food images in advertising, television, film and popular music—where the messages transmitted often penetrate public consciousness with little critical reflection. The study of McDonalds in East Asia by Watson (1997) and his collaborators links the anthropology of food to the theme of globalization. Anthropology's symbolic and biocultural approach is particularly useful in studying the growing epidemic of eating disorders, including anorexia nervosa, bulimia, and compulsive eating. These disorders strike women in

much greater numbers than men and seem to have psychocultural causes associated directly with women's subordinate status and socially constructed role as those who should feed others but not themselves. The cross-cultural study of the spread of, and resistance to, eating disorders in Third World countries where they were previously unknown will provide important insights into their causes, consequences, and cures.

As multinational corporations increasingly dominate food production and distribution, anthropologists will need to keep a close eye on the effects of food profit-making on access to and quality of food. Issues surrounding the bioengineering, genetic manipulation, loss of genetic diversity, and environmental pollution and protection in agricultural production will be paramount. Because of the centrality of food to human physical well being and cultural expression, anthropologists must continue to document and promote efforts to end hunger and to establish food as a human right.

C. M. Counihan

Food Preference

Food and food choice constitute a major part of waking human activity, and, in the Third World, the major expense. Furthermore, food choice may be the single most important selective force in animal evolution, as suggested by the fact that many animal groups are named for their food habits (e.g., carnivores, insectivores). In human evolution, adaptations to enable the exploitation of large animals as foods played a significant role in the evolution of the human brain and human social organization. As argued persuasively by Jared Diamond (1999), early advances in food procurement, agriculture, and domestication set the stage for major advances in technology, the development of urban centers, and warfare. As a fundamental and frequent part of human life, food has served as a foundation for the cultural evolution of non-food systems; thus, food plays a major role in religion, ritual, and social exchange. It is also a source of metaphors, with words such as 'bitter,' 'meat,' and 'swallow' used in many non-food contexts. Thus, an understanding of human relationships to food promises to enlighten a major area of human concern, as well as other areas. The full range of food in human life is beautifully described in Leon Kass' book, *The Hungry Soul* (1994).

1. The Basic Relationship Between Humans and Their Food

For any person, the world can be divided into the self and everything else. Eating involves taking matter from outside the self and putting it inside the self. This

is a very intimate act. It is not surprising that people feel strongly about what they eat. The costs in terms of toxins, microorganisms, or imbalanced nutrients are high, but the benefits are at least as high: survival is at stake.

Humans (and rats and cockroaches) are food generalists. They eat a wide range of foods; virtually anything that can fit into the mouth is potential food. Generalists have few innate determinants of food choice, simply because it is not easy to predict the nutritive and toxic properties of a potential food on sensory grounds. There are only a few documented innate biases in human (and rat) food choice. First, there are innate predispositions to like or dislike certain tastes. There is an innate preference for sweet tastes, which, in nature, are predictive of calorie sources. The long history of sweetness in human culture, from fruit preferences, to cultivation of fruits, to extraction of sugar from fruits, to colonization of the Americas partly to get a source of sugar, to the development of sugar substitutes, is all driven by the innate liking for sugar.

There is also an innate tendency to dislike bitter tastes, and there are probably innate predispositions to reject very strong tastes including oral irritation (as from peppers) and to like fatty textures. Second, there is a suspicion about trying new foods (on account of potential toxicity), but also a conflicting interest in them (on account of their potential as a new nutrient source). This has been described as the generalist's dilemma. Third, there is a special learning mechanism that allows learning about the consequences of ingestion, even when these may occur hours after ingestion. Fourth, there are a few specific internal states that seem to signal the need for specific nutrients. The best example is thirst. Hunger, of course, signals a general need for energy, and there may be a specific internal signal associated with sodium deficiency.

Humans are mammals, and hence have a unique first food, milk. Humans and other mammalian generalists make a transition from this single food to a very wide range of foods. This transition is made under the guidance of parents and other caretakers, and usually consists of a scheduled and graduated introduction of new foods. For all mammal species except a subset of modern humans, milk is a food limited to infancy. The development of dairying afforded the opportunity for humans to exploit milk and its products as adult foods.

2. Determinants of Human Food Choice

For humans, food choice is accounted for by some combination of biological, psychological, and cultural factors. The role of biological factors is limited for two reasons. One, as discussed above, is the human generalist orientation to food. Second, the modern

developed-culture world presents to its members a food world that is vastly different from the ancestral world in which the biological predispositions evolved. A shortage of food has been replaced by a surplus of food. A modest range of natural, local foods has been replaced by an enormous range of foods, representing most of the world's cuisines at a neighborhood supermarket. A major risk of food poisoning from toxins and microorganisms has been sharply reduced; the longer lifetime that has resulted from this and other medical advances establishes a new and more subtle link between degenerative diseases and dietary patterns over decades. Limited knowledge about foods and their consequences is replaced by exposure through the media to massive amounts of evidence relating dietary pattern to wellness and disease. And finally, the linkage between energy expenditure and finding food (or finding anything else) has been almost eliminated. Thus, while the ancestral food environment focused on shortage and short-term consequences of eating, the modern environment stresses overabundance and long-term consequences.

Culture is the most powerful determinant of human food choice. More can be learned about an individual's food attitudes and preferences from his or her cultural identity than from any other single piece of information. Food choice is highly constrained by availability and cost, and both of these are primarily determined by culture. In addition, since availability and cost control exposure to food, they indirectly affect the developing of liking for foods, since that is substantially determined by exposure.

Cost and availability aside, human preferences and food attitudes can be framed by a psychological (as opposed to nutritional) taxonomy of foods, developed by Paul Rozin and April Fallon. A basic distinction can be drawn between preferences based on liking, that is on the intrinsic, sensory properties of foods, and instrumental preferences, based on the consequences of eating particular foods. There appear to be three types of reasons for rejecting or accepting a food: sensory-affective, that is, how pleasant a food tastes and smells; anticipated consequences, what the expected consequences are of eating a food; and ideational, what is known about a food (for example, where it comes from, what the nature of it is).

Food rejections can be understood in terms of the selection and interplay of these reasons. One category of rejections is called 'distaste.' These are entities rejected because of negative sensory-affective properties, such as lima beans, broccoli, beer, or chili pepper, for those who find these foods distasteful. A second category is 'danger.' These are things rejected primarily because they are believed to be harmful, because of acute or long-term consequences. The emotion of fear is often associated with their consumption. A third category of rejected things—the largest category—is called 'inappropriate.' These are things that the culture labels as inedible, such as

pencils, grass, paper, or cloth. They might taste good, and might be harmless, but they are rejected for ideational reasons. The fourth category is 'disgust.' Rejection of food as disgusting is, like the previous category, based on ideational, culturally transmitted information but, unlike inappropriates, there is a strong belief that disgusts taste bad and are harmful. Unlike the affectively neutral response to inappropriates, the response to disgusts is strongly negative and emotional. Disgust is the most powerful reaction people have to food. Disgusting entities are so powerful that if they touch an otherwise acceptable food, they render it undesirable, disgusting, and inedible (the principle of contamination or contagion; see *Disgust, Psychology of*).

On the positive side, there are four comparable categories. Good taste (acceptance principally because of sensory properties), beneficial (acceptance largely because of consequences), appropriate (acceptance because it is culturally designated as food, or food for a particular occasion), and transvalued (food enhanced because of its prior history). The transvalued category is much weaker and smaller than the disgust category, in most cultures. In Hindu India, food that has been 'shared' with the gods (via donation to the priests in the temple, and then returned, in part), called *prasad*, is an example of transvaluation.

3. The Acquisition of Food Preferences

For newborn infants, the only functioning categories are good taste (e.g., sweet) and distaste (e.g., bitter). Generally, infants will place in their mouth anything that might fit in, including feces and potentially toxic foods. They reject only on the basis of sensory properties. Gradually, they acquire distastes or good tastes, and learn about danger and beneficial foods. It is much later that the full manifestations of disgust appear. The full adult categorization is in place by roughly five to eight years of age.

Most is known about the distinction between distaste and danger. When ingestion of a food is followed by nausea, it tends to become disliked, that is, a distaste. However, if ingestion of a food is followed by most other negative symptoms (e.g., lower gut pain, skin rash, respiratory distress), the food typically becomes a danger. That is, people reject a food that has caused such symptoms, but it does not usually become a disliked taste. This distinction has also been demonstrated in the laboratory with rats. With respect to affect and emotion, it is notable that dislikes (distastes) and dangers have very different properties, although the outcome (rejection) is the same. The nausea-based acquired distaste (often called a conditioned taste aversion), unlike dangers, is not based on a legitimate sense of danger. Even if a person knows that the nausea/upper gastrointestinal illness was not produced by the food, the aversion remains.

Thus, people who get nauseous and often vomit after a meal usually develop an aversion to some food in the meal, even if they know that the illness was simply the onset of influenza.

The acquisition of good tastes is more complex and less understood. Mere exposure to a food, in itself, often seems sufficient to produce an acquired like. In addition, the pairing of a food with an already positive event (an already-liked food mixed with it, positive regard by a respected person, a pleasant environment), by a process called evaluative conditioning, can lead to acquired likes (or acquired dislikes, if the paired events are negative, as in conditioned taste aversions). Leann Birch has demonstrated that indications of liking by a significant other (peer, older child, teacher, parent) may cause acquisition of liking. The process at work here is not understood. It could be a form of evaluative conditioning. But it also may involve an important instance of communication of affect or emotion. The expressed pleasure by a significant other, on consuming a food, may directly induce a pleasant state in an observer, or it may induce a mimicked positive facial expression. Either of these responses may cause enhancement of liking. Birch has demonstrated, in the laboratory, that efforts by adults to promote liking by emphasizing the beneficial consequences (better health, a specific reward for eating) seem to block the acquisition of liking for the food. It seems that when a child observes respected others enjoying a food, this promotes liking; when she is rewarded for consuming it, this seems to block the acquisition of liking.

The acquisition of knowledge of appropriate and inappropriate foods seems to be largely cognitive, and affect free. The affect-laden acquisition of disgust contrasts with this. Some communication of affect (facial and other) is almost certainly involved, but there are also important cognitive aspects; it is the nature of the foods and their history that is central to this category. Disgusting foods have contamination properties. This property requires a realization that appearance does not equal reality: a contaminated food looks like any other food, but is distinguished by its history. Young children have difficulty making the appearance–reality distinction, and it is only by age four to seven that we see signs of the ability to appreciate contamination, and hence disgust.

Individuals in specific cultures develop likings (the good taste category) for some foods that are innately unpalatable (e.g., bitter, very strong tasting, irritating). Innately unpalatable foods are typically among the favorite foods: chili pepper, black pepper, ginger and other irritant spices, coffee, bitter chocolate, tobacco, alcohol, burnt foods, and highly salted foods. Such reversals of innate aversions are common in humans, and rare in animals. We do not know how these preference reversals occur. In part, it may be through the same processes that produce normal likes: mere exposure, evaluative conditioning, and social approval. But there may also be special mechanisms that

are involved in preference reversals. One is that innately negative foods may come to produce the secretion of endorphins, chemicals secreted in the brain in response to pain and irritation. These may modulate the displeasure, and like their pharmacological analog, morphine, can produce pleasure. Normally, one ceases to interact with a bad-tasting food. However, cultural forces continually reintroduce innately unpalatable foods to the child. It may be that with repeated exposures, the body endorphin response becomes stronger, and eventually cancels and then overwhelms the displeasure. Another account is that it is the very displeasure that is the source of the pleasure. This places liking for innately unpalatable foods in the same category as thrill-seeking activities such as roller coaster riding. That is, humans get pleasure out of situations in which innate aversions or fears are stimulated, but in which there is no real danger. Roller coasters are safe, and so is chili pepper. This may be case of pleasure derived from ‘mind-over-matter.’

4. *Family Influences and the Family Paradox*

There are strong arguments for high parent–child resemblance in food habits. There is the common genetic heritage, the fact that parents control access (and hence exposure) to foods, and that the principal affective signals about foods in early life come from the parents. Yet parent–child correlations in liking for foods are very low, in the range of 0 to 0.3, in comparison to parent–child correlations in values (such as attitudes to abortion), temperament, or abilities. These low parent–child correlations appear whether the children studied are four-year-olds or college students. This family paradox cannot presently be explained. However, it suggests that the second six years of life, when children are much more heavily influenced by peers and teachers, as opposed to parents, may be more critical for establishing adult preferences than the first six years.

5. *Preferences and Values: Moralization and Vegetarianism*

Selecting and consuming a food has social and moral implications, as well as physiological consequences. The source of a food (e.g., who prepared it, animal or vegetable origin) can powerfully influence acceptance. Particular food or food product boycotts in recent decades testify to this fact. Hindu Indian concerns about food fall largely within the moral domain. In the United States, there is a long history linking particular foods with the good life or immorality. Through the process of moralization, choice of a particular food may move from the domain of preferences to the domain of values. This has clearly happened with cigarette smoking in the United States, and it fre-

quently happens in the course of developing vegetarianism. For some vegetarians, eating of animals is an immoral act. When ingestion of a food becomes moralized, censure of consumers becomes licensed and governments and institutions may take limiting or prohibiting actions. Such foods often become offensive (disgusting), and the rejection becomes intrinsic as opposed to instrumental.

6. Food, Fear, and Pleasure: Cultural Perspectives

In the non-human animal world, and among traditional humans, food is basically a source of pleasure. Even in the developed world, cost and availability aside, the principal factor influencing food choice is taste, that is to say, pleasure. Convenience and health issues are also important determinants. However, with the major changes in the human environment in the First World, obesity and the consequences of long-term exposure to particular diets have become more salient. As a result, the earlier simple pleasure of eating has given way, for many people, to ambivalence, or even outright fear. This is most well developed in American women, who often fear food as much as they savor it. In some, there is now embarrassment and guilt about consuming high fat foods, great concern about thinness, and great concern about the healthfulness of every bite of food. This is not a necessary consequence of the modern environment since, in France, the pleasures of eating still dominate.

P. Rozin

Food Production, Origins of

A bird's eye view of the human career from inception to now reveals four major landmarks: origins of hominids; origins of *Homo sapiens sapiens*; origins of food production; origins of urbanized, state-based civilizations. Like the other categories of origins research, the emergence of the first farmers and herders has long attracted attention from archaeologists, anthropologists, historians, and other scholars. Early in the twentieth century, a prominent archaeologist, Vere Gordon Childe, discussed the origins of agriculture in arid western Asia at the end of the Ice Age (Childe 1936, Chap. V 'The Neolithic Revolution,' and 1942, Chap. III 'Neolithic Barbarism'). It was not Childe, however, but another archaeologist who set himself the task of actually digging up evidence for the food producing revolution in western Asia.

1. The Origins of Food Production in Western Asia

Shortly after the end of World War II, Robert J. Braidwood (1960) organized the Iraq-Jarmo Project aimed at excavating the oldest agropastoral community known anywhere in the world at that time: Jarmo in Iraqi Kurdistan. Braidwood's expeditions to Jarmo between 1948 and 1955 are famous for their interdisciplinary nature, and for his suggestion that food production in western Asia began in environments like that of Jarmo, a situation he described as 'the hilly flanks of the Fertile Crescent.' He was referring to the foothill and piedmont zone, extending from the Levantine coast along the southern slopes of the Taurus and down the westerly face of the Zagros Mountains, where wild species ancestral to the earliest plant and animal domesticates were distributed.

Following Braidwood's example, interdisciplinary, international archaeological teams undertook intensive research on agricultural origins in the hilly flanks and other regions of western Asia. The work is ongoing today wherever political conditions permit; hence the evidential base is continually changing. At present, however, it appears that the first recognizably domestic food plants are small grains (rye, wheat, barley) and legumes (lentils, peas, vetches) from sites in the Levant, and in the hilly flanks zones of northwest Syria, southeastern Anatolia, and northern Iraq. Archaeobotanist Daniel Zohary (1996) thinks that most of the founder crops (wheat, barley, and legumes) were domesticated only once or twice, and then spread both east and west. The first domesticated food animals are sheep and goats from sites in the Zagros mountain portion of the hilly flanks, pigs and cattle appearing later. Although the archaeological and paleoenvironmental data are by no means unambiguous, most scholars invoke climatic factors prominently (especially fluctuations between warmer and colder intervals in the aftermath of the last Ice Age) to explain how and why food production arose in western Asia (for further details see Bar-Yosef and Meadow 1995, Miller 1992, Harris 1998, Hillman 2000).

2. The Origins of Food Production in other World Areas

Systematic research on agropastoral origins is now widespread around the globe. Interdisciplinary archaeological projects are recovering evidence for early food production in Africa, South and East Asia, New Guinea, and the Americas. At present, it appears that there may have been no more than seven independent trajectories to agriculture, or agropastoralism during the Early and Middle Holocene (i.e., between 10,000 and 5,000 years ago). A brief global survey follows.

2.1 Africa

The lower and middle Nile Valley portion of northeastern North Africa is linked to agropastoral developments in western Asia. Domestic species of wheat, barley, sheep, and goat were derived from the Levant by about 7,000 years ago, and were combined with the earlier gathering, hunting, fishing economy. It is likely, however, that cattle were domesticated in the eastern Sahara from local populations of wild *Bos primigenius* by 9,000 years ago. Many of the early herders of cattle, sheep, and goats were probably also systematically harvesting wild species such as sorghum, *Cenchrus* (krem krem), and the oil plant *Canarium*, but in ways (e.g., beating into trays or baskets) that did not result in morphologically identifiable domesticates.

On the present scanty evidence, there are no domesticated plants in Africa outside the Nile Valley prior to about 4,000/3,500 years ago. Domestic pearl

millet (*Pennisetum*) of that date is reported from archaeological sites across central Africa, probably introduced by Saharan herders. Other plants believed to have been first domesticated in Africa include African rice, sorghum, finger millet, tef, enset, and noog. Domestic sorghum and rice are present at the site of Jenne-Jeno in Mali about 2,000 years ago, whereas finger millet, tef, noog, and enset are East African plants first domesticated in the Ethiopian/Eritrean region (by ca. 1,200 years ago for finger millet; no data as yet for tef, enset, and noog).

There are several other plants, including a number of roots and tubers, that were used intensively, extensively, or both in various parts of sub-Saharan Africa, with little or nothing in the way of archaeological histories as yet. In South Africa, agriculture and pastoralism are thought to have arrived in the early Iron Age about 2,000 years ago with the spread of food producers into this part of the continent (for further details see Harlan 1992, Marshall 1998, Wetterstrom 1993, 1998).

2.2 South Asia

The origin and spread of agriculture and pastoralism in South Asia are complex, long-term processes beginning about 9,500 years ago. Most experts think domesticated wheat and barley as well as sheep and goats were introduced from western Asia, but humped cattle (*Bos indicus*) are thought to have been domesticated indigenously by 7,000 years ago, as perhaps were water buffalo.

Agriculture in the northerly portion of South Asia was altered significantly beginning about 4,500 years ago when a series of summer crops were introduced and grown in various combinations with the winter wheat and barley: finger millet, pearl millet, and sorghum, all from Africa; broomcorn millet, foxtail millet, and rice, all probably from East Asia. One other millet was apparently indigenously domesticated by about this same time: little millet (for further details see Meadow 1998).

2.3 East Asia

A great deal of archaeological work has been carried out at early village sites in China since World War II, but only very recently have explicit, systematic efforts been made to obtain archaeobotanical and zooarchaeological materials from them. Most of the present evidence comes from South China and centers upon rice. Of the 14 direct (AMS) radiocarbon dates on rice remains reported by Crawford and Shen (1998), the oldest is 9,000 years bp ('bp' = before present; this is a calibrated date) at the site of Hemudu (on the east coast of China south of the Yangtze delta) with 9,000 to 8,000bp determinations on rice grains at Pengtoushan (in Hunan Province), and the northerly site of

Jiahu (Henan Province). Crawford and Shen say that the people who lived in these three early sites were harvesting rice, but whether it had been planted, or was being reaped from wild stands is unknown. In any case, it appears that rice was probably first domesticated somewhere in the general region of the middle Yangtze River drainage, and domestic rice may have spread to Korea and Japan between 6,000 and 3,000 years ago.

The other indigenously domesticated Chinese grain crops are foxtail millet (believed to have been domesticated by ca. 7,500 (calibrated) years ago at one site in Hebei Province, and at three sites in Henan Province); and broomcorn millet, domesticated prior to 8,500 years ago in the Yellow River drainage. On the present evidence, rice use (and domestication) in the central Yangtze drainage of southern China seems to predate the appearance of domestic millet in the Yellow River drainage.

Even less is known about the origins of domestic food animals in China than about domestic plants, but dogs, pigs, and probably domestic chickens seem to be present in North China sites at about the same time as the millets. Although the data are not very detailed, the origin of food production in China appears to have entailed processes somewhat more like those of western Asia (i.e., a suite of founder species, which then spread widely) than like the patchier, mosaic pattern of Africa and South Asia (for further details see Cohen 1998, Crawford 1992, Crawford and Shen 1998).

2.4 Southeast Asia and the Islands of the Southwest Pacific

Although much of the older literature on the development of Southeast Asian agriculture focuses heavily on rice (now thought to have diffused there from China's central Yangtze River region), there was a complex and important array of early tuber, root, and tree crops in Southeast Asia, New Guinea, and the islands of the southwestern Pacific. Evidence of these is difficult to retrieve archaeologically, and much of the discussion about them revolves around ethnographic, ethnobotanic, and linguistic data as well as delineation of prehistoric agricultural terraces, ditches, and other landscape features. A strong case has been made for landscape modification in New Guinea, presumably in the interests of growing taro and native yam species, long preceding the ca. 3,500 bp expansion of people from Southeast Asia onto the Pacific islands, accompanied by domestic animals (probably dogs, chickens, and pigs) and an array of domesticated tuber and root species (see *Pacific Islands, Archaeology of*). There is, however, considerable disagreement about the exact nature of pre-3,500 bp highland New Guinea agriculture, and how significant it was prior to the arrival of Southeast Asian derived agricultural systems. (Hence, although some scholars regard New Guinea as one of the world

areas that witnessed an independent transition to agriculture in prehistory, that claim is still being debated. For further details see Bellwood 1996, Golson 1989, Hather 1996, Spriggs 1996).

2.5 The Americas: Mexico

Maize is the most famous crop of the Americas, and by far the most complex of the world-class grains domesticated in prehistory. Although its wild ancestor (teosinte) and its origin place (the Balsas River drainage in western Mexico) are generally agreed upon, the exact details and the chronology of initial domestication are still under debate. AMS dates on early maize from excavations directed by Richard MacNeish in the 1960s at two rockshelters in the Tehuacan Valley, Puebla, and from two other rockshelters in the Ocampo region of Tamaulipas have established that none of these specimens is more than about 5,000 years old, previous estimates having ranged from 7,000 to 5,000 bp or even older. Some researchers, persuaded by seemingly early pollen and phytolith data, continue to advocate very early estimates for domestic maize in spite of concerns by other scholars about the dating of these microremains. Similarly, there is lack of consensus on how, and how rapidly, domesticated maize spread north and south from its place of origin.

Archaeological work at the Mexican sites noted above, plus excavations by Kent Flannery in 1966 at another dry rockshelter—Guila Naquitz in Oaxaca—have resulted in information about several other cultigens: squashes, bottle gourd, beans, and chili peppers. Also present at some of these sites are *Amaranthus*, *Chenopodium*, *Agave*, and several root crops and tree fruits thought to have been encouraged and harvested if not actually domesticated in early prehistory. Recent AMS dates on squashes from MacNeish's excavations in Tehuacan and Tamaulipas (*Cucurbita pepo*, *C. argyrosperma*, *C. moshata*) and from Flannery's work at Guila Naquitz (*C. pepo* gourds) have returned 9,000 bp determinations for *C. pepo* there, and 4,000 to 5,000 bp for the other two cucurbits. No fieldwork on early Mexican agriculture comparable to MacNeish's and Flannery's has taken place since the 1960s (for further details see Fritz 1994, Piperno 1994, Smith 1997a, 1997b).

2.6 The Americas: Central and South America

Origins research on early agriculture in the American lowland neotropics is being actively pursued, with new information emerging at a rapid rate. The foci of attention in the lowlands are tubers and root crops (including potatoes, sweet potatoes, yams, and manioc), as well as tree fruits, pineapple, chili peppers, avocados, maize, squashes, beans, cotton, and bottle gourd. Because of preservation problems, macro-

botanical remains are less likely to be recovered from humid regions than from arid locales like those of the Mexican rockshelters. Hence, several researchers have turned to pollen, phytoliths, and starch grain analyses. This is important, innovative work, but does pose serious problems for secure dating, and—because these trajectories are so new—for consensus in identifications and interpretations.

The Andean highlands of South America are very different from the tropical lowlands, but similar in that the origins of food production there are archaeobotanically documented only preliminarily). The crops centrally involved are *Chenopodium quinoa*, squashes and gourds, beans, cotton, maize, and several tuber species including the potato, *Solanum tuberosum*. Early animal domesticates are llamas, alpacas, and guinea pigs. Chronologies and other details are not precise, but quinoa may have been domesticated by 5,000 to 4,000 years ago, gourd and squash perhaps somewhat earlier, common beans by 4,400 bp (calibrated). There are no direct AMS dates for prehistoric finds of possibly domestic potatoes, and the chronology for llama/alpaca and guinea pig domestication is also vague. Estimates for domestication of all three animal species range around the same time as for quinoa, and the potato may have been domesticated about the same period or even earlier.

The arid west coast of South America in Peru and Chile has its own food-producing story to tell, related to that of the highlands in some ways, but with significant differences. Preservation of even very delicate plant parts as well as textiles and human remains makes the archaeology attractive to professionals and to looters. Evidence for plant use begins early at some sites, perhaps as far back as the Early Holocene for gourds, and includes many of the same species referred to above for other areas of South America. The coastal valleys of Peru currently provide the oldest directly dated evidence for beans (one lima bean pod) at ca. 5,600 bp (calibrated); Mexican common and tepary beans are no older than 2,500 bp (calibrated) (for further details see Pearsall 1992, 1995, Piperno et al. 2000, Piperno and Pearsall 1998).

2.7 The Americas: Eastern North America, with Comparative Reference to the Southwestern United States

Since 1980, archaeological and paleoethnobotanical research has shown that an indigenous agricultural system was created in Eastern North America beginning about 4,500 years ago. Sunflower, sump weed, goosefoot, may grass, bottle gourd, and pepo gourd are the initial members of the complex at 3,000 bp, with knotweed, little barley, and tobacco being added several hundred years later. Maize first appears in Eastern North America 2,000 years ago, but is a very minor component of the archaeobotanical record until

ca. 1,200 bp when it became a major staple in communities of the Ohio and Mississippi River drainages. Common beans enter the picture even later (ca. 700 bp). The two gourds are present in a few places 7,000 years ago—well before the rest of the complex appears—but it is not clear whether they were domesticated that early, or were simply being harvested from wild plants. In any case, they were probably domesticated separately from parallel processes in Mesoamerica and South America, just as *Chenopodium* seems to have been domesticated separately in Eastern North America, Mexico, and South America. Fritz (1999) has argued persuasively that the early solo presence of cultivated or domesticated gourds of whatever kind does not mean the gourd cultivators were farmers. Full-scale agriculture may appear much later, as seems to be the case in several places within the Americas.

The archaeobotanical database in Eastern North America—arguably the best in the world—demonstrates use of wild plant and animal foods throughout the entire sequence from early Middle Holocene to the time of European contact. Domesticates appear in differing combinations and at different levels of intensity across space and time in an intricate mosaic.

Formerly, it was thought that the Mexican agricultural triad of maize, squash, and beans diffused north into the southwestern US, then much later moved across the Plains to Eastern North America. It is now abundantly clear, however, that the Southwest and the East were on separate trajectories, each area experiencing its own complex set of developments. Maize did arrive in the Southwest earlier than it appeared in the East (pre-3,000 bp vs. 2,000 bp) with squash and beans arriving perhaps about the same time, but these plants were adopted into very different kinds of pre-existing Archaic societies across the region: some small, mobile, and staying that way, others already somewhat sedentary and becoming more so. In all cases, considerable use was made of indigenous southwestern plants, some domesticated, others semi-domesticated or encouraged, and others harvested from wild stands. The only domesticated mammal was the dog, but turkeys were kept in some places. Hunting of deer, antelope, rabbits, and other small game was very important everywhere throughout the entire prehistoric sequence (for further details see Fritz 1990, Minnis 1992, Smith 1992, Yarnell 1994).

3. Discussion and Conclusions

There is a vast literature on agricultural origins and the development of prehistoric food-producing economies. The actual corpus of empirical, archaeological, archaeobotanical, zooarchaeological evidence about early food production is much, much smaller. Only in Western Asia and Eastern North America is there sufficient data to constrain conjecture in any signifi-

cant way. Nevertheless, it is clear that humans, plants, and animals everywhere were always interdependent in multiple ways, and that there were many specific pathways to food production. The areal sketches provided in the previous section indicate how diverse those pathways could be. The present evidence, viewed from a high level of abstraction, suggests that there were seven world areas where indigenous and distinctive food-producing economies were developed: Western Asia, Saharan and sub-Saharan Africa (perhaps with West African and East African foci), East Asia (perhaps with separate foci in North China and South China), Eastern North America, Mexico, Central and South America (with neotropical and highland foci), and—intriguing but enigmatic—highland New Guinea.

Discussion of early crops in all these places centers heavily upon those that dominate modern world economies (wheat, rice, maize), sometimes to the detriment of understanding the nature and functioning of ancient subsistence systems, whether food producing or not. Given present concerns about the grave dangers of monocropping on an areal, let alone a global, scale, this tendency is doubly unfortunate. Lost crops, lost breeds, and lost varieties of current crops and domestic animals are vital resources for modern agropastoralism, but can be retrieved only through the interdisciplinary work of archaeologists, paleoethnobotanists, zooarchaeologists, on the one hand, and molecular biologists and plant and animal breeders on the other.

Two more issues central to any consideration of ancient food-producing economies are chronology and explanation. Was the origin of food production a nearly simultaneous event around the world triggered by Late Pleistocene/Early Holocene climatic change? Were the causes and processes of all six or seven independent, indigenous transitions to food production essentially the same? How one answers these questions obviously depends almost entirely on how detailed and how secure areal chronologies and areal databases may be. There is, at best, only semi-security for two of the pristine-origins candidates. Nevertheless, one can argue a negative response to both questions. On the evidence of present chronologies, created and continuously refined via heavy dependence on AMS radiocarbon dating, it appears that only in West Asia and East Asia was there significant impact by end Pleistocene/Early Holocene climatic changes to impel intensification of the food-producing sort. In both places, food production economies seem to be phenomena of the earliest Holocene, taking shape in the first two millennia after the end of the last ice age, and spreading relatively rapidly, almost in package form. Elsewhere, when sufficient information is available, chronologies for the origins of food production are longer, with food-producing systems being more fluid and patchy or mosaic-like, varying considerably through time and across space. David

Harris (1996, pp. 557, 568) contrasts the temperate West Asian package (small grains, legumes, sheep, goat) with the vegeticultural systems (roots, tubers, rhizomes) nutritionally (the latter is heavy on carbohydrates, the former also includes fat and protein) and territorially (the former is expansive, the latter is not). Somewhat similarly but from a global perspective, Jared Diamond (1997) points out the great contrasts among geography, flora, and fauna that contextualize subsistence systems in different parts of the world.

Prime movers used to aid explanation of transitions to food production range from the older favorites, climatic or environmental change (see above) and population pressure (e.g., Cohen 1977) to newer models drawn from economics and evolutionary ecology, to competition among lineage or clan heads, or to the necessity of intercommunity trade for forging alliances guaranteeing mutual assistance in hard times (e.g., Bender 1978, Hayden 1996, Price and Brown 1985). Some of these models are quite ingenious, and plausible for specific origins cases, but they do not fit others at all, making them less than satisfactory as general explanations for *the* origin of food production in the human past. That abstraction is very useful for certain purposes, but self-destructs when placed in contact with all the evidential bases now available, meager though many of them are. Although we do not know nearly enough, we do know too much, and what we know is changing too rapidly, to sustain current general explanations for why food production happened in prehistory. We know, for example, that gatherer–hunter–fisher–foragers always manipulated and managed their physical and biological environments, that they often cultivated and/or harvested wild plants, tamed wild animals, and restructured the topography as well as the native plant and animal distributions in their home territories; and that they were quite capable of intensifying any or all of these management procedures if they perceived intensification to be necessary or desirable. We know that in some places and times the kind of intensification we call food production was implemented, but that mostly it was not; that gatherer–hunters could and did coexist for long periods (centuries, millennia) with food producers; and that food producers in some times and places became gatherer–hunters as well as vice versa.

In spite of this chronic mismatch between theory and data, inevitable in a field as broad and lively as agricultural origins research, it is essential that high-level, theoretical formulations be devised and tested against independent relevant data, explicitly sought if not already available, because that is the most efficient means to expand knowledge about what, in the abstract, is indeed the most important transition in human prehistory.

Food Security

Food is undoubtedly one of the most basic human needs. Access to enough food to lead an active and healthy life is also one of the most fundamental human rights. Although the global food supply is generally satisfactory, the basic food needs of hundreds of millions of people are not satisfied, and the right to food is widely neglected. This article defines food security, assesses the current and future world food situation, and presents theoretical and conceptual approaches to analyze food security from the perspective of the social and behavioral sciences.

1. Definition of Food Security

Although nutritional scientists distinguish between 'food security' (availability of food on global, national, local, and household levels), on the one hand, and 'nutrition security' (satisfactory nutritional status of individuals), on the other (Oltersdorf and Weingärtner 1996, p. 23), social and behavioral scientists tend to consider 'food security' as a more comprehensive term that incorporates both concepts. This view is evident from most of the definitions available on food security, not only in social science, but also in official GO and NGO documents (see M. Smith et al. 1992). The following World Food Council (WFC) definition may serve as an example:

Food security implies two things. First, it implies that food is available, accessible, affordable—when and where needed—in sufficient quantity and quality. Second, it implies an assurance that this state of affairs can reasonably be expected to continue; or in other words, that it can be sustained. To put it simply, food security exists when adequate food is available to all people on a regular basis (World Food Council 1988, p. 2).

This definition will serve as the base for the following discussion on social and behavioral aspects of food security.

Along the line of this definition, food insecurity implies problems with the availability, accessibility, and affordability of food. This links the concept of 'food insecurity' to the notion of the 'food system'

which is widely used in the discussion of food (in)security (Cannon 1991). Food systems are defined as integrated systems of the four subsystems of production, exchange, delivery, and consumption (Cannon 1991, p. 298).

It is important to distinguish between two kinds of food insecurity, chronic and transitory. The difference between the two is emphasized by a World Bank definition (1986, p. 1):

Chronic food insecurity is a continuously inadequate diet caused by the inability to acquire food. It affects households that persistently lack the ability either to buy enough food or to produce their own. Transitory food insecurity is a temporary decline in a household's access to enough food. It results from instability in food prices, food production, or household incomes—and in its worst form it produces famine.

2. The World Food Situation

A comprehensive assessment of the world food situation by experts from the International Food Policy Research Institute (Pinstrup-Andersen et al. 1997) addresses recent developments, emerging issues, and long-term prospects, and also distinguishes between production, distribution, and consumption issues. On the one hand, in the past couple of years, developments in global food supply, demand, and trade have raised concerns about the world's future food supply. Prices of grain rose rapidly, and at the same time global cereal stocks fell sharply. Many countries of Eastern Europe and the former Soviet Union failed to make significant advances in economic transition and agricultural development. Moreover, flows of food aid and official development finance to developing countries declined. In sub-Saharan Africa, the population growth rate has exceeded the rate of growth in food production considerably. Weather fluctuations and climate change could lead to sizeable food production shortfalls and deterioration in food security in many parts of the world. Declining natural base, first of all growing water scarcity and declining soil fertility, put severe threats on future agricultural development. Stagnating income levels of the poor, high rates of underemployment, and severe cuts in the social security budgets put further stress on the food security of the poor and vulnerable sections of society. South Asia alone is home to around 50 percent of the world's poor and food insecure (ACC/SCN 1997). Moreover, there are escalating concerns about genetic engineering and food quality.

On the other hand, other developments offer glimmers of hope. The United Nations, for example, has once again revised its population projections downward, thus reducing expected pressures on future food supplies. Progress has also been made on international trade liberalization, although developing countries do not equally benefit as developed countries. The World

Food Summit of November 1996 has raised awareness for world food security problems and is expected to stimulate commitments for action.

Projections of food production, distribution, and consumption to the year 2020 offer some signs of progress, but prospects of a food-secure world, a world in which each and every person is assured of access at all times to the food required to lead a healthy and productive life, remain bleak if the global community continues with business as usual (Pinstrup-Andersen et al. 1997, p. 8). Projections for the future world food situation under several scenarios show that, under the most likely scenario, 150 million children under the age of six years will be malnourished in 2020, just 20 percent fewer than in 1993. Projections by the Food and Agricultural Organization (FAO) on the number of food insecure people paint a similarly mixed picture. FAO projects that 680 million people could be food insecure in 2010, down from 840 million in 1990–2. Worldwide, per capita availability of food is projected to increase around 7 percent between 1993 and 2020. However, the future world food situation will be significantly influenced by issues such as rapid urbanization, declining resource base, policy-induced draw down of cereal stocks, and greater variability in agricultural production caused by climate change. Widespread conflict and political instability are increasingly adding to food insecurity in many countries of the world.

To conclude with the IFPRI study (Pinstrup-Andersen et al. 1997, p. 7):

All of these issues suggest potentially larger fluctuations in food production and prices, and higher associated risks of food insecurity for the world's most vulnerable countries and people. The challenge for policy makers, researchers, and others is how best to minimize these risks to achieve food security for all people.

3. Food Security Research and Theoretical Approaches

The scientific debate on the causes of food insecurity was opened by Thomas Malthus (1798) more than 200 years ago. Malthus's basic argument was that the world's natural resources could not assure expansions in food supply that would match population growth. This argument was turned around by Boserup (1965) who postulated that population growth is one of the most powerful driving forces for agricultural development and increased food production.

Experience has proved that Malthus certainly underestimated both technical innovations in agricultural productions and checks in population growth. Although the Malthusian arguments are still prevalent, first of all in the context of the current situation in sub-Saharan Africa, the debate has now shifted away from perspectives of food availability to concerns with food

entitlements. This paradigmatic change can be traced back to Amartya Sen's seminal work on *Poverty and Famines* (1981) which won him the Nobel Prize in Economics in 1998. The entitlement concept has primarily addressed the conditions under which chronic food insecurity collapses into mass starvation and in this sense, it endeavors to provide a theory of food crisis and famine causation. A person must necessarily starve if his/her entitlement set does not include a commodity bundle with enough food; a person is reduced to starvation if his/her endowment or exchange entitlement makes it no longer possible to acquire a commodity bundle with sufficient food (Sen 1990, p. 37).

Sen's entitlement theory can be regarded as a milestone in social science risk research, in general, and in the field of food vulnerability analysis, in particular. However, when addressing issues of vulnerability to food insecurity and famine, recent debates have clearly shown that there can be no single theory of food (in)security, because the problems are simply too complex. Consequently, Watts and Bohle (1993) and Downing et al. (1994) have tried to integrate three theoretical vantage points, namely human ecology, entitlement theory, and political economy, into a comprehensive concept of vulnerability analysis which combines issues of demography, ecology, poverty, empowerment, and long-term structural crisis proneness into one causal model.

A new strand of research is to systematically perceive food systems from two different perspectives, namely an 'external' and an 'internal' side. As Chambers had already pointed out in 1989, vulnerability is:

the exposure to contingencies and stress, and difficulty coping with them. Vulnerability has thus two sides: an external side of risks, shocks and stress to which an individual or household is subject; and an internal side which is defenselessness, meaning a lack of means to cope without damaging loss (Chambers 1989, p. 1).

Contrary to the 'external' side of vulnerability, the 'internal' side of coping is still awaiting a firm theoretical base. Recent empirical research has revealed the enormous complexity in the scope, mechanisms, and efficiency of people's coping strategies for food security (for example, Spittler 1989, Bohle and Adhikari 1998). Thus, concepts are being developed currently that address the structural and behavioral context of coping strategies in more general terms, for example the 'access' model (Blaikie et al. 1994) or the notion of 'assets' as propagated by UNDP (HDR 1997/1999).

4. Future Directions

Although there is a wealth of empirical social science and behavioral studies on food security, their theoretical foundation is still rather weak, especially in the

fields of risk analysis and coping behavior. Moreover, the link between scientific approaches and practical needs is still underdeveloped. The theoretical frameworks are generally not operational for practitioners, although vulnerability analysis as developed by social sciences has become a standard procedure in food security projects and programs. Social and behavioral sciences should systematically provide insights into processes that allow goal-oriented structural changes for enhanced food security (e.g., promoting access and providing relevant assets). Finally, food security concerns have to be integrated more systematically into broader issues of 'human security' (HDR 1997/1999). In the field of transitory food insecurity (food crisis and famines), social and behavioral science has started to develop concepts for early warning and mitigation, such as risk mapping, to contribute to more precise social and geographical targeting procedures for food security. There is still broad scope for social and behavioral science in these fields.

For

Foreign Investment: Direct

Direct Foreign Investment or Foreign Direct Investment (FDI) is defined as the ownership (partial or full) and control of assets in one country by foreign residents. FDI in the USA is defined as the foreign ownership or control of, directly or indirectly, at least 10 percent of the voting securities of an incorporated US business enterprise or an equivalent interest in an unincorporated US business enterprise. Two major forms of FDI are the acquisition of an existing firm or real property or the establishment of new operations. The OECD countries account for most FDI flows in the world. Furthermore, large-scale mergers and acquisitions, particularly between British firms, and US firms have been an important development in the 1990s. The USA is the top ranking country in terms of both FDI inflows and outflows followed by the UK. Other dominant sources of FDI are Canada, Japan and the West European countries. With the exception of Japan, both Canada and West European countries are also the top ranking recipients of FDI. Notable trends in the 1990s include the flow of FDI in East European economies and China in response to national level policy changes towards foreign investments. Another development has been the growth of FDI in East and Southeast Asia in the 1990s by non-Asian firms in response to deregulation, as well as opportunities for low-priced acquisition following the Asian financial crisis. Prior to the Asian crisis, intra-Asian investments dominated FDI flows in East and Southeast Asia.

FDI studies can be classified into two broad categories: (a) analyses of factors affecting the flow of FDI from one country to another country; and (b) the location characteristics of FDI within a host economy. Other important topics include the analysis of the impact of FDI (e.g., employment and technology transfer) in source and host countries. However, due to data limitations, impact analyses are limited to corporate surveys.

Most explanations of FDI have been based on the trans-nationalization process of large USA based multinationals in manufacturing industries (Caves 1971, Hymer 1976, Vernon 1966). In the 1970s and 1980s, the upsurge of FDI from Western Europe, Japan, and the newly industrializing nations, as well as FDI in service industries called for a critique of the existing explanations and further theorization of the determinants of FDI (Dunning 1989, Lall 1983). In

the 1980s, the USA became the top recipient of FDI and several studies focused on the spatial and temporal dynamics of FDI in the USA with a special emphasis on FDI from Japan (Bagchi-Sen and Wheeler 1989, McConnell 1980, O'Huallachain 1985). The worldwide growth of FDI also led to the analysis of multinational activity in other destinations (e.g., the UK, Australia, Eastern Europe, and East and Southeast Asia) (Dicken 1998, Edgington 1990).

1. *Determinants of FDI*

Initially, the principle of comparative advantage was presumed to govern foreign investment flows. However, the neoclassical explanation did not account for the continuation of the bilateral flow of investment among capital-rich nations such as the USA and the countries of Western Europe. The neoclassical explanation of trade also failed to recognize the importance of technology, know-how, and managerial or marketing expertise, as significant determinants of FDI

1.1 *The Industrial Organization Approach*

Hymer's analysis of the trans-nationalization process of firms based on the theory of market imperfections suggested that foreign direct investors must possess specific advantages over competing host country firms (Hymer 1976). These competitive advantages can be derived from the factor market (e.g., discriminatory access to capital, technology, and managerial expertise), product market (through product differentiation and pricing policy), internal and external economies of scale, and government regulations (e.g., limitations on output or entry). These advantages will allow the direct investor to overcome barriers (e.g., the lack of information about local markets, legal issues, infrastructure and logistics, and culture among others) encountered in the host country. Caves (1971) suggested that in order to compete with domestic firms, foreign firms must internalize certain firm-specific advantages, such as patented technology, managerial know-how, marketing strategy, product differentiation techniques and economies of scale. Internalization refers to an extension of firm's activities rather than the externalization of such activities through contracts with independent host country firms. Alternatives to internalization, such as licensing, man-

agement contracts, franchises, and subcontracts are not feasible methods of appropriating firm-specific advantages.

1.2 The Product Cycle Theory

One of the major explanations of the internationalization process of firms as a sequential development is the product cycle theory (Vernon 1966). The product cycle theory explains why market-oriented firms replaced their export markets with direct investment in overseas facilities. The relevance of this theory becomes questionable when a firm's investment approach involves risk diversification through the integration of worldwide operations rather than the dependence on one market alone. Furthermore, some firms do not follow the sequential process and may skip the export phase altogether and undertake a direct investment. In the case of Japanese FDI, some products (e.g., color television) were developed exclusively for the US market. Europeans on the other hand reacted to US investor's pricing strategy in European markets by undertaking FDI in the USA (exchange of threat). The analysis of multinationals from developing countries shows that innovative power and wealth are not necessary preconditions of FDI—these firms often undertake FDI following defensive, imitative, dependent, and opportunist strategies.

1.3 The Eclectic Approach

In recent years, Dunning's eclectic paradigm has been used to explain FDI in both manufacturing and services from all possible sources (Bagchi-Sen and Sen 1997). Ownership, location, and internalization advantages are the three determinants of trans-nationalization (Dunning 1977). Once a firm possesses ownership-specific advantages (knowledge, management-marketing-financial skills, control of resources and markets, and the ability to diversify risks) and successfully internalizes its proprietary know-how, remaining variables that further influence the choice of a destination are location or country-specific characteristics (e.g., market demand, trade barriers). The analysis of firm structure and behavior of US-based, German and Japanese firms by Pauly and Reich (1997) highlights source-country based differences in corporate governance, financing, research and development, direct investment activities and intra-firm trade. The findings emphasize that a global model of internationalization is not the norm.

2. Spatial and Temporal Variations in FDI

Studies on location preferences of foreign investors offer a variety of explanations based on samples drawn from different regions, time periods, and groups of

firms (Hayter 1997). Selected findings from these location analyses over the past three decades are discussed. The most prevalent pattern is the location of foreign firms in the core regions of host countries (Blackbourn 1974, McConnell 1980). These core regions offer economies of agglomeration and lower search cost as well as uncertainty for newcomers. In the USA, for example, the major mode of entry is acquisitions—therefore, core regions are preferred because these regions offer an array of possibilities for mergers and acquisitions. In both developed and developing countries, the large metropolitan centers attract FDI, especially FDI in service sectors (Bagchi-Sen and Sen 1997, Edgington 1990). Latecomers in manufacturing have shown the tendency to locate in emerging industrial spaces (e.g., the preference of foreign manufacturers to locate in the southern and western part of the USA as opposed to the north-eastern and New England states) or sometimes foreign investors create their own industrial corridors in a host country (e.g., the location of Japanese automakers and suppliers in southern Ontario, Michigan, Indiana, Ohio, Illinois, Kentucky and Tennessee in North America). A preference for peripheral areas for new investments is often influenced by the incentive packages offered by state and local governments. Investments by state/local governments to attract Japanese autoproducers ranged between US\$33 million to US\$149 million in the USA. Similar investments have been incurred by local governments in other countries such as Setubal (Portugal), West Midlands and north-east England (UK), and Lorraine (France), among others, (Dicken 1998) to attract automakers from the USA, Korea, and Germany. A further observation is that foreign investors often prefer particular regions based on sector characteristics of FDI, physical proximity of the investor to the host, and personal choice/bias of the decision-maker. For example, Japanese automakers avoided places with existing US auto plants and States where another Japanese autoproducer had located their manufacturing operations.

3. Conclusion

The growth of FDI in the 1990s surpassed the growth of exports in goods and services, world output and gross domestic capital formation. The importance of FDI in host economies cannot be ignored because in several countries FDI's share of gross domestic product is well over 10 percent. Furthermore, the impact of FDI is far reaching. A nation's capital and financial markets, employment pattern, industrial structure and competitiveness, technology, as well as trade and development patterns, are affected by FDI. The nature of the impact depends on the characteristics of FDI (e.g., mode of entry, function, and attributes), the timing of FDI and the bargaining relationship between the foreign entity and the nation state (Cantwell 1989 Dicken 1998).

Foreign Language Teaching and Learning

Foreign language learning and teaching refer to the teaching or learning of a non-native language outside

of the environment where it is commonly spoken. A distinction is often made between 'foreign' and 'second' language learning. A second language implies that the learner resides in an environment where the acquired language is spoken. In the area of research, however, the term second language acquisition is a general term that embraces foreign language learning. Research into the acquisition of a non-native language includes the disciplines of psychology, linguistics, education, neurobiology, sociology, and anthropology. Inquiries of learning and teaching innovations have provided new insights into successful language learning strategies and environments designed to increase language achievement and proficiency.

1. Definition

A language is considered foreign if it is learned largely in the classroom and is not spoken in the society where the teaching occurs. Study of another language allows the individual to communicate effectively and creatively and to participate in real-life situations through the language of the authentic culture itself. Learning another language provides access into a perspective other than one's own, increases the ability to see connections across content areas, and promotes an interdisciplinary perspective while gaining intercultural understandings. Language is the vehicle required for effective human-to-human interactions and yields a better understanding of one's own language and culture. Studying a language provides the learner with the opportunity to gain linguistic and social knowledge and to know when, how, and why to say what to whom (National Standards in Foreign Language Education Project 1996).

Language scholars distinguish between the terms acquisition and learning: 'acquisition' refers to the process of learning first and second languages naturally, without formal instruction, whereas 'learning' is reserved for the formal study of second or foreign languages in classroom settings. One usually distinguishes between the relatively effortless process of second language acquisition by children and the more formal and difficult second language acquisition by adults. Foreign language education refers to the teaching of a modern language that is neither an official language nor the mother tongue of a significant part of the population.

2. Theories of Language Learning

Foreign language learning and teaching have undergone a significant paradigm shift as a result of the research and experiences that have expanded the scientific and theoretical knowledge base on how students learn and acquire a foreign language. Traditionally, learning a foreign language was thought to be a 'mimetic' activity, a process that involved students repeating, or imitating new information. Grounded in

behaviorist theories of learning and structural linguistics, the quality and quantity of language and feedback were regarded as the major determinants of language learning success. A popular method of teaching in the 1950s, called the audio-lingual approach (ALM), promoted an imitation and practice approach to language development. The major figure in the ALM classroom was the instructor who was cast into the role of drill sergeant, expert, and authority figure. Students were relegated to practicing and imitating patterns to a point of automatic response in the belief that the learner would then merely have to slot in lexical items appropriate to the conversational situation. It was believed that the first language interfered with the acquisition of the second language and that a transfer would take place from the first to the second language, resulting in errors. In 1959, Noam Chomsky's review (Chomsky 1959) of B. F. Skinner's (1957) *Verbal Behavior* dramatically changed the way of looking at language by arguing that language was a rule-governed activity, not a set of habits. Chomsky argued that stimulus-response psychology could not adequately account for creativity involved in generating novel utterances using internalized rules. The creative aspect of language behavior implies that the human mind is involved in deep processing of meaning rather than in memorized responses to environmental stimuli. Chomsky's view of language and cognitive psychology, dubbed generative transformational grammar, regarded language acquisition as an internal thinking-learning process. Chomsky claimed that children are biologically programmed for language and have an innate ability to discover for themselves the underlying rules of a language system. Chomsky's ideas led to the demise of structural linguistics, behaviorist psychology, and the ALM approach to language learning.

An alternative theoretical position emerged centered on the role of the linguistic environment in combination with the child's innate capacities in acquiring language. This position (interactionist) viewed language development as the result of a complex interplay between innate language capacities of the learner and the learner's environment. Unlike the innatist position (e.g., Chomsky 1959), the interactionists claimed that language had to be modified to the ability of the learner. According to Long (1985), language input was made comprehensible by simplifying the input, by using linguistic and extralinguistic cues, and by modifying the interactional structure of the conversation. Long maintained that speakers adjust their language as they interact or negotiate meaning with others. Through negotiation of meaning, interactions are changed and redirected, leading to enhanced comprehensibility. Long proposed that learners, in order to acquire language, cannot simply listen to input, rather they must be active co-constructive participants who interact and negotiate the type of input they receive.

Each of these theories of language acquisition addresses a different aspect of a learner's ability to acquire a language. Behaviorist explanations explain systematic aspects, whereas innatist explanations explain the acquisition of complex grammar. Interactionist explanations assist in understanding how learners relate form and meaning in language, how they interact in conversation, and how they use language appropriately.

3. *Emphases in Second Language Research and Teaching*

Research has revealed that knowledge of language structures demonstrated on discrete-point tests does not ensure communicative ability when the measure of language knowledge is one of more spontaneous language use. Further studies have shown that there is little correlation between the rules learners are taught and their developing knowledge of the second language. Language scholars have demonstrated that certain aspects of second language learning cannot be altered through instruction and that intermediate, non-native-like second language competencies, known as stages of interlanguage, characterize the progression of second language acquisition. Selinker (1974) viewed interlanguage as an intermediate system located on a continuum stretching from the native language to the target language. Corder (1978) stated that, in the interlanguage process, the learner constantly and progressively adjusts the native language system to approximate the target language system more closely (restructuring continuum). Corder noted that not all learners showed evidence of transfer from native language to target language and suggested that there was a uniformity about the way second language learners progress and that they follow approximately the same sequence of development regardless of their native language (developmental continuum). According to this view of second language acquisition, the controlling factor is the innate ability for learning language that all human beings possess. Pica (1983) determined that all language learners progressed through a fixed series of stages, known as developmental sequences, in learning particular linguistic subsystems, such as word order, negation, or relative clauses. In English negation, for example, when communicative samples were examined, it was revealed that both foreign language and second language learners progressed through the same four-stage sequence, defined in terms of placement of negation. Ellis (1986) reviewed several studies that involved Japanese, Spanish, German, and Norwegian children, adolescents, and adult learners. He concluded that all English-as-a-second language learners pass through the following prescribed set of stages: (a) no + phrase, e.g., 'No drink'; (b) negator moves inside the phrase, e.g., 'I no can swim'; (c) negator is attached

to modals, e.g., 'I can't play this one'; and (d) auxiliary system is developed and learner acquires correct use of not and contractions, e.g., 'He doesn't know anything.' This suggests that learners make particular kinds of errors at particular stages in the acquisition of a structure. Each stage marks some kind of restructuring in the mind of the learner regarding that particular structure. Structure evolves over time. These studies had significant implications for how foreign languages should be taught.

4. Learner-centered Instruction

Two communicative approaches, the input model and the input interaction model represent two models of foreign language theory and teaching that investigate the language acquisition process from the perspective of the learner. Krashen (1982) is the principal advocate of the input model of foreign language teaching. His theory is grounded in (a) Chomsky's generative linguistics, (b) research on the effectiveness of different second/foreign teaching methods, and (c) research on affective factors (motivation, anxiety, personality, etc.). Krashen posited that second language acquisition occurs when the learner comprehends the language input in a low-anxiety, high-motivation situation, and proposed that the teacher's role is to create such a learning environment. Krashen further claimed that conscious grammar teaching/learning is effective only in a monitoring capacity to check for grammatical accuracy, not in the acquisition of the second language itself.

Because classrooms remained a major setting for language learning, the pursuit to determine those elements that enhanced classroom language achievement became particularly important. Why do two learners who seemingly have the same instructional opportunity achieve varying levels of language proficiency? Investigations focused on individual skills or abilities and environmental factors that may impact foreign language achievement and proficiency.

Individual cognitive (e.g., intelligence, aptitude, or ability) and affective (e.g., attitude and personality variables) factors were analyzed. Skehan (1986) noted a fairly strong relationship between cognitive variables such as aptitude, intelligence, and language achievement for learners in foreign language classrooms. The predictive power of such traits, however, decreased as the criteria for language proficiency became more communicative and the learning setting became more natural (versus formal and instructional). The most avid pursuit in research occurred in investigations of the role of motivation in learning language and the learner's attitude toward the target language and culture. Using Gardner and Lambert's (1972) differentiation between integrative and instrumental motivation, researchers reported no significant advantage for an integrative (intrinsic) motive and others

reported an advantage when the learner was driven by instrumental (extrinsic) motives. Integrative motivation was defined as one in which the target language was being learned by an individual in order to be accepted by the native speaker community. Instrumental motivation was one in which the language was being learned for external benefits, such as securing a better job.

Results of studies investigating environmental factors reported on the effect on achievement scores. Carroll (1975) conducted a survey of French instruction in eight countries and noted effects on achievement by gender, school type, and teacher gender, and mixed effects according to parental interest. Social factors outside the school were determined to have a significant impact on the development of language proficiency. Both cognitive and affective factors were investigated to explain the variance in foreign language achievement. Motivation, attitudes, anxiety, self-esteem, tolerance of ambiguity, risk-taking, cooperation, and competition proved to be key variables that explained individual differences in foreign language learning (Ellis 1994). Successful language learning was determined to be largely dependent on who was learning the language, under what circumstances, and for what purposes. Foreign language acquisition was revealed to be a complex, multidimensional process influenced by both learner and environment variables. The questions generated by these theories and research studies began to focus on significant new responsibilities on the part of the teacher in the design and support of individual and personalized learning tasks.

5. Learning and Measurement

Language teaching throughout the 1990s has experienced numerous curricular innovations in response to the importance of providing students with opportunities to acquire and practice the foreign language in contextualized and meaningful language communicative tasks at all stages of the second or foreign language acquisition process. Communicative language teaching (CLT), the term most associated with current discussion of method, emerged as a significant approach that found universal resonance and support in theory and application in many contexts and across disciplines (linguists, methodologists, curriculum developers). Central to the rise of CLT was the realization that linguistic competence does not on its own achieve communicative competence (Canale and Swain 1980) and that language used in meaningful, authentic contexts is more readily acquired.

Pair work, group work, cooperative/collaborative learning settings, authentic materials, culturally integrated lesson content and interactive tasks focused on the cognitive and affective domains were integrated into foreign language classrooms. Constructivist

teaching practices, influenced by Vygotsky's emphasis on social interaction in learning and development, helped learners to internalize and reshape new information. The theoretical underpinnings of Vygotsky's (1978) view of language learning that maintained contextualized input in cooperative, meaningful interactions with others enhanced language acquisition took hold in classrooms around the globe. The interaction between an expert (teacher) and novice (learner) in a problem-solving task (scaffolding) in which the expert's role was to provide the novice with scaffolded help became the model for communicative tasks in the foreign language classrooms. The expert's/teacher's role was to gain the learner's interest in the task, simplify the task, keep the learner motivated, point out important features, reduce anxiety and frustration during problem solving, and model appropriate form.

In accordance with the new responsibilities, the role of the classroom teacher shifted to that of an architect, creating meaningful, interactive, cooperative learning tasks designed to engage the learner actively in negotiating language meaning in authentic contexts.

The focus on student language proficiency as measured through performance-based tasks made itself felt both in language learning research and in teaching. Questions emerged regarding how language proficiency could be enhanced and how best to measure the level of language proficiency.

As the proficiency movement gained momentum in the 1980s, most especially in the USA, consensus was sought about describing and measuring language abilities. The development of the Provisional Proficiency Guidelines by the American Council on the Teaching of Foreign Languages (ACTFL) defined what language users are able to do with language in speaking, listening, reading, and writing at various levels of performance. These Guidelines marked a major shift in language pedagogy from methodology to measurement and a focus on learner outcomes. In 1996, content standards were published (National Standards in Foreign Language Education Project 1996) that delineated what learners should know and be able to do. More recently, the ACTFL Performance Guidelines for K-12 Learners (ACTFL 1999) described language performance within three modes of communication (interpersonal, interpretive, presentational) to assist teachers in understanding how well students demonstrate language ability at various points along the language-learning continuum. A similar effort by the International Association for the Evaluation of Educational Achievement's Language Education Study is seeking a comparison and evaluation of the outcomes of different educational systems across Europe. The Standards Movement, seeking to promote the establishment of guidelines for the teaching of foreign languages for all learners, indicates the growing concern with learner outcomes and accountability. In a standards-driven environment the shift to

student performance will require that teachers have a repertoire of approaches that target specific goal areas or standards.

6. Future Directions

Future directions in research should investigate the potential use and effect of computer technology on foreign language learning. As classroom tasks become more focused on real-world issues, texts, or events, and problem-solving-based tasks, computers introduce a new dimension to the teaching and learning process. Technology allows students to manipulate learning materials/language at their own pace and according to individual needs. Students examine reports, authentic documents and web pages to find information that can be synthesized and discussed later and can collaborate electronically with youth from around the world. In such a learning environment the role of the teacher changes from one of authority figure/expert who delivers knowledge to one who facilitates guides and supports student learning. The teacher assumes greater responsibilities in designing and supporting individual and personalized learning tasks. This has tremendous implications for teacher educators and teacher trainers to act as agents of change.

One of the most effective research methodologies that emerged in the last few years has been action research. Inquiring into one's own instructional practices through classroom-based investigations, teachers actively contribute to the research endeavor and change practices based on findings. Such research promises to improve teaching practices that are of interest to both researchers and teachers.

Methodologically classroom-oriented research has been largely conducted within the framework of correlational approaches, case studies, survey research, ethnographic research, experiments, and discourse analysis (Johnson 1992). While the choice of research method is largely determined by the nature of the research question to be investigated, or by the hypothesis to be tested, thoughtful combinations of qualitative and quantitative research on foreign/second language learning conditions will provide valuable insights into language-acquisition processes. Greater use of qualitative methods investigating students in their classrooms with special attention to cultural, situational, and longitudinal contexts is needed and recommended. As foreign language research draws on related disciplines (psychology, psycholinguistics, neurobiology, neurolinguistics, sociology, linguistics) to better explain conditions that lead to greater language proficiency and differential success among foreign language learners, a deeper understanding of how languages are acquired and consequently how they should be taught will be gained. As learning and teaching innovations are

tested and researched, new insights will be gained that will influence teaching practices globally.

Foreign Policy Analysis

What causes states to adopt certain foreign policies? Why do some nations seek to extend their influence abroad while others define their interests in narrower,

more inwardly focused terms? Statesmen, historians, and political scientists have long pondered these questions. Though there is no shortage of answers, most observers have followed one of two distinct paths: the first emphasizes states' external or international situation; the second stresses their internal or domestic makeup. This article examines each of these traditions or approaches in turn.

1. Realpolitik

'Realism,' which emphasizes a state's relative position in the international distribution of power, is usually regarded as the dominant approach to the study of foreign policy. Certainly, it is the oldest. Ever since Thucydides (1972) wrote about the Greek city-states' struggle for power and security, many have embraced realism's basic postulates as the best guide to explaining state behavior: anarchy is the basic, irreducible fact of international life (Waltz 1959). In the absence of a central authority to settle disputes over territory and wealth, states must provide for their own security and welfare. Exactly how they go about this, and the conditions that make success most likely, are the central issues animating realism.

1.1 The Classical School

Although scholars classify realism into different variants ('offensive' and 'defensive' realism and 'classical' and 'structural' realism), in the foreign policy field, the term is most often associated with classical realists, scholars like E. H. Carr (1939), Nicholas Spykman (1942), and Hans J. Morgenthau (1978). Writing during the years between World Wars I and II, these self-proclaimed realists sought to catalogue the 'do's' and 'don'ts' of international power politics. Their work continues to be a touchstone of realist thinking about foreign policy.

Classical realists start from the assumption that states are influence-maximizers: they seek, first and foremost, to control and shape their external environment and, all things being equal, will seek more rather than less influence. How ambitious and single-minded their leaders are in this regard depends on many things, but for the realist none is more essential than a nation's power, or more precisely, its relative power, where power refers to its share of material resources such as military strength, world trade, and population.

For realists, power is indispensable. Knowing how much a nation has, they argue, tells much about the foreign policies it will likely pursue. In general, as states' international power or capabilities increase, they will seek to extend their political interests abroad; as their power ebbs, their actions and aspirations will be scaled back accordingly. In short, power

shapes intentions: the stronger the state's international position, the more expansive its foreign policy interests will be.

1.2 Realism's Strengths and Weaknesses

One of realism's great virtues is that it reminds us of the importance of power in understanding state behavior. Big changes in a nation's international position—such as Britain's rise to great powerdom in the late eighteenth century, Germany's ascent under Otto von Bismark after 1870, and American dominance after World War II—can lead to big changes in its foreign policies. The theory that a country's power determines its intentions is crisp and parsimonious, and much of realism's appeal stems from this fact.

A major weakness of realism, however, is that it is underdetermining. A nation's international position may well create incentives for action. But rarely is a state's 'relative power' vis-à-vis its allies, competitors, and neighbors clear and unambiguous, and rarely is there a consensus among its leaders over the appropriate response to foreign policy opportunity or challenge. For every rising state that has acted as realism predicts, there is one that has not. The same is true about states in decline (Kennedy 1987). Declining powers often continue to expand abroad, failing to make the adjustments realism predicts. Sometimes this results in disaster as realism would predict, but sometimes they get away with it.

Realists try to address this shortcoming in one of two ways. The first involves substituting 'elite perception' about international strength for objective reality. By dispensing with objective measures of power in favor of policy makers' perceptions of power, it is possible, realists contend, to explain gaps or lags in a country's response to increases (or decreases) in its power as assessment failures (Friedberg 1988, Jervis 1976). Strategic miscalculations or misjudgments arise because of difficulties inherent in judging military strength, commercial prowess, and so on accurately.

A second solution to the problem of indeterminacy involves the introduction of domestic decision-making structures into the model. Even if leaders assess their nation's power correctly, they may not be able to respond appropriately because of domestic institutional constraints (Krasner 1978, Zakaria 1998). The weaker (i.e., the more fragmented and decentralized) a state's political institutions, the harder for its leaders to mobilize internal resources and act with dispatch. Here, state strength functions as an 'intervening variable,' mediating the transmission of capabilities (realism's independent variable) into behavior (its dependent variable).

Such efforts to bring theory and reality into line are useful. But introducing variables such as elite perception and state strength also carries a methodological price, most notably a loss of parsimony. One

needs to know a great deal about the country in question, as well as its decision makers, to make the theory work. Even more serious is the inevitable loss of distinctiveness that accompanies such broadening of the theory. The more realists turn to domestic variables, the harder it becomes to distinguish *Realpolitik* from its competitor: *Innenpolitik*.

2. *Innenpolitik*

If relative power in the international arena is realism's core idea, *Innenpolitik*'s is domestic political structure. Like realism, this approach claims that the context in which foreign policy decisions are made shapes policy. Where they differ is how they understand 'context' or, more accurately, in their judgment about which setting, the international or the domestic, should receive pride of place in the analysis. For realists, a state's external situation is determinant; for *Innenpolitikers* a country's internal makeup is decisive.

2.1 Many Theories, One Approach

Like realism, *Innenpolitik*'s roots are European. The approach traces its origins back to early-twentieth-century accounts of British imperialism and German *Weltpolitik*, though at least one variant of the general approach, the so-called 'democratic peace theory,' can be traced to Immanuel Kant's discourses. Vladimir I. Lenin's (1916) theory of colonialism, and economist Joseph A. Schumpeter's (1955) theory of imperialism are classic examples of the *Innenpolitik* genre. In the North American context, the earliest example is historian Charles Beard's (1934) revisionist account of America's entry into World War I.

As these examples suggest, *Innenpolitik* is less a single theory than a family of theories, each stressing a different, specific domestic variable in the explanation of foreign policy outcomes. Some argue for the importance of a nation's culture, others its socioeconomic structure, and still others its political institutions. What ties these theories together is the common assumption that foreign policy is best understood from the 'inside out,' as a product of domestic conditions and circumstances.

In its strongest forms, *Innenpolitik* makes predictions about foreign policy based solely on information about a state's domestic makeup. The notion that democracies behave differently from non-democracies is a popular, if overdrawn, example. A more subtle version of the argument is democratic peace theory (Doyle 1983). Liberal institutions and norms, it is claimed, make democracies less inclined to fight each other, even if they show no such reluctance when dealing with authoritarian regimes.

The key distinction in democratic peace theory is regime type—democratic or authoritarian. How war-

prone states are depends upon their domestic political institutions. The implication is clear: change a state's domestic structure, and its foreign policy behavior will change accordingly. International conditions, while not completely ignored, are secondary. They neither constrain nor dictate foreign policy; they provide opportunities. Whether states seek to exploit international opportunities or not depends on how constrained or motivated their leaders are by 'checks and balances,' interests of domestic constituencies, and pressures to gain office in a competitive political environment.

A focus on states' domestic makeup also informs many theories of imperialism, the most well-known of which, Marxism, claims that capitalist states, due to problems of overproduction and underconsumption, are more prone to expansionism than non-capitalist ones. Whether or not they pursue an aggressive imperialist foreign policy, and how likely they are to succeed if they do, may depend on the international balance of power, but their expansionist impulses do not. They are internally generated. Again, domestic structure is determinative.

2.2 Choice and Decision-making

Theories of democratic peace and imperialism are structural theories, and in this regard are like realism. Strictly speaking, information about the beliefs, perceptions, and prejudices of decision makers is unnecessary. For *Innenpolitik*, the implicit claim is that states with similar domestic structures will pursue similar foreign policies. Conversely, dissimilar states will differ in their foreign policies.

The problem is that there are many examples of states with similar domestic structures that have acted differently in foreign policy. The reverse is true, too: dissimilar states sometimes act similarly. It turns out that just as a state's external position rarely precludes a range of responses, its internal makeup leaves room for meaningful choice. To understand how those choices are made, domestic-level theorists, like realists, have sought to incorporate decision-making into their models.

The decision-making theory that has had the biggest impact on the *Innenpolitik* approach to studying foreign policy is 'bureaucratic politics.' A form of interest-group theory, its central claim is that foreign-policy decisions are the result of bargaining among government officials and agencies (Allison 1971). Foreign-policy choices are thus seen as a product of the distribution of power and initiative among governmental actors, which varies by policy issue.

That government officials' choices matter in the making of foreign policy is clear. Yet how useful bureaucratic politics is in explaining those choices is less obvious. One problem is that the decision-making process inside government is not as autonomous and insulated from larger political processes as bureau-

cratic politics theorists would have it: 'palace politics' often reflects larger social interests and powers. Moreover, the theory seems to work best when it matters least: on issues that are not seen as crucial to the state's security, and that are therefore handled mostly inside the foreign-policy-making bureaucracy.

3. The State of the Art

As structuralist theories, realism and *Innenpolitik* both seem to flatten the sense of choice and politics that characterizes statecraft. The future of foreign policy studies lies in finding systematic ways to transcend this problem: that is, to introduce choice and politics into models that recognize that foreign-policy making is constrained by domestic institutions and international balances of power.

Some possible strategies have been proposed. One is to introduce politics by analyzing the uneven impact of international forces on the different constituencies, sectors, or interest groups within one country (Gourevitch 1986, Trubowitz 1998). Groups compete within the framework of domestic political institutions to promote what is, in the final analysis, an inherently partisan vision of 'the national interest.'

Another is Robert Putnam's (1988) solution, which is to envision statesmen as rational maximizers who are engaged in 'two-level games.' Foreign-policy makers must strategize in domestic political arenas, as 'democratic peace' theorists suggest, and at the same time seek stability or advantage in the competitive international settings that are the centerpiece of realist analysis.

Finally, there are constructive theories that dissolve the distinction between 'international' and 'domestic' (Katzenstein 1996). Constructivist writers see 'structural constraints' themselves—understandings of international power balances, state interests, and domestic priorities—as the product of ideologies, cultural bias, and discourses about state and nation.

The main empirical challenge for foreign policy analysts is to figure out ways to conceptualize 'international context' and 'national interest' at a time when international relations is fluid and dominated increasingly by forces not controlled directly by governments (such as international capital flows), and when traditional definitions of security must be broadened to include environmental, economic, and other non-state sources of challenge.

Forensic Psychiatry

A number of definitions of forensic psychiatry must be considered. The American Academy of Psychiatry and the Law (AAPL) (1985) endorses the definition of forensic psychiatry adopted by the American Board of Forensic Psychiatry Incorporated which is:

Forensic Psychiatry is a subspecialty of psychiatry in which scientific and clinical expertise is applied to legal issues in legal contexts embracing civil, criminal, correctional or legislative matters: forensic psychiatry should be practiced in accordance with the guidelines and ethical principles enunciated by the profession of psychiatry.

In the preface to the British textbook of forensic psychiatry, its field of operation is defined as

the overlap, interface, and interaction of psychiatry and the law in all its aspects; criminal behaviour, civil litigation, family law, the diagnosis, care and treatment of psychiatric patients where the disorder is associated with abnormalities of behaviour, legislation and numerous other problems such as the management of violence in the study of sexual deviation.

It adds that

forensic psychiatry continues to be concerned primarily with mentally disordered offenders, but now encompasses a wide range of offences and gives much more prominence to diagnosis, management and treatment in prison, hospital or the community using the skills of psychologists, nurses, social workers, and probation officers in addition to psychiatrists.

The Canadian approach to forensic psychiatry mirrors the British definition as is seen in the recent application for subspecialty status by forensic psychiatry under the auspices of the Canadian Academy of Psychiatry and the Law. The goal of forensic psychiatry is defined as

promoting the mental health of Canadians involved in legal matters. We aim to provide a functional interface between psychiatry and the law and to improve Canadian society as a whole through early intervention programs, better diagnosis and treatment and ultimately a reduction in offending.

In twentieth-century Europe, forensic psychiatry has generally centered on advances in the fields of neurology, psychiatry, and sciences related to these disciplines. In general terms, although there is no single definition of forensic psychiatry in Europe, it would tend to follow the British and Canadian approaches. In summary therefore, as we move into the twenty-first century there appears to be a convergence of the American definition of forensic psychiatry with the British, Canadian, and European definitions which relate to the evaluation and treatment of the mentally abnormal offender while at the same time being involved in the psychiatric assessment (for legal purposes) of fitness to stand trial, criminal responsibility in forensic psychiatry dealing with criminal matters, and similar assessments involving the civil aspects of the law. As we approach the twenty-first century, forensic psychiatry in all parts of the world appears to be moving and establishing its roots as a medical specialty and a subspecialty of psychiatry.

Even though the medical roots are emphasized, it is quite clear that the forensic psychiatrists must be familiar with basic issues in law.

1. The Concept

The forensic psychiatrist needs to be an expert clinician as well as being well versed in law and psychiatry as it applies in the jurisdiction where he or she lives. Law is understood to encompass criminal, civil, and mental health law. In medicine as well as the social sciences there is an increasing number of attempts to complete research studies involving large samples in order better to define the characteristics of disease and aberrant as well as normal behavior. This has led to progress in many areas including forensic psychiatry. This allows the individual to be classified according to whether they have certain clinical and other characteristics in common with a certain reference group. An estimate of the individual's personality characteristics can be measured against a reference sample. The difficulty in forensic psychiatry is that the legal system looks at unique characteristics of a given individual before the courts, rather than any theoretical concept of how he or she may fit a given reference group. This can potentially create a conflict where the scientific aspect of forensic psychiatry could be seen as more prejudicial than probative in the context of the legal system.

The development of forensic psychiatry in Britain, Europe, and the United States was based on historical events in the eighteenth and nineteenth centuries. In Britain the writings of Sir Mathew Hale and the trials of Arnold, Ferris, Hadfield, Oxford, and McNaughton were major landmarks in the recognition of forensic psychiatry. The development of the Bethlem Hospital and later Broadmoor as special facilities for the criminally insane were also fundamental to the growth and development of forensic psychiatry. This was extended to other facilities such as the special psychiatric facilities at Rampton and Parkhurst in the early part of the twentieth century.

The development of forensic psychiatry in Europe followed a similar path. Forensic psychiatry emerged from events in the eighteenth and nineteenth centuries. The French Revolution brought to light documents about prisons, workhouses, and civil hospitals being used to detain members of the public. This was directed specifically to the way and rationale for the detention of persons who had been found insane. Concerns over the method of detention led to pressure for scientists of the day to define insanity more precisely. The influence of religion declined and this allowed the scientific roots of modern clinical psychiatry to develop. Philippe Pinel had an enormous influence in his *Medico-Philosophical Treatise on Mental Alienation or Mania*, which was rapidly translated into English and German. This led to a system of classifying mental disorders that was soon adopted in Europe and

England. This helped in the development of forensic psychiatry as it brought more consistency to the testimony in insanity hearings before the courts. Esquirol, Morel, Lombroso, Krafft-Ebing, and others contributed to these important advances. As in Britain, special institutions for the criminally insane were developed and further research occurred in these institutions.

The United States saw a similar development with Benjamin Rush delivering the first lecture on forensic psychiatry under the guise of medical jurisprudence. The lecture covered topics ranging from civil incompetence caused by psychiatric disorder, and financial incompetence, to mental disorder and criminal responsibility. Rush was followed by Beck who in 1823 published *Elements of Medical Jurisprudence*. He referred to British and French psychiatry as well as Benjamin Rush in his book. Isaac Ray followed Rush and Beck and published the *A Treatise on the Medical Jurisprudence of Insanity* in 1838. This was used to defend Daniel McNaughton. Ray's approach in which he carefully studied the law and the judicial opinions of the day—in particular, anything in the law that obstructed the psychiatrically ill (the insane) being able to receive treatment. He became the superintendent of the Maine Insane Asylum and later the Butler Hospital. Perhaps most importantly he was one of the original founders of the American Psychiatric Association, and was its President from 1855 to 1859. In 1869 Ray went on to write a paper *Confinement of the Insane* that has remained fundamental to forensic psychiatry throughout the twentieth century.

In the first place, the law should put no hindrance in the way of the prompt use of those instrumentalities which are regarded as the most effectual in promoting the comfort and restoration of the patient. Secondly, it should spare all unnecessary exposure of private troubles and all unnecessary conflict with popular prejudices. Thirdly, it should protect individuals from wrongful imprisonment. It would be objection enough to any legal provision, that it failed to secure these objects, in the completest manner. (Ray 1869)

Highly significantly, Quen writing in *The Principles and Practices of Forensic Psychiatry* (1990) reports 'These elements remain necessary, valid, and unachieved in America today.'

As outlined above forensic psychiatry was fundamental to the development of psychiatry in the eighteenth and nineteenth centuries and was adopted by the founders of British, European, and American psychiatry as part of their role to promote psychiatry as a medical specialty.

2. Criminal Law and Forensic Psychiatry

This involves fitness-to-stand-trial evaluations and assessments for criminal responsibility. It involves the forensic psychiatric assessment of mentally abnormal

offenders. The forensic psychiatrist is, by virtue of his or her professional training, an expert in psychiatry and specifically in mentally abnormal offenders. This expertise is applied to legal matters such as fitness to stand trial and criminal responsibility. The challenge to the forensic psychiatrist is that the traditional doctor-patient relationship does not exist under these circumstances. The traditional aims of psychiatry of treating or helping the patient are also not obvious and may even be contradicted. The definition of forensic psychiatry by the well-known American forensic psychiatrist Dr Seymour Pollack (1974) addresses these contradictions. Pollack defined forensic psychiatry thus:

forensic psychiatry is limited to the application of psychiatry to evaluations for legal purposes. Psychiatric evaluation of the patient is directed primarily to the legal issues in which he is involved, and consultation is concerned primarily with the ends of the legal system, rather than the therapeutic objectives of the medical system.

Pollack is correct in terms of evaluations for fitness to stand trial and criminal responsibility. In the former, the initial role of psychiatric evaluation is to establish the diagnosis, from the standpoint of either a medical illness or a psychiatric disorder affecting the person's mental functioning. Once this has been established the next task for the forensic psychiatrist is to assess whether the degree of disorder present affects the person's capacity to proceed to trial. The legal basis may vary slightly between jurisdictions but all are similar and would be analogous to Section 2 of the Criminal Code of Canada, which defines 'unfit to stand trial' as follows:

unfit to stand trial means unable on account of mental disorder to conduct a defence at any stage of the proceedings before a verdict is rendered or to instruct counsel to do so, and, in particular, unable on account of mental disorder to
(a) understand the nature and object of the proceedings
(b) understand the possible consequences of the proceedings, or
(c) communicate with counsel (Section 2 Criminal Code of Canada 2000).

The process is clearly conducted for a legal purpose and, arguably, not necessarily in the person's best interest, as it may mean finding them fit for trial which may in turn result in a guilty verdict and possibly lengthy incarceration in a correctional setting. Alternatively, if they were found unfit and remained unfit, while they would still be incarcerated, they would probably be detained in a hospital setting. In Canada and most other jurisdictions, a finding of unfitness means that a judicial hearing would follow as to whether psychiatric treatment would render the individual fit to stand trial. In Canada this could result in a treatment order issued by a judge, ordering psychiatric treatment (most commonly antipsychotic medication) to render the person fit to stand trial. This

can be done independently of the person's capacity to consent or refuse psychiatric treatment.

An assessment of criminal responsibility involves judging whether the person's mental status at the time the crime took place rendered him or her incapable of appreciating the nature of their actions as well as knowing whether their actions were wrong. It is beyond the scope of this article to go into criminal responsibility in detail as the legal basis varies considerably in different jurisdictions. This particularly true in the United States where the criminal law is under state jurisdiction and therefore each state varies in terms of what it uses as the legal basis for a finding of not criminally responsible on the basis of mental disorder. The most commonly used standard in Western countries is the M'Naughton Test or some modification of the test. In recent years a number of American states have either abolished or severely limited the application of 'insanity' (mental disorder) to reduce the *mens rea* component of criminal responsibility. In order to be criminally responsible for a crime the state must prove the accused committed the unlawful act (*actus reus*) and that they also had the intent to commit the crime (*mens rea*). Mental disorder if present at the time the crime was committed can negate *mens rea*, leading to a finding of 'not guilty by reason of insanity,' not criminally responsible on the basis of mental disorder, or guilty but mentally ill. Such a verdict usually results in confinement in a forensic psychiatric facility until the acqutee is regarded as having recovered and no longer being dangerous to the community at large. In other cases, a mental disorder may result in a diminishing of criminal responsibility, allowing the accused to be found guilty of a lesser offence carrying a less severe penalty. This is seen in situations where a homicide has been committed and the individual suffered from a mental disorder at the time of the homicide. The degree of mental disorder is regarded as not sufficient to negate *mens rea* but to reduce it. This could result in a finding of manslaughter as opposed to murder where the intent to kill was reduced although the accused was still criminally responsible for the death of the victim. The original M'Naughton Test was strictly a cognitive test. In its original form it was:

To establish a defence on the grounds of insanity, it must be clearly proved that at the time of committing the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or if he did know it, that he did not know he was doing what was wrong. (Quoted in Hunter and MacAlpine 1963.)

Various modifications of the original M'Naughton Test have occurred in the United States and elsewhere. The most important of these has been the adoption, in the United States, of the American Law Institute Test (ALI Test), which includes both cognitive and volitional aspects. To complicate things even further the

actual legal interpretation of the meanings of the various tests of criminal responsibility is subject to case law. This means the interpretation may change, depending on a specific interpretation by a particular judge in a specific court case that is upheld by various appeal courts. Forensic psychiatrists who act as expert witnesses in cases of criminal responsibility based on mental disorder are therefore becoming involved in a very complicated process where they have to use their psychiatric skills initially to establish a psychiatric or medical diagnosis. Drawing on the observations of others as well as the medical history of the accused, they must establish, by a process of reconstruction, whether the disorder was present at the time of the offence. If it was present, they must assess its degree or severity and how that would affect the operating mind of the accused both cognitively and possibly volitionally. Then they must form an opinion with reference to the legal test for criminal responsibility in the particular jurisdiction where the trial is being held. He or she will need a working knowledge of the case law interpretations as they apply in the specific jurisdiction and in the specific case. Finally, as expert witness he or she must understand the facts of the case as they emerge at the time of the trial and be able to incorporate them into the opinion being rendered.

In addition to criminal responsibility and fitness to proceed with trial, forensic psychiatrists are also involved in the sentencing of mentally abnormal offenders. Here the role of an expert is to address the third principle of sentencing, which is rehabilitation (the first two being retribution and deterrence). In certain jurisdictions this may be the most prominent role for the forensic psychiatrist as it is used to mitigate the sentence while at the same time allowing the judge to direct treatment in a correctional facility for a psychiatric disorder. It therefore provides a link between forensic psychiatry and correctional psychiatry. This linkage varies in different jurisdictions and countries according to the degree of development of forensic psychiatry and the availability of treatment resources in the correctional system. A highly contentious issue related to sentencing is the participation of forensic psychiatrists in the death penalty process in the United States, including pretrial assessment, the sentencing phase, the determination of competence to be executed, and most controversially the assessment of restoration of competence to be executed as a result of psychiatric treatment.

3. *Civil Law and Forensic Psychiatry*

This branch of forensic psychiatry involves psychiatric malpractice; psychiatric disability determinations; personal injury evaluations; testamentary capacity and guardianship; and family law matters, including parental competence and child custody evaluations. Included here is the specialty of the child and ado-

lescent forensic psychiatrist. These individuals must combine the skills of two psychiatric subspecialties, namely, child and adolescent psychiatry, and forensic psychiatry. In some university divisions of forensic psychiatry these skills are available through a family court clinic. This clinic would receive consultations from the family court system to evaluate parental competence in child abuse and neglect cases and also assist in determining the best interests of the child in divorce custody cases. Family court clinics have also traditionally provided evaluation of young offenders. The evaluation of young offenders, principally adolescents, requires the clinical skills and experience necessary for evaluating children and adolescents. The importance of these dual skills cannot be underestimated and at times has called for the recognition of a sub-subspecialty of child and adolescent forensic psychiatry in some countries.

Testamentary capacity may be a relatively small component of forensic psychiatry, but there is no doubt as to its complexity and the special skills necessary for these retrospective evaluations and being able to communicate the evaluation to the legal authorities.

4. *The Legal Regulation of Psychiatry and the Forensic Psychiatrist*

The legal regulation of psychiatry involves informed consent and competence; the right to refuse psychiatric treatment and the right to psychiatric treatment; psychiatric hospitalization and involuntary civil commitment; outpatient civil commitment; confidentiality; the duty to warn or protect against professional misconduct, including the impaired physician, competence to practice, and professional sexual misconduct. These are areas of psychiatry and the law where the average psychiatrist also needs to develop skills and competence and are, therefore, not an exclusive area of practice for the forensic psychiatrist. The forensic psychiatrist, however, contributes special skills and training in the legal system, and the skill to be a competent expert witness. This means their role is to assist the non-forensic psychiatrist by consultation and advice and, in the more complex cases, forensic psychiatric expertise may be desirable.

5. *Special Clinical Skills of the Forensic Psychiatrist*

A wide range of special clinical skills is unique to the forensic psychiatrist. Special skills in evaluating and treating violent psychiatric patients are a fundamental requirement for all forensic psychiatrists. This is also expanded to include the assessment of the danger posed by an offender and risk assessment, as well as the risk management of violent mentally abnormal

offenders. Associated with these clinical skills are skills in assessing antisocial personality disorder as well as impulse control disorders. Because of the association between organic brain dysfunction and impulsivity and violence, forensic psychiatrists need to develop skills in assessing the neuropsychiatric aspects of psychiatric conditions that can result in violence or can affect competence. They also need to be able to evaluate and treat the most severe and violent major mental disorders. Forensic psychiatrists must develop special skills in evaluating malingering and the use of hypnosis. The forensic psychiatric aspects of certain psychiatric disorders (e.g., multiple personality disorder) are also within the skill set of the average forensic psychiatrist. The assessment and treatment of sexual deviation is also a required skill.

6. Correctional Psychiatry

The strict definition of correctional psychiatry is 'psychiatry practiced within a correctional system.' Broader definitions would include any agency of social control that is involved in the treatment and rehabilitation of adult or juvenile offenders. These populations have significant psychiatric morbidity and clearly would benefit from psychiatric intervention and this had led to a growth of correctional psychiatry in the last few decades. There is a close relationship between correctional psychiatrists and forensic psychiatrists with correctional psychiatric programs often being outreach programs of university departments of forensic psychiatry (as, for example, in Canada).

7. Organization and Future of Forensic Psychiatry

This is a subject of debate in North America at the beginning of the twenty-first century. There is a consensus that the future growth and development of forensic psychiatry must lie within the field of medicine as a subspecialty of psychiatry. This is already well established in general terms in Canada and Europe. If we accept this consensus, some comment as to the ideal forensic program is warranted. This author strongly endorses the subspecialty status of forensic psychiatry as a critical component of its future development. This implies that the ideal forensic program would be an academic division within a university department of psychiatry. In turn, this would mean that education, clinical training, and research would be fundamental components of the program. General psychiatric residents should be required to do a rotation as part of their residency requirement. As the largest interface between medicine and the law is between psychiatry and the law, it should be part of the basic training of all psychiatric residents. It is almost impossible for the average psychiatrist to go through his career without some

interaction with law and psychiatry tribunals, the criminal justice system, or the civil legal system.

An ideal program would provide fellowship training in forensic psychiatry in an accredited program for a minimum of one year. The forensic clinical program should have a medium or maximum inpatient assessment unit to provide pretrial evaluations of fitness and criminal responsibility. In addition, inpatient and outpatient facilities are required for the treatment and rehabilitation of individuals who have been found unfit to stand trial or not criminally responsible on the basis of mental disorder. The length of stay should allow for both acute and chronic care so a cautious approach to treatment and rehabilitation would prevail. There also need to be outreach programs to correctional facilities and an active participation in pretrial diversion programs. In an ideal situation, specialized clinics for the assessment and treatment of sexual deviation, and aggression and impulse control disorders should also be present. A family court clinic with child and adolescent forensic psychiatrists on the staff should also be included. A multidisciplinary team approach to assessment and treatment is essential. Research into all aspects of forensic psychiatry is critical for its future growth and the development of its profile as a medical subspecialty.

Forensic Psychology

Forensic psychology is the branch of psychology concerned with the production and application of psychological knowledge and principles within the legal process. (The term 'forensic,' meaning 'legal' or 'judicial,' is derived from the Latin word *forensis*, which literally means 'relating to the forum or market.' In ancient Rome, a forum was an open square, which served as a market, as well as a place where legal matters were disposed of.)

1. Historical Background

Since both psychology and law are concerned with human behavior, they have been intertwined since the dawn of recorded history (Gudjonsson and Haward 1998). Indications of interest shown in the law by philosophers, from whose ranks psychology would later develop, are found in the earliest Asian, Egyptian, Greek, and Latin writings. Later Greek philosophers continued to express themselves on practical questions of law and topics that today constitute the subject matter of psychology. For example, Plato (ca. 427–347 BC) in his *Republic* considered the question whether mentally disordered people were responsible for their behavior (Allan 1995). However, it took more than 2000 years for psychological knowledge to mature to a level where it was officially allowed in the courtroom for the first time. This happened in 1896 when Albert Von Schrenk-Notzing, student of Wilhelm Wundt who founded the first psychology laboratory in Germany in 1879, testified in a murder trial concerning the effect of pretrial publicity on memory and suggestibility (Blau 1998). Since then, forensic psychology has made great strides. As we enter the twenty-first century, there is hardly an area of the law where psychological expert testimony is not implemented. Ewing (1985) believes that the modern justice system could not function without significant participation by behavioral scientists such as psychologists.

2. Roles of the Forensic Psychologist

As both psychology and law essentially cover all aspects of human behavior, it is understandable that the forensic psychologist serves as an expert on a variety of matters including those considered in the following sections.

2.1 Competency to Stand Trial

Also known as fitness to plead, competency to stand trial refers to the defendant's mental capacity to make a proper defense, i.e., to understand the legal proceedings and the charges against him or her.

Contrary to popular opinion, the mere existence of a mental disorder *per se* does not render an individual incompetent to stand trial. Many mental disorders are of such a nature and intensity that the defendant's competency is not significantly influenced. The crucial question is whether the mental disorder affects the defendant's current functional abilities within the context of relevant legal criteria for determining competency (Gudjonsson and Haward 1998).

As laws and 'legal cultures' differ from country to country, it is understandable that statistics concerning competence to stand trial will vary considerably. For example, proportionally speaking, about 100 times more defendants in the USA are found incompetent than in England and Wales. Even within one country, the percentage of defendants found to be incompetent often varies between 1 percent and 80 percent across jurisdictions.

It does seem that individuals adjudicated incompetent to stand trial often have certain characteristics in common, such as a history of mental health treatment (especially for schizophrenia and depression), lower intellectual functioning, and a present charge of violent crime.

The evaluation of competency is usually very reliable and the agreement rate between psychologists often exceeds 80 percent. Next to the traditional assessment techniques, particularly the clinical interview, several competency assessment instruments are also used.

2.2 Criminal Responsibility

Criminal responsibility (liability/accountability) should not be confused with competency to stand trial. Competency to stand trial is specifically concerned with the defendant's mental capacity during the legal proceedings. Criminal responsibility, also known as the insanity defense, refers to the time of the alleged offense and more specifically asks the question whether the defendant had the mental capacity to distinguish between right and wrong at the time of the alleged offense and could control his or her conduct accordingly. Should the defendant be found not criminally

responsible, he or she rarely goes free. The person is usually referred to a mental health facility where he or she will remain as long as the commitment criteria are met.

The insanity defense is one of the most controversial issues in criminal law. One reason for this are the many misconceptions surrounding this plea. For example, although the public believes (probably as a result of the publicity given to such cases) that the insanity plea is very often entered, such cases are rare: often fewer than 1 in every 1,000 criminal cases. The success rate of the defense varies from country to country and from jurisdiction to jurisdiction, with 25–50 percent as a broad average.

Most defendants whose insanity pleas are successful are diagnosed with major psychotic disorders and have extensive mental health histories, often accompanied by prior civil commitments or findings of incompetence (Golding et al. 1999).

Insanity evaluations are usually regarded as more complex than competency evaluations. It is, after all, exceedingly difficult to determine what another person was thinking, feeling, and doing at the time of an offense that usually happened weeks, months, or even years earlier (Bartol and Bartol 1994). However, it seems that specialized training and experience can lead to an agreement rate between mental health professionals of more than 80 percent. Several measuring instruments have been developed to assist mental health professionals in their assessment of the insanity plea.

2.3 Other Defenses

Next to competency to stand trial and criminal responsibility, the expertise of psychologists is employed in several other defenses in both criminal and civil cases.

(a) *Intoxication* by alcohol or other drugs, because it is self-induced and temporary, is seldom given complete exculpatory effect (Melton et al. 1997). The major exception is when the substance abuse has been prolonged to a point where it has produced a serious mental disorder. However, in most countries voluntary intoxication can be used as a diminished capacity defense claim. In such cases mental health professionals have to produce evidence that the intoxication did indeed affect the defendant's mental capacity significantly.

(b) *Amnesia* (the total or partial loss of memory) at the time of the offense is one of the most common defenses heard in the criminal court, especially concerning violent crimes (see *Amnesia*). It is also one of the most difficult defenses to assess. It is not only difficult to determine the weight that should be given to the claimed amnesia, but also to distinguish between genuine and simulated amnesia. An even more complex task is to determine whether the defendant was

really amnesic when committing the crime, or whether he or she only developed the amnesia afterwards. Although psychologists frequently give expert testimony on amnesia, their ability to assist the court with scientific evidence is questioned. Courts are therefore often skeptical about accepting their testimony as a viable defense element.

(c) *Dissociative identity disorder*, formerly called *multiple personality disorder*, is primarily characterized by the presence of two or more distinct personalities that in turn take control of the person's behavior (American Psychiatric Association 1994). However, the disorder is highly controversial and sometimes called the 'UFO of mental health.' Many mental health professionals believe that the disorder does not exist and amounts to no more than role playing. Although screening instruments and structural interviews have been developed and hypnosis is used to diagnose dissociative identity disorder, experts admit that it is very difficult to distinguish between real cases and malingering (Alloy et al. 1999). It is therefore understandable that legal professionals tend to be very cautious about making use of this defense. However, in rare cases in several countries, dissociative identity disorder has been accepted as a defense, ranging from an insanity plea to extenuating circumstances.

(d) *Post-traumatic stress disorder* (PTSD) is characterized by intensely distressing symptoms (e.g., irritability and sleeplessness) caused by exposure to a traumatic event such as rape, death, combat, accident, and even harassment and difficult work conditions (see *Post-traumatic Stress Disorder*). PTSD can therefore be a factor in both criminal and civil cases. However, establishing the existence of PTSD poses several difficulties for the forensic psychologist. For example, the validity of the diagnoses is often questioned. Although psychological measuring instruments and techniques to assess PTSD are available, they are usually based on self-report. The result is that malingering cannot be ruled out easily.

2.4 Prediction of Violent Behavior

As one of the primary duties of the court is to protect society, assessing the offender's potential for future violence often forms an integral part of the judicial process. This is especially true if the offender is charged with a violent crime. Determining the propensity for future violence is therefore an important part of the forensic psychologist's functions. However, the role of the mental health professional in violence prediction is controversial (see *Clinical Psychology: Validity of Judgment*). The main reason for this is that past research showed that mental health professionals have a bad track record when it comes to predicting the probability of a person committing future violence, and even more so when it comes to predicting the type and severity of such potential violence. As such,

professionals can pay a heavy social, professional, and legal price for failing to predict violent behavior, they tend to 'play it safe' and therefore often overpredict. The result is that research has shown that more than 50 percent of persons predicted likely to commit future violence, do not do so.

Ongoing research in this field is fortunately beginning to bear fruit. For example, several variables have been identified which can be regarded as risk factors for violence, e.g., a history of violence, substance abuse, symptoms of a psychosis or antisocial personality disorder (psychopathy), weapon availability, early onset of violent behavior, and absence of social support. Measuring instruments to assist psychologists have also been developed.

2.5 Eyewitness Testimony

'It is...inevitable that what a witness says in court will be a subjective and incomplete version of 'the truth' interspersed with small portions of fiction.' Although most psychologists will agree with this statement by Ainsworth (1998, p. 3), the testimony of an eyewitness still remains a very important part of evidence presented in both criminal and civil cases. However, as a result of a rapidly growing data bank in this widely researched area, especially in the 1980s and 1990s, the courts are currently examining some of their assumptions about the reliability and thus the value of eyewitness testimony. It is therefore understandable that courts increasingly rely on psychologists to provide expert testimony in this regard (see *Expert Witness and the Legal System: Psychological Aspects*).

The following are some of the more important research findings that have been used in court by psychologists: (a) eyewitnesses tend to be less accurate in stressful situations; (b) people experience difficulty making cross-racial identifications; (c) eyewitnesses focus on weapons rather than faces; (d) memory decay starts immediately after a perception; (e) memory gaps are often and easily replaced by unconscious fabrication or by external suggestions; (f) there is not necessarily a correlation between the degree of certainty evinced by the eyewitness and accuracy (Melton et al. 1997); and (g) although younger children are often more suggestible and remember less detail than older children and adults, they do not necessarily have poorer memories (Saywitz and Goodman 1996).

2.6 Personal Injury

The world is progressively becoming a litigious society in which monetary compensation is sought for almost any maloccurrence (Tsushima and Anderson 1996). As many such claims involve 'psychological pain and suffering,' psychologists are increasingly becoming

involved in so-called mental injury cases. Although determining the presence and cause of mental injury constitutes the bulk of psychologists' work in this field, they are also involved in injury claims of a more physical nature, e.g., to assess brain damage or determine the psychological effect of losing a limb.

To assess whether the plaintiff does indeed suffer from a mental injury is not always easy. First, it has to be proved that there is a causal relationship between the specific incident and the plaintiffs symptoms, i.e., that the symptoms did not already exist before the incident or were not caused by other factors after the accident. Second, as possible financial remuneration is involved, plaintiffs often tend to exaggerate or even fake their symptoms. No foolproof method to determine such relationships and distinctions is available. However, by using the most objective, valid, and reliable tests appropriate to the complaints, conducting thorough interviews, and carefully recording case notes and test reports, psychologists can make a valuable contribution towards clarifying the extent to which psychological factors may be involved in personal injury cases (Butcher and Miller 1999).

2.7 Sentencing

If a defendant is found guilty of the charge against him or her, the court has to impose an appropriate punishment. In most countries the aim of such punishment consists of a combination or all of the following: deterrence, retribution, prevention, and rehabilitation. Since these goals have a strong psychological element and psychologists are supposed to be well equipped to provide the court with a psychological profile of the defendant, they often testify in this regard. For example, the psychologist can provide the court with information concerning the defendant's potential for future violence, the sincerity of the repentance shown, the possibility of rehabilitation, a variety of mitigating factors, and the effect of different sentences on the defendant as a unique individual.

Although there seems to be a high correlation between psychologists' recommendations and the final sentencing decision of the courts, it remains an open question as to what extent the courts do indeed take the testimony of the psychologist into account or merely use it to 'scientifically' justify decisions they have already made (Melton et al 1997).

2.8 Profiling

Criminal profiling refers to the process in which the nature of a crime is used to make inferences about the personality and other characteristics of the likely offender.

The sensational and dramatic elements of profiling portrayed in various well-known movies, television

series, and books (usually those depicting a serial killer) seem to be in sharp contrast with reality. Profiling is not widely accepted in the psychological and legal community, and some courts have even ruled profiling testimony inadmissible. There are two main reasons for this (Gudjonsson and Haward 1998). First, a criminal profile only gives a broad indication of the type of person who may have committed the crime. It does not indicate a specific individual who happens to fit the profile. The profiler is therefore unable to say whether it is more probable than not that a specific offender did, in fact, commit the crime. Second, there is no scientific evidence to support the reliability and validity of criminal profiling in solving crimes. Indeed, it seems that when profiling does assist the police in solving a case or in opening up new lines of inquiry, it is the exception rather than the rule.

On the other hand, it cannot be denied that criminal profiling has proven helpful in some, albeit exceptional, cases. However, much more research needs to be done before criminal profiling will earn its place as a valuable forensic tool.

A variation of profiling that has evoked some interest in the news media is psychological autopsy, which comprises the compilation of a psychological profile of especially well-known deceased individuals. It is also used in suicide cases, for example, to determine whether the deceased could indeed have committed suicide. However, as in the case of criminal profiling, its reliability and validity are also questioned.

2.9 Child Custody

With the worldwide increase in divorce rates and the resulting child custody battles between divorcing parents, mental health professionals have come to play an increasingly important role in such disputes.

Two principles play a major role in courts' decisions in child custody cases: the tender-years principle and the best-interest-of-the-child principle. The tender-years principle reflects the traditional belief that the mother is inherently better equipped to care for children of a 'tender age' (which particularly refers to children around or under the age of seven). However, several factors have led to the questioning and even abolishment of this principle in some courts. For example, research has shown that fathers and mothers are equally capable of fulfilling the psychological and other needs of children in their 'tender years.' The principle is also seen as a violation of equal gender rights. Most courts base their decisions in child custody cases on the best-interest-of-the-child principle, which involves criteria such as (a) the love, affection, and other emotional ties between parent and child, as well as between the child and his or her siblings or any other significant person; (b) the ability of the parent to provide for the child's psychological, educational, cultural, and environmental develop-

ment; (c) the ability of the parent to provide the basic physical needs of the child, e.g., food, clothing, and housing; (d) the mental and physical health and moral fitness of the parent; and (e) the child's preference as to his or her custodian. However, this principle has also come under fire from critics who, for example, claim that many of the criteria are vague, difficult to assess, and open to subjective interpretation.

Assessment in child custody disputes usually includes interviewing the parents and children, as well as any other third-party source that may provide valuable information, observation of the interaction between especially parents and child, and the use of traditional psychological and specialized tests. However, the interview is usually recommended as the best method. The reasons are the following. The observation technique is regarded as artificial and thus unreliable (the individuals know that they are being observed). The traditional psychological tests are often irrelevant (e.g., there is no correlation between good parenthood and IQ). The specialized tests are also not very reliable and valid. It is generally accepted that a psychologist, acting according to professional guidelines, can make a valuable and often decisive contribution in child custody cases.

3. Forensic Assessment

Forensic assessment refers to the procedures, methods, and techniques that psychologists use to gather information in order to assist the court in coming to a final decision. The nature of the assessment will depend on the theoretical orientation, training, experience, and preference of the psychologist, as well as the nature of the specific case. Usually a combination of procedures, methods, and techniques are used.

The forensic interview can be considered the central element of the assessment process. The interview can be structured (the questions being determined and systematized in advance), unstructured (the interview being allowed to develop spontaneously), or a combination of the two. The forensic interview is much more than just an 'ordinary' interview. It is a scientific method for gathering information and requires specialized training and experience. As mentioned, it is usually necessary to interview not only the specific individual, but also family members, friends, and other third-party sources. Such collateral information may be helpful not only in acquiring a broader picture, but also in determining the reliability of the information provided by the different sources.

In addition to this basic assessment method, several others are employed, and examples are given below.

3.1 Psychological Testing

Virtually all forensic psychologists incorporate psychological tests in their assessment armament. Psycho-

logical test results can be powerfully persuasive instruments because of society's long-standing high regard and respect for these measuring instruments (Tsushima and Anderson 1996). Many courts also seem to expect that such tests will be used.

However, it has also become clear that psychological tests have not always conformed to the high qualities attributed to them. Not only are the reliability and validity of many of the tests used by psychologists generally disputed, but also they have not been developed specifically for forensic issues. The result is that their usefulness in forensic settings is questioned. Attempts to develop specialized forensic assessment instruments have also not yet been very successful, mainly owing to psychometric flaws. Another problem especially encountered in underdeveloped and developing countries is that tests are used on groups for which they have not been developed. An example is the worldwide use of various American tests developed for the US population on groups for which they were not standardized. Cultural differences cast doubt on the reliability of such results.

On the other hand, can there be little doubt that, in the hands of a well-trained and experienced examiner who is well aware of the pitfalls, psychological tests can be very valuable tools and can provide valuable information.

3.2 Forensic Hypnosis

There are few topics in psychology more shrouded in mystery and misconception than hypnosis. Mainly responsible for this is the sensational representation of this technique by the movie industry, news media, and stage hypnotists. Even in the scientific world controversy surrounds the hypnosis phenomenon, with some regarding it as a valuable tool in many areas, while others do not believe in the existence of such a state, and mainly contribute it to suggestion and role-playing (see *Hypnosis, Psychiatry of*).

The primary use of forensic hypnosis centers on enhancing the memory of a witness, victim, or even defendant, especially with a view to helping him or her remember forgotten or vague details of a crime. Most research shows that, compared with people who have not been hypnotized, people under hypnosis tend to recall more detail about an event. They also usually feel confident that their recollections are correct. However, their stories contain a great deal of inaccurate information, even more so than in the case of nonhypnotized subjects. It is generally accepted that forensic hypnosis is seldom more efficient in improving memory than any other standard psychoforensic procedure. Courts therefore hesitate to accept testimony acquired through hypnosis. In some countries such testimony is even inadmissible. Others do allow it, but usually only if certain safeguards and guidelines

are applied. It is therefore important that forensic psychologists meet these preconditions if they wish to employ this controversial forensic tool.

3.3 Polygraph

The polygraph, also called 'lie detector,' is an apparatus that measures physiological variables such as heart rate, blood pressure, and respiration rate. Polygraphers believe that when people are asked threatening questions to which they respond by lying, physiological changes will occur which will show up on the polygraph record. This makes the polygraph a potentially valuable forensic tool.

Unfortunately, the validity of the polygraph leaves much to be desired. Polygraph results seem to be wrong in at least 30 percent of all cases. This concerns innocent people who are wrongly accused, as well as guilty persons who plead innocence. For this reason, most courts do not admit evidence based on polygraph results, or admit it only if it adheres to certain stipulations (e.g., that all parties agree to the test before it is administered).

Ironically, it seems that one of the polygraph's biggest strengths lies in people's belief that it is reliable. It seems that about 30 percent of suspects confess after they have failed a polygraph test (Memon et al. 1998). However, it does not necessarily mean that these suspects had been lying. It could also be that innocent suspects tend to confess because, having failed the test, they see little possibility of convincing the court of their innocence thereafter. By confessing they hope to get a lighter sentence.

4. The Future

Only a few decades ago the relationship between psychology and law was compared to an unhappy marriage. In the twenty-first century, it is rather regarded as a 'normal' marriage with its ups and downs, but definitely not heading for a divorce. There can be no doubt that both professions find the interaction and collaboration enriching.

However, in order to make full use of this interdependent relationship, much more needs to be done. The key lies in research, aimed not only at developing new procedures, methods, and techniques, but also at determining weaknesses in the general professional approach of forensic psychologists. Forensic psychologists should especially try to move away from the 'hired guns' stigma attached to them. This can only be achieved by telling 'the truth and nothing but the truth.' This principle can be best served by presenting objective and critical both-sides-of-the-story evidence without subjectively favoring one party.

The saying, 'It is not a question whether forensic psychology is good, but what it is good at,' should also serve as a principle guideline for acknowledging that there are areas where little or no contribution can be made and sticking to those areas where it is clear that psychologists are held in high esteem by courts. With such an approach and quality research, there can be no doubt that forensic psychology will flourish in the future.

D. Louw

Foucault, Michel (1926–84)

Michel Foucault is one of the most influential, and also most controversial, social thinkers of the century. His work represents a sustained effort to reconstruct the way in which the specifically modern Western form of subjectivity has become what it is through institutionalized practices of truth-telling and the search for knowledge.

1. Foucault's Intellectual Trajectory

Foucault was born on October 15, 1926 in Poitiers. His upbringing was organized around knowledge since his early childhood (he started to attend school at the age of three), while major political events, especially wars (the Ethiopian war, the Spanish Civil War, and World War II) also had a major impact on his formation. In September 1945 he moved to Paris where he listened to the lectures of Jean Hyppolite during a preparatory high-school year, and was then admitted to the prestigious *École Normale Supérieure*. These were troubled years for Foucault, intellectually, personally, and politically alike. He had a short spell with the Communist Party and had difficulties in managing his homosexuality.

After graduating in philosophy in 1951, he received further qualifications in 1952 and 1953 in psychopathology and experimental psychology. He then started teaching, working on his thesis and also attending the St Anne psychiatric hospital. However, under the impact of an intensive reading of Nietzsche, his interests gained focus, and he decided to leave the standard academic career, even the country.

In between 1955 and 1960 Foucault worked as a cultural diplomat, first in Uppsala (at the invitation of Georges Dumézil), then in Warsaw and Hamburg. He thus experienced personally the different economic and political regimes of the period, noticing their latent similarities, and also worked on his doctoral thesis. This was defended in 1961, under the supervision of Georges Canguilhem, and published as *Folie et déraison (Madness and Unreason)* with the support of Philippe Ariès.

After completing the book, Foucault continued his work on the reconstruction of the joint emergence of modern forms of scientific (especially medical) knowledge and its institutional context, and published in 1963 *The Birth of the Clinic*. At the same time, he also got increasingly involved in literary criticism, publishing various essays and a book on Raymond Roussel. As a result, he came to 'bracket' institutional practices temporarily in his work and turned towards language and discourse—a shift he would later much regret. The result was *The Order of Things*. Published in 1966, at the height of structuralism, the book immediately became a huge success, identifying Foucault as a main protagonist of the field.

Becoming increasingly uneasy about this label, Foucault soon embarked on a major self-reflexive exercise, attempting to clarify his project and its underlying methods for others and for himself. This eventually led to the *Archaeology of Knowledge* and a series of major methodological papers. At the same time, he moved from Paris to Tunis, and this is where he lived during the events of May 1968. However, instead of a systematic and final clarification, the reflexive exercises rather brought about a major reorganization of Foucault's entire work. Appointed as Chair of the History of Systems of Thought at the prestigious *Collège de France*, a few months after his inaugural lecture, Foucault suddenly shifted his intellectual interest from knowledge to power, and at the same time he became engaged in political struggles as the founder of GIP (group for information on prisons).

His new interests led to the publication of *Discipline and Punish*, easily his most widely read and influential work. However, around the time of its publication, Foucault was again already reflecting on his work. This yielded a book-length study published as the first of six planned volumes on the *History of Sexuality* and a series of significant and quite influential interviews and shorter pieces (see Foucault 1980). But perhaps most importantly, it led to another major reorientation of his project. When trying to specify the main characteristics of his approach to the study of power, he eventually came to realize that the question of power was not central to his work. This change—often interpreted as Foucault's 'crisis'—is visible in successive displacements of the time horizon of the work, first to the fifteenth–sixteenth centuries, then to early Christianity, and finally to Greco-Roman Antiquity; and also in a reorganization at the level of central concepts: from power-knowledge to government by truth; from the genealogy of power to the hermeneutic of the subject; from technologies of power to techniques of self. It was strongly influenced by Foucault's encounter with the works of major scholars of antiquity such as Pierre Hadot and Peter Brown. At the same time he also increasingly recognized affinities with the works of social scientists like Norbert Elias and especially Max Weber. These encounters, together with a systematic reflection on the trajectory of his past work, helped Foucault to identify the underlying problem of his work as being concerned neither with power, nor with discourse, rather with the link between truth and subjectivity (Foucault 1997, p. 281).

The new orientation is visible in the published Volumes Two and Three of the *History of Sexuality* project that discuss the way practices related to pleasure were problematized in ancient Greece and Rome, respectively. Volume Four, covering early Christianity, only exists in the form of an uncorrected manuscript, as Foucault was hospitalized, terminally ill, just days after he started to revise it for publication.

The best guides for the last, arguably most significant period of Foucault's work are the courses he

gave at the Collège de France in between 1978 and 1984, especially the last two courses on *parrhesia* or frankness of speech and truth-telling. Foucault died in Paris on June 25, 1984.

2. The Work and its Context

Throughout his writings, covering over three decades, Foucault's work focused around the reasons and manner in which the individual subject, especially its 'true being,' has become the center of attention in the pursuit of knowledge and the search for social order, considered as an evident starting point and foundation. Thus proceeding, Foucault posed question marks to what has been taken for granted by the main available approaches in philosophy and the social sciences, without dismissing them as mere ideology or illusion. This explains much of both the dynamics of Foucault's intellectual trajectory (discussed in this section) and its reception (covered in the next).

The trajectory has three major peculiarities. First of all, far from following a straightforward path of development, it was quite bumpy and curvy, progressing through crises (see Szokolczai 1998). This was probably unavoidable as Foucault's work did not simply represent an addition to the existing stock of knowledge, neither a general attack on it, rather a problematization of the taken for granted. Furthermore, and for much the same reasons, the trajectory cannot be separated from the substance of the ideas. Given its detours, it would seem particularly desirable to get over such details and focus on the main results. However, this would undermine the effectivity of Foucault's undertaking, as doing so one would fail to problematize one's own hidden related preconceptions. Finally, Foucault was quite aware of the pitfalls of his project, and throughout his career kept reflecting on its directions and stakes. These reflections had a significant effect on the trajectory and contain a concise introduction to Foucault by Foucault, a starting point for any interpretative effort.

For these reasons the exact mapping of Foucault's early steps is of crucial relevance, as this not simply defines the starting point of the investigation that would later be assumed as given, rather indicates the way in which Foucault plunged into the questioning and mapping of the aspect of the taken for granted he singled out for attention as problematic. The first anchorage point to be questioned was academic philosophy that assumed, from Descartes through Kant to Husserl and Merleau-Ponty that the 'subject of knowledge' or the 'transcendental ego' was the starting point of any philosophical undertaking. Foucault recognized that behind the epistemological assumptions of this approach there lay an entire anthropology, and was particularly interested in Kant's related work, which he translated and introduced as his minor thesis.

Given his problems with academic philosophy, he turned to psychology, or an empirical approach to the Kantian question ‘what is man.’ At the same time, he experimented with the two main alternative theoretical frameworks to academic philosophy, Marxism and psychoanalysis, finding them unsatisfactory. It is in this combination that the profound significance and originality of Foucault’s work lies. His background incorporates both theoretical and empirical work: the philosophy of the subject in its various kinds and positivism on the one hand, and their main critiques, the works of Marx and Freud on the other, while being orthogonal to this entire epistemological field.

In his attempts to go beyond the available approaches, Foucault found inspiration in the works of Nietzsche. Instead of starting from the experiences of the subject, gained through a combination of sense perception and the application of ‘universally’ valid categories of mind, Foucault rather posed the question of how this subject has been actually historically formed *through* experience.

In his last writings, Foucault would argue that there are three main axes of experience: knowledge, power, and subjectivity. This conceptualization, however, was only the fruit of late reflection on his own work. In his first major book, *Folie et déraison*, all three axes were dealt with, and their separation was not at all clear-cut. Furthermore, instead of directly reconstructing the subject of knowledge, he rather started at the opposite end, as if following a reflexive strategy, by reconstructing the opposite or the mirror, the subject of nonknowledge or the ‘nonsubject,’ the mad, the carrier of ‘unreason.’ The aim was to show that ‘mental illness’ was not simply an objective aspect of the human condition that was there, waiting to be discovered finally by the methods of true science, but as a complex form of behavior was itself shaped by these very methods and their institutional context.

In this book and the follow-up work, *The Birth of the Clinic*, Foucault tied closely together the reconstruction of the views concerning the aim and methods of collecting knowledge about individual human beings and its context of closed or total institutions, or the knowledge and the power axis. This changed with his third main book, *The Order of Things*, where the institutional dimension or actual scientific and social practice was left out of the picture. On the one hand, this enabled Foucault to sharpen his tools here and in the following, reflexive works, defining his archaeological method as ‘an attempt to introduce the diversity of systems and the play of discontinuities into the history of discourses’ (Foucault 1991). On the other hand, however, this also meant a certain one-sidedness, the suspension of the study of the link between displacements in thought and broader historical processes.

As a result, in the 1970s, Foucault reversed his approach and turned to the power axis, developing conceptual tools like power-knowledge (which never

meant a simple identification between knowledge and power, only the assertion of the impossibility of a complete separation) or the microphysics of power. This meant a shift of disciplinary allegiances from philosophy and the life sciences to sociology and the social sciences, and a reorientation of focus from the ‘subject of knowledge’ of phenomenology to the liberal individual as a subject of rights, the taken for granted starting point of modern political and social theory. Here as before, Foucault chose an indirect approach, focusing his reconstructive historical work on the formation of the subject deprived of rights: the criminal.

Discipline and Punish not only returned Foucault’s interest to institutional practices but sharpened his analytical tools concerning the power axis. However, if his work in the 1960s was slightly affected by flirtations with literary criticism and structuralism, his new work showed too much affinity with the contemporary leftist, neo-Marxist vogue, most visibly at the level of rhetorics.

Foucault’s next series of works on sexuality were intended to continue and complement the studies of power-knowledge as started in *Discipline and Punish*. However, when finishing the first, reflexive and methodological volume of the series, *La volonté de savoir*, Foucault again stepped back from his approach and undertook another major reorientation. This meant that while previously, whether focusing on knowledge or institutional practice, Foucault studied how certain human beings shaped other human beings as objects of power and knowledge, now he set out to analyze directly how individual human beings were driven to reflect on their own being as subjects.

This was accompanied by a marked change in style, even a refocusing of his entire project. While Foucault’s aim so far was to render visible the singularity of the idea that the individual subject should be the foundation of knowledge and social order, now he recognized the seriousness of the problem to which this came to be the answer. The shifting of the focus of interest to the individual was not simply an epistemological mutation, nor a particularly cunning turn in the exercise of power, but was an answer to the manner in which being has become problematized at a certain point; the way in which human beings came to pose question marks to ‘what they are, what they do, and the world in which they live’ (Foucault 1984a). While this turn on the one hand rendered visible the Heideggerian inspiration behind his work, on the other it also brought to the surface the close affinities between Foucault and Max Weber.

3. The Foucault ‘Effect’

Foucault has been one of the most influential social theorists of the past decades. His works are widely read in all branches of the humanities and the social

sciences, including philosophy, sociology, history, anthropology, cultural studies, and literary criticism. However, they have always been controversial and most probably will remain so in the future.

Both characteristics can be traced to the same source. Foucault's work developed not simply as a dissent from the then ruling paradigms in philosophy and psychology, phenomenology and positivism, but was similarly critical, after some initial flirtation, of the undertakings of Marx and Freud. Based on his reading of Kierkegaard, Heidegger, and especially Nietzsche, Foucault went into directions that did not easily fit on the contemporary intellectual landscape. This led to a persistent problem of understanding, reception, classification, and (mis)labeling. It was only deepened by some strategic concessions Foucault made when trying to establish bridges between his lonely undertaking and the work of his contemporaries.

Foucault's work first gained wide currency in the mid-1960s when, after the publication of *The Order of Things*, he was considered as a prime exponent of structuralism, together with Barthes, Lacan, and Lévi-Strauss. His archaeological method, aiming at the establishment of discontinuities at the level of discourses and considering texts written in between two breakpoints as belonging to a discursive formation, governed by certain autonomous rules, is still influential in wide circles within philosophy and literary criticism. The work largely followed the footsteps of Foucault's earlier works, relying more on Dumézil, Canguilhem, and Bachelard than on Lacan or Lévi-Strauss. It was also different from the structuralist project and mentality, as it made no attempt at developing formal schemes with claims of general validity. Still, the label 'structuralist' stuck due to the gestures Foucault made in its last chapter to the then rising structuralist tide.

Though Foucault's work of the 1970s on power-knowledge came to be inserted in a different debate and exerted its impact on a different field, the modalities were remarkably similar. As a conscious break with his earlier work, *Discipline and Punish* aimed at direct political relevance and impact. While *The Order of Things* was critical of Marxism and took up no side in the political landscape, the new work was clearly aiming at making contact with the far left and started by using a language heavily indebted to Marxism. As the work progressed, Foucault steadily retrieved his central interest in the formation of the self through 'true' discourse, in this case the shaping of the criminal. However, in its style and rhetoric, the ballast was still present, and the work came to be read and regarded as a prime example of the 'poststructuralist' and 'postmodern' alternative to old-fashioned Marxism. While in the 1960s Sartre considered Foucault's work as the 'last rampart' of the bourgeoisie, his work of the 1970s served as a lifebuoy for many on the sinking boat of the radical left.

Soon Foucault became just as deeply disturbed by this reception of his work as with the structuralist label in the 1960s. His self-reflexive exercises of the late 1970s and the early 1980s not only helped him to regain focus in his own work but also to find at the end, after some flirtation with the thought of the Frankfurt school, the most fruitful intellectual connections with the works of philosophers such as Gadamer and Hadot, and social scientists like Elias and Goffman. Most important of all, however, was his late in-depth encounter with the work of Max Weber, in whom he recognized a kindred spirit and a selected predecessor.

Though this was not lost in some segments of the Foucault reception (Dreyfus and Rabinow 1982, Gordon 1991, Owen 1994), by then the damage had already been done. Foucault thus came to be regarded as a prime exponent of the very intellectual currents whose presuppositions he wanted to question and map in his work. In this, his fate can again be best compared to Max Weber's. As a result, in the burgeoning literature for or against Foucault, the problem he started to pose almost half a century ago concerning the taken for granted, allegedly universal but quite peculiar and questionable character of the way modern Western subjects form their subjectivity (selfhood or identity)—a problem very close to the Weberian interest in inner-worldly asceticism and in the methodical conduct of life, or the interest of Elias in the formation of *habitus* through the civilizing process—became lost. This is demonstrated most paradoxically in the way the new literature on sexual, gender, race, etc., identities takes Foucault as one of its sources, although his work should rather be seen as a most effective way in which this 'politics of identity' could be criticized.

While Foucault, just like Weber, is one of the most widely read social theorists of the century, his work is similarly still more of an unfulfilled promise than a closed, exhausted chapter in the history of thought.

Fourier Analysis

1. Fourier Series

1.1 Trigonometric Functions

The term Fourier analysis originally refers to the possibility to approximate functions (up to scaling) in the open unit interval $I :=]-1/2, +1/2[$ by linear combinations of trigonometric functions

$$t_0(x) := 1, t_{2n}(x) := \sqrt{2} \cos(2\pi nx), \\ t_{2n-1}(x) := \sqrt{2} \sin(2\pi nx) \quad \text{for } n = 1, 2, 3, \dots \quad (1)$$

and commemorates the role that the French baron Jean-Baptiste-Joseph Fourier played in furthering the development of this method. (Here, the colon marks that side of an equation which is defined by the other side; thus, the symbol ‘:=’ could be read as ‘defined as.’) Fourier’s influential work has its precursors in early studies of the vibrating string by the Swiss mathematicians Daniel Bernoulli and Leonhard Euler. The formulas for what are nowadays called Fourier coefficients date back as early as 1728 and are due to Bernoulli. These formulas are best understood by invoking the geometric metaphors of length and orthogonality, which can be described in terms of a so-called inner product $\langle \cdot | \cdot \rangle$, in our current context specifically given by

$$\langle f | g \rangle := \int f(x)^* g(x) dx \quad (2)$$

for f, g in the set $BC(I)$ of bounded, continuous, complex-valued functions on I (here z^* denotes the complex conjugate of the complex number z ; for real numbers r we have $r^* = r$). As a matter of convenience and simplicity of notation we may consider the integral in Eqn. (2) to extend over the whole real line $\mathbb{R}$ by considering f, g as well as the functions $t_k, k = 0, 1, 2, \dots$, as defined on $\mathbb{R}$ but vanishing outside the interval I .

The inner product induces the concept of a distance between two functions $f, g \in BC(I)$ defined by $\|f - g\| := \sqrt{\langle f - g | f - g \rangle}$. Here, ‘... $\in$...’ should be read as ‘... element(s) of ...’. In particular, the distance of such a function f to the constant function 0 (with value zero for all arguments) $\|f\| = \|f - 0\| = \sqrt{\langle f | f \rangle}$ is called the norm (or length) of f . Functions f with norm $\|f\| = 1$ are called normalized. Two functions f and g are called orthogonal when their inner product vanishes, that is, when $\langle f | g \rangle = 0$. In fact, the specific functions of the family $(t_n)_{n \in \mathbb{N}}$, where $\mathbb{N} := \{0, 1, 2, \dots\}$ denotes the set of natural numbers, are all normalized and pairwise orthogonal if we interpret t_n to be zero outside of the unit interval I . A family of functions such as $(t_n)_{n \in \mathbb{N}}$ is, therefore, also called an orthonormal system. The interest in such orthonormal systems is based on the simplicity with which ‘best approximations’ to given elements can be found in terms of linear combinations of elements of such orthonormal systems. Indeed, let $f \in BC(I)$ be given, then

$$\|f - \sum_{k=0}^N \langle t_k | f \rangle t_k\| \quad (3)$$

is the smallest possible distance between f and any linear combination of the t_k for $k = 0, 1, 2, \dots, N$. The so-called Fourier coefficients $\langle t_k | f \rangle, k = 0, \dots, N$, are obviously independent of $N \in \mathbb{N}$ as N grows. It should be emphasized that this feature is indeed shared by any orthonormal system. The term Fourier coefficients is also used in the general situation. For sake of brevity,

however, we will have to focus here and in the following predominantly on the issue of Fourier analysis in a narrower sense.

1.2 Fourier Series

Letting $N \rightarrow \infty$ one finds that the quantity in Eqn. (3) tends indeed to zero. This property is known as the completeness of the orthonormal system $(t_n)_{n \in \mathbb{N}}$. According to the Fischer–Riesz theorem the convergence of $\sum_{k=0}^{\infty} c_k t_k$ (with respect to the norm $\|\cdot\|$) is determined completely by the convergence of the numerical series $\sum_{k=0}^{\infty} |c_k|^2$. It turns out that there are more functions than just functions in $BC(I)$ which can be approximated by Fourier series, that is, by series of the form $\sum_{k=0}^{\infty} c_k t_k$ (assuming only that the Fourier coefficients are such that $\sum_{k=0}^{\infty} |c_k|^2$ exists). The set of all such functions is denoted by $L_2(I)$, which is the set of measurable, square-integrable functions. Identifying functions $f, g \in L_2(I)$ if $\|f - g\| = 0$, we obtain a 1-to-1 and onto correspondence between elements of $L_2(I)$ and complex number sequences in $\ell_2(\mathbb{N}) := \{(c_k)_{k \in \mathbb{N}} \mid \sum_{j=0}^{\infty} |c_j|^2 \text{ convergent}\}$. Indeed, one finds

$$\|f\| = \left(\sum_{j=0}^{\infty} |\langle t_j | f \rangle|^2 \right)^{1/2} \quad (4)$$

for all $f \in L_2(I)$ and

$$f = \sum_{j=0}^{\infty} \langle t_j | f \rangle t_j \quad (5)$$

Thus, the mapping $\mathcal{T}$ —defined as the association of $f \in L_2(I)$ with the sequence $(\langle t_k | f \rangle)_{k \in \mathbb{N}}$ —is norm-preserving if we define

$$\|(c_k)_{k \in \mathbb{N}}\|_{\#} := \left(\sum_{j=0}^{\infty} |c_j|^2 \right)^{1/2} \quad (6)$$

for $(c_k)_{k \in \mathbb{N}} \in \ell_2(\mathbb{N})$ as norm in $\ell_2(\mathbb{N})$, that is

$$\|\mathcal{T}f\|_{\#} = \|f\| \quad (7)$$

This means in particular that all the information of f is preserved just in the sequence of the Fourier coefficients.

The advantage of using the functions in Eqn. (1) as an orthonormal system is that real-valued functions result in real Fourier coefficients. However, using the equivalent complex orthonormal system $(\eta_k)_{k \in \mathbb{Z}}$

$$\begin{aligned} \eta_k(x) &:= \exp(2\pi i k x) \\ &= \cos(2\pi k x) + i \sin(2\pi k x) \quad \text{for } x \in I \end{aligned} \quad (8)$$

for $k \in \mathbb{Z} := \{\dots, -3, -2, -1, 0, +1, +2, +3, \dots\}$, yields a simpler, more unified description $(\eta_k)_{k \in \mathbb{Z}} =$

$(\exp(2\pi i k \cdot))_{k \in \mathbb{Z}}$. The relation between the new Fourier coefficient $(\langle \exp(2\pi i j \cdot) | f \rangle)_{j \in \mathbb{Z}}$ and the previous ones is (due to Eqn. (8)) easily established. Similarly, as before we obtain

$$f = \sum_{j=-\infty}^{\infty} \langle \exp(2\pi i j \cdot) | f \rangle \exp(2\pi i j \cdot) \quad \text{in } L_2(I) \quad (9)$$

and the mapping $\mathcal{F}_{\#}$ associating the sequence of Fourier coefficients

$$\begin{aligned} &(\langle \exp(2\pi i k \cdot) | f \rangle)_{k \in \mathbb{Z}} \in \ell_2(\mathbb{Z}) \\ &:= \left\{ (c_k)_{k \in \mathbb{Z}} \mid \sum_{j=-\infty}^{\infty} |c_j|^2 \text{ convergent} \right\} \end{aligned} \quad (10)$$

with the element $f \in L_2(I)$ is also norm-preserving, that is

$$\|\mathcal{F}_{\#} f\|_{\#} = \|f\| \quad (11)$$

2. The Fourier Transform

The Fourier coefficients $(\langle \exp(2\pi i j \cdot) | f \rangle)_{j \in \mathbb{Z}}$ suggest the following definition

$$\hat{f}(p) := \langle \exp(2\pi i p \cdot) | f \rangle \quad \text{for } p \in \mathbb{R} \quad (12)$$

where f should now vanish outside a bounded interval (rather than just the unit interval I). The mapping $\mathcal{F}$ that associates with f the function $\hat{f}$ is called the Fourier transform (see Gaskill 1978, Goodman 1968 as general references). The function $\hat{f} = \mathcal{F}f$ is referred to as the Fourier transform (or the spectrum) of f . In view of the Fourier coefficients, we note that any such function can be forced into $L_2(I)$ by rescaling with a suitably large scaling factor $L \in \mathbb{R}$: $\sigma_L f := \sqrt{L} f(L \cdot)$. The Fourier transform interacts with rescaling in the following way

$$\begin{aligned} \mathcal{F}(\sigma_L f) &= \sqrt{|L|} \mathcal{F}(f(L \cdot)) \\ &= \frac{1}{\sqrt{|L|}} (\mathcal{F}f)(\cdot/L) \\ &= \sigma_{1/L}(\mathcal{F}f) \quad \text{for } L \in \mathbb{R}, L \neq 0 \end{aligned} \quad (13)$$

Any such function may also be considered as an element of $L_2(\mathbb{R})$ (the set of measurable, square-integrable functions on $\mathbb{R}$).

Using rescaling with -1 , that is, reflection at the origin, we get $\mathcal{F}^* := \sigma_{-1} \mathcal{F}$ as the inverse Fourier transform and so we are led to the so-called Fourier inversion formula

$$f = \int \exp(2\pi i p \cdot) \hat{f}(p) dp =: \mathcal{F}^* \hat{f} \quad (14)$$

From Eqn. (14) it can be concluded that $\mathcal{F}$ is norm-preserving (and so also preserves the inner product $\langle \cdot | \cdot \rangle$)

$$\|\mathcal{F}f\| = \|f\| \quad (15)$$

which in turn allows the extension of the Fourier transform (as well as Eqns. (14), (15), (13)) by continuity to all $f \in L_2(\mathbb{R})$ (although then the original integral Eqns. (13) and (14) do not in general make sense any more). Analogously to Eqn. (15), the inverse Fourier transform $\mathcal{F}^*$ also preserves the inner product. We note the following important relation between $\mathcal{F}$ and its inverse $\mathcal{F}^{-1} := \mathcal{F}^*$

$$\langle \mathcal{F}f | g \rangle = \langle f | \mathcal{F}^*g \rangle \quad (16)$$

for all $f, g \in L_2(\mathbb{R})$. Equation (15) shows again that by transforming with $\mathcal{F}$ no information is lost. This information is, however, encoded in such a form that local information in $\hat{f}$ represents global information in the original f . This feature is utilized (actually for the two-dimensional case; see the brief discussion in Sect. 5) in image processing where local information is removed from or added to the Fourier transform $\hat{f}$ of an image f (modeled as an illumination distribution function f) to actually improve the visual appearance of the original f by, for example, removing grid structures or sharpening edges. The visual system appears to perform image processing, at least approximately, in this manner (see Cornsweet et al. 1984, Georgeson 1979, Graham 1981). Another application of the particular properties of Fourier transform encoding can be found in holography (see Stroke 1969). Holographic encoding has been utilized as a model for particular features in memory and perception (Pribram et al. 1974). The resistance of the original signal f against ‘noise’ afflicting the Fourier transformed signal $\hat{f}$ is also utilized in data transmission security.

In concrete applications one has to deal with real quantities (the complex notation just being a matter of formal convenience). In this context the so-called power spectrum $|\hat{f}(\cdot)|^2$ is of particular interest (the inverse Fourier transform of the power spectrum is known as the autocorrelation function). Also note that if f is even, that is, $f(-x) = f(x)$, then $(\mathcal{F}_{\cos} f)(x) := \langle \cos(2\pi x \cdot) | f \rangle = (\frac{1}{2}(\mathcal{F} + \mathcal{F}^*)(f))(x)$ (the Fourier cosine transform) and if f is odd, that is, $f(-x) = -f(x)$, then $(\mathcal{F}_{\sin} f)(x) := \langle \sin(2\pi x \cdot) | f \rangle = (\frac{1}{2i}(\mathcal{F} - \mathcal{F}^*)(f))(x)$ (the Fourier sine transform) all of which are real quantities. The Fourier cosine transform would recover the even part $E(f)(x) := \frac{f(x) + f(-x)}{2}$ of f from $\hat{f}$ and the Fourier sine transform its odd part $O(f)(x) := \frac{f(x) - f(-x)}{2}$. Readers who are uncomfortable with complex numbers may restrict their attention to odd and even functions separately (the less mathematically inclined reader may also find in Weisstein 1980 an interesting and entertaining survey on Fourier

transforms). Their information is then fully preserved by the (real) Fourier cosine and the (real) Fourier sine transform, respectively.

To give at least a flavor of how Fourier transforms act, we give two interesting examples (for a visual approach to Fourier transforms see Harburn et al. 1975). The Gauss distribution function γ —well-known from statistics—is given by $\gamma(x) := \exp(-\pi x^2)$ for $x \in \mathbb{R}$. It has the remarkable property that

$$\mathcal{F}_{\cos} \gamma = \mathcal{F} \gamma = \gamma \quad (17)$$

Let χ_M denote the characteristic function of a set M (given by

$$\chi_M(x) := \begin{cases} 1 & \text{for } x \in M \\ 0 & \text{for } x \notin M \end{cases} \quad (18)$$

for $x \in \mathbb{R}$). The characteristic function $\Pi := \chi_I$ of the above unit interval I has the so-called sinc function as Fourier transform

$$\mathcal{F}_{\cos} \Pi = \mathcal{F} \Pi = \text{sinc} \quad (19)$$

where

$$\text{sinc}(x) := \begin{cases} \frac{\sin(\pi x)}{\pi x} & \text{for } x \neq 0 \\ 1 & \text{for } x = 0 \end{cases} \quad (20)$$

for all real x . The sinc function is important in connection with the Shannon sampling theorem.

A discretization of Eqn. (14) yields the finite sum

$$\exp(-2\pi i(N/(2L)) \cdot) \sum_{j=0}^{N-1} \hat{f}((j-N/2)/L) \times \exp(2\pi i(j/L) \cdot) \frac{1}{L} \quad (21)$$

as an approximation for f as N and L become large. Representing f by the samples of

$$f((\cdot - N/2)/L) \quad (22)$$

at the points $j = 0, 1, 2, \dots, N-1, N$ and letting $L = \sqrt{N}$ we may consider Eqn. (21) as a product of a column vector by the matrix $\frac{1}{\sqrt{N}}[\exp(2\pi i(jk/N))]_{j,k=0,1,\dots,N-1}$ approximating f . This matrix is unitary and known as the inverse discrete Fourier transform (IDFT). Consequently, its inverse, the unitary matrix

$$\frac{1}{\sqrt{N}}[\exp(-2\pi i(jk/N))]_{j,k=0,1,\dots,N-1} \quad (23)$$

is called the discrete Fourier transform (DFT). For practical purposes it is worth noting that the number

of numerical operations required to calculate the discrete Fourier transform (or its inverse) can be dramatically reduced by a factorization technique known as the fast Fourier transform (FFT).

The connection to the Fourier series transform $\mathcal{F}_\#$ is apparent. However, since the transform $\mathcal{F}_\#$ can be recovered from the Fourier transform $\mathcal{F}$ (see Eqn. (45) below), we will here and from now on focus on the latter.

3. The Fourier Transform as a Spectral Representation

3.1 Derivatives

The significance of representing a function in terms of its Fourier transform becomes apparent if we consider how that transform interacts with differentiation ∂ . Introducing for convenience the symbol $D := \frac{1}{2\pi i} \partial$ we find that

$$D = \mathcal{F}^{-1} \mathbf{m} \mathcal{F} \text{ in } L_2(\mathbb{R}) \quad (24)$$

where $\mathbf{m}$ stands for the multiplication-by-argument operation, that is

$$(\mathbf{m}f)(p) := pf(p) \text{ for all } f \in L_2(\mathbb{R}), p \in \mathbb{R} \quad (25)$$

It should be noted that being in the domain of the differential operator D (as naturally characterized by the well-definedness of the right-hand side of Eqn. (24)) implies a generalized concept of differentiability. The elements in the domain turn out to be even in $BC(\mathbb{R})$. Equation (24)—it is called a spectral representation of D —shows the equivalence of differentiation $\frac{1}{2\pi i} \partial$ with multiplication-by-argument $\mathbf{m}$. The obvious symmetry of $\mathbf{m}$, that is

$$\langle \mathbf{m}f | g \rangle = \langle f | \mathbf{m}g \rangle \quad (26)$$

implies the symmetry of D , that is

$$\langle Df | g \rangle = \langle f | Dg \rangle \text{ in } L_2(\mathbb{R}) \quad (27)$$

3.2 Functions of D

The Fourier transform spectral representation in Eqn. (24) gives rise to an extension to polynomials in D and $\mathbf{m}$, respectively. Equation (24) thus suggests to generally define functions of D by letting

$$S(D) := \mathcal{F}^{-1} S(\mathbf{m}) \mathcal{F} \text{ in } L_2(\mathbb{R}) \quad (28)$$

where S can be fairly general (and even matrix-valued, in which case the Fourier transform is to be carried out component-wise). This concept is extremely powerful, since a large class of models discussed in so-called linear systems theory (see Gaskill 1978, Norman 1981)

can be understood as such functions $S(D)$ acting on an input u resulting in an output $S(D)u$. Characterizing properties of such systems are that their input–output relations are linear and translation invariant, that is, sums, multiples, and shifts of input result in sums, in (up to scaling) the same multiple, and equally shifted output. Indeed, translation τ_h defined by its action on functions f as a shift of the argument

$$\tau_h f := f(\cdot + h) \quad (29)$$

is itself a function of D in the above sense

$$\tau_h = \exp(2\pi i h D) = \mathcal{F}^{-1} \exp(2\pi i h \mathbf{m}) \mathcal{F} \quad (30)$$

It may be interesting to note that by substituting the series expansion for the exponential function, this formula (if applied to suitable functions) is recognized as nothing but the Taylor expansion. Such translation-invariant, linear systems occur (usually in their higher-dimensional form, compare Sect. 5) as good approximations of many aspects of visual and auditory perception.

3.3 Convolution

The action of a function $\hat{S}(D)$, where $\hat{S}$ is the Fourier transform of S defines what is called convolution (of S with g)

$$S * g := \hat{S}(D)g \quad (31)$$

which is defined for any g in the domain of $\hat{S}(D)$. In many cases, $S * g$ is actually given as an integral expression, the convolution integral

$$(S * g)(x) = \int S(x - y)g(y) dy \quad (32)$$

In accordance with Eqn. (31) for such convolution integrals the so-called convolution theorem holds

$$\mathcal{F}(S * g) = \hat{S} \hat{g} = \hat{S}(\mathbf{m}) \hat{g} \quad (33)$$

Particularly, the above-mentioned relationship between the autocorrelation and the power spectrum reveals that the autocorrelation is a convolution.

4. Generalized Fourier Transform and Some Applications

Generalizing the meaning of $\langle \cdot | \cdot \rangle$ we introduce generalized functions f (also called distributions) as linear functionals by prescribing the value of

$$f(\varphi) := \langle f | \varphi \rangle \quad (34)$$

for any smooth φ vanishing outside a bounded interval in $\mathbb{R}$ —we shall write $\varphi \in C_0^\infty(\mathbb{R})$ —such that linearity holds, that is

$$\langle f | \varphi + \alpha \psi \rangle = \langle f | \varphi \rangle + \alpha \langle f | \psi \rangle \quad (35)$$

for all complex numbers α and all $\varphi, \psi \in C_0^\infty(\mathbb{R})$. Clearly, any $f \in L_2(\mathbb{R})$ is also such a generalized function, but also $\exp(2\pi i p \cdot)$, although not an element of $L_2(\mathbb{R})$, is such a generalized function, as Eqn. (12) of the Fourier transform shows. A generalized function, which is indeed *not* given by a function, is featured by the distribution $\delta_{\{t\}}$ defined by

$$\delta_{\{t\}}(\varphi) = \langle \delta_{\{t\}} | \varphi \rangle := \varphi(t) \quad \text{for all } \varphi \in C_0^\infty(\mathbb{R}) \quad (36)$$

(this distribution apparently takes a sample of the ‘test function’ φ at point $t \in \mathbb{R}$). The special choice $\delta := \delta_{\{0\}}$ is the so-called Dirac δ -distribution. Since it can only be distinguished from 0 by testing with $\varphi \in C_0^\infty(\mathbb{R})$ satisfying $\varphi(0) \neq 0$ we say $\delta = 0$ on $\mathbb{R} \setminus \{0\}$. However, δ is (by definition) not identically zero as a functional. It is particularly useful in many contexts to have $\delta_{\{t\}}$ ($= \tau_{-t}\delta$) as a model for something very small but nevertheless non-negligible such as a mass point, an elementary charge, a light point, a short impulse, or a molecule at location t (see (Sect. 5) for the particularly interesting higher-dimensional case). With sufficient care a large class of such distributions f (e.g., the so-called tempered distributions) can be established for which the concept of derivative, multiplication by the argument, and Fourier transform can (guided by Eqns. (27) and (16)) be generalized by defining

$$\begin{aligned} \langle Df | \varphi \rangle &:= \langle f | D\varphi \rangle \\ \langle \mathcal{F}f | \varphi \rangle &:= \langle f | \mathcal{F}^*\varphi \rangle \\ \langle \mathcal{F}^*f | \varphi \rangle &:= \langle f | \mathcal{F}\varphi \rangle \end{aligned} \quad (37)$$

for all $\varphi \in C_0^\infty(\mathbb{R})$. As an example for this generalized differentiation we find for the characteristic function $\chi_{]0, \infty[}$ of the interval $]0, \infty[$ of all positive real numbers

$$D\chi_{]0, \infty[} = \frac{1}{2\pi i} \delta \quad (38)$$

The Fourier transform of the distribution $\delta_{\{t\}}$ is according to Eqn. (37)

$$\mathcal{F}\delta_{\{t\}} = \exp(-2\pi i t \cdot) \quad (39)$$

and conversely we have

$$\mathcal{F}\exp(2\pi i t \cdot) = \delta_{\{t\}} \quad (40)$$

The latter fact can be used to detect oscillatory behavior of frequency t which may be hiding in seemingly random data. The oscillation would show up in the Fourier transformed data as a ‘peak’ at point t .

The concept of functions of D and in particular the concept of convolution can also be carried over to tempered distributions. This will be illustrated by a few applications.

4.1 Impulse Response

The importance of the Dirac δ -distribution is that a translation-invariant, linear system $S(D)$ is completely described by its impulse response $S(D)\delta$. Indeed, the general response $S(D)f$ is given by convolution with the impulse response

$$S(D)f = S(D)(\delta * f) = (S(D)\delta) * f \quad (41)$$

In the case that $S(D)$ is the solution operator $S(D) = P(D)^{-1}$ of the differential equation $P(D)u = f$, P being a polynomial, the impulse response is also known as a fundamental solution (or Green’s function).

4.2 Shannon’s Sampling Theorem

Another distribution of particular interest is the (sampling or) comb distribution $\text{III} := \sum_{n=-\infty}^{+\infty} \delta_{\{n\}}$ which takes samples at every integer point. This distribution is reproduced by the Fourier transform, that is

$$\mathcal{F}\text{III} = \text{III} \quad (42)$$

(which is another way of stating the Poisson summation formula). If $f \in L_2(I)$ then $\text{III} * f$ is simply the periodic extension of f to all of $\mathbb{R}$. Therefore, by ‘cutting-off’ with the characteristic function Π we recover

$$f = \Pi(\text{III} * f) \quad (43)$$

As we now demonstrate, the so-called Shannon sampling theorem follows from Eqn. (42). In fact, applying Eqn. (43) to $\hat{f} \in L_2(I)$ we get after the inverse Fourier transformation has been applied that

$$\begin{aligned} f &= \mathcal{F}^*(\Pi(\text{III} * \hat{f})) \\ &= \text{sinc} * \left(\sum_{n=-\infty}^{+\infty} f(n) \delta_{\{n\}} \right) \\ &= \sum_{n=-\infty}^{+\infty} f(n) \text{sinc}(\cdot - n) \end{aligned} \quad (44)$$

Any function f with $\hat{f}$ vanishing outside a bounded interval is called band limited. Since any such function can be easily rescaled to have $\hat{f} \in L_2(I)$, Eqn. (44) shows that any band-limited function f can be completely recovered from equidistant sampling. It is worth noting that by interchanging the role of f and $\hat{f}$ in the Shannon sampling theorem we obtain

$$\hat{f} = \mathcal{F}(\Pi(\text{III} * f)) = \sum_{n=-\infty}^{+\infty} \hat{f}(n) \text{sinc}(\cdot - n) \quad (45)$$

and after applying the inverse Fourier transform the Fourier series Eqn. (9) is recovered. The sampling theorem has many applications, in particular in the analysis of auditory and visual perception (see, e.g., Yellot 1990).

4.3 Wavelets

It is interesting to note that $(\tau_{-n}\text{sinc})_{n \in \mathbb{Z}}$ is also an orthonormal system in $L_2(\mathbb{R})$. By virtue of $(\tau_{-n}\text{sinc})_{n \in \mathbb{Z}}$ being an orthonormal system we get (as for the trigonometric series)

$$\sum_{n=-\infty}^{+\infty} \langle \tau_{-n}\text{sinc} | g \rangle \tau_{-n}\text{sinc} \quad (46)$$

as the best approximation of g in these terms. According to Eqn. (44) we have that for functions with bandwidth less than or equal to 1 (i.e., $\hat{f} \in L_2(I)$) g actually is represented by this sum. To cover all band-limited functions one would have to allow for sufficiently large scaling factors L . Letting, for example, $L = 2^p, p \in \mathbb{Z}$, then $(\sigma_{2^p}\tau_{-n}\text{sinc})_{p,n \in \mathbb{Z}}$ can be used to approximate any element $f \in L_2(\mathbb{R})$. All elements of $(\sigma_{2^p}\tau_{-n}\text{sinc})_{p,n \in \mathbb{Z}}$ are generated by the combination $\sigma_{2^p}\tau_{-n}$ of scaling and translation from the single function sinc , the so-called scaling function of this particular construction. Unfortunately, $(\sigma_{2^p}\tau_{-n}\text{sinc})_{p,n \in \mathbb{Z}}$ is only orthonormal for fixed $p \in \mathbb{Z}$. By a suitable orthonormalization procedure (multiresolution analysis) one can obtain, however, that $(\sigma_{2^p}\tau_{-n}(\text{sinc} - \sqrt{2}\sigma_2(\text{sinc})))_{p,n \in \mathbb{Z}}$ is an—even complete—orthonormal system in $L_2(\mathbb{R})$. Any orthonormal system generated by $\sigma_{2^p}\tau_{-n}, p, n \in \mathbb{Z}$, from a so-called mother wavelet—here $\text{sinc} - \sqrt{2}\sigma_2(\text{sinc})$ —is called an orthonormal wavelet basis. Wavelets derive their utility largely from the fact that they do not have a fixed base scale like, for example, the Fourier system $(\exp(2\pi i n \cdot))_{n \in \mathbb{Z}}$, which by allowing for translations would also yield an orthonormal system $(\tau_r(\exp(2\pi i n \cdot)))_{n,r \in \mathbb{Z}}$ for $L_2(\mathbb{R})$. Wavelets naturally allow for the ‘right’ scale in $L = 2^p, p \in \mathbb{Z}$, to emerge for any given f according to their weight in its orthonormal expansion. As the Fourier transform may be considered to be a continuously scaled Fourier series, there are also continuously scaled versions of wavelet expansions known as wavelet transforms.

5. Higher-dimensional Fourier Transform

Much of what has been explored above can be generalized to higher dimensions. This is due to the particular product structure of the higher-dimensional exponential

$$\begin{aligned} & \exp(2\pi i(x_1 p_1 + x_2 p_2 + \dots + x_n p_n)) \\ &= \exp(2\pi i x_1 p_1) \exp(2\pi i x_2 p_2) \dots \exp(2\pi i x_n p_n) \end{aligned} \quad (47)$$

for $x_i, p_i \in \mathbb{R}, i = 1, 2, \dots, n$, that is, $(x_1, x_2, \dots, x_n), (p_1,$

$p_2, \dots, p_n) \in \mathbb{R}^n$. Thus, the n -dimensional Fourier transform, $n \in \mathbb{N}, n \geq 2$, can be understood as a repeated one-dimensional Fourier transform, that is

$$\begin{aligned} (\mathcal{F}f)(p) &= \iint \dots \int \exp(-2\pi i x p) f(x) dx_1 dx_2 \dots dx_n \\ &= \int \exp(2\pi i x_1 p_1) \int \exp(-2\pi i x_2 p_2) \dots \\ &\dots \int \exp(-2\pi i x_n p_n) f(x) dx_n \dots dx_2 dx_1 \end{aligned} \quad (48)$$

where $x = (x_1, x_2, \dots, x_n), p = (p_1, p_2, \dots, p_n)$, and $xp = \sum_{i=1}^n x_i p_i$. As a consequence, many of the above considerations can be carried over to the higher-dimensional case. For example, with $x^2 := xx, x \in \mathbb{R}^n$, the definition of the Gauss distribution function carries over to the n -dimensional case and Eqn. (17) remains true. The n -dimensional Dirac δ -distribution $\delta_{\{x\}}$ simply takes a single sample at $x \in \mathbb{R}^n$ and still has Fourier transform $\exp(-2\pi i x \cdot)$. Also, $\text{III} := \sum_{x \in \mathbb{Z}^n} \delta_{\{x\}}$, which takes samples at every point of $\mathbb{R}^n$ with integer coordinates, still satisfies

$$\mathcal{F}\text{III} = \text{III} \quad (49)$$

Thus, in particular, corresponding variants of the Shannon sampling theorem and of the Fourier series expansion hold. The scaling, however, has to be generalized to $\sigma_L f := |L|^{n/2} f(L \cdot)$, but then Eqn. (13) also carries over to the n -dimensional case. The higher-dimensional Fourier transform finds its applications in higher-dimensional, translation-invariant linear systems (Norman 1981). A particularly prominent application is in optics (see, e.g., Gaskill 1978, Goodman 1968, Taylor 1978). As pointed out earlier, the visual system may be considered at least approximately to be a two- or three-dimensional example and may be analyzed with Fourier techniques (see e.g., Cornsweet et al. 1984, Georgeson 1979, Graham 1981, Julesz 1980, Yellot 1990).

Fourth World

The Fourth World is both an imagined community and a political coalition of indigenous peoples, transcending the borders of nation states. Indigenous identity is grounded in a people's claim to be descended from the original inhabitants of a country, vis-à-vis ethnic groups which came later as conquerors and colonists; it also implies a radical difference from other life ways. Thus, the Fourth World aligns indigenous peoples with the Third World (see *Third World*) in opposition to the neocolonialism of the First (capitalist) World, but opposes them to both and to the Second (communist) World, in rejecting modernity in favor of spirituality and closeness to nature. Notwithstanding their weakness in terms of conventional political resources, and their often minuscule numbers, Fourth World peoples were able to achieve substantial recognition in the second half of the twentieth century, by linking local with global mobilization.

1. Recognizing Indigenous Peoples

The current use of the term 'indigenous' has its origins in the European colonization of the New World, and the settlers' attempt to make their homes in places that were already inhabited. It can be dated conveniently from Columbus's landfall in the Americas in 1492, though events subsequently followed a similar course in Australasia, parts of Africa, and some Pacific

islands. Settler societies commonly identified indigenous populations by the use of generic terms such as Indians, natives, aborigines, and indigenes. 'Indigenous' has become the preferred term, particularly in Fourth World discourse.

People identifying as indigenous live alongside the descendants of settlers and also recent immigrants in the former colonies of the Americas and Australasia, and most of the governments of these states recognize their presence. Indigenous groups also exist in Arctic Scandinavia and Russia, and in Japan, following the extension of central government into marginal areas, and incursions by the majority populations. These peoples survive either as internal colonies, or integrated with lower strata of the majority society. Some minorities in the recently decolonised nations of Africa and Asia have also identified themselves as indigenous, in resisting the encroachments and intrusions of a dominant population and government. There are other people who might be regarded as indigenous but who have been unable to participate in the Fourth World coalition, or who prefer some other kind of identification.

2. Indigenous Peoples and National Governments

Official criteria of indigenous status vary; thus, some Latin American countries recognize only those who speak an indigenous language, regarding others as assimilated; Australia accepts a combination of self identification and community recognition, while in the US, status derives from treaties made between the government and certain tribes. Taking official estimates from a selection of countries, the indigenous population exceeds 40 percent in the Andean republics and Guatemala; ranges between five percent and 20 percent in New Zealand, Chile, Mexico, Panama, and Nicaragua; between one and four percent in Australia, the United States, Canada, Colombia, Norway, Malaysia, and the Philippines. The percentages are even smaller in Brazil, Sweden, Russia, Japan, and Botswana. However, the size of an indigenous population is no guide to its political visibility on the global arena. From the metropolitan perspective, the position of indigenous peoples is more or less marginal. From their own perspective, keeping the majority at arm's length enables them to preserve an indigenous space, perhaps grounded in a distinctive mode of livelihood, such as fishing or herding or subsistence cultivation. However, the history of indigenous peoples has been characterized by encroachments on this space, and if they can no longer disengage, their lives become hostage to the schemes of the majority. In the second half of the twentieth century indigenous spaces all around the world were subjected to a new round of incursions, in such forms as logging, agribusiness, mining, commercial fishing, and tourism. Resistance to previous incursions had been localized, and often

violently suppressed, but from the 1960s, changes in international relations provided indigenous peoples with new freedoms and opportunities.

3. *International Politics and Transnational Coalitions*

In the context of the Cold War and the replacement of the old imperial domains by nonaligned 'new nations', colonialism and racial discrimination became issues in international politics and reproaches that most governments preferred to avoid. The new medium of television transformed domestic issues such as the African-American civil rights movement in the US and the Bantu struggle against *apartheid* in South Africa, into global dramas, on which people elsewhere could make judgments and relate to their own situations. The eruption of the Cold War in Latin America and Southeast Asia created a climate of dissent in the metropolitan countries involved, as well as others that were not directly involved, for example, in Western Europe.

From the 1970s the world became more receptive to indigenous demands, and indigenous mobilization took on an international dimension, both through coalitions of indigenous peoples across national borders, and the involvement of nonindigenous organizations. Indigenous Americans were the first to mobilize across national borders, with the formation of the International Indian Treaty Council 1974 (Ortiz 1984). In 1975 indigenous Americans formed the World Council of Indigenous Peoples (WCIP), presently opening their ranks to Aboriginal Australians, New Zealand Maori, and Norwegian Saami; others followed. Sympathetic governments facilitated the travel of indigenous spokespersons and several hosted the world conferences that have been held annually ever since. The United Nations recognized the WCIP and its participant organizations in 1977.

As early as the 1950s, the International Labor Organization had drafted a resolution on discrimination against indigenous peoples (Ortiz 1984); but it was not until 1972 that the UN, in response to representations from various nongovernmental bodies, set up the United Nations Sub-Committee on the Prevention of Discrimination and the Protection of Minorities and commissioned a study of the situation of indigenous peoples (Van Cott 1994, Pritchard 1998). In 1977, after further lobbying from nongovernment organizations, the UN convened a conference in Geneva on discrimination against indigenous populations in the Americas, in which the main participants were indigenous. In 1982, it set up the Working Group on Indigenous Populations, bringing to Geneva indigenous peoples not only from the Americas but Australasia and Europe.

Following the Columbus quincentennial, the UN proclaimed an International Year and Decade of

Indigenous Peoples. Since 1995, its Commission on Human Rights has been discussing a draft declaration on the Rights of Indigenous Peoples, to be ratified by the participating governments. These developments at the international level have coincided with the emergence, in Europe as well as North America, of nongovernment organizations specifically concerned with indigenous peoples. The World Council of Churches has also maintained a continuous interest since 1972 and organizations with broader concerns, such as the environmentalists, have discovered interests in common with indigenous groups. As a result of these developments, governments must expect not only to have their own indigenous minorities subject to international scrutiny, but also to take a position on the practices of other governments.

4. *Political Process and Indigenous Mobilization*

Indigenous groups have finally to settle matters with the governments of the countries in which they live, but appealing to international opinion now offers a means of applying a pressure that is not otherwise available. Through the Internet, indigenous organizations are able to disseminate information instantly to sympathisers around the world, and through them to national media and political bodies; where indigenous activists are at risk of reprisals, international observers can be on the scene at short notice. In less critical circumstances, indigenous protesters can take advantage of a national festivity, when the international media are watching, to publicize their grievances through what has become the politics of embarrassment. Otherwise powerless indigenous groups have become skilled in the performance of protest, deploying the signs of their identity in colorful ethnodramas which draw the television cameras (Paine 1982).

The outcome of indigenous mobilization depends on the relative strength of the opposing interests, and—since indigenous peoples live under a variety of regimes—the forms of political process available to them. Even in democracies, a small, low status, or inaccessible minority may have difficulty in attracting the attention of voters. International pressure has induced governments to be more responsive to indigenous claims than their electorates. In some countries, legal process has proved more productive than political process and there has been a substantial development in the law of indigenous rights, with the sharing of experience and insights across national boundaries (Pritchard 1998).

5. *The Politics of Indigenous Difference*

It took some time for a distinctively indigenous politics to take shape. At first indigenous people might mobilize within a framework of agrarian struggle or

civil rights campaigns, with class or race as the basis for alliance. With the emergence of difference politics in the 1970s, the indigenous movement began to articulate its own special needs and aspirations. Thus, a Bolivian Aymara leader argued the need to progress from 'democratic and political reductionism, to an ethnic democracy' (Van Cott 1994).

Despite the diversity among indigenous peoples, certain issues are now regarded as characteristic of all Fourth World peoples, being woven into a transnational discourse of indigeneity. Definitive is the trope of survival, referring to a past of resistance to domination and assimilation, and a future in which indigenous peoples will regain the space, physical and cultural, in which to practice their unique kind of difference. This difference often is grounded in subsistence economic practices that use resources in ways quite different from those of the mainstream economy. Land is not only an economic resource but also the site of the group's mythology and history. Where the land has been expropriated, there is a demand for its return to the traditional owners, and the legislation of some kind of native title. Where recuperation is not a possibility, there may be a call for compensation, to acquire other lands, or for royalties that can be used to underwrite some other basis for indigenous revival.

Indigenous peoples also demand the rehabilitation of their cultural heritage, including language. However, a return to a precolonial existence is rarely an option. Revival of indigenous religion raises particular difficulties, since the groups in question may not only have been practicing Christians for generations, but be indebted to the church for local support and international linkages in its political struggles. Adherents of New Age religions may welcome the return of the old religions, but more common is a negotiation with the churches over the indigenization of clergy and forms of worship. Whether in Christian or other form, the Fourth World proclaims its spirituality in the face of the materialism of developed and developing worlds.

The demand of Fourth World peoples for the restoration of sovereignty constitutes the most direct challenge to the state, just as the claim to be 'first nations' challenges the self image of the nations which encompass them. Many indigenous peoples are too small, too scattered, or too dependent economically, for sovereignty to be realizable. A number have been able to negotiate a degree of self determination within the framework of the state, in respect of a particular territory; the Nunavut agreement in Northern Canada is the most far reaching arrangement of this kind. Peoples who live interspersed with the majority population are harder to accommodate, but the Saami Parliaments in Scandinavia and the Aboriginal and Torres Strait Islander Commission in Australia have assumed responsibility for some of the special needs of their constituents. As with land ownership, it may not be possible or appropriate to try to recreate pre-

existing institutions of government, so that new forms have to be devised. As with the Aboriginal and Torres Strait Islander Commission, power is more centralized than formerly. In the US, by contrast, power continues to lie mainly with the tribes, constituted as a result of treaties drawn up in the nineteenth century.

The Fourth World can be described as an imagined community (Anderson 1991) but it is not one that aspires to nationhood; the aim of coalitions such as the WCIP is to enhance rather than assume the sovereignty of its constituent peoples and to enable them to proclaim their particular kinds of difference to their world. It has, nevertheless, provided the milieu in which a Fourth World discourse could be articulated.

6. The Fourth World and its Constituents

Fourth World discourse represents indigenous peoples as the custodians of a unique wisdom which, if lost, will be lost to all humankind. Cultural survival, then, is not just a matter of minority rights but of global concern. The qualities that make up indigeneity are more or less explicitly alternative to modernity including a spiritual rather than exploitative attitude towards the environment and a focus upon essential human needs over material accumulation and economic development. It is because of these shared qualities that indigenous people are able to talk to one another and imagine people like themselves, even though they have not met them.

Fourth World discourse necessarily presents the qualities of indigeneity as generalities, but this is on the understanding that their value is only realized through their embeddedness in particular local life ways. While it celebrates the special qualities that indigenous peoples share, any tendency to standardize or homogenize them runs up against the countervailing emphasis on the cultural diversity of the constituency. Consistent with this, Fourth World gatherings are celebrations of particularity, in which the various groups perform their cultures in such accessible forms as music and dance, and cuisine. Removed from their sociocultural settings, these practices cannot be apprehended in their full complexity; they are rather the signs of identity, cultural capital which is deployed to achieve a sense of equivalence among Fourth World peoples, and to display difference to others.

While Fourth World leaders speak as members of the particular peoples from which they come, participation in the transnational arena takes them away from their communities for long periods; some may be exiled from their homelands. Thus, paradoxically it is possible to speak of cosmopolitan indigenes, whose time is spent working with other indigenous peoples, and representing the Fourth World to nonindigenous people, leaving little time to keep contact with their grass roots. For the present, however, the Fourth

World is a culture of negotiation and representation; it is not an identity in itself.

7. Scholarly Studies of the Fourth World

The discipline of anthropology emerged in the wake of colonization as a study of the peoples whose descendants make up the Fourth World. The original aim of this research was to reconstruct the early history of humanity. However, from early in the twentieth century anthropologists along with ethnohistorians studied the effects of European settlement and colonization on indigenous peoples and the ways they responded to these influences (Wolf 1982).

Since the 1960s, anthropologists and ethnohistorians have also been involved in the indigenous rights movements, coming forward as experts in court cases, and advising community leaders. Anthropologists tend to work from the perspective of the local community but there have been comparisons of conditions within both North and South America (Kroeber 1994; Urban and Sherzer 1991), and between continents (Dyck 1985). Studies at the level of the nation state have been rather the province of historians, political scientists, and lawyers, some of whom have also worked comparatively, and on the relation between indigenous peoples and the UN (Ortiz 1984, Van Cott 1994, Pritchard 1998). Nongovernmental organizations, such as Cultural Survival, Survival International, and the International Work Group for Indigenous Affairs, are concerned specifically with indigenous peoples and also sponsor and publish research in these areas. What remains unresearched is the actual working of Fourth World conferences and delegations and the development of a meta-indigenous culture among those indigenous people who work at this level.

Free Will and Action

According to the standard account of action, an agent's acts are those of his bodily movements that spring in an appropriate way from his will. Bodily movements that are caused in some other way—the bodily movement of someone who gets blown over by the wind, say—are not among the actions agents perform. More precisely, an agent's actions are those of his bodily movements that occur because he wills them to, where an agent's will is, in turn, identified with his desires and means-end beliefs: actions are bodily movements that occur because an agent desires some outcome and believes that the outcome can be produced by his moving his body in the relevant way. Bodily movements that trace their causal history to other states or events in an agent's psychology, or to nonpsychological states or events, are not actions (Davidson 1963, 1980).

The standard account of action suggests that all animals that are capable of desire and belief, whether those animals are human or nonhuman, are capable of action. The bodily movement of a mouse that occurs because it wants some cheese and believes that it can get some by running in the direction of the crumbs on the floor is an action of the mouse, just as much as the intricate performance of a gymnast or a ballet dancer. By contrast, the movement that the mouse makes when it is picked up by a cat and flung across the room is not an action, any more than the movement of a ballet dancer who is unceremoniously dropped to the floor by her partner.

Not all of an agent's actions, whether the agent is human or nonhuman, are free, however, notwithstanding the fact that they all spring from his will. When a mouse is caught in a trap by its tail, it may give up the struggle and sit down near the trap. Its body remains under its control, not under the control of some alien force, but staying near the trap is not something that the mouse does freely. Similarly, when

a man is locked in a prison cell he may give up the struggle and sit on his chair behind bars. But staying behind bars is not something that he does freely. What, then, within the class of actions, is the mark of those of an agent's actions that are free, as opposed to those that are unfree?

Some hold that free actions are all and only those that are done intentionally: that is, they are those of an agent's actions which, suitably described, can be seen to have been rationalized by his desires and beliefs (Davidson 1973, 1980). This idea is supposedly supported by paradigm cases of unfree action, such as that of the man and the mouse. For though the mouse stays near the trap and the man stays behind bars, neither does what they do intentionally under these descriptions. The man, for example, intentionally sits on a chair, as opposed to on the ground—that is something that is rationalized by his desires and beliefs—and one consequence of his sitting on the chair is that he stays behind bars. But he does not have any desires and beliefs that rationalize his staying behind bars. That is merely a consequence of what he does intentionally, not itself something that he does intentionally.

But though this certainly captures one sense in which we might say of actions that they are under an agent's control, it does not capture the idea of a free action. It entails, for example, that whenever someone who acts in a certain way knowingly, but not intentionally, he does not act freely, and this is surely quite wrong. Suppose that someone, A, desires to convey to another, B, the low opinion he has of a third person, C. But let's suppose further that he goes on to tell B in full knowledge of the fact that C is standing within earshot, and so causes C to become embarrassed. He could have waited until C left, but he didn't because he didn't care. A then knowingly causes C to become embarrassed, but he does not do so intentionally, as there is no desire of A's such that he believes he can satisfy that desire by embarrassing C. C's embarrassment is merely a foreseen consequence of what he does do intentionally, which is to tell B his low opinion of C. It would, however, be extremely implausible to suppose that the fact that C's embarrassment was merely foreseen, rather than intentionally produced, makes it the case that A didn't cause C's embarrassment freely. It was, after all, entirely up to A whether or not C would be embarrassed by what he said. He wasn't forced to embarrass C.

The more standard idea has thus been that an agent's acts are free just in case he could have done otherwise than he in fact did when he acted (Wiggins 1973). The question 'Did the agent act freely?' is in this way supposed to reduce to the question 'Did the agent have any alternative option?' A's causing C to become embarrassed is therefore indeed a free action, on this way of seeing things, because A had the option of acting in some other way instead. He could have waited until C was out of earshot. This is the relevant

sense in which free actions are under an agent's control. The reason that a mouse caught in a trap does not stay in the vicinity of the trap freely is thus that it has no other option: it cannot do otherwise but stay near the trap. The reason a man who sits on a chair in a locked prison cell does not stay behind bars freely is that he, too, has no other option: he cannot do otherwise than stay behind bars.

However, this more standard account of free action immediately raises a difficult question, for without a special explanation of what the 'could' means, it seems to imply that freedom of action is impossible in a deterministic world. Every action performed by an agent in a deterministic world is fixed by the way the world was long before the agent was born together with the operation of causal laws. In a very familiar sense of 'can,' no agent can ever do otherwise than he in fact does. Agents are therefore always forced to do what they do by their past and the forces of nature.

Incompatibilists—those who think that freedom is impossible in a deterministic world—happily accept this conclusion (van Inwagen 1975). But they in turn divide over the substantive question whether the world is or is not deterministic. Those who think that it is—the so-called 'hard' determinists—draw the conclusion that there are no free actions. Those who think that there are free actions—the 'libertarians'—draw the conclusion that the world is not deterministic. But not everyone is an incompatibilist. Compatibilists find it difficult to see how the mere fact of causal determinism is supposed to undermine freedom of action. If anything, they insist, things are the other way around. Events that cannot be explained causally are completely random: this is what it means to say that an event eludes causal explanation. But free actions can hardly be randomly produced. Free actions, like all actions, are produced in a very reliable fashion by the desires and beliefs of their agents. They therefore conclude that free actions, if there are any, are caused by desires and beliefs, and hence that the sense of 'can' at issue must be different from the one that so impresses the incompatibilists (Ayer 1954, 1982).

Compatibilists have therefore coupled the suggestion that an agent's acts are free just in case he could have done otherwise with a special explanation of what this 'could' means. To say of an agent that he could have acted otherwise, in the sense relevant to establish freedom of action, is, they suggest—or, at any rate, this is the way the suggestion was originally put—to say of him that he would have done otherwise if he had chosen to (Moore 1911). In other words, freedom of action turns on whether or not, in the nearby possible worlds in which agents choose to do otherwise than they do in actuality—these are possible worlds in which the past is ever so slightly different—they succeed in doing what they choose to do. The truth of falsity of determinism is irrelevant.

The intuitive idea here should be clear enough, for the suggestion amounts to the claim that agents enjoy freedom of action if the way the external world presents no barrier to their efforts to act as they will: freedom is a matter of the absence of such external barriers or constraints. To see how this allows us to sort cases of free from cases of unfree action, consider the difference between two men who stay in a prison cell, one of whom is locked in, and one of whom isn't. The difference is that the one, but not the other, would have walked out of his prison cell if he had chosen to do so: in the nearby possible worlds in which the agent who is locked in his prison cell chooses to walk out, he fails to do so, as he is still locked in, whereas in the nearby possible worlds in which the agent who is not locked in his prison cell chooses to walk out, he succeeds in doing so, as his cell presents no barrier to him. The one has the option to walk out, whereas the other doesn't. Moreover this account is, apparently, fully general. Of two mice that stay nearby a trap, the one whose tail isn't caught in the trap, and so moves away in the nearby possible worlds in which it chooses to do so, stays nearby the trap freely, whereas the one whose tail is caught in the trap, and so doesn't move away from the trap in the nearby possible worlds in which it chooses to do so, does not stay nearby the trap freely. The external world presents a barrier to the movements of the latter, it serves as a constraint, but it presents no such barrier or constraint to those of the former.

Intuitive though this idea might be, however, the suggestion in the form in which it was originally made is problematic. The problem is that, since choosing is an action, it is something that people can do freely or unfreely (Chisholm 1964, 1982). But now suppose we ask whether a particular action is free. This turns on whether the agent could have done otherwise than he in fact did, and, according to the suggested analysis of 'could,' this turns on what happens in those nearby possible worlds in which the agent chooses to act otherwise. But now note that, whatever answer we give to this question, we have been forced to admit that the status of the original action as free or unfree turns on what happens when another merely possible act is performed, an act whose status as free or unfree in turn needs to be determined. Moreover, the status of this merely possible act turns on whether or not, in those nearby possible worlds in which the agent chooses otherwise than to choose to act otherwise, he succeeds in so choosing. Whatever answer we give to this question, it follows that we have therefore been forced to concede the possibility of yet another act whose status as free or unfree needs to be determined. And so we must go on.

The problem here is the need to posit further acts of choosing to act otherwise, and choosing otherwise than to choose to act otherwise, and so on. The problem is not just that questions about freedom of action are never answered, once and for all—every

question answered leaves another posed but unanswered, and so on *ad infinitum*—the problem is rather that it is implausible to suppose that every creature capable of free action is capable of such ever higher and higher order acts of choosing. In order to raise the mundane question whether a mouse, caught in a trap, sits nearby the trap freely or unfreely, it is surely quite incredible to suppose that we must thereby concede the possibility of its choosing to do otherwise than to sit near the trap, and choosing otherwise than to choose to do otherwise than to sit near the trap, and so on. Mice simply aren't cognitively sophisticated enough to make such choices.

How are we to solve this problem? The suggested analysis of 'could have done otherwise' clearly needs to be rephrased so that the possibility of the freedom of an agent's actions does not entail the possibility of his making ever higher and higher order acts of choice. We should therefore suppose that for it to be true that an agent could have done otherwise it has to be the case that he would have done otherwise, not if he had chosen, but rather *if he had wanted*. This not only removes the problem just encountered—it is indeed possible for agents whose acts are free, men and mice alike, to want other than they actually want, and that possibility does not commit us to the possibility of their making higher order acts of choice—it also better captures the intuitive idea presented at the outset, the idea that an agent's actions are free to the extent that they are dependent on his will. For, as we saw, an agent's will is to be identified with his wants and means-end beliefs. To say of an agent, be he man or mouse, that he acts freely is thus, according to the rephrased suggestion, to say of him that, in the nearby possible worlds in which he wants something different, he acts in that different way. This is what it is for him to have alternative options.

Note two consequences of this account of free action. The first is that certain acts which we would ordinarily suppose to be unfree aren't really unfree. When someone says 'Your money or your life!' and I give him my money, we would ordinarily say that I don't act freely because I have been forced to hand over my money. But, according to the account on offer, I do act freely. I have another option: I refuse in those nearby possible worlds in which I want not to give him my money more than I want him not to kill me. Many are unhappy about this. They think that there must still be a sense in which my freedom is compromised by such a threat. They point out that though, in the nearby possible worlds in which I want to refuse, I do refuse, it isn't the case that wanting to refuse would be at all reasonable, in those circumstances. Indeed, not only would it not be reasonable, it would be completely crazy. There is, they suggest, thus the following sense in which the person who threatens me forces me to act: he puts me in circumstances in which there is no other reasonable option but to comply with his threat. But if this right—that is, if this

is the sense in which threats compromise my freedom—then it seems to follow that people who make me irresistible offers equally compromise my freedom, for they too put me in circumstances in which the only reasonable option is to accept their offer. Whether it is acceptable to suppose that the only sense in which threats compromise my freedom is a sense in which offers also compromise my freedom clearly thus needs much more thought (Frankfurt 1973, 1988).

The second consequence concerns the relationship between free action and moral responsibility. According to this account of free action, freedom is not sufficient for an allocation of moral responsibility. Mice often act freely, but they are not morally responsible for any of their acts. Something else is therefore required. Other more complicated cases tell in favor of the same conclusion. Consider, for example, the plight of a reluctant alcoholic who wants to have a drink, and so has one, knowing he shouldn't. He presumably drinks freely, in the sense provided by the above account of free action, as in the nearby possible worlds in which he wants not to have a drink, he does not drink. Yet it is surely an open question whether or not he is morally responsible for his drinking. If, for example, his desire to drink is literally irresistible, then he is not responsible. Indeed, we would even think that he isn't free, in the important sense of being unable, in the circumstances, to want to do anything else except to drink. This more complicated case thus suggests that in order to understand the conditions of moral responsibility we must look not so much to an account of free action, but rather to an account of freedom of the will. The idea is that, though the alcoholic's actions may be free, his will is not, and that this is therefore the source of our judgements about moral responsibility (Frankfurt 1971, 1988).

Is the performance of a free action a necessary condition of moral responsibility? The answer seems to be that we can and do hold agents responsible for acting when they have no alternative, and that acting freely would thus seem not to be a necessary condition either. Those who act in the false belief that their acts are free are often held morally responsible for what they do, notwithstanding the fact that they don't act freely. Imagine, for example, that when a family visits an old prison they disperse so that they can explore the place individually, but that they agree to meet at a certain time to go home. When the agreed time to leave arrives suppose that one of the children fails to turn up. His parents look for him and find him in a cell. Because he doesn't want to leave, he has hidden from them. But now suppose that the cell door is closed, and that, unbeknown to the child, it is not just closed but also locked. It then follows that the child had no alternative but to be in the prison cell when it came time to leave. He couldn't have met the rest of his family. Is the child off the hook in terms of responsibility? Hardly. His parents would surely quite rightly continue to hold him morally responsible

for failing to turn up. The fact that he couldn't have done otherwise is irrelevant because it doesn't figure, in the right kind of way, in the explanation of the child's failure to meet them. In order to see what is relevant, though, we must once again look at what does figure. This case, too, suggests that we need to look more carefully to an account of freedom of the will (Frankfurt 1969, 1988).

Now that we have seen what it is for an agent's acts to be free, we must ask what it is for his will to be free. It might be thought that we should model our account of freedom of the will on the account we give of freedom of action. Thus, the suggestion might be, just as freedom of action is a matter of being in circumstances in which one can do whatever one wants to do, so freedom of the will is a matter of being in circumstances in which one can want whatever one wants to (Frankfurt 1971, 1988). Where freedom of action is a matter of the absence of external constraints on action, so freedom of the will is a matter of the absence of internal constraints on wanting. An agent's will is free just in case, in those nearby possible worlds in which he wants to want to act in a certain way, he wants to act in that way.

There is clearly something right about this idea. Those who enjoy freedom of the will do seem to have the capacity to control their will, where this includes the capacity to control their first-order desires. The problem with the reluctant alcoholic seems to be that he has no such ability: his desire to drink is beyond his control. What is less clear, however, is that this idea is well captured by the suggestion just made. The desires an agent has about his first-order desires are, after all, just more desires he has, and are hence just another part of his will, a part which may or may not be under the agent's control (Watson 1975, 1982). Thus, even supposing it to be true that in those nearby possible worlds in which an agent wants to want to act otherwise, we can always imagine that the agent is unable to have wanted to want to act otherwise. If the agent were unable to want to want to act otherwise then we must surely ask in what sense he enjoys freedom of the will. Certain of the desires such an agent has in certain possible worlds are controlled by certain others in those worlds, but the agent himself doesn't seem to be in control of any desires at all.

Some theorists have argued that in order to solve this problem we need to postulate a special kind of higher order desire: a desire which captures the agent's own sense of identity (Frankfurt 1987, 1988). When an agent has this sort of higher order desire, they suggest, he identifies himself with the lower order desires that are this higher order desire's objects. Freedom of an agent's will is, the suggestion goes, a matter of his being able to have desires that match this sort of higher order desire: in other words, it is a matter of having desires with which he identifies.

The difficulty with this suggestion, however, is to come up with a suitably independent account of

identification. There certainly is a sense in which an agent who acts of his own free will identifies with the desires on which he acts, as he is himself the originating source of such desires. But this is not an independent sense of identification. It is a sense that we define in terms of the idea of desires originating in a free will. There is also at least the following independently characterizable sense of identification. Some people who take drugs against their will, and who struggle to overcome their addiction, ultimately give in, and so come to identify with their addiction in the sense of building all of their expectations around it. In other words, they come to see themselves as hopeless drug addicts: this becomes their self-conception. But this is hardly a sense of identification that will help us understand the idea of desires originating in a free will.

There is something right about connecting freedom of the will with the possession of desires with which an agent identifies, however. Since agents are the originating source of such desires it does seem that, when they act of their own free will they express their true nature. The desires on which they act are, in some sense, essential to who they are. But though this seems right, it in fact suggests a quite different account of free will, one which does not depend crucially on our having an independent idea of what it is for an agent to have desires with which he identifies.

Since the Enlightenment we have come to conceive of people as being essentially truth-oriented reasoners. They are creatures who have the capacity to recognize the truth and to respond appropriately to it. Insofar as we are deliberators, what this suggests is that we are essentially creatures who have the capacity to recognize and respond to the facts about what we have reason to do. Thus, according to this account, an agent whose will is free is someone who asks himself what there is reason to do and, in answering this question, he is sensitive to the available evidence. This is not to say that he will inevitably acquire true beliefs about what there is reason to do, but it is to say that when he fails to do so, and when the evidence was available to him, his failure will be traceable to a failure to exercise his belief-forming capacities appropriately: he could and should have formed the correct belief, but he failed to do so. Moreover, an agent whose will is free is someone who, in the formation of desires, is sensitive to the beliefs he has about what he has reason to do. Again, this is not to say that he will inevitably form desires that accord with his beliefs about his reasons, but it is to say that when he fails to do so, his failure will be traceable to a failure to properly exercise self-control: he could and should have formed the correct desire, but he failed to do so (Wolf 1990).

As is perhaps clear, this conception of free will differs crucially from the one suggested earlier. What is important for freedom is indeed a capacity to desire otherwise, but the possession of this capacity is not to be analyzed in terms of what happens in nearby possible worlds in which the agent wants to want

otherwise. Instead it is to be analyzed in the same way, whatever that way is, that we analyze the ability rational thinkers possess to respond appropriately to evidence in the formation of their beliefs. Just as a rational thinker who fails to adjust his beliefs to the available evidence makes a mistake he shouldn't have made, and so, we suppose, must have had the capacity to make the adjustment and believe rightly instead, so a rational deliberator who fails to form beliefs about what he has reason to do in accordance with the available evidence, or who fails to desire in accordance with his beliefs about what he has reason to do, makes a mistake he shouldn't have made, and so is supposed to have had the capacity to control himself and acquire the correct belief or desire instead (Pettit and Smith 1996).

Note two consequences of this account of freedom of the will. The first is that it looks tailor-made to provide an account of the conditions of moral responsibility. Those who have no capacity to believe that they have reason to do anything other than they in fact believe they have reason to do, or to desire to do anything other than they in fact desire to do, can hardly be praised for having the right beliefs and desires, if it so happens that they're right, or blamed for having the wrong ones, if it so happens that they're wrong. This explains why we don't hold the alcoholic responsible. The irresistible nature of his desire to drink makes him incapable of an exercise of self-control, despite the fact that he believes, correctly, that he has reason to abstain. It also explains why we don't hold mice morally responsible for what they do. Their lack of cognitive sophistication deprives them of the capacity even to form beliefs about their reasons for doing what they do, let alone the capacity to desire accordingly.

Moreover, nothing other than the capacity to form the right beliefs and desires would seem to be required for people to be responsible either. This is why we hold the child described earlier morally responsible for failing to meet his parents at the appropriate time, notwithstanding the fact that he was locked in a prison cell and so couldn't have met them. We hold him responsible because we assume that his behavior was in fact the product of a desire he had which accorded with his beliefs about what he had reason to do, a belief that we take to be culpably mistaken. It is this that attracts our censure.

The second consequence concerns the possibility of freedom of the will in a deterministic world. To my knowledge, no one yet has a fully worked out theory of what it is for someone to have a rational capacity. It therefore follows that, to this extent at least, a proof that freedom of the will is possible within a deterministic world is yet to be provided. Provision of such a proof would, after all, require a demonstration that individuals in a deterministic world have the where-withal to possess just such a rational capacity. On the face of it, however, it must be said that there doesn't

look to be any particular difficulty in principle involved in providing such a demonstration. We regularly discriminate between people who do and people who don't have rational capacities, and, in so doing, we seem to pay no regard whatsoever to issues of determinism. This is because even if determinism is true, that only shows that people will make the mistakes that they make. It doesn't show that they couldn't help making those mistakes, in the sense of having no rational capacity to get things right.

But, whatever we ultimately come to think about the possibility of rational capacities in a deterministic world, the crucial lesson of this account of freedom of the will is that, if there do turn out to be such difficulties, then it isn't just the idea of freedom of the will that becomes problematic, it is the very idea of a rational agent as someone who has the capacity to recognize and respond appropriately to the truth. Whether freedom of the will is possible in a deterministic world or not, its possibility goes hand in hand with the possibility of agents who have the capacity to form beliefs and desires in a rational manner.

Freedom/Liberty: Impact on the Social Sciences

The concept of freedom, or in another rendering in the English language: liberty, is one of the most basic concepts in social and political thought. In many respects, it is the basis of all thought about politics and society. The assumption, in some form, of free will in human beings, namely, raises the question of action as making a difference in the world, and the relation of that difference to the course of the world had no action occurred (see *Free Will and Action*). More particularly, the term political freedom describes the possibility of a multitude of human beings deliberating about what they want in common and acting in common (see *Freedom: Political*).

The tension between the freedom of the singular human being and political freedom is at the center of all modern political thought, that is, all political thought that assumes the human ability of giving themselves their own laws. (Sometimes, this difference finds expression in the terminological choice between liberty, more consistently used for individual freedom, and freedom, for political freedom. Most authors, however, do not make any distinction between these two terms, and none will be made here.) It is also in the background of the theoretical *problématique* of agency and structure in the social sciences.

Comparative research on the history of the idea of freedom is but little advanced, partly due to prevailing preconceptions about the Western origins of freedom, partly due to the intrinsic difficulties of historical comparisons of the most basic linguistic concepts. Refraining from any explicit comparison, however, it is possible to state that the 'Western' tradition of political thought is marked by the confluence of both ideas, individual and political freedom (Patterson 1991). The latter originated in ancient Greece with the idea of self-government of the city states, and led into the Republican tradition, first of the Roman Republic, and then refounded by the Italian city republics, emerging from under the imperium, in the course of

what then became called the Renaissance (Skinner 1978). The former had important roots in early Christianity, as a religion that established more direct links between the singular human beings and their conscience and God, not least under conditions in which the declaration of Christian belief could lead to persecution by the political rulers.

The tension between the two concepts of individual freedom and political freedom is widely acknowledged in political philosophy (see, for instance, Berlin 1969, Miller 1991). This is not to say, however, that a resolution of that tension, or a reconciliation between the concerns that stand behind the two ideas, is not possible. Many authors argue, for instance, that republicanism is a political theory that succeeds in combining both exigencies (see *Republicanism: Impact on Social Thought*), or that romanticism is a social philosophy that underpins self-realization while also developing an idea of a viable polity (see *Romanticism: Impact on Social Thought*). Historically, though, it has been the case that a political theory emerged as central for the self-understanding of the European nation-states as well as for the USA that was based on the concept of individual liberty. Increasingly so during the nineteenth and twentieth centuries, republican views of political freedom were marginalized, and romanticist views of the embeddedness of the singular human beings were assigned a merely supportive, even though not insignificant, role in sustaining polities.

Recent research in the history of political concepts has emphasized that this shift in balances between various political languages took place between the middle of the eighteenth and the middle of the nineteenth century. This period is at the same time the period of the emergence of the early social sciences. It is also the period of the 'democratic revolutions' (R. R. Palmer), of the American and the French Revolution, which are often seen as aiming at giving institutional expression to the principle of liberty. It is from this historical constellation that an assessment of the impact of the concept of liberty on the social sciences has to start out.

1. Liberty and the Moment of the Revolutions

The pervasiveness of political issues, and in particular of the issue of liberty, in the early social sciences, that is, in authors like Smith, Condorcet, or Hegel, is evident. In political terms their modes of reasoning were, however, marked by a curious paradox. These authors were working in the shadow of liberal thinking (in a very broad sense), namely accepting the right of human beings to self-determine their individual and social lives, even though not always without important qualifications (see *Liberalism: Impact on Social Science*). At the same time, though, they were holding that the free action of human beings would not actually

generate, as one might innocently assume, a very wide range of possible individual and social forms and orientations of behavior. Given complete autonomy, human beings would reveal themselves not to be free in a radical sense, but driven by a limited number of well intelligible inclinations. One might even infer that it was exactly this predictability and order that gave grounds and reasons—to these authors themselves and to more hesitant others—not to reject the normative project of liberty. And this linkage of freedom and predictability became particularly important at the historical moment when the externally imposed barriers to free deliberation were threatened to be removed, the moment of the American and French Revolutions.

These revolutions gave institutional expression to the political aspect of a broader culture of individual autonomy that is a key element of modernity. In this sense, much of this era can be seen as a liberation of human beings from imposed ties, but this liberation was far from unproblematic. As Lefort (1986, pp. 214–15) once described this feature of modernity: 'When he is defined as independent, the individual does not exchange ... one certainty against another one. ... The new mode of existence of the individual within the horizons of democracy does not merely emerge as the promise to control one's own destiny, but also and not less as the dispossession of the assurance as to one's identity—of the assurance which once appeared to be provided by one's place, by one's social condition, or by the possibility of attaching oneself to a legitimate authority.' Liberation is here interpreted as an increase of contingency and uncertainty in the lives of human beings.

If this view were unequivocally valid, one should expect a philosophy of contingency—in Rorty's style (1989), for instance—linked to a liberal-individualist political theory to dominate the intellectual scene forever after the successful revolutions. However, historically this was not at all the case. In contrast, 'the historical moment, about which we speak, emerges in such a way that the real rising of the political instance entails its theoretical abatement' (Manent 1994, p. 123). Instead, the historical moment of liberty coincided with the rise of the social sciences. 'Society' as the object of the social sciences has been a 'post-revolutionary discovery'; or, to put it even more succinctly, 'the sociological point of view constitutes itself in the moment when the notion of liberty becomes the principal articulation of the human world' (Manent 1994, p. 75, 113, Therborn 1976, for an earlier analysis of the emergence of sociology 'between two revolutions'). Such apparent paradox reveals the aporia of political thought after liberation. Very generally speaking, the social sciences are exactly a part of the response human beings gave to their new condition of—self-incurred, one might say—contingency and principled uncertainty. Being unable to rely any longer on externally defined certainties,

political thinkers started searching for regularities and continuities which exist without being commanded. The social sciences have been a means to decrease contingency.

2. Concepts of Liberty before the Revolutions

Earlier political thought had already recognized the inevitable circularity of a reasoning in which unity should rise from diversity as well as, at the same time, impose itself on diversity. At that time, however, there was room to try to approach the issue by mere conceptual construction and theoretical determination. As long as there were barriers to the practice of liberty, every conceivable view on its outcomes and consequences for the polity could be held. The mode of reasoning was bound to change when those barriers were removed and experiences were made and when practical issues, such as the founding of political institutions, had to be tackled.

Political philosophy, in its prerevolutionary versions from Machiavelli and Hobbes onwards, gradually had developed an understanding of that which people have to regulate in common on the basis of the assumption that they do this on their own, without any external demands. The line of thinking that leads from Hobbes to Locke and Rousseau is often seen as the source of Western liberalism. It is most often presented as the theory of the social contract in which free individuals relinquish some of their rights in exchange for security and the regulation of the common realm provided by the state. In recent years, however, it has become common to distinguish the Hobbesian from the Machiavellian tradition. In this view, liberals define liberty as non-interference. The Hobbes–Lockean state, founded by free contract, dominates over the individuals, but it interferes with their liberties only to the degree in which the maintenance of order makes this necessary. The liberal tradition needs to draw a strong boundary between the public and the private, and since non-interference of the public into the private is the supreme principle, it can only have a ‘thin’ concept of membership in a polity. Significantly, the concepts of the state and of membership can be developed in the abstract, since they are based on a reasoning each rational individual is seen to arrive at, regardless of the situation.

In contrast, republicans define liberty as nondomination. Drawing via Machiavelli on Roman political thought, nondomination is conceptualized in stronger terms than noninterference; it requires security against interference. Such security stems at least in part from the ways in which citizens relate to each other, so that there is a less sharp divide between the private and the public and a ‘thicker’ concept of membership than in liberalism (see Pettit 1997, Skinner 1998 for recent accounts). As a consequence, the shape and substance

of each republican polity is specific, since it depends on its members and their deliberations. Most contributors to this recent debate emphasize the distinction between liberalism and republicanism to underline that individualist liberalism was not the only alternative available to provide the discursive underpinning of political modernity at its onset. However, they also agree that republicanism was by and large abandoned around the turn of the eighteenth century, and liberalism, though it neither appeared particularly powerful nor coherent before, very soon emerged as the pivotal political theory in postrevolutionary polities.

3. The Impact of the Revolutions on the Concept of Liberty

At a closer look, it is not too difficult to understand such intellectual shift through a look at the deep shock the revolutions meant to political thinking (Wagner 1998). The revolutions were certainly inspired by republican thinking. Looking at them in the somewhat stylized way that an emphasis on the French experience has long suggested, one recognizes, however, that they aimed at combining two objectives that proved to be practically impossible to hold together. On the one hand, they aimed at transforming state sovereignty in the hands of the monarch into popular sovereignty, that is, they worked with extended notions of citizenship and liberty. On the other hand, they held such a transformation of the polity to be conceivable only in the form of the existing territorial state and within its dimensions.

Such double transformation entailed, first, that the existing relations between the people, tainted with the suspicion of domination and privilege characteristic of feudal society, had to be weakened or abolished. Thus, however, a major available resource for a substantive, ‘thick’ grounding of a modern republic was rejected. Second, the idea of extending political rights widely cast doubts about the viability of a demanding concept of liberty such as the one upheld in the republican tradition. Caution seemed to demand, not least for some more conservative observers, to limit the substance of the concept at the moment at which its reach was extended. As a consequence, the public realm, the state, was robbed of most of its substance and the formal process through which common deliberations were reached was emphasized instead. About such processes, though, there is much less to reason in politico-philosophical terms. The liberal conception that things regulate themselves as soon as atomistic individuals are endowed with the right and the capacity to follow their own interests and passions makes political thought almost superfluous. It suggests that nothing beyond some basic assumptions and rules as to how to set up such processes is needed (though

such rules are much less innocuous than it may have appeared to some of the revolutionaries).

This change is most visible in the context of the foundation of the United States of America, at least in a reading of it, inspired by Gordon Wood, that tries to go beyond the debate over the republican or individualist beginnings of the American polity. In their reaction against obtrusive and illegitimate government, the Americans consciously tried to build institutions so that 'power may not actualize itself anywhere.' The 'disembodiment of government ... goes along with a disentangling of power, of the law, and of the knowledge of the ultimate ends of a society' (Lefort 1991, p. 27). Many of the most important themes of earlier political philosophy were simply ejected as illegitimate from reasoning about political institutions. 'For the first time, the place of power is easily recognized as being empty' (Lefort 1991, p. 27). The Americans of the revolutionary generation had 'broken through the conceptions of political theory that had imprisoned men's minds for centuries' through the renunciation of any substantive foundation of the polity and 'a total grounding of government in self-interest and consent' (Wood 1998, p. 614, 612).

Even in the American context, this deliberate political construction could not exorcise all concerns about the substantive foundations of the public realm. Beyond the calls for republican virtue during the early period, the search for a preordained unity emerged in the nineteenth century, pursued often by Americans with some German intellectual background (Gunnell 1991). However, such political science could not establish itself as a dominant paradigm and was mostly abandoned after the end of the nineteenth century. In Europe with its long-established statist institutions, the idea of unity was not abandoned, but it was transformed rather radically. As in the US, the observation seemed undeniable that, once the reasonable will of the human beings had been cast into institutions, the political order must be seen as intrinsically satisfactory (Manent 1994, pp. 228–9). In this organized context, however, the fear that such new order based on human liberty might turn out unsustainable was much greater than in North America. 'The effect of liberty to individuals is, that they may do what they please: We ought to see what it will please them to do, before we risque congratulations,' as Burke (1993 [1790], pp. 8–9) put it in his reflections on the French Revolution.

4. Liberty and the Rise of the Social Sciences

In this situation, individualist liberalism provides the less demanding concept of ('negative') liberty as noninterference that may live up to Burke's requirements under the proviso that the state is capable of maintaining order for and above the individuals.

However, there is another way out of the aporia of liberty, namely the attempt to arrive at knowing 'what it will please them to do' by other means. In Europe, indeed, the idea of an emptiness of the political space did not fully emerge. In the Enlightenment combination of freedom and reason, the state was rather reinterpreted as the incarnation of reason once the expression of human freedom fed into its construction. This is one of the central themes of Hegel's writings, but it can be found in many other contemporary works as well (Wuthnow 1989, p. 315). This linkage of knowledge and politics, the idea of 'legislative reason' (Bauman 1987), was characteristic of much of the early social science thinking during the revolutionary period in Europe. Reason, rather than merely serving as an ideal point of philosophical orientation (which it also continued to be), was to be made practical in the elaboration and application of the rules of politics. The movement to transform political reason into a science of politics found its most ardent spokespersons in France where politics had most radically been put onto new foundations. Beyond the voluntary commitment to construct a new social order, there was also a feeling of dire necessity to do so on well-informed grounds, not least motivated by the shock of revolutionary terror. The writings of Saint-Simon and Comte mark one major line of such thinking.

The American and French revolutions, thus, strongly suggested to study what held human beings together, how they would actually organize their lives—individually, in 'associations' or 'social movements,' and in the polity and the 'nation'—and what kinds of regularities and orders could be expected, if people were permitted to do so on their own, without imposed restrictions. This is the search for social ties that is one major root of the social sciences, and it is in this sense a politically motivated search.

The hope and aspiration was that the moral and political sciences should and could now achieve 'the same certainty' as the physical sciences (Baker 1975, p. 197). Certainty was a requirement of some urgency, since the new political order needed assurances of its viability. But it was also regarded as an historically new possibility, since political action was liberated of the arbitrariness of decisions by rulers of doubtful legitimacy and given into the hands of the multitude of reason-endowed human beings. The 'blend of liberalism and rationalism' (Baker 1975, p. 385, about Condorcet) can thus be explained as stemming from the same source, the Enlightenment linkage of freedom and reason—though possibly in its most optimistic version.

This linkage, if it could be sustained, made a science possible, where according to the classical view it would have been unthinkable, in the realm of the political. Condorcet subscribed to the new concept of free expression of political wills, but for him there was no contradiction between that view and the possibility of scientific analysis. 'Societal choice' could well be

transformed 'into the rational decision-making of the idealized republic of science' (Baker 1975, p. IX, 193).

5. Varieties of Social Science Responses to Liberty

The rights-endowed individual became thus, in such views, the only conceivable ontological as well as the methodological foundation of a science of political matters after the revolutions. Once the rights of man had been generally accepted as self-evident and unalienable, it seemed obvious, to Turgot and Condorcet for instance, that they were also 'the logical foundation of the science of society' (Baker 1975, p. 218). In rights-based liberalism, the individual is the only category that need not, often in fact: cannot, be debated. The individual is simply there, whereas everything else—for instance, what criteria of justification are to be applied when determining the collective good—needs to be argued about. Substantive aspects of human interaction are subject to communication and consensus. And, to make the issue even more complicated, with whom one should enter into communication, that is, the boundaries of the community, is itself not given, but subject to agreement.

Once this assumption was accepted, basically two avenues of constructing a science of the political had opened. Both these forms of social theorizing connect modernist political philosophy, that is, individualist liberalism, to a science of the political. One possibility was to try to identify by theoretical reasoning the basic features of this unit of analysis, the individual human being, and its actions. Since this unit was conceived as an ontological starting-point, devoid of all specific, historical and concrete, ties to the world, its characterization was to proceed from some inherent features. From earlier debates, those features had often been conceived as twofold, as passions and as interests. In the late Enlightenment context, the rational side of this dichotomy was regarded as the one amenable to systematic reasoning. It thus allowed the building of a scientific approach to the study of at least one aspect of human interaction with the world, namely the production and distribution of material wealth. This approach inaugurated the tradition of political economy, later to be transformed into neoclassical economics and, still later, into rational choice theory. The moral and political philosophy of the so-called early modern period split into a political theory based on the idea of the social contract and a rationalized moral theory based on the idea of exchange. In both cases, the individual is the starting-point and unit of the analysis.

While political economy was based on a highly abstract, but for the same reasons extremely powerful, assumption of human rationality, the other conclusion

from the individualist foundational principle was arguably even more reductionist but much more cautious. Avoiding any substantive assumptions on the driving forces in human beings at all, the statistical approach, often under the label of political arithmetic, resorted to the collection of numerically treatable information about human behavior. The space of substantive presuppositions was radically emptied in this thinking, but the methodological confidence in mathematics increased in inverse proportion (Brian 1994, Desrosières 1993).

Thus, two strands of political thought that had been proposed and elaborated for some time rose to new and greater prominence, political economy and political arithmetic. The denominations these approaches were known by in the late eighteenth century referred explicitly to political matters. Both were to lose these attributes in the nineteenth century when they had consolidated their ways of proceeding and when the application of these cognitive forms had established predominance over political deliberation in decision on common matters, at least in the view of many economists and statisticians. Mostly, this terminological change has been interpreted as an autonomization of cognitive approaches and as a differentiation of the sciences into disciplines. However, it is not exactly appropriate to say that economics and statistics separated from politics. Once the approaches of the former two are accepted as valid, there is nothing political left to study.

The acceptance of the economic and the statistic ways of conceiving of the social world did not go without criticism; and they were never accepted as the only possible ways anywhere. However, the critiques and alternatives that were proposed most often accepted the fundamental change in political reasoning after the construction of a polity based on the assumption of free individuals. (Since nineteenth-century polities all worked with restrictions that are incompatible with a full-fledged individualist liberalism, one should say more precisely that such a polity was put on the horizon of political debate through the revolutions, rather than made actual in institutional form.) After such a polity had begun to come into existence, new problems were identified. These were now essentially liberal problems; they resulted, one might say, from the observation that not everything that was needed for organizing a liberal polity could indeed be derived from an 'original position' (John Rawls). Two main types of problems may be distinguished by reference to the hypothetical original position in which individuals meet under a veil of ignorance.

On the one hand, the range of conclusions that could be drawn from the assumption of free and equal individuals was too limited. These individuals' relations were structured by the existence of politically important 'prepolitical' social facts, of orientations and links between human beings that were seen to

already exist before individuals entered into political communication and deliberation. On the other hand, the working of the liberal rules would themselves produce new kinds of social relations, 'postpolitical' relations, which would have a structuring impact on the polity in turn.

Attempts to theorize prepolitical relations all start out from the critical observation that the human being who enters into political relations is not such a kind of individual as liberal political theory described it, and that the hypothesis of any original position would lead to serious flaws in the conclusions. This thinking emphasizes the rootedness of the singular human beings in contexts from which their ways of giving meaning to the world stem. The broadest intellectual movement of this kind has been the cultural-linguistic theory of the boundaries of the polity, which inaugurated culturalist thinking in the social sciences and also became one source of later nationalism.

The other main line of 'postrevolutionary' social thought started out from the insights, first, that the basic liberal assumptions, once they were cast into effective rules, would have durable and important effects on what social scientists would soon call the 'structure' of social relations. In this sense we can refer to those relations as being conceived as 'postpolitical.' And second, the question of such relations was forced onto the agenda of social and political thought by the fact that the liberal assumptions on their own did not suffice to create and justify a political order. The observation of structures of representation served the interest of enhancing some stability and certainty in political procedures that could appear to be opened to all contingencies by the abolition of any legitimacy of preordained orders (see *Representation: History of the Problem*). We find here again the two main strategies for rediscovering certainties, systematic observation and reflective conceptualization. These two intellectual responses to the political *problématique* inaugurate two further modes of social theorizing, the behaviorist and the structural-functional one. Unlike economics and statistics, they do not make individualistic assumptions but aim at grounding sociopolitical life in purely social forms.

After the claim for a social science had been made by authors like Saint-Simon or Comte, the themes of the emerging social sciences formed around the observation of this internal structuration of societies. In Germany, Lorenz von Stein reported about the 'social movements' in France that announced a major change in the social order. At mid-century, Robert von Mohl diagnosed a transitory situation after the *Ancien Régime* had disassembled and no liberal order had been able to assert itself in the German states, while beginning industrialization and urbanization placed new demands on the political orders (Maier 1980, Wagner 2000). Karl Marx gave a central place in his social theory (and philosophy of history) to the newly forming social phenomenon, the 'working class.' And

Émile Durkheim provided a representation of society in which the elements of the social order were defined according to their position in the division of social labor and their relations regarded as interlocking in the form of 'organic solidarity.' Steps like these marked the construction of a sociological view-point which was clearly identifiable around the turn of the twentieth century.

6. Liberty after the Social Sciences

All these approaches to the social sciences can, under one aspect, be regarded as ways of dealing with the problem of contingency after the assertion of human freedom. It is on those grounds that sciences of the social and the political are proposed. If, in contrast, politics is seen as that human activity that by its nature is open, plural, and diverse (Arendt 1958), then any cognitive linkage of free action and predictable outcome is inconceivable. Orderly outcomes can only result from planned or routine activities, work, and labor in Arendt's terminology, over which certainty can be established before they are started. In contrast, political action in a context of liberty must go along with contingency of outcomes. From an Arendtian viewpoint, thus, those early social scientists established an impossible connection. If they were heading for a 'social science' trying to identify laws and regularities of human action and societal development, then they necessarily abandoned the heritage of political philosophy, the emphasis on creative agency, irreducible diversity, and the permanent possibility of unpredictable beginnings. It is in the light of such considerations that the closing decades of the twentieth century have witnessed a revival of political philosophies of freedom, often going beyond concepts of liberty as held in liberal political theory. These works, by authors such as Claude Lefort, Pierre Manent or, more historically oriented, Quentin Skinner, are not merely contributions to political philosophy or its history. Rather, they challenge the very separation of the social sciences from political philosophy.

Freedom of the Press

No press system is absolutely free from various social, political, economic, or legal controls of its society.

Most discussions of freedom of the press center on the relationship of government and the press, and here the basic question is not whether government controls the press, but how and to what extent. Freedom of the press refers to negative freedom—freedom from governmental constraint, or it may refer to positive freedom—the capacity to do or achieve certain ends. Most issues concerning press freedom have revolved around negative freedom, understood as the independence of the news media from governmental restraint.

1. The Term 'Press'

The 'press' in 'freedom of the press' is elusive. The general public considers the word press as the conventional institutional news media including newspapers, magazines, and radio and television broadcasters. But the popular image of the term press is too limiting to be accepted in US constitutional law. The press goes beyond mainstream newspapers and magazines to 'every sort of publication which affords a vehicle of information and opinion' (Lovell v. Griffin 1938).

Can the term press be distinguished from 'speech' in 'freedom of speech?' Thus far, the answer to this press–speech dichotomy question is 'No' in US law. The now well-established US rejection of the distinction between press and nonpress communicators presents a striking contrast to the clear-cut statutory recognition of the press in continental Europe and some Asian countries. It should be emphasized, however, that the presence (or absence) of a direct press law does not necessarily ensure a privileged (or unprivileged) press in a country: 'The theory that a special press law in itself constitutes a threat to press freedom has merit only if a special press regime is identified with an authoritarian press regime' (Lahav 1985).

2. Theories of Press Freedom

The key values sought by society in protecting freedom of expression are that freedom of expression assures individual self-fulfillment, helps to discover the truth, secures participation by citizens in social and political and economic decision-making, and promotes a stable change in society (Emerson 1966). The press is protected as the surrogate of the public when performing its informing and checking functions as a Fourth Branch, supplementing the executive, legislative, and judicial branches of government.

The foremost value of press freedom comes from the premise that a press free from government control is essential to a political system based on the will of the people. The 'checking value' of a free press posits that the press should be guaranteed freedom to report

abuses of power by public officials. This compels a logical conclusion that the government should not prohibit the people from receiving news critical of the government. *New York Times* columnist Anthony Lewis succinctly discusses the relationship between the news media's checking function and the media's quest for information:

If big government is to be effectively criticized and controlled, it will take more than the exhortations of an orator. It will take the countervailing force of big newspapers and broadcast networks and public-interest groups and lobbying organizations of all kinds. And they cannot succeed without information. In our society information is power. Officials struggle to control it and, in that struggle, the *citizen-critic* needs constitutional support (Lewis 1980).

The libertarian concept of press freedom, most fully developed and most ardently supported in the US, focuses exclusively on negative freedom. Since the 1940s, it has been challenged by views that emphasize 'freedom for' as much as 'freedom from.' Concerned about the inexorably growing influence of the mass media on society, so-called 'social responsibility' theories of the press have emerged as a significant counterpoise to the *laissez-faire* libertarian view. The increasing significance of broadcasting, regulated by government 'in the public interest' from early on, has no doubt contributed to this emphasis.

The criticism of a libertarian concept of press freedom stems from an innovative proposition that freedom of the press carries little meaningful value unless it is supported by an independence of editorial decision-making from both internal and external pressures. In this context, 'journalistic freedom' is distinguished from press freedom. Journalistic freedom is concerned with a relationship between the working journalists of a news medium and the managing executives and editors of the news medium. It is an individualized, not institutional, type of press freedom (Merrill 1989, Baker 1989).

In the US, press freedom is to a large degree guaranteed and practiced institutionally, but journalistic freedom is rarely accepted. But several free-press countries in Europe and Asia try to accommodate the conflict between the institutional press freedom and the internal journalistic freedom. A case in point is South Korea. To ensure separation between the editorial department and management, the *Hankyoreh Shinmun* (One Nation Newspaper) and several Korean newspapers have reporters directly involved in deciding on the overall editorial policy of their newspapers, with managing editors elected by reporters or selected from those recommended by them. The stronger voice of the editorial departments of an increasing number of Korean newspapers has resulted from reactivated labor unions of journalists since 1987, when the Korean government embraced a series of sweeping sociopolitical democratic reforms.

3. Censorship of the Press

In connection with press freedom, both institutional and journalistic, censorship is an unending concern to the print and broadcast media around the world. Censorship is 'the systematic control of the content of any communications medium, or of several or all of the media, by means of constitutional, judicial, administrative, financial or purely physical measures imposed directly by, or with the connivance of, the ruling power or a ruling elite. It may or may not be accompanied by violence, it may or may not be total, it may or may not include propaganda. But the concept of a *systematic* imposition of controls is...essential to determining whether or not censorship is being practised in a given country, just as is the concept of intent' (Scammell 1988).

Censorship is intertwined with power so inextricably that it is referred to as the 'handmaiden of power.' Censorship in the sense of prior restraint on the press is more effective than subsequent punishment because of its broader scope and lack of countervailing mechanism such as public appraisal of its rationale. And it has a propensity to decide against publication. 'The function of the censor is to censor. He has a professional interest in finding things to suppress' (Emerson 1955).

Censorship can be 'total' when all the media are systematically controlled, 'partial or selective' when the censorship is selectively enforced, or 'random' when it is capricious or arbitrary. Further, the methods of censorship are multifarious, ranging from prior restraint to fines and prison sentences for violations to suspensions of a publication to closing down a publication to the many varieties of self-censorship journalists exercise to stay out of trouble (Scammell 1988).

Does freedom of the press start to flourish when control of the media through state censorship ends? It is not as simple as that. An enterprising press is not the rule but the exception in societies in transition to democracy. Where journalists have been accustomed to being told what to report and what not to report, they have been trained and tamed by censorship and do not necessarily take advantage of their new-found freedom easily (Williams 2000).

3.1 Censorship Checklist

Censorship is a crucial criterion against which press freedom is measured. The World Press Freedom Center (WPFC) in the US asks 20 questions to determine whether the news media in a particular country are free:

- (a) Are there restrictive press laws?
- (b) Who owns the media, print, and broadcast? Private, government, or both?
- (c) Are journalists prosecuted for what they write?

- (d) Are journalists in jail? Reasons.
- (e) Is libel a civil or criminal offense?
- (f) Are journalists required to have a government enforced license to work?
- (g) Do journalists have unrestricted access to government proceedings?
- (h) Are journalists harassed while covering the news?
- (i) Does the government pay journalists?
- (j) Are newspapers or broadcasters subsidized?
- (k) Is there government-supported censorship? Is there self-censorship?
- (l) Are there restrictions on the means of production, such as government allocations of paper, control of distribution systems, and ownership of printing facilities?
- (m) Is government advertising allocated fairly?
- (n) Is there a legally mandated right of reply, which includes government officials?
- (o) Are insult laws routinely used to shield officials' conduct from public scrutiny?
- (p) Are courts able to judge news media cases independently?
- (q) To what extent are media outlets owned by political, government-linked entities, or others desiring to control content?
- (r) Are crimes against journalists prosecuted by authorities?
- (s) Are the activities of government—courts, legislature, officials, records—open to the press?
- (t) Do journalists themselves consider themselves free to write or broadcast the news as they find it? (Greene 2000).

3.1.1 Right of reply. The WPFC checklist reflects a US-centric approach to evaluating press freedom against the exercise of censorship in that it emphasizes the negative-freedom view on the press rather than positive freedom. The right of reply is a good illustration. In the US, the mandatory right of reply statutes governing the news media as a whole and the print press in particular are seen as violations of freedom of the press.

The US Supreme Court in 1974 struck down a right of reply statute on the ground that it would infringe upon the editorial rights of the press: 'A newspaper is more than a passive receptacle or conduit for news, comment, and advertising. The choice of material to go into a newspaper, and the decisions made as to limitations on the size and content of the paper, and treatment of public issues and public officials—whether fair or unfair—constitute the exercise of editorial control and judgment. It has yet to be demonstrated how governmental regulation of this crucial process can be exercised consistent with First Amendment guarantees of a free press as they have evolved to this time' (Miami Herald Publishing Co. v. Tornillo 1974)

At least 13 countries in Europe, including Germany and France, however, recognize the right of reply. The right of reply in German law is derived from French law. The policy justifications for the right of reply in Germany are not so much to provide the public with access to the media as to protect individuals from false defamation. This differentiates German law from the South Korean law on the right of reply. The right of reply in Korea is justified partly because it can contribute to the public's discovering truth and forming diverse public opinions by creating a more open marketplace of ideas by enhancing the objectivity of news information. In this vein, the right of reply offers access for the Korean public to the news media in a positive way. Especially noteworthy is the international acceptance of the right of reply. The International Convention on the Right of Correction and the American Convention on Human Rights provide the right of reply.

The explicit recognition of the right of reply in several civil-law countries in Europe and Asia and under international law signifies that there are alternative visions of press freedom, which stand in sharp contrast with the US approach to the negative freedom of the press, that is, access to the press is not entirely antithetical to freedom of the press, but it can be viewed as a plausible 'positive' notion of press freedom in ensuring more opportunity for freedom of expression.

3.1.2 Press subsidies. Do government subsidies for the press create a cause of concern for censorship? Evidence from the Scandinavian press subsidies disproves an assumption underlying the adversarial press-state relations in America that newspapers receiving direct public subsidies will lose their editorial independence and autonomy to the government. The Swedish subsidy program 'has had little effect on the willingness of subsidized publications to criticize government' (Gothberg 1983, Gustafsson 1980)

3.1.3 Licensing of journalists. Licensing of journalists is incompatible with freedom of the press as a basic human right. As the Inter-American Court of Human Rights (IACHR) ruled in 1985: 'Such a law (on licensing of journalists) would contain restrictions to freedom of expression...and would consequently be in violation of not only the right of each individual to seek and impart information and ideas through any means of his choice, but also the right of the public at large to receive information without any interference' (IACHR 1985).

3.1.4 Administrative vs. judicial censorship. The legality and scope of press censorship is sometimes

examined by focusing on who primarily dictates the censorship mechanism. Is censorship entirely in the hands of executive officers with no judicial oversight? On this issue, the US differs from Japan. The US law does not allow even court-issued prior restraint under the First Amendment to the US Constitution. In Japan, however, the anticensorship principle does not extend to judicial restrictions because censorship is limited to administrative imposition of prior restraint on the press.

4. Self-censorship of the Press

Self-censorship is viewed as a widespread and insidious problem among reporters and editors. Journalists resort to self-censorship when they decide to avoid legitimate stories not because of their professional judgments but on nonprofessional grounds. In some cases, self-censorship can be intimately intertwined with state censorship. This is the case in Israel: 'When acting as concerned members of society, editors and journalists are of one mind with the censors concerning the prohibition of public exposure of issues considered crucial to the physical welfare of Israel or to its ideological *raison d'être* (even though the public may not share that view)' (Liebes 1997).

Intrusion of commercial interests into editorial decision-making is another major cause of self-censorship. 'Market forces are seen as the primary reason why worthwhile stories are not pursued, and this factor is especially prevalent in the broadcast arena,' reports a recent survey of American journalists on self-censorship (Kohut 2000). Self-censorship is related closely to threat of lawsuit for defamation, invasion of privacy, breach of confidentiality agreements, and related issues.

4.1 Libel Law

Libel was one of the earliest legal actions available against the press, and it is still the most common legal danger to the media. Libel is an occupational hazard for media professionals. Seventy percent of all libel actions are filed against the mass media; at least two-thirds of those actions are brought against newspapers in the US. Libel law protects the reputational interests of individuals because it involves the expression of opinions about them by others. It also attempts to compensate for economic and emotional injury and promotes human dignity by providing a civilized forum in which a dispute is settled. Most importantly, however, libel law acts as a deterrent on the publication of false and injurious speech through the award of damages. In addition, libel law serves a vital social interest by providing a check on media power. It

opens the newsgathering and decision-making process of the media to public scrutiny and accountability.

4.1.1 Transnational libel litigation. The globalizing media confront a new type of libel threats as off-shore litigation against US and other transnational news media is growing. One much-publicized case involved Ariel Sharon, the former Defense Minister of Israel, who sued against Time, Inc. for a defamatory article published in *Time* magazine. Sharon filed his lawsuits in a US federal court and in an Israeli court in 1983.

Most recently, former Indonesian President Suharto filed a \$27 billion lawsuit against the US-based *Time* magazine in a Jakarta court. Suharto claimed that *Time* published an article alleging that he had transferred billions of dollars from Switzerland to an account in Austria in an effort to stash his multibillion-dollar fortune abroad. The Indonesian court ruled in November 1999 that it had the authority to try Suharto's civil libel suit against *Time*.

Suing American media in foreign courts is one thing; enforcing foreign court judgments in the US is another. Thus far, American courts have consistently refused to recognize and enforce foreign libel judgments, holding that the judgments were based on libel law repugnant to the US Constitution on press freedom.

4.1.2 Internet libel. The 'information superhighway' epitomized by the Internet exerts an enormous impact on libel law all over the world. This is especially the case with jurisdiction and enforcement of libel law. While other countries are still in the process of sorting out a vast array of jurisdictional and other issues, the US Congress in 1996 passed a law immunizing Internet service providers (ISPs) from liability for third-party postings of libelous material. One leading English libel lawyer suggested that the US law would pressure England and other European countries to adopt similar standards for Internet libel 'to reflect the transnational nature of such publications' (Hooper 2000).

5. Preventive Counseling for News Media

Because freedom of the press is litigated in increasing frequency in the US, England, and other countries, media organizations involve lawyers in prebroadcasting and prepublication reviews. Lawyers in newsrooms have now become a fact of life for many, if not all, reporters and editors in dealing with a host of legal problems ranging from libel to access to in-

formation. Some journalists are concerned about the chilling effect of lawyers' presence in and outside the American newsroom. CBS News anchor Dan Rather claimed: 'I'd rather take my chances in front of a jury than take my chances in front of corporate lawyers' (Grossman 1996). Nonetheless, the journalist-lawyer relationship is not necessarily harmful to freedom of the press insofar as lawyers are sufficiently 'sensitive to the murky line between legal advice and journalistic or artistic judgment' (Smolla 2000). No less important is the fact that journalists, the integral part of the media system, are more often responsible than lawyers for determining what to broadcast or publish or what not to broadcast or publish in the US. Likewise, a 1997 study of the impact of libel law on the media both in England and in Scotland concluded, '(A) solicitor's advice is just that, and ... on occasion editors do decide to ignore it' (Barendt et al. 1997).

6. Access to Information and Free Press vs. Fair Trial

The press's role of serving as a 'public watchdog' on the government and of imparting information on matters of public interest is difficult, if not impossible, to fulfill without access to public records. Without some protection for seeking out the news, freedom of the press could be a farce. Now freedom of information (FOI) is accepted more widely around the world than ever. This is a profound development in freedom of the press as a positive concept. In this connection, it should come as no surprise that the Scandinavian countries that embrace a 'proactive' concept of press freedom has the most comprehensive FOI laws. For example, Sweden, whose government information statute is considered the oldest in the world, has adopted the policy on access to official records as a fundamental foundation of its democracy since 1766. The presumption of openness in government documents in Sweden is unambiguous when the Swedish FOI act states that all official records are public if there is no specific statute restricting the access to the records.

Traditionally, freedom of the press has been confined to the right of news reporters and editors to disseminate any information in their possession, which does not necessarily extend to the legal right for the media to gather information. But newsgathering has now emerged as a vital issue for most journalists and news media organizations. In the US, how to deal with access to government records, meetings, institutions, courtrooms, and the like constitutes by far the largest body of mass media law.

Freedom of the press is often in conflict with the accused's right to a fair trial in that court proceedings and judicial records are an important source of news information, and trials are government proceedings for the public to know. Some countries such as

Australia, Sweden, and the US favor open proceedings. Other countries including the UK are more restrictive of the press coverage of trial proceedings.

7. Journalist's Privilege to Shield Confidential Sources

Equally important is the issue of whether journalists should be privileged to protect their sources' confidentiality from forced disclosure. In the US, a journalist's privilege is qualified and lags far behind Australia, France, Germany, and Sweden, where the strongest legal protection is provided to the confidentiality of sources. In the European countries, the protection of confidential sources is premised on the conclusion that 'society is better served by encouraging people to disclose matters of public interest to the press, even when the information may include evidence of their own wrongdoing, than by identifying and possibly convicting a particular wrongdoer,' and 'journalists rarely divulge information that would compromise sources, courts rarely compel disclosure, and even more rarely do courts enforce a disclosure order through imprisonment' (Coliver 1993).

8. Freedom of the US Press in the Globalizing Era

Freedom of speech and the press has been the international buzzword since the end of the Cold War in the late 1980s. And the positive concept of press freedom has crystallized the undisputed paradigm throughout the world and it inspires the standard for quality journalism. The growing impact of the now modified libertarian press theory, with an emphasis on the affirmative role of the state in expanding press freedom, on many newly independent countries and emerging democracies in Asia, former eastern Europe, and Latin Africa is credited partly to the American successful experiment with a free press over the past 200 years. Professor Owen M. Fiss of Yale Law School offers a cogent note: 'In building a free press, the reformers [in formerly Soviet bloc nations] should look to the American experience, but only selectively. They must create for the press a measure of autonomy from the state without delivering the press totally and completely to the vicissitudes of the market' (Fiss 1996).

Freedom: Political

1. Introduction: Liberty, Equality, Fraternity;
Two Concepts of Liberty

Since the bourgeois revolutions, modern states have been committed, at least formally, to the ideals of liberty, equality, and fraternity. From the start there

have been tensions between those three aspirations. Attempts to resolve these tensions have taken different forms, from rampant *laissez-faire* libertarianism to interventionist, redistributivist socialism. The theories examined in this article focus mainly on the relation between liberty and equality, with an occasional nod towards fraternity. Since political freedom or liberty is an essentially contested concept, it is impossible to start from a shared definition of it. One can only trace the sources of a number of incompatible conceptions and establish an elementary taxonomy of them.

An important moment in the modern debate about political freedom is Berlin's *Two Concepts of Liberty* (1958). It is an unsystematic mixture of different elements: conceptual analysis, political engagement in the postwar antitotalitarian struggle, and a rich, if eclectic, essay in intellectual history. But for all its shortcomings, it made the opposition between positive liberty and negative liberty central to much subsequent discussion.

Berlin's political task was to unmask the perversion of language by Stalinist ideologues, who presented the worst forms of oppression as 'real (socialist)' freedom, as opposed to 'mere bourgeois (formal)' freedoms. Berlin aligned the former with 'positive,' and the latter with 'negative,' liberty, and reasserted the value of the latter against its critics.

Historically, Berlin identified negative liberty with liberalism, the tradition that defended the individual against 'interference,' particularly when exercised by the state. But the idea of 'interference' is hard to tie down. Berlin himself was ambivalent as to whether the interference must be deliberate or not, but he was adamant that an inability caused by the social structure (e.g., the inability of the worker to control the means of production in traditional Marxist theory) is not a case of unfreedom. He agreed that the 'classical English political theorists' were 'prepared to curtail freedom in the interests of other values and indeed of freedom itself.' They held that without law, 'freedom for the pike is death for the minnow.' A natural interpretation of that insight is that the law positively creates freedom for the minnow, allowing it to do things it would otherwise be unable to do. In the words of Locke (a quintessential negative libertarian for Berlin): 'the end of Law is not to abolish or restrain, but to preserve and enlarge freedom.' Berlin could agree that the pike's freedom is restricted for the sake of the minnow's freedom ('curtailed in the interests of liberty itself'), but his polemical drive was against partisans of positive liberty who would maintain that the pike's freedom too is (really) enhanced by the restriction.

Another ambivalence within negative liberty concerns the connexion between freedom and wishes. Berlin began by tying the two together directly, defining oppression as 'the part I believe to be played by other human beings ... in frustrating my wishes.' But later he rejected the definition of freedom as 'the

ability to do what one wants' because it is compatible with a situation in which all one's wants are restricted by brainwashing or the removal of desirable objects. At the heart of negative liberty lies 'the right to be let alone,' but that right turns out to be remarkably elusive.

If negative liberty (NL) is hard to tie down, positive liberty (PL) is even more so. PL contains both (a) political elements (PL-pol) and (b) moral ones (PL-mor). (a) is essentially the freedom to participate in the political process; (b) includes the ability to be the autonomous master of one's own drives, which is associated with the romantic notion of the divided self. Rousseau says that both (a) and (b) are the outcome of entering civil society, but he is careful not to identify them. When Constant (1988) introduced the distinction between the 'liberty of the ancients' and the 'liberty of the moderns,' he was concerned with (a). His polemical claim was that the 'liberty of the ancients' nowadays meant the unbridled exercise of popular sovereignty (PL-pol) to the detriment of NL. For Berlin, the danger of modern totalitarian ideology is that it harnesses (a) to (b). It suggests that, through laws endorsed by 'the people,' irrational empirical selves should be forced to coincide with rational ends (their 'real selves').

Five broad approaches to political freedom can now be distinguished. In each of these, the three fundamental values of liberty, equality, and fraternity are addressed. Writers inspired by Berlin focus on incompatibilities between those values. Others seek to show that when they are more clearly understood, it will be seen either that they are compatible or that the very idea of balancing one against the other must be abandoned. In their analyses, the terminology of PL and NL frequently recurs, but the distinction made above between dimensions (a) and (b) of PL frequently is ignored.

The approaches to be considered are: (a) Welfare liberalism; (b) Libertarianism; (c) Freedom, economics and power; (d) Freedom and community; (e) Civic republicanism.

1.1 Welfare Liberalism

For theorists of welfare liberalism, political freedom is exercised in a context of representative democracy constrained by constitutional checks to protect individual rights and by a fluctuating sense of obligation to redress the inequalities thrown up by the operation of the market. The two outstanding proponents of this approach are John Rawls and Ronald Dworkin.

1.1.1 Rawls. Rawls's *A Theory of Justice* (1971) is the most comprehensive, systematic work of modern political philosophy. In it the author expounds the

moral basis of pluralist welfarism, combining the three elements of liberty, equality, and fraternity into a coherent whole.

At the heart of the book lie the Two Principles of Justice. The First Principle states that 'Each person is to have an equal right to the most extensive total system of basic liberties compatible with a similar system of liberty for all.' 'Basic liberties' are specified as 'roughly speaking, political liberty (the right to vote and to be eligible for public office) together with freedom of speech and assembly; liberty of conscience and freedom of thought; freedom of the person along with the right to hold (personal) property; and freedom from arbitrary arrest and seizure as defined by the concept of the rule of law.' These are what Marxists called 'bourgeois liberties.' The list is not equivalent to NL-pol, since they include certain 'positive' political elements, even if the 'negative' liberties of privacy may be more important than 'positive' ones to modern citizens.

In subsequent work, Rawls (1993) has responded to Hart's criticism that the idea of 'maximizing freedom' is incoherent. He has rewritten the First Principle to read: 'Each person has a claim to a fully adequate scheme of basic rights and liberties, which scheme is compatible with the same scheme for all; and in this scheme the equal political liberties, and only those liberties, are to be guaranteed their fair value.' He has also added the 'integrity' (physical and psychological security) of the person to the list of basic liberties to be protected by the First Principle. But he has not modified the central claims of *A Theory of Justice* that the modern liberal state must (a) guarantee 'basic liberties,' and (b) strive to maximize the welfare of the worst-off members of society by redistributive mechanisms, and that the First Principle must not be sacrificed to the Second, since 'liberty can be restricted only for the sake of liberty.'

Most of the other important revisions have concerned structure and methodology rather than content. Rawls has anchored the Two Principles more explicitly in a conception of citizens of a modern pluralist state, as it has developed since the Reformation. They are 'regarded as free and equal persons,' endowed with 'two moral powers ... namely a capacity for a sense of justice and a capacity for a conception of the good.' Such citizens display their freedom in the following ways. They have 'the moral power to have a conception of the good' and are 'capable of revising and changing this conception.' They 'regard themselves as self-authenticating sources of moral claims.' They are capable of taking responsibility for their 'ends.'

The Two Principles of justice remain unaltered and are still subject to attack from both left and right. Left-wing critics charge that First Principle 'bourgeois' liberties are hollow and worthless for the mass of the population. To them Rawls had already responded in *A Theory of Justice* by distinguishing equal liberty

from equal worth of liberty, acknowledging that it is the latter that is important, and predicting, perhaps optimistically, that it would be enhanced by the application of the Difference Principle. Right-wing 'libertarian' critics reject all redistributive mechanisms, because they infringe the individual's unrestricted right to accumulate property. Rawls' response to them is also contained in *A Theory of Justice*, namely that individuals have a basic right to own *personal* property, but that right does not entail any particular property system, whether capitalist or socialist. In each particular case the choice of system will be determined by its ability to maximize the welfare of the worst-off.

1.1.2 Dworkin. Dworkin's political philosophy is an attempt to 'fine-tune' both the methodology and the political recommendations of Rawls's welfare liberalism. Methodologically, Dworkin denies that liberalism must balance liberty against equality. That image wrongly presupposes that liberty can be quantified, so that 'fundamental' liberties weigh more heavily than trivial ones. Instead, 'the fundamental liberties are important because we value something else that they protect.' And that 'something else' is, unexpectedly, a form of equality, the principle that a government should treat all its citizens with 'equal concern and respect.' The 'fundamental' liberties, then, are entailed by the equality principle itself, according to which 'the government (should) treat all its citizens as free, or as independent, or with equal dignity.' Dworkin accepts the Rawlsian requirement that 'political decisions must be ... independent of any particular conception of the good life ...' Thus governments are bound by the negative requirement to be neutral between lifestyles, and also by the positive requirement to 'respect' the 'dignity and independence' of its citizens.

In terms of political recommendations, Dworkin proceeds from a tension at the heart of Rawls's Two Principles. While the First Principle defends the conditions of basic freedoms, and addresses people as autonomous agents, the Second Principle might undermine people's motivation to exercise their freedom to 'better themselves,' addressing them as passive recipients of benefits. In response to this tension, Dworkin introduces a key modification. He follows Rawls in compensating people for 'irrelevant differences, like differences in talent.' But he argues that people should be 'responsible for the costs of their choices.' The system, in short, must be both 'ambition-sensitive' and 'endowment-insensitive.' But Dworkin's modification may have introduced a new tension of its own, since however finely tuned it is, its two requirements must work against one another: 'the more we try to make the distribution sensitive to people's ambitions, the more likely it is that some

people disadvantaged by circumstances will be undeservedly penalized, and vice versa' (Guest 1997). Everything now hinges on the possibility of making a realistic distinction between ambition and endowment, between 'personality' and 'circumstances.' The fact that this is so difficult suggests that the tension between freedom and equality may still be unresolved.

2. *Libertarianism, Freedom as the Unrestricted Right to Own Private Property: Nozick*

Nozick's *Anarchy, State and Utopia* (1974) was a polemical response to Rawls' *A Theory of Justice*. At the time of its publication, there was a backlash against welfarism and state intervention in the economy. That backlash was driven by the economic theory that managed markets are inefficient, since redistribution through taxation takes away incentives. But although Nozick's book was congenial to that theory, his philosophical position is independent of it. Nozick would defend his position on the grounds that it was the correct one, even if it were inefficient. He would in fact reject appeals to economic efficiency as improperly utilitarian.

Though labeled a 'libertarian,' Nozick's starting point is not the idea of 'liberty' or 'freedom,' but rather the Lockean one of 'self-ownership.' This has polemical value because it allows Nozick to proceed against Rawls' (and other welfarists') programs of redistribution by appealing to a hatred of slavery shared by all across the political spectrum since the 'bourgeois revolutions,' and suggesting, by a rhetorical sleight of hand, that 'taxation of earnings from labor is on a par with forced labor.' The slide has some source in Locke's 'labour theory of property,' the idea that you have a property right to something if you have 'mixed your labour with it.' But Locke did not suggest that that right is absolute in the same sense that your right to your bodily integrity is.

The sleight of hand at the heart of libertarianism is this. We all agree that if A has the right to make use of B's body, of which B is the rightful owner, without B's consent, then B is A's slave. By parity of reason, it is suggested, if A has the right to make use of B's property, of which B is the rightful owner, without B's consent, by taxing B, then B is A's slave. The sleight of hand depends on accepting the extension of self-ownership from ownership of one's own body to ownership of whatever one has acquired legally, an extension which is not evidently justified. Nonetheless, libertarians may be able to deploy a 'slippery slope' argument against welfarism without making this particular sleight of hand. Rawls's Two Principles of justice are intended 'to balance the twin demands of (a) respecting choices and (b) rectifying circumstances.' Rawls intends (a) to be applied to individuals, (b) to groups. But, according to the libertarian, there is

nothing within Rawls's theory to prevent the radical welfarist from extending rectificatory treatment to individuals too. How is one to define what intervention is legitimate in order to rectify circumstances? If the line is to be drawn around the body, it would seem to mean that any nonbodily interference is at least in principle legitimate in order to rectify circumstances. And that sounds sinister even to those who are not extreme 'libertarians.'

3. Freedom, Economics, and Power

In the past, egalitarians, Marxists and non-Marxists alike, derided 'bourgeois freedoms' for masking from the workers their real enslavement. The modern egalitarians considered in this section all take seriously the demand for real equality of freedom. But unlike their predecessors, they all also take seriously the importance of the 'basic' freedoms that lie at the heart of liberalism. The three positions considered in this section are linked by the insight that freedom and equality are linked intimately, and that the conditions of equality and inequality are zero-sum relations of economic power. In each of the three, real freedom is 'positive' in the sense that it requires more than just the 'right to be let alone.' On the other hand, it is not the 'liberty of the ancients,' since it recognizes the importance of private life in the modern world.

3.1 Neo-Marxism: Cohen

In the most sophisticated version of neo-Marxism, that of Cohen, 'there is ... a conflict between social equality and the liberty of some people,' but that should not stand in the way of 'the pursuit of social equality, since a humane concern for liberty must first of all direct itself to the condition of those who enjoy hardly any of it.'

Neo-Marxists thus agree with liberals that freedom of the individual is the most important political value, and that modern capitalism delivers it to all members of society, including proletarians, in several important ways. First, all members of a capitalist society (worker and capitalist alike) are legally free. Second, any particular worker is always legally free, and often economically free, to leave the proletariat and become a petty bourgeois or even a capitalist. But, within a capitalist society, 'although most proletarians are free to escape the proletariat, indeed even if all are, the proletariat is an imprisoned class.' Third, capitalism has delivered 'important freedoms beyond that of buying and selling.' These include 'freedom of speech, assembly, worship, publication, movement, political participation ...'. The neo-Marxist Cohen is agnostic about 'how accidental the connexion between capitalism and those freedoms has been and is,' but is committed to the view that only 'freedom to buy and

sell belongs to capitalism's inmost nature.' But Marxists must still acknowledge that 'bourgeois freedoms' really are freedoms: '... when socialists suggest that there is no real liberty under capitalism, or that socialism promises liberty of a higher and unprecedented kind ... their line is theoretically incorrect and politically disastrous. For liberty under capitalism is, where it exists, just that, liberty; and if socialism will not give us plenty of it, we shall rightly be disappointed.'

In recent writings, Cohen (1995) has begun to investigate the idea of real freedom, understood as 'autonomy, the circumstances of genuine control over one's own life.' With this turn, neo-Marxism returns to the old site of conflict, since we must 'ask what kind and degree of control over external things a person must have to enjoy autonomy, and then to ask whether such control is compatible with socialist equality.' Cohen's project now is to translate the idea of real freedom into terms that are applicable to the real world, and, where possible, quantifiable. His model of 'equal access to advantage' now stands alongside van Parijs's (1995) and Sen's (1992) models. It thus forms part of a rich developing research program. Whether it should still be called Marxist is another question.

3.2 Post-Marxism: van Parijs

In the post-Marxist program of van Parijs, the normative goal of equalizing access to freedom is maintained. At the same time, the Marxian *theory* of exploitation is abandoned, and the capitalist market is now seen as the only vehicle that can deliver 'real freedom for all' in *practice*. The goal is to 'empower' the greatest number of people. The method is to guarantee them an unconditional 'basic income' that will prevent personal dependence and allow individuals to make meaningful choices between life-styles. The 'basic income' project has now entered the real political agenda in western Europe.

The goal of the post-Marxists is to reconcile freedom and equality by the principle to 'maximization of an unconditional income, subject to formal freedom being protected and to no-one's endowment being unanimously found worse than someone else's.' That would guarantee the widest, and fairest, distribution of 'real' freedom that could also be delivered by a 'sustainable' economic system. Van Parijs maintains that that system would be a highly regulated, interventionist form of capitalism. His reasons are fourfold. First, it is (probably) more efficient than socialism. Second, it can (probably) guarantee a higher basic income than socialism can. Third, it can (certainly) guarantee formal freedoms, whereas socialist régimes have still to prove that they can. Last, and this is a decisive consideration, even if there are reforms of international economic affairs, it will be impossible to promote an 'autarkic' socialist régime in one country

without imposing unacceptable restrictions on the movement of its people to other (higher paying) countries.

3.3 *Neo-Aristotelian Freedom as Capability: Sen*

The third egalitarian model combines sophisticated economic theory with a deep philosophical anthropology derived from Aristotle. The leading proponent of this model is Sen.

The aim here is to construct a model of freedom which is sufficiently objective to be used in cross-cultural comparisons, but which is also sensitive to the different weightings given to the elements of a flourishing life in different cultures. Sen (1992) draws up a list of 'functionings' that include 'being adequately nourished' and 'having self-respect,' and defines 'well-being freedom' as the capability to achieve those functionings. But there is also 'agency-freedom,' defined as the capability to achieve whatever one's objectives are. Since many people have objectives other than their own well being, these two freedoms may conflict.

It is agency freedom that has been at the center of most liberal discussion. Sen acknowledges its importance, but weighs it alongside well-being freedom in evaluating the totality of a person's life. Even within agency freedom, Sen advises liberals not to exaggerate the importance of the agent's direct control of an outcome. Instead, he proposes a counterfactual formula, 'I am free when control is exercised in line with what I would choose.' That formula can be generalized to cover all forms of freedom, even when the term 'freedom' is extended to cover 'freedom from hunger,' 'freedom from malaria,' etc.: 'One values living without malaria, desires such a life, and would have chosen it, *given the choice*.'

Society has different obligations to its members concerning their well being and their agency. It has an evident 'responsibility to a person's well-being, especially when it is in some danger of being particularly low' which it does not have for that person's particular agency objectives. In advanced liberal societies at least, 'in which the focus is on the *freedom* that people have,' no patterned outcome can be imposed. For 'even when complete equality of well-being freedom is ... entirely realized, this need not lead to an equality of well-being *achieved*, since different individuals may give different priority to the pursuit of their own well-being.' In rejecting patterned outcomes, Sen has shown that the capability model does not conflict with the central values of liberalism expounded by Rawls and Dworkin.

The capability model inherits from Aristotle the idea that human beings are endowed with specific capacities that can be more or less fully realized in a flourishing life. In his presentation of the model, Sen is concerned that Aristotle's particular 'view of human

nature (with a unique list of functionings for a good human life) may be tremendously overspecified.' He prefers to leave open 'both ... the exact grounds underlying the determination of relative weights, and the actual relative weights chosen.' This gives Sen's version of the 'capability approach' a degree of incompleteness relative to Aristotle's, but also, he thinks, a 'considerable "cutting power"' for use in the real world of cultural diversity.

3.4 *Freedom as Attaining Autonomy Through Community: Raz*

Communitarian critics including Taylor, MacIntyre, and Sandel brought two charges against liberalism. At the level of theory, they claimed that it is based on a methodological individualism which in turn derives from an impoverished, atomistic conception of human nature. At the level of practice, they argued that because the liberal order fails to provide a satisfactory sense of identity for its members, 'intolerance flourishes most where forms of life are dislocated, roots unsettled, traditions undone.'

Along with the communitarians, Raz (1986) rejects methodological individualism, but against them he argues that this does not entail a rejection of liberal values. Raz's liberalism, 'the doctrine of limited government,' is rooted in a 'non-individualist conception of morality.' In opposition to Rawls's antifoundationalism, Raz propounds a 'doctrine of political authority which rests on a perfectionist political defence and promotion of liberty and autonomy.' But this is not a brutish libertarianism, since freedom is 'a distinct value, but one which is intimately intertwined with others, and cannot exist by itself.' Raz in short is a foundationalist, who seeks to establish a 'continuity' between a moral base and a political-legal superstructure.

For someone to attain 'the ideal of autonomy' and live an autonomous life, certain conditions must be satisfied. These are the possession of 'appropriate mental abilities,' of an 'adequate range of options,' and of 'independence.' The ideal is positive, comprehensive. It constitutes the moral base of the system, but is not 'moralistic.' In particular, it does not involve a teleological conception of self-realization, since, as an autonomous person, one is free to choose whether or not to realize oneself. But without teleology it is difficult to make autonomy foundational. If autonomy involves integrity ('identification with one's life'), self-awareness and commitment to a project, it can still be asked why it is valuable. It is insufficient to answer that 'many people desire to be autonomous,' since people's desires are many, conflicting, and mutable. Rather, says Raz, 'the value of autonomy does not depend on choice ... the conditions of autonomy concern a central aspect of a whole system of values of a society ...' The kind of society in question

is a pluralistic society, which both supports and is supported by this central value 'valuing autonomy leads to the endorsement of moral pluralism.'

Other modern liberals, notably Rawls, are cautious about seeking to found political legitimacy on a particular understanding of freedom. They hold that particular individuals and groups can value freedom for different reasons, some welcoming it because it is a purely negative guarantee against interference, others because it embodies their highest aspirations. Against them Raz holds that most people in a liberal state must subscribe to the positive value of freedom as autonomy, otherwise its tolerant pluralism will perish.

4. Civic Republicanism

In the fifth model of political freedom, the 'liberty of the ancients' re-enters the modern debate. In both versions of 'civic republicanism' considered below, political participation plays a key role, a purely instrumental role in the first, and a constitutive role in the second.

4.1 The Instrumental Notion of Civic Republicanism: Skinner

Skinner's model, known variously as 'civic republicanism,' 'classical republicanism,' and 'neoromanism,' is rooted in the Renaissance, in particular in the idea derived from Machiavelli that a state which is 'free from all external slavery' guarantees 'personal liberty, understood in the ordinary sense ... each citizen remains free from any elements of constraint, especially those which arise from personal dependence and servitude, free to pursue his own chosen ends ... To be free ... is simply to be unconstrained from pursuing whatever goals we may happen to set ourselves.' The independence of the state is linked to the freedom of the individual insofar as 'a self-governing republic is the only type of régime under which a community can hope to attain greatness at the same time as guaranteeing its citizens their individual liberty.' Such a state requires two capacities or virtues from its citizens, courage and determination to defend their community against external attack, and practical reason which qualifies them to play an active part in public life. That means that the state can, legitimately, force the citizen to be free. Despite appearances, this 'strenuous view of citizenship' is, according to Skinner (1990), consistent with negative liberty in two respects. First, it does not presuppose any specific teleological theory of human nature. Second, when we are 'forced to be free,' we are being forced not to 'reason about ends,' but to 'recognize the range of actions we have good reason to perform in order to bring about the ends we actually desire.' Skinner illustrates the latter point by a contrast between 'liberals' like Hobbes and Locke on the one hand, and Machiavelli on the other.

The 'liberals' hold only (a) that the law preserves A's freedom by coercing B (the potential law-breaker). Machiavelli holds both (a) and (b) that the law also preserves A's freedom by coercing A 'into acting in a particular way ... forcing us out of our habitual patterns of self-interested behaviour ... into discharging the full range of our civic duties and thereby ensuring that the free state on which our own liberty depends is itself maintained free of servitude.' In short, because 'freedom depends on service and so on our willingness to cultivate the civic virtues ... we may have to be coerced into virtue and thereby constrained into upholding a liberty which, left to ourselves, we would have undermined.' Skinner comments that 'contemporary liberalism ... is in danger of sweeping the public arena bare of any concepts save self-interest and individual rights.' Ideologies suspicious of the whole modern agenda of individual freedom have stepped in to fill that vacuum. Skinner (1998) thinks that 'republican freedom' provides a robust defence against such reactionary positions.

4.2 The Constitutive Notion of Civic Republicanism: Pettit

In the second version of civic republicanism, espoused by Pettit (1997), Berlin's dichotomy of the positive freedom of self-mastery and the negative freedom of noninterference is not exhaustive. Beyond those two lies republican freedom, which means absence of domination, not absence of interference. Domination differs from interference in important respects. Domination is a function of the relationship of unequal power between persons or groups of persons. It relates to the *capacity* of one person or group of persons to interfere in the choices of other persons or groups, rather than to actual *instances* of interference. But that would not be enough to pick out the undesirable character of domination, since any non-anarchist social order will empower certain persons or groups, giving them authority over others in given circumstances. So domination is not just the possession of power, but the possession of *arbitrary* power. The goal of republican freedom, then, is that 'no-one is able to interfere on an arbitrary basis—at their pleasure—in the choices of the free person.' With this formula Pettit seeks to extract the rational kernel of both negative and positive freedom, while showing that neither of them is sufficient in itself. On the one hand, freedom as nondomination 'will facilitate the achievement of autonomy,' as positive freedom requires. On the other hand, it will respect people's empirical choices, as negative freedom requires, but it will go beyond it by showing that dominated people are not really free even if they have the good fortune to suffer no interference when their dominators choose to refrain from exercising their arbitrary power.

Insofar as republican freedom is tied to power, it is essentially egalitarian. It is held to protect each

individual against arbitrary power, and also to be a 'communitarian good,' allowing people to identify with a state that protects their freedom. This version of republican freedom is heavily influenced by Rousseau, purged of totalitarian accretions and updated to the advanced capitalist societies of the late twentieth century. They are now explicitly inclusive, bestowing their benefits on all members of society, and also multicultural, displaying liberal neutrality towards different substantive conceptions of the good. How far such societies can provide a stable balance between the participatory core of republican freedom and the centrifugal drives of modern pluralism remains to be seen.

French Revolution, The

The French Revolution was a momentous historical event that set enduring patterns for modern revolutionary movements and for much of modern politics in general. Contemporaries experienced the French Revolution as a set of interlocking changes or stages that seemed driven by some kind of mechanism or impetus. Analysis of this mechanism has preoccupied revolutionaries and scholars ever since. The conflicting political reactions to the French Revolution fed into the development of ideologies from conservatism to communism. Scholarly controversies about the significance and interpretation of the French Revolution have been animated in particular by Karl Marx and Friedrich Engels' use of it as the prime example of a 'bourgeois revolution' that prepared the way for the triumph of capitalism. Although the controversies over the Marxist interpretation continue, recent scholarship has turned in new directions: gender relations; the notion of citizenship and its connection to religion, ethnicity, and race; and the Revolution's impact on the colonies.

1. The French Revolution as Event

The year 1789 marks the clear beginning of the French Revolution, but opinion is much more divided about its ending: did it end in 1794 with the fall of Maximilien Robespierre, in 1799 with the rise of Napoleon Bonaparte, in 1804 when Napoleon established his empire, or in 1815 with the final defeat of Napoleon at the Battle of Waterloo? Debate on the question of endings cannot be resolved definitively because it is so closely entwined with interpretive questions. The choice of ending depends on the determination of the central significance of the French Revolution.

What most struck contemporaries and has fascinated commentators ever since was the unpredictability and yet seeming inexorability of the unfolding of events. Even in the midst of this unfolding, political actors and witnesses spoke of 'the system' of 'the French Revolution,' as if revolutionary events had an internal logic or mechanism pushing in a consistent direction. After spending years studying this logic, and having published his enduringly influential study of the French Revolution, Alexis de Tocqueville still complained of his difficulty in grasping 'this malady of the French Revolution,' this 'virus of a new and unknown kind' (Tocqueville 1977).

1.1 Revolutionary Stages

As a series of political events, the French Revolution is usually divided into five periods or stages: the constitutional monarchy or liberal revolution of 1789–91; the second revolution and the Terror of 1792–4; the

Directorial regime or liberal republic of 1795–9; Napoleon Bonaparte's consulate of 1799–1804; and the Napoleonic empire of 1804–15. This vertiginous succession of regimes established many of the prototypes of modern political authority and even much of modern political language, including the key distinction between Left and Right (determined by the location of deputies vis-à-vis the speaker in the National Assembly). The very possibility of ascertaining periods or stages—already apparent to contemporaries—raised questions about the natural history or morphology of revolution: was it like a sickness or fever from which a polity eventually recovered? Or was it rather a kind of speeding up of historical development, a bootstrap up to the next stage of capitalism or modernity?

1.2 Models of Political Authority

As the French Revolution moved from stage to stage, the revolutionaries generated at least three different models for modern (secular, nonmonarchical) political authority. By abolishing 'feudalism' (eliminating serfdom and seigneurial dues), suppressing noble titles, declaring the 'rights of man,' and founding the first French republic with universal manhood suffrage (1789–92), the French revolutionaries laid the foundations for democratic, representative government. By arresting dissidents, executing opponents, and carrying out a cultural revolution in the form of de-Christianization and republican political re-education (the Terror of 1793–4), the revolutionaries set the mold for 'totalitarian' government with its repressive insistence on political conformity in the name of a future social good. Napoleon Bonaparte developed a third model of paternalist, authoritarian government by a state with a strong military caste. In other words, the French Revolution adumbrated virtually all the possibilities of modern political authority.

2. The Origins of Ideology

The French Revolution gave birth both to the term 'ideology' and to many different ideologies that have continued to organize political discussion right up to the present day. Under the impact of revolutionary events, tradition lost its givenness, hierarchy no longer seemed natural, and monarchy no longer went without justification. The revolutionaries showed that society could be reorganized by an act of self-conscious political will (the definition of revolution itself). The attempt to reshape hearts and minds through festivals, paintings, engravings, operas, plays, and even ordinary items such as snuffboxes and playing cards drew dramatic attention to revolution as a mode of action. This attempt did not produce unanimity,

however; rather it produced social conflict. As a consequence, revolution brought 'the social' as a category into sharper relief. As early as 1792, Antoine Barnave wrote his *Introduction à la Révolution française*, arguing that new forms of wealth produced ineluctably new forms of political authority (Barnave 1988). As the social determinants of politics became more visible, i.e., more of a problem to be investigated, ideologies took shape as formal doctrines about the proper relationship between politics and society.

2.1 From Conservatism to Communism

The first ideology to emerge from the French Revolution was conservatism. Its founding text, Edmund Burke's *Reflections on the Revolution in France* (1790), was written in response to the events of 1789. The National Assembly's efforts to remake the French constitution led Burke to denounce what he termed a new 'political metaphysics' based on natural rights and abstract reason. Unlike many reactionary royalists, however, Burke did not just excoriate the French Revolution as the incarnation of evil and impiety. He understood that the revolutionaries were in the process of erecting an entirely new foundation for politics, and he undertook to counter them point by point. By arguing for a conservatism that accommodated change through practical experience and gradual amelioration, he admitted the necessity of confronting demands for change and the parallel demand for an elaborated doctrine to support the status quo. Even for conservatives, then, the French Revolution changed the rules of the game. The status quo now required explicit defense.

Although liberalism had its origins in the social contract theory of John Locke and the political economy of Adam Smith, after 1789 liberals too had to announce their position vis-à-vis the French Revolution. Most liberals supported the constitutional revolution of 1789 and rejected the Terror of 1793–4. This distinction was not always easy to uphold, for conservatives routinely accused liberals of supporting policies and positions that might open the way to more radical experiments, just as those of the revolutionaries of 1789 had opened the way to the Terror of 1793–4. The unfolding of stages in the revolutionary process thus shaped ideological debate, either explicitly or implicitly, for many generations after the French Revolution.

Socialists, and especially Marxists, traced their lineage directly back to the French Revolution. The early socialists—Claude Henri de Saint-Simon and Charles Fourier, for example—concluded from the French Revolution that society could be reorganized according to a technocratic project (thus 'utopian socialism' according to Marx). Marxists believed that only class struggle could produce a new social order. According to Marx and Engels, the French Revolution marked

the overthrow of the aristocracy by the bourgeoisie. The bourgeoisie would develop capitalism on the ruins of the feudal order it dismantled, thus preparing the way for a subsequent revolution in which the proletariat formed by capitalist development would overturn the bourgeoisie and replace capitalism with communism. The French Revolution was therefore a crucial stage in the class struggle and an essential forerunner to the future communist order.

Marx's emphasis on the need for self-conscious revolutionary organization had been at least partially inspired by Gracchus Babeuf and his 'Conspiracy of Equals' of 1796. Although Babeuf had few followers and his plans were foiled by police infiltration, his dream of a revolutionary seizure of political power by a secretly organized conspiratorial group lived on through the efforts of the Italian revolutionary Filippo (or Philippe) Buonarroti. Buonarroti, a member of Babeuf's circle in 1796, published a history of the Conspiracy of Equals in 1828. It brought the message of revolutionary seizure of power to secret societies throughout Europe. One of Buonarroti's followers, the French revolutionary socialist Auguste Blanqui, combined Buonarroti's appeal for a secret revolutionary brotherhood with the idea of a 'dictatorship of the proletariat,' a term coined by Blanqui to define the political goal for socialism. Marx and Engels incorporated both Babeuf's and Blanqui's notions into their program for proletarian revolution.

2.2 The Foundations of Modern Social Science

Because the French Revolution brought the relationship between society and politics into sharper focus, it also accelerated the development of the social sciences, first in France and then more broadly in Europe. The Directory regime created the first research institute for the social sciences with its department of political and moral sciences in the Institut. Bonaparte, himself a member of the Institut, took more than 150 scientific experts with him on his expedition to Egypt in 1798. They set up an Institut d'Egypt in Cairo and helped inaugurate 'oriental studies' in Europe. They also discovered the Rosetta Stone which enabled experts to decipher Egyptian hieroglyphics.

The French Revolution had an especially dramatic impact on historical studies in France. The first full-length histories of the Revolution were published in the 1820s by François-Auguste Mignet and Adolphe Thiers, journalists and editors in the political opposition. They used the history of the French Revolution to defend the notion of a constitutional monarchy and to criticize the restored Bourbons. In the 1840s, Louis Blanc, Alphonse Lamartine, and Jules Michelet wrote histories of the Revolution as part of their campaign for a republic. Although Marx did not write a history of the French Revolution of 1789, he did read the French historians and made

constant reference in his work to the French Revolution of 1789.

Marx was not alone in considering the French Revolution an important stage in historical development. As the notion of historical evolution spread in the nineteenth century, the French Revolution almost inevitably became an important benchmark. Auguste Comte, one of the founders of sociology, took as his point of departure the last writings of the Marquis de Condorcet, a French nobleman and revolutionary who committed suicide rather than face the guillotine in 1794. Comte proposed three stages of historical development: the theological, the metaphysical, and the positive or scientific. The French Revolution helped bring about the ongoing transition to the third, positive stage by liberating modern social elements from the dead hand of the Old Regime. The task of social science was to complete this transition, which could only be accomplished finally in ideas and opinions, according to Comte, not by revolutionary action. The ultimate aim of his system was the reorganization of society by means of scientific sociology.

Alexis de Tocqueville, who helped lay the foundations for political sociology and political science with his *L'ancien régime et la Révolution* (1856), considered the French Revolution not as a stage so much as an accelerator of the general modern trend toward democracy and equality. Tocqueville had read the previous historians of the French Revolution, though he rarely cited them, and absorbed the view that social changes had inevitable political repercussions. He wove his analysis of social changes into a subtle examination of French political culture and especially the dominance of the central state. In so doing he created an alternative to the Marxist emphasis on class struggle. Tocqueville considered the French Revolution pivotal in the advance of modernity but largely negative in its effects. Tocqueville saw in the French Revolution the tendency of democratic revolution to reproduce the despotism of monarchical authority by leveling all institutions that might have provided a check on state power. Although the French made their revolution for liberty and equality, they gave up liberty in order to be assured of equality and ended up with an equality of servitude to the Napoleonic state. This line of analysis had a long posterity—Hannah Arendt's analysis of revolution has clear affiliations to Tocqueville's—and continues to influence political and social theory right down to the present.

3. Scholarly Controversies

Since analysis of the French Revolution has played such a prominent role in the development of competing political ideologies, it is hardly surprising that it has generated disputes among scholars as well. In the nineteenth century writers used the French Revolution

to argue for and against monarchy, empire, or republicanism as a form of government. After the eruption of the Russian Revolution in 1917, however, debate shifted to the terrain defined by Marxism and communism, and in particular, the French Revolution as the exemplar of bourgeois revolution.

3.1 The Question of Marxism

Within France, Marxist historians of the French Revolution enjoyed the advantage of having captured the chair of the history of the French Revolution at the Sorbonne (University of Paris). For most of the twentieth century, the chair was occupied by a succession of talented socialists and communists. They pioneered the study of social tensions and social classes, of 'history from below.' The most remarkable of them was Georges Lefebvre, who wrote wide-ranging studies of the peasantry during the Revolution. Lefebvre's combination of narrative skills and analytical studies gave him an unrivaled reputation; even those who objected to his Marxist views regarded him as the most accomplished academic historian of the Revolution.

The Right did not have the same initial foothold within the French university system. Hippolyte Taine, for example, wrote his four volumes on the Old Regime and the French Revolution as a general literary and cultural critic, not as a professional historian. Taine's views remained fundamental to the Right-wing criticism of the Revolution. He had nothing but contempt for 'the people' so beloved by Michelet. He frequently likened the lower classes to beasts or insects; at worst, they were a crazed, frenzied rabble. Augustin Cochin toned down this virulence, arguing that the lower classes were manipulated by professional politicians who came to power through the activities of secret societies such as Masonic lodges. The Right took up some of the claims of the Left—that the French Revolution foreshadowed the Russian Revolution of 1917—but gave them a negative rather than a positive spin.

Before the 1970s, the Marxist Left enjoyed the dominant position in French academic debates, in part because of its strength within the university, and in part because the Right was associated with anti-democratic politics. The balance began to shift, however, as critics of the Revolution finally accepted the republican form of government. A more moderate republican Right got support from a growing body of work produced in the Anglophone countries, especially the United States and the United Kingdom, which attacked the central Marxist thesis that the French Revolution was a bourgeois revolution. Critics argued that the capitalist bourgeoisie had not made the Revolution (first aristocrats and then middle-class officials and lawyers had led it, not manufacturers);

that the Revolution had not overthrown feudalism (because feudalism no longer existed); and that the Revolution did not pave the way for capitalism (since industrialization did not take place until the 1840s).

François Furet, a former communist, brought together the new Anglophone work in a frontal assault on the Marxist interpretation. This 'revolutionary catechism,' this 'Lenino-populist vulgate,' he argued, fundamentally distorted the history of the French Revolution by depicting it as a class struggle that anticipated communism. Furet claimed as his ancestors Tocqueville and Cochin; he did not reject democracy, but rather wanted to understand why democracy in the French Revolution developed into Terror or totalitarianism. The social underpinnings of the French Revolution could never explain this skidding out of control into Terror, he maintained; revolution was an autonomous political and ideological movement, not the expression of a social class (Furet 1978). By 1989, the year of the bicentennial of the French Revolution, Furet's version of the French Revolution had become the new orthodoxy. The political balance had shifted, not only in France but almost everywhere else as well. The French Revolution no longer seemed a communist preserve.

3.2 Current and Future Directions

Since 1989, as the polemics over Marxism have subsided, the work of historians from other countries has attracted more attention. American, British, German, and Italian historians now offer alternative views of their own. No one school, whether Left-wing or Right-wing, French or Anglophone, currently dominates the historiography of the French Revolution. The shift of political interest away from Marxism has opened up new areas of research, including gender relations, definitions of citizenship, and the role of the colonies. These new perspectives reflect concerns with human rights and globalization.

Since the French Revolution began by enshrining the notion of 'the rights of man,' it has been a prime site for work on the dilemmas of universalism. Feminists have pinpointed the Enlightenment's masculinist bias as the chief cause of the failure of the revolutionaries to include women in their promise of citizenship; Enlightenment writers, especially Montesquieu and Rousseau, used nature and reason to justify women's exclusion from the public sphere, and the revolutionaries simply drew the logical conclusion from these assumptions. Other feminists, however, have insisted that the Revolution opened up new opportunities for women, legalizing divorce, assuring equal inheritance to girls, and affording women the opportunity to establish political clubs. Unlike women, men who were Protestants, Jews, free blacks, mulattos, or even slaves gained political rights during

the French Revolution. Yet even these enfranchisements revealed telling fault lines in the revolutionary conception of citizenship; the National Assembly, for instance, insisted that the Jews must give up their particular identity and corporate privileges as Jews in order to become French citizens. Since discussions of free black and slave rights inevitably involved the slave colonies, and since France's colony of Saint Domingue (San Domingo) was home to the first successful slave revolt in history beginning in 1791, the interest in citizenship has also stimulated study of France's slave colonies. Because the French Revolution put both revolution and modernity on the agenda, it continually offers rich possibilities for historical and theoretical debate.

Frequentist Inference

1. Data, Models, and Inference

The starting point of a statistical analysis is a set of data, for example, of counts or measurements. One aim may be simply to study what these data have to tell us. If they consist of a set of real numbers we might want to see, for example, whether they are small or large; tightly concentrated or spread out, whether they are stable or tend to increase with time, etc. If they are points in the plane we can get an idea of the shape of this set of points, for example, whether they cluster about a line. The branch of statistics dealing with this kind of investigation used to be called descriptive statistics, but now goes by the name data analysis or, more precisely, exploratory data analysis (EDA), a term introduced by Tukey (see *Exploratory Data Analysis: Univariate Methods*). Instead we consider how we can quantify the conclusions or decisions drawn from an analysis. Frequentist inference requires that any quantifying measure be interpretable in terms of frequentist probability of events (see *Frequentist Interpretation of Probability*). That is, we assume the data are random quantities produced by some probability distribution and that something is known about this distribution. For example, if we have a set of n measurements of some quantity, we may assume that these measurements are independently and identically distributed. We may stop there or may go further and make some assumptions about this common distribution.

Statistical analyses based on such assumptions were common in the nineteenth century, and isolated instances can be found in the eighteenth century; but the first general framework was proposed by R. A. Fisher (1922) (see *Fisher, Ronald A (1890–1962)*). He states:

The object of statistical methods is the reduction of data. A quantity of data which usually by its mere bulk is incapable of entering the mind, is to be replaced by relatively few quantities which shall adequately represent the whole.

This object is accomplished by constructing a hypothetical infinite population of which the actual data are regarded as constituting a random sample. The law of distribution of this hypothetical population is specified by relatively few parameters, which are sufficient to describe it exhaustively in respect of all quantities under discussion.

In modern terminology we might paraphrase this proposal by saying that we construct a mathematical model, according to which the data are produced by a probability distribution assumed to belong to some specified parametric family of distributions.

What are the statistical methods based on these models supposed to achieve? Fisher called the aim 'inductive inference' or 'inductive reasoning,' and described it variously as 'learning by experience' and

as ‘drawing inferences from the particular to the general, from consequences to causes’ or—using statistical language—‘from the sample to the population.’ ‘The purpose of inductive reasoning based on empirical observations,’ he wrote ‘is to improve our understanding of the systems from which these observations are drawn.’

This interpretation was criticized by Neyman (1961) who objected that ‘After a conscientious effort to find the exact meaning of this term [inductive reasoning] I came to the conclusion that, at least in the sense of Fisher, the term is empty.’ Neyman proposed instead that the purpose of statistical analysis is to serve as guide to appropriate action; and, in contrast to Fisher’s inductive reasoning, named it inductive behavior (see also *Neyman, Jerzy (1894–1981)*).

Neyman’s point of view was taken up by Wald who used it to construct a comprehensive framework for statistical decision making (Wald 1950). It involved three principal elements

(a) A family of probability distributions representing the various possible true situations.

(b) A set of actions from which it is the statistician’s task to choose the most appropriate one.

(c) A loss function which measures the loss resulting from any action taken for any of the possible true situations.

Wald’s formulation was castigated by Fisher as completely inappropriate for scientific work. ‘It is important,’ he wrote (Fisher 1973, p. 106) ‘that the scientific worker introduces no cost functions for faulty decisions. To do so would imply that the purposes to which new knowledge was to be put were known and capable of evaluation. As workers in Science we aim at methods of inference which shall be equally convincing to all freely reasoning minds, entirely independently of any intentions that might be furthered by utilizing the knowledge inferred.’

While it is difficult not to sympathize with Fisher’s stress on scientific aims as an alternative to immediate utilitarian use, his statements are distressingly vague. An effort to be more specific, which still seems rather vague, was made by Tukey (1960). For the outcome of a nonaction-oriented statistical analysis he proposed the term ‘conclusion.’ Concerning the difference he writes: ‘Conclusions are established with careful regard to evidence but without regard to consequences of specific actions in specific circumstances. Conclusions are withheld until adequate evidence has been accumulated.’

The distinction between Fisher’s point of view and that of Neyman and Wald, between conclusions and decisions, concerns the interpretation of the results of a statistical analysis. How those results are reached from the given model by means of frequentist inference forms the subject of this article. (For the frequentist meaning of probability see *Frequentist Interpretation of Probability*.) It includes the derivation of appropriate procedures, the comparison of different pro-

cedures, investigating the sensitivity of a procedure to departures from the assumed model, and the checking of the suitability of the model. Another topic of interest, considered in Sect. 3.6, is the selection of an appropriate model.

There is an alternative approach to inference which can embody both the decision theory aspects of the Neyman–Wald approach and Fisher’s views on learning by experience. This is the Bayes approach which requires not only the frequentist’s specification of a family of possible distributions for the observation, but also that the distribution of the observation has itself been drawn from the specified model according to a known probability mechanism. This is coupled with the subjective point of view of probability in which the chance of an event represents a quantitative measure of the observers’ odds on the occurrence or nonoccurrence of the event. This point of view, though attractive, puts a burden on the observer to specify his or her state of mind with possibly unreasonable precision and, of course, leaves open the issue of the generalizability of the conclusions by scientists at large (see also *Bayesian Statistics*).

The problems of inference have been the subject of much discourse among philosophers as well as scientists whose primary interest was not statistics. We refer to Keynes (1921), von Mises (1928) and Jeffreys (1939) among others.

A problem in discussing frequentist inference is that, while distinctions such as those between Fisher, Neyman, and Wald are required in order to formulate the goals of theory, they are artificial in practice. Even in scientific inquiry the cost of initiating extensive further investigation on the basis of weak evidence has to be kept in mind. On the other hand, the most interesting consequences may not be foreseen and the costs of actions difficult to quantify. Is foisting a slightly better-than-average drug with serious side effects on most patients better than doing nothing? What if the drug turns out to have major benefits for a small group of patients not represented in the original clinical trial of the drug? A chemist, E. B. Wilson (1952), after considering the work of the thinkers we mention, pleads eloquently, ‘There is a great need for further work on the subject of scientific inference. To be fruitful it should be carried out by critical original minds who are not only well-versed in philosophy but also familiar with the way scientists actually work (and not just with the way some of them say they work).’

Wilson concludes pessimistically: ‘Unfortunately the practical nonexistence of such people almost suggests that the qualities of mind required by a good philosopher and those needed by a working scientist are incompatible.’

In what follows we

(a) begin, for illustrative purposes, by describing a few simple models that have arisen from a frequentist point of view (Sect. 2), and

(b) discuss by example the principal frequentist inference procedures (hypothesis testing, point estimation, confidence regions, prediction, and model selection) (Sect. 3).

We use the term frequentist inference if all probabilities involved (such as significance level, power, and coefficient) are interpreted as frequentist probabilities in the sense of the article (*Frequentist Interpretation of Probability*). In particular, the assertion that the value of such a probability is p then means that in a large number of independent cases with probability p of some outcome, we expect the outcome to occur with a frequency close to p . In this connection it is important to realize that there is no need for these situations to be at all like each other, as long as the probability p is the same in each (see Neyman 1937).

2. Some Simple Models

Frequentist models are characterized by two principal features.

(a) The variability of the data. If the observations were repeated, different values would be obtained. This variability is represented in the model by postulating that the data are generated by a probability distribution.

(b) The unknown aspect of the situation which the statistical investigation is to elucidate. This unknown feature is represented in the model by the fact that the probability distribution of the observations is assumed to be only partially known.

These two features are seen clearly in the following model, which was mentioned briefly in the preceding section.

Example 1. (Error-measurement model) If $X_1, \dots, X_n$ denote n measurements of an unknown quantity θ , this model can be written as

$$X_i = \theta + \varepsilon_i. \quad (1)$$

Here θ represents the unknown quantity we wish to estimate or test. The errors ε_i are the source of the variability of the observations. This frequency model assumes that, in a replication of the situation, the unknown value of θ would be the same but that the ε 's would take on different values. The most common assumption concerning their variability is that they are independent random variables with a common distribution with mean zero. This distribution may be assumed to be known. More usually it too embodies some unknown features; for example, its form may be known but it may contain an unknown scale parameter.

Simpson and others toward the middle of the eighteenth century considered various possible forms for this distribution; but by the early nineteenth

century it was agreed generally that the most suitable distribution of such measurement errors, in most cases, was the normal. The basis for this belief was the hypothesis of 'elementary errors,' which assumes that observational errors are the sum of a large number of small, elementary errors; and, by the Central Limit Theorem, are therefore approximately normally distributed.

If the ε 's in (1) are assumed to be independently normally distributed with the mean 0 and variance σ^2 , the model (1) is equivalent to assuming that

$$X_1, \dots, X_n \text{ are independent } N(\theta, \sigma^2). \quad (2)$$

Example 2 (Normal one-sample model) Model (2) arises also in contexts quite different from the measurement situation described above. Suppose X is some numerical characteristic of a person such as height, weight, blood pressure, intelligence, etc., or of an animal, plant or manufactured product. However, this time we are not taking several observations X_i on the same subject but one observation each on different subjects drawn at random from a population which, in the model, we shall assume to be infinitely large. In this setting θ is the mean value of X in the population, and (2) is called the normal one-sample model. (The measurement situation can be viewed as a special case if one considers the n measurements actually taken as a sample from an essentially infinite number of measurements that could be taken.)

In these applications the assumption of normality is frequently made even though it is often not suitable and each situation ought to be considered in its own right. Often normality can be brought closer by applying it not to the observations X_i themselves but to some transformation $T(X_i)$. In other cases the normal model (2) is replaced by the more general model

$$X_1, \dots, X_n \text{ are independently distributed} \\ \text{according to } F(x - \theta) \quad (3)$$

where F has mean zero and otherwise is arbitrary, or where it is assumed to be an arbitrary distribution that is symmetric about zero. Some smoothness conditions may also be imposed; for example, that F has a density f .

Example 3. (Linear Model) Large areas of statistical methodology are based on the following extension of (1), due to Gauss (1809) and known as the linear model

$$X_i = \sum_{j=1}^p \beta_j z_{ij} + \varepsilon_i \quad (i = 1, \dots, n) \quad (4)$$

where the z 's are known constants (sometimes called explanatory variables) and the β 's unknown parameters. The ε 's are the observational errors as before and are assumed to have expectation zero.

Examples of (4) abound. Here are a few.

(a) The measurement model (1) is the special case of (4) with $p = 1$, $z_{i2} = 1$ and $\beta_1 = \theta$.

(b) The two-sample problem with $n_1 + n_2$ independent variables $X_1, \dots, X_n: N(\theta_1, \sigma^2)$ and $X_{n_1+1}, \dots, X_{n_1+n_2}: N(\theta_2, \sigma^2)$ corresponds to $p = 2$,

$$z_{11} = \dots = z_{1n_1} = 1, \quad z_{1n_1+1} = \dots = z_{1n_1+n_2} = 0, \\ \beta_1 = \theta_1 \quad (5)$$

and

$$z_{21} = \dots = z_{2n_1} = 0, \quad z_{2n_1+1} = \dots = z_{2n_1+n_2} = 1, \\ \beta_2 = \theta_2 \quad (6)$$

(c) The k -sample model is defined analogously. The two-way layout without interactions assumes that the variables X_{ijk} ($k = 1, \dots, n_{ij}; i = 1, \dots, a; j = 1, \dots, b$) are independent normal with common variance σ^2 and with means

$$E(X_{ijk}) = \mu + \alpha_i + \beta_j (\Sigma \alpha_i = \Sigma \beta_j = 0). \quad (7)$$

The k -sample model and the two-way layout are the simplest cases of analysis of variance models.

Another important class of examples of (4) are models for regression. The simplest case is

(d) Simple linear regression, given by

$$X_i = \alpha + \beta t_i + \varepsilon_i \quad (8)$$

where the t 's are known constants, and α and β unknown parameters.

This is a special case of

(e) Polynomial regression, with

$$X_i = f(t_i) + \varepsilon_i \quad (9)$$

where f is a polynomial (for example, quadratic) of known degree and with unknown coefficients.

Other functions f , of course, are also possible.

A modification of (4) that is sometimes suitable is to have some of the z 's random. For example (7) in some situations is replaced by

$$X_{ijk} = \mu + A_i + \beta_j + \varepsilon_{ijk} (\Sigma \beta_j = 0) \quad (10)$$

where the A 's are unobservable random variables assumed to be independent $N(0, \sigma_A^2)$ and independent of ε . For more, see *Linear Hypothesis*.

When the distribution of the observational errors the ε 's in (1) and (4) is specified, the models considered so far are parametric, that is, they can be smoothly parameterized by Euclidean labels. Models such as (3) with the distributional form of errors unspecified up to

symmetry are semiparametric. Nonparametric models are ones in which as little is assumed as possible.

Example 4. (Nonparametric regression) This model is suitable in situations where, on each member of a sample of size n from some population, we observe not only a response Y but also observe characteristics (covariates) $\mathbf{Z} = (Z_1, \dots, Z_k)$. For example, Y might be the income of a randomly sampled individual, Z_1 might be age, Z_2 educational level, etc. Of principal interest here is the average relation between Y and $\mathbf{Z}$

$$E(Y|Z_1 = z_1, \dots, Z_k = z_k) \equiv m(z_1, \dots, z_k). \quad (11)$$

If we assume nothing about the form of m , then subject to the assumptions that $E|Y| < \infty$ and that $(Y_1, \mathbf{Z}_1), \dots, (Y_n, \mathbf{Z}_n)$ are independent and identically distributed, this model is completely general since we can always write

$$Y_i = m(Z_{i1}, \dots, Z_{ik}) + \varepsilon_i \quad (12)$$

where $E(\varepsilon_i|Z_i) = 0$. Note that if we assume

$$m(z_1, \dots, z_k) = \sum_{j=1}^k \beta_j z_j,$$

then, given $\mathbf{Z}_i = z_i$ ($i = 1, \dots, n$) we are back in the linear model (4).

In order to identify m in (12) we need to make some assumptions, for instance that m is continuous.

An important method for constructing more complex models from simpler ones is that of hierarchical models. As exemplified in (10), such models often contain unobservable random variables which are themselves of interest.

From this point of view Bayes models can be considered as two-stage hierarchical models in which the first stage is a frequentist model involving unobservable parameters for which the Bayes model specifies a distribution as a second stage. If the frequentist model is itself hierarchical, a last stage is added when the model is Bayesianized. To this difference—that the unknown parameters of the frequentist model become unobservable random variables in the corresponding Bayes model of course, is added the difference in interpretation of the probabilities involved as frequentist or subjective.

3. Inference Methods

As indicated in Sect. 1 linked closely with the frequentist paradigm is that of decision theory. The principal types of problems considered in that framework are

- (a) hypothesis testing,
- (b) point estimation,
- (c) confidence regions,

- (d) prediction,
- (e) model selection.

We shall discuss these in the above order.

3.1 Hypothesis Testing

Wald's decision theory grew out of the Neyman–Pearson theory of hypothesis testing (Neyman and Pearson 1933) which the authors formulated as choosing between two decisions, whether a prespecified statement (the hypothesis H) about the distribution P generating the data is or is not correct. If $\theta \in \Theta$ parameterizes the model, this is equivalent to determining whether $H: \theta \in \Theta_0$ or the alternative $K: \theta \in \Theta_1$ is true.

This formulation is satisfactory in many practical contexts such as occur, for example, in medicine, agriculture, or industry. For instance, in Example 3(b) the two samples may correspond to control and treatment groups of patients. In Example 3(b) the assumption of normality is made, and implicitly that of an additive treatment effect measured by the difference $\theta_2 - \theta_1$. The hypothesis to be tested is usually formulated as $H: \theta_2 \leq \theta_1$; i.e., that the treatment has no beneficial effect. The alternative $K: \theta_2 > \theta_1$ claims the existence of a beneficial effect.

The test for this problem is a test function δ which takes on the values $\delta(x) = 0$ or $\delta(x) = 1$ for the sample points x for which we decide to accept or reject H . The performance of such a test is measured by the probabilities of

- (a) Type I errors—rejecting H when H is true, and
- (b) Type II errors—accepting H when H is false, that is, by the probabilities

$$\begin{aligned} P_\theta[\delta(x) = 1] &\text{ when } \theta \in \Theta_0 \quad \text{and} \\ P_\theta[\delta(x) = 0] &\text{ when } \theta \in \Theta_1. \end{aligned} \quad (13)$$

The test δ is required to satisfy the condition

$$P_\theta(\text{Type I error}) \leq \alpha \quad \text{for all } \theta \in \Theta_0, \quad (14)$$

where the level α of the test is preassigned (usually as 0.05 or 0.01) as the maximum probability of false rejection to be tolerated. Subject to (14) we look for tests δ which make P_θ (Type II error) as small as possible.

This formulation is meaningful if it is possible to distinguish sharply between hypothesis and alternatives, between those θ -values for which rejection of H is clearly desirable or undesirable. In Example 3(b), for instance, we can specify that only beneficial effects exceeding $\varepsilon\sigma$ (for some given $\varepsilon > 0$) are of interest. Such a distinction is often possible in the contexts we have mentioned.

The Neyman–Pearson formulation of hypothesis testing in terms of the two types of error works well when we have clear definitions of both the hypothesis and the alternatives. In scientific contexts it is often the

case that the hypothesis is clear but the alternatives are vague. It is then the unlikelihood of observations that would be surprising if the hypothesis were true (but less so if the vaguely entertained alternatives were valid) which takes on particular significance. It is still necessary to define a test statistic T and to suppose the hypothesis is rejected when its values are sufficiently large, since such values would be surprising if H were true but not if H were false. Then the probability of observing values greater than or equal to the observed value of T is the p -value or significance probability of the hypothesis. If it is sufficiently small, it draws attention to anomalies not expected under H . The calculation of such probabilities is central to science. However, whether such attention should be followed by action as assumed in the Neyman–Pearson theory depends on extraneous considerations.

The Bayesian approach to testing assigns prior probabilities to hypothesis and alternative and calculates the ratio of posterior probabilities, the Bayes factor, as a measure of evidence in favor of or against the hypothesis rather than the significant probability. This approach is very attractive in providing exactly what everyone wants: the probability of the hypothesis being true, given the data. However, this probability depends on the prior probability distribution assigned to the parameters; and these priors can overwhelm strong opposite data evidence. Disparate priors can result in conflicting conclusions based on the same data by analysts holding different prior opinions (see also *Hypothesis Testing in Statistics*).

3.2 Point Estimation

The decision-oriented point of view of Neyman and Pearson led to the full-fledged decision theory of Wald, based on assigning losses to the consequences of inappropriate decisions. Perhaps the most successful example of this approach is point estimation (for which the idea of loss functions had already been discussed by Gauss and Laplace).

The prototypical estimation problem is that of estimating an unknown physical constant subject to measurement error discussed in Example 1. The loss function most commonly considered is squared error leading to its expected value, the mean squared error (MSE), as its risk. The standard assumption of independent normal errors with mean zero and common variance implies that the sample mean $\bar{X}$ is the appropriate estimator according to a number of different criteria.

(a) Minimax. This is a worst case analysis in which the maximum risk is minimized.

(b) Uniform minimum variance unbiased. An estimator of θ is said to be unbiased if its expectation is equal to θ . For unbiased estimators the MSE is equal to the variance; and, in the present case, $\bar{X}$ minimizes the variance among all unbiased estimators.

(c) Maximum likelihood (ML). This is a non-decision-theoretic approach based on the likelihood the density of the data viewed as a function of the parameter. Fisher considered the likelihood of an observation as a measure of support for the different θ -values that might have generated it and proposed the θ -value maximizing it as an appropriate estimator of θ . When a uniform prior distribution can be placed on the parameter, the ML estimator is just the mode of the posterior distribution. However, when θ ranges over the infinite line (as is the case in the measurement model and many others), no uniform probability distribution for θ exists; and only an ‘improper Bayes’ interpretation is then possible.

The ML principle is popular for a number of reasons

- (a) general applicability,
- (b) invariance under reparameterization,
- (c) in cases such as Example 2, where meaning can be attached to ‘large sample sizes,’ the method is approximately optimal,
- (d) in many standard cases it leads to explicit solutions.

However, there are examples in which the resulting estimators are completely misleading, (LeCam 1990, Ferguson 1996). In particular, ML is either not applicable or can lead to very poor results in many non- and semiparametric models such as Example 4. For a general discussion of different approaches to estimation see, for example, Bickel and Doksum (2000), Lehmman and Casella (1998).

The assumption of joint normality of the data, for instance in Examples 1–3, is often seriously in doubt. In such cases robustness criteria are invoked and lead to alternatives to the linear procedures appropriate for normally distributed data. For example, the median rather than the mean (or some intermediate trimmed mean) might be used in Example 1, and minimum L_1 (least absolute values) rather than L_2 (least squares) estimators in Example 3. For an extended discussion of robustness see Hampel et al. (1986) and Staudte and Sheather (1990).

3.3 Bayes Estimation

Still another principle is that of Bayes estimation, i.e., minimizing the expected risk under a prior distribution π of the parameter θ . Since this is the same as minimizing the average risk, averaged with respect to the weight-function π , such estimators are of interest both from a Bayesian and a frequentist point of view. For estimating a real-valued parameter $g(\theta)$ with data X and squared error loss, the Bayes estimator is

$$E[g(\theta)|X] \quad (15)$$

the mean of the posterior distribution of $g(\theta)$ given X .

Bayes estimators are essentially never unbiased (Girshick and Savage 1951) since they naturally ‘pull’

the estimator toward one’s prior opinion, the prior mean of $g(\theta)$. For example, in the one-sample model of Example 2. If π is normal (μ, τ^2) , the Bayes estimator is

$$\left(\frac{n\bar{X} + \mu}{\sigma^2 + \tau^2} \right) / \left(\frac{n}{\sigma^2} + \frac{1}{\tau^2} \right). \quad (16)$$

Frequentist and Bayes inference generally merge for large sample sizes since the data then wash out the influence of the prior distribution (provided the prior does not exclude parts of the sample space); see, for example, Blackwell and Dubins (1962).

In estimation even more can be said. If the prior distribution is locally uniform, Bayes estimators are asymptotically optimal in a frequentist sense by the Bernstein–von Mises theorem (see, for example, Lehmann and Casella 1998, Bickel and Doksum 2000). This is, however, a limit result; in practice, the effect of a strong prior often persists even for substantial sample sizes.

Both aspects can be illustrated by the Bayes estimator (16). For fixed μ , the difference of this estimator from $\bar{X}$ is of the order $1/n\tau^2$. For fixed τ^2 , it is accordingly of the order $1/n$, while the difference of both estimators from θ is of the order $1/\sqrt{n}$. On the other hand, the convergence of (16) can become arbitrarily slow if $\tau^2 \rightarrow 0$ as $n \rightarrow \infty$. The basic message is that optimal frequentist estimators are appropriate for Bayesian problems and vice versa.

For the sake of simplicity, we have here focused attention to the estimation of real-valued parameters. Of course, estimation problems arise also for multi-variate parameters (for instance, in Example 3) and for function-valued parameters such as the function m in Example 4 or in the estimation of an unknown density. Squared error loss is then replaced by summed or integrated MSEs. However, the univariate and multi-variate situations present unexpected differences. For example, the typically unique minimax estimator of the univariate case is replaced by an infinite set of minimax estimators; and among these the natural extension of the classical univariate estimator is no longer optimal (Stein 1956).

Point estimates by themselves are hardly ever sufficient. Typically one also requires an idea of the error committed in using the estimator; that is, an estimate of the MSE. This is again the problem of estimating a parameter, and there is little to add. However, interpretation of the estimated measure of error is often difficult. It is clarified by the concept of confidence estimation, which we take up next.

3.4 Confidence Regions

When estimating θ in the measurement error model of Example 1, it is customary to indicate the reliability of

the estimate $\bar{X}$ by attaching to it the error estimate $\pm S/\sqrt{n}$ with $S^2 = \Sigma(X_i - \bar{X})^2/(n-1)$ as a proxy for $\pm \sigma/\sqrt{n}$. In the case of normal errors with mean zero.

$$P_\theta \left[\bar{X} - \frac{\sigma}{\sqrt{n}} \leq \theta \leq \bar{X} + \frac{\sigma}{\sqrt{n}} \right] = 0.67 \quad \text{for all } \theta. \quad (17)$$

If σ is known, (17) provides intervals of fixed length (and with random midpoints) which, in many repetitions of the experiment of taking n measurements, will 'cover' the true θ 67 percent of the time whatever are the true values of θ and σ . The intervals (17) are confidence intervals for θ with confidence coefficient 0.67.

In practice, σ is usually unknown. We can then obtain confidence intervals for θ by replacing σ by its estimator S . If t_α is the $100(1-\alpha/2)$ percent point of the t -distribution with $n-1$ degrees of freedom, the intervals

$$\bar{X} - t_\alpha \frac{S}{\sqrt{n}} \leq \theta \leq \bar{X} + t_\alpha \frac{S}{\sqrt{n}} \quad (18)$$

cover the true θ with probability $1-\alpha$ so that the statement (18) is correct about $100(1-\alpha)$ percent of the time. The length of the intervals is no longer fixed but random, its length tending to increase as the accuracy of the observations (the inverse of which is measured by σ and estimated by S) decreases.

In general, in estimating a parameter θ taking values in an arbitrary space Θ , a $100(1-\alpha)$ percent confidence region for θ is a random subset $C(X)$ of Θ , depending on the data with the property that

$$P[\theta \in C(X)] \geq 1-\alpha \quad (19)$$

for all probability distribution P in the model. Here the region $C(X)$ can, for example, be an interval as above, an ellipse as in the Scheffé regions for the parameters of the linear model in Example 3, or a 'band' about an unknown distribution function.

Confidence regions can be viewed as simultaneously making statements about the acceptability of a family of hypotheses (see Lehmann 1986). In particular, they provide a measure of the acceptability of the alternatives. A 95 percent confidence interval for the treatment effect of Example 3(b), for instance, which includes zero, tells us not only that the null hypothesis is accepted at the 5 percent level but also specifies all alternatives to the null hypothesis which are accepted at that level. An interval which does not contain zero but to which zero is close suggests that although we have seen something that is surprising under the null hypothesis, the data are consistent with alternatives that do not differ materially from zero.

The interpretation of confidence regions is conceptually difficult because the probability statements refer not to any random variation of the parameter, which, although unknown, is considered fixed, but to that of

the data-dependent region. In contrast, a Bayesian analysis views θ as random and constructs credible regions $C^*(X)$ such that the posterior probability of θ falling into $C^*(X)$ is $\geq 1-\alpha$. This is just the kind of conclusion one would like to make; but, as in the case of testing, tends to be strongly influenced by assumptions concerning the prior.

Again, as in point estimation, Bayes regions derived on the basis of optimality criteria of size (length, volume, etc.) for large sample sizes agree approximately with frequentist confidence regions satisfying minimax size properties subject to fixed probability of coverage (see also *Estimation: Point and Interval*).

3.5 Prediction

This is the part of frequentist inference that is closest to the Bayesian approach and that fits least well into the decision-theoretic framework. Typically we are given a sample from a population of the form $(\mathbf{Z}_i, Y_i)$, $i = 1, \dots, n$ where $\mathbf{Z}_i$ is a vector of predictors. Using this sample (which provides information concerning the relationship of $\mathbf{Z}$ and Y) and a new $\mathbf{Z}_{n+1}$ we wish to predict the unobserved Y_{n+1} . The predictor of Y_{n+1} is a function

$$\delta(\mathbf{Z}; \mathbf{Z}_1, Y_1, \dots, \mathbf{Z}_n, Y_n) = \hat{\delta}(\mathbf{Z})$$

such that $\hat{\delta}(\mathbf{Z}_{n+1})$ is used to predict Y_{n+1} . In the continuous case (regression), the classical measure of loss resulting from incorrect prediction is squared error,

$$[Y_{n+1} - \hat{\delta}(\mathbf{Z}_{n+1})]^2.$$

On the other hand, in the case of categorical variables taking on values $\{1, \dots, k\}$ (classification), the standard loss function takes on the value 0 if $Y_{n+1} = \hat{\delta}(\mathbf{Z}_{n+1})$ and 1 otherwise. Prediction has the attractive feature that it allows nonparametric estimates of error since for any procedure we can compute its performance by applying it to the training sample on which it was built, for instance, $(1/n) \sum_{i=1}^n (\delta(\mathbf{Z}_i) - Y_i)^2$. This measure typically underestimates error, but techniques such as cross validation can be used to adjust it.

3.6 Model Selection

An important aspect of a frequentist analysis is the specification of a model. As an illustration, consider Example 3(e) where the regression function is assumed to be well approximated by a polynomial. Suppose the errors are normally distributed with zero mean and common variance. To complete the specification of the model, it is then necessary to decide on the degree d of the polynomial. With classical (least squares) prediction methods, the variance of the prediction error increases and its bias decreases with d . On a frequentist

basis the data can then be used to select d so as to obtain a desirable balance between these two aspects. Criteria for selecting d (and making analogous choices within a family of proposed models in other problems) have been developed by Akaike, Mallows, Schwarz, and others (for more details, see, for example, Linhart and Zucchini 1986):

Bayesian solutions to this problem differ in a number of ways, reflecting whether we assume that the true model belongs to the hypothesized class of models (e.g., is really a polynomial) or can merely be approximated arbitrarily closely by such models. For more on this topic see Shao (1997).

Frequentist Interpretation of Probability

If the outcome of an event is observed in a large number of independent repetitions of the event under roughly the same conditions, then it is a fact of the real world that the frequency of the outcome stabilizes as the number of repetitions increases. If another long sequence of such events is observed, the frequency of the outcome will typically be approximately the same as it was in the first sequence.

Unfortunately, the real world is not very tidy. For this reason it was necessary in the above statement to insert several weasel words. The use of ‘roughly the same,’ ‘typically,’ ‘approximately,’ and ‘long sequence’ make it clear that the stability phenomenon being described cannot be stated very precisely. A much clearer statement is possible within a mathematical model of this phenomenon. This discovery is due to Jacob Bernoulli who raised the following question.

It is well known, Bernoulli says in Part IV of his book *Ars Conjectandi* (published posthumously in 1713), that the degree to which the frequency of an observed event varies about the probability of the event decreases as the number of events increases. He goes on to say that an important question that has never been asked before concerns the behavior of this variability as the number n of events increases indefinitely. He envisages two possibilities.

(a) As n gets larger and larger, the variability eventually shrinks to zero, so that for sufficiently large n the frequency will essentially pinpoint the probability p of the outcome.

(b) Alternatively, it is conceivable that there is a positive lower bound below which the variability can never fall so that p will always be surrounded by a cloud of uncertainty, no matter how large a number of events we observe.

Bernoulli then proceeds to prove the law of large numbers, which shows that it is (a) rather than (b) that pertains. More precisely, he proves that for any $a > 0$

$$\Pr \left(\left| \frac{X}{n} - p \right| < a \right) \rightarrow 1 \quad \text{as } n \rightarrow \infty \quad (1)$$

where X/n is the frequency under consideration.

It is easy to be misled into the belief that this theorem proves something about the behavior of frequencies in the real world. It does not. The result is only concerned with properties of the mathematical model. What it does show is that the behavior of frequencies in the model is mirrored in a way that is much neater and more precise, the very imprecise stability phenomenon stated in the first paragraph of this article.

In fact, a result for the model much more precise than (1) was obtained by De Moivre (1733). It gives the normal approximation

$$\Pr \left(\left| \frac{X}{n} - p \right| < c/\sqrt{n} \right) \rightarrow \int_{-c/\sqrt{pq}}^{c/\sqrt{pq}} \phi(x) dx \quad (2)$$

where ϕ denotes the standard normal density. This is again a theorem in the model. The approximate corresponding real-world phenomenon can be seen, for example, by observing a quincunx, a mechanical device using balls falling through 'random' paths to generate a histogram.

De Moivre's result was given a far reaching generalization by Laplace (1810) in the central limit theorem (CLT) concerning the behavior of the average $\bar{X}$ of n identically, independently distributed random variable $X_1, \dots, X_n$ with mean ξ and finite variance σ^2 . It shows that

$$\Pr \left(|\bar{X} - \xi| < c/\sqrt{n} \right) \rightarrow \int_{-c/\sigma}^{c/\sigma} \phi(x) dx. \quad (3)$$

This reduces to (2) when X takes on the values of 1 and 0 with probabilities p and q , respectively. The CLT formed the basis of most frequentist inference throughout the nineteenth century.

The first systematic discussion of the frequentist approach was given by Venn (1866), and an axiomatization based on frequencies in infinite random sequences (*Kollektives*) was attempted by von Mises (1928). Because of technical difficulties his concept of a random sequence was modified by Solomonoff (1964), Martin-Löf (1966), and Kolmogorov (1968), with the introduction of computational complexity. (An entirely different axiomatization based on events and their probabilities rather than random sequences was put forward by Kolmogorov in 1933, and has successfully served as a basis for both frequentist and subjective interpretations of probability). For more details on these different approaches see Barnett (1982).

The frequentist concept of probability described so far has met considerable criticism. One of the main objections is that it is not applicable to many situations to which one might want to apply probability assessments. To see this, consider the following three possibilities.

(a) An actual sequence of repetitions may be available; for example, a sequence of coin tosses or a sequence of independent measurements of the same quantity.

(b) A sequence of repetitions may be available in principle but not likely to be carried out in practice; for example, the polio experiment of 1954 involving a sample of over a million children.

(c) A unique event which by its very nature can never be replicated, such as the outcome of a particular historical event; for example, whether a particular president will survive an impeachment trial. The conditions of this experiment cannot be duplicated.

The frequentist concept of probability can be applied in cases (a) and (b) but not in the third situation. An alternative approach to probability which is applicable in all cases is the notion of probability as degree of belief; i.e., of a state of mind (for a discussion of this approach, see Robert (1994)). The inference methods based on these two interpretations of the meaning of probability are called frequentist and Bayesian, respectively.

Although frequentist probability is considered objective, it has the following subjective feature. Its impact on a particular person will differ from one person to another. One patient facing a surgical procedure with a 1 percent mortality rate will consider this a dire prospect and emphasize the possibility of a fatal outcome. Another will shrug it off as so rare as not to be worth worrying about.

There exists a class of situations in which both approaches will lead to the same probability assessment. Suppose there is complete symmetry between the various outcomes; for example, in random sampling which is performed so that the drawing favors no sample over another. Then we expect the frequencies of the various outcomes to be roughly the same and will also, in our beliefs, assign the same probability to each of them.

Let us now turn to a second criticism of frequentist probability. This concerns the difficulty of specifying what is meant by a repetition in the first sentence of this section. Consider once more the surgical procedure with 1 percent fatalities. This figure may represent the experience of thousands of cases, with the operation performed by different surgeons in different hospitals and—of course—on different patients. The rate of fatalities may vary from one hospital or surgeon to another and may, in particular, vary drastically with the condition, for example, the age and general health, of the patient.

Suppose a young woman requires this operation although her general health is very good. The frequency of a fatal outcome with patients sharing these characteristics may be much lower, and the 1 percent figure in that sense would be quite misleading for her. And yet she might be considered to have been obtained under 'roughly the same conditions,' namely to be drawn at random from the total population of persons

requiring this surgery. To obtain the most useful figures one should identify the most important variables, classify the cases accordingly (for example, young, middle-aged, old; male, female; etc.) and then provide the frequency for each class. They will, of course, be meaningful only for the classes which contain a reasonable number of cases.

1. A Terminology Note

A source of much confusion in the discussion of probability is the fact that 'probability' is used both as a mathematical term, i.e., as a concept in the mathematical model and also in everyday language when talking about real events. When reading about probability, it is important to be aware of these two meanings and to keep them distinct.

P. J. Bickel and E. L. Lehmann

Freud, Sigmund (1856–1939)

1. Family Background and Early Life

Sigmund Freud, neuroscientist turned founder of psychoanalysis, was born on May 6, 1856, in Freiberg, Moravia, now part of the Czech Republic. His father,

Jakob (1815–96), a wool merchant, came from Galicia, and married Amalie (1835–1930, nee Nathansohn), 20 years younger, when he was 40. Jakob had two sons by a previous marriage, Emanuel and Philipp. Jakob was warm and affectionate, with a strong sense of humor, and Freud evidently admired and respected him. Amalie was a lively and attractive woman who was proud of Sigmund, her first-born.

The family multiplied quickly: five daughters and two more sons were born within 10 years. The first of these, Julius, died when 8 months old and Sigmund was aged 19 months. Both parents were Jews, with no religious affiliations, though a devout Catholic Nanny took Sigmund to Church. She left when he was two and a half. A nephew, John, a year older than Freud was very close to him: the two fought and played together. That childhood ambivalence, Freud reflected years later, must have had a profound effect on his character and on his ability to defend himself (Freud 1900).

Financially, times were hard. In 1859 the family moved to Leipzig, and in the following year to Vienna. Freud missed the beauty of the countryside round Freiberg. Although the children were well looked after, poverty was not assuaged by rapid family growth. By 1875 family fortunes improved: Amalie's family were helping, making possible a move to a larger house. Freud had a room of his own that served as a study.

Freud's memories of his childhood as revealed in his writings are without early detail, but one unforgettable recollection was of urinating in his parents' bedroom while they were present. Reprimanding him, his father said bluntly: 'The boy will come to nothing!' Freud's wounded ambitions were reflected recurrently in dreams in which he listed his achievements as if to say: 'You see! I have come to something!' (Freud 1900; see also Shengold 1993).

2. Education and Early Interests

Freud's schooling began with his mother, until his father took over before sending him to a private school. Freud learned rapidly, and was reading Shakespeare (whom he loved all his life) from the age of eight years. When nine years of age, he won a place at the Sperl Gymnasium, where he was a distinguished pupil, passing out, at 17, with the distinction '*summa cum laude*.' He became an accomplished linguist, with a firm foundation in Latin and Greek, a sound knowledge of Hebrew, fluency in English and French, and good Italian. He corresponded with an adolescent friend in Spanish. He became one of the greatest stylists in the German language (Kaufmann 1980). He studied at every opportunity. He loved the Arts, but took an early dislike to music, which he never felt able to appreciate. He was fond of walking, swimming, and skating. He liked travel, and made his first visit to England at the age of 19.

3. Early Career and Scientific Outlook

Freud (1925) said that curiosity and human concerns motivated his interest in medicine, but it was 'hearing Goethe's beautiful essay on Nature read aloud...that decided me to become a medical student.' He was attracted strongly by Darwin—a necessary step towards his own evolutionary approach to the history of the individual's mental development. His neurological work was affected profoundly by the evolutionary approach of John Hughlings Jackson, the founder of modern neurology. Furthermore, Freud's admiration of Goethe as scientist as well as writer was life long. Goethe's belief in the importance of observation and reflection was profound, and his meticulous examination of a single sheep's skull in 1790 led to his deduction that the vertebrate's skull developed from vertebrae. This type of detailed study—applied by Freud to the individual case—is the essence of poetic (or romantic) science that stands in contrast with (though not in opposition to) Newtonian (or classical) science. (Goethe's unfortunate opposition to Newton's theory of color does not vitiate this point.) In psychology, the corresponding distinction is between the ideographic (romantic) approach and the nomothetic (classical). Both methods have drawbacks and advantages; for Freud's psychology, in particular, the nomothetic approach has serious limitations. The distinctions have been discussed extensively by Kaufmann (1980) and by the founder of modern neuropsychology, Luria (1979). It is impossible fully to appreciate Freud's work outside this context.

Freud began his medical training in October 1873 and qualified MD in March 1881. The years were crowded: Freud dealt with the tedium of a year's compulsory military service by translating a book by John Stewart Mill (Jones 1953). He was influenced by many illustrious figures, none more important than Ernst Brücke (1819–92) head of the Institute of Physiology. Freud, as a research scholar, studied the histology of nerve cells, and his work led to a number of significant conclusions. After qualification, Freud continued working at the Institute, where his love for research had full scope. He had already found 'rest and full satisfaction' there (Freud 1925).

4. Neuroscience

But in 1882 Freud was still poor and, reluctantly, accepted Brücke's advice to practice medicine. He left the laboratory to start work in the General Hospital. He spent 6 months under Theodor Meynert (1833–1892), the Professor of Psychiatry, whose work and personality Freud greatly admired. His research at the Institute of Cerebral Anatomy led to important publications. He began to study nervous diseases, and quickly established a reputation as an outstanding diagnostician. He was still urgently short of money: he

was by now engaged to Martha Bernays (1861–1951), and the need to earn enough to keep a wife and family was compelling.

In the spring of 1885 Freud was appointed Lecturer (*Dozent*) in Neuropathology. Brücke's influence resulted in the award of a valuable Traveling Bursary, and Freud fulfilled an old ambition to visit Paris and learn from Charcot at the Salpêtrière. His offer to translate a new volume of Charcot's lectures into German was accepted by the great man, and Freud was soon admitted to Charcot's inner circle. Charcot's lectures and demonstrations were outstanding, but Freud was astonished by his investigations into hysteria. Charcot demonstrated that hysterical symptoms were genuine; that hysteria was common in men as well as women; and that hysterical paralyses produced by hypnosis were identical with spontaneous attacks. Charcot met skepticism with patience and firmness: once, faced with an objection made on theoretical grounds, he replied: 'Theory is all very well, but it doesn't stop facts from existing.' Freud never forgot that remark.

The Paris visit changed the direction of Freud's career. Charcot had broadened his grasp of neurology, but the neuroses had captured his imagination. He left Paris at the end of February 1886, intent on further investigations of hysteria. But before he returned to Vienna he stayed for some weeks in Berlin to study nervous disorders in children, and this important detour led in time to the publication of a number of monographs. Freud's report on his visits, to his sponsors in Vienna, is a model of clarity and concise exposition (Freud 1956).

Indeed, Freud's interest in neuropathology by no means stopped abruptly. Important papers lay ahead: observations on hemianopsia in two very young children (Freud 1888) and his monograph on *Aphasia* (Freud 1891b) occupy a permanent place in the history of aphasiology. Freud had already abandoned the strict localisation theory of brain functioning—to which Meynert strongly adhered—in favor of the hierarchical model, with its concomitant theory of evolution and dissolution of the nervous system, advanced by Hughlings Jackson (e.g., 1884). Freud recognized the importance of these major advances, which were otherwise scarcely appreciated for another quarter of a century. With his young friend Oscar Rie he wrote a work on the unilateral cerebral palsies of children—a book still of repute in neuroscience (Freud 1891a). Freud's overall contributions to the field were massive, and he published around 200 papers.

On his return to Vienna, however, Freud was trying to build up a practice to support a family: he married Martha in September 1886, starting a life long partnership of unusual harmony and mutual support. Both were devoted to their six children: in order, Mathilde, Martin, Oliver, Ernst, Sophie, and Anna—the only one to follow Freud into psychoanalysis. The first 5 years of marriage covered the closing phase of

neurological work, and saw the growth of a friendship with the distinguished physician Joseph Breuer (1842–1925), with profound effects on Freud's career.

5. *The Birth of Psychoanalysis*

Between 1880 and 1882 Breuer had treated the now famous Frau Anna O. for severe hysterical symptoms, including multiple limb paralyses, disturbances of sight and speech, contractures, an intense cough, and anorexia. Accounts of the illness, its treatment, outcome, and significance for the foundations of psychoanalysis, and its effect on the Breuer–Freud friendship vary (e.g., Breuer 1882, Breuer and Freud 1895, Freud 1914, 1925, 1932, Jones 1953, Gay 1988, Ellenberger 1972, Hirschmüller 1989), but, at the risk of distortion by brevity, the present summary seems safe. Anna O. suffered from states of autohypnosis alternating with near-normality. When, under self-hypnosis, she recounted the history of one of her symptoms, recalling the details of its first appearance, Breuer was astonished to find that it disappeared. Under induced hypnosis other symptoms were treated in similar fashion, and the method was christened the 'talking cure.' Breuer told Freud about it in 1882, and during the next two years they discussed it repeatedly. But, in Paris, Charcot showed little interest in the story, and Freud allowed the matter to lapse.

Back in Vienna, Freud treated a number of hysterical patients by hypnotic suggestion. But 'recovery' was too often transient, and Freud's interest in Breuer's treatment of Anna O. revived. When her first symptom appeared, the patient was nursing her dying father, and her recall resulted in 'abreaction' (the release of pent-up emotion attached to the event). Adopting this 'cathartic method' over several years, Freud repeatedly confirmed Breuer's findings. The links with traumata were hitherto unconscious.

A preliminary communication by Breuer and Freud (1893) preceded the *Studies on Hysteria* (Freud 1895d). Breuer contributed a theoretical chapter and an account of Anna O; Freud, four case histories. Differences of opinion became a strain in 1894, and the collaboration ceased in 1896. Freud valued Breuer's achievement, but was thinking on different lines. Breuer believed that pathological processes arose during 'hypnotic states' (e.g., Anna O's autohypnosis). For Freud, this begged the question of how 'hypnotic states' arose. He considered that psychoneurosis involved psychic defences against unacceptable internal states of 'emotional excitation,' habitually sexual in kind. The actual neuroses, however, were states of anxiety arising from unrelieved sexual excitation linked with abstinence or *coitus interruptus*. Breuer could not accept these views; he had failed to find any sexual component in Anna O's disturbance. But Breuer had never recognized Anna O's strong attachment to him ('transference') as sexual; alarmed by its intensity, he brought the treatment to an end. Anna

O. responded to this loss with a phantom pregnancy (Freud 1932). Breuer continued to see mentally ill patients, but never again used the cathartic method.

In time, Freud abandoned the use of hypnosis altogether. The power of transference (from the patient's unrecognized re-experience, in the treatment process, of infantile relationships) meant that excellent clinical progress could still be vitiated by disturbances in the doctor/patient relationship. That recognition profoundly affected the future development of psychoanalysis.

For a time, Freud used encouragement, persuasion, and similar measures as aids to treatment, but increasingly found them unnecessary. They were replaced slowly by the developing technique of free association, which took over completely by 1897–8. The patient lay on a couch (as before) with the analyst sitting behind him, but was now expected to try to say everything that entered his mind, irrespective of apparent irrelevance, distastefulness, or indiscretion. The analyst listened impartially, without giving more weight to any one utterance than he did to another. This major shift in clinical method had surprising results. Conflicting mental forces, undetected by hypnosis and related devices, were now revealed. Memories of striking internal and external mental experiences in early life had been denied access to consciousness because they had been 'alarming or painful or shameful by the standards of the subject's personality' (Freud 1925). Memory was actively opposed by the force of repression, experienced by the clinician as resistance to unwelcome material. Forces striving to break through this barrier stemmed from the drives, founded substantially in infantile sexuality.

6. *Psychoanalytic Career*

Until the spring of 1897 (Jones 1953) Freud believed his female adult patients whose associations pointed to seduction in childhood, usually by the father, as the traumatic root of their illness. But what at first presented as memory was found increasingly to be fantasy. Seduction in childhood undoubtedly occurred, but could no longer be invoked as the root of all neurosis. As it stood, Freud's theory was wrong. This devastating conclusion nonetheless pointed to the importance of fantasies in mental life, and to the realization that fantasy that is dynamically unconscious, that is, inaccessible to introspection, had all the force of reality since it could not be tested in the light of objective experience. A second, fateful, event, did more to foster psychoanalytic thinking than anything else: Freud courageously (and painfully) undertook his self-analysis, beginning in 1897 and continuing systematically through and beyond the writing of *The Interpretation of Dreams* (1900). With interruptions, it was life long.

Freud's letters to his friend Wilhelm Fliess (1858–1928), an ear, nose, and throat specialist living in

Berlin, provide a unique source of information about these events. Never intended for publication, they were rescued by Princess Marie Bonaparte of Greece (the letters from Fliess have not survived). Starting in 1887, they set out in astonishing detail Freud's reflections, doubts, and formulations as they arose, and can be followed until after the turn of the nineteenth century. An edited version (Freud 1954) was followed by the complete letters (Masson 1985). The demise of the seduction theory and Freud's comments on his self-analysis are described in both.

The self-analysis was crucial for the development of basic psychoanalytic concepts. The richness and complexity of infantile life, including its sexuality, was not fully appreciated until well after *The Interpretation of Dreams* saw the light of day. The Oedipus complex, for example, is described in that book, but its fuller significance was underlined only in footnotes added much later. But Freud regarded the dream book as his single most important work. With copious illustrations from his self-analysis and clinical experience with patients, the study goes beyond the meaning of dreams and approaches the baffling problem of how the mind works.

The theory is involved, but a few key points may be mentioned. The function of dreaming is the preservation of sleep. Stimuli arising from outside the organism (noises, the pressure of bedclothes) or from within (pain, excitation), could often be contained when switched into nonmotor channels (dreaming). The formation of the dream is more complex. In normal waking life, accessible mental content is either conscious at any given moment, or is preconscious—capable of reaching awareness with varying degrees of difficulty. But some mental content is dynamically unconscious—barred from reaching the preconscious by repression. During sleep, this barrier is relaxed, and a partial regression to earlier forms of thinking allows normally unacceptable childhood wishes to find expression, though only in disguise. Even in sleep a censorship is partially operative, and the result is a distorted representation of infantile wishes that gives the dream its seemingly bizarre character. Any semblance of coherence is imposed during waking and recollection: the repression barrier is restored and the dream is (unwittingly) clothed in a measure of rationality.

The recollected (manifest) dream content arises from several sources. Stimuli that threaten sleep are the most obvious, but events and experiences of the day before (day residues) are also used as building blocks. These have no intrinsic importance: they simply provide convenient representations for forbidden wishes. But emerging wishes are themselves distorted by primitive thinking before they are disguised further by the censorship. For Freud, the dream was a hallucinatory wish fulfillment, though generally far removed from the wishes of everyday appearance.

Do dreams provoking anxiety or portraying pun-

ishment also conceal wishes? Freud argued that, even in sleep, a wish can be so strong that its forbidden character can still be recognized and occasion distressing anxiety. In punishment dreams, the transgression portrayed brings with it a wish for punishment. This became clearer still when Freud, later, had conceptualized an unconscious sense of guilt.

The model of the mind outlined in the dream book was the foundation for all Freud's later theoretical formulations. Since it was written during his self-analysis, his pride in it also reflected a new self-confidence. Jones (1955) claims that, at the age of 45, Freud had reached full maturity: intellectual development, always precocious, had not hitherto been matched emotionally. For many years there had been 'continual periods of restlessness, uncertainty, instability and even more definitely neurotic disturbance.' A deep self-assurance had been hidden behind 'strange feelings of inferiority, even in the intellectual sphere.' He had over-idealized men who were, certainly, important to him; of these, Breuer had already withdrawn his support, and the relationship with Fliess was loosening. Self-analysis had revealed the neurotic nature of the tie.

Intellectual loneliness did not diminish productivity. *The Psychopathology of Everyday Life* (Freud 1901) dealt with unconscious motivations in forgetting, slips of the tongue and pen, as well as some 'accidents.' The *Fragment* of Freud's analysis of 'Dora' (1905) described her treatment in 1900. *Three Essays on the Theory of Sexuality* (Freud 1905) met with ferocity hard to imagine today. Freud had widened the concept of sexuality: all existing definitions failed to fit the facts and could not, for example, account for the sexual perversions. Sexuality was now understood within a much wider, developmental perspective. It was considered diphasic: development from infancy to roughly the age of five, centered around bodily erotogenic zones, was followed by a period of comparative quiescence (latency) before a second stage of sexual efflorescence started around puberty. *Jokes and their Relation to the Unconscious* (Freud 1905) arose out of the work on the dream book.

7. *The Growth of the Discipline*

By the time these works appeared Freud was no longer intellectually isolated. Already, in 1902, two young Viennese doctors, Kahane and Reitler, and, more famously, Stekel and Adler were intrigued by psychoanalysis. Freud invited them to meet him for discussions; they gathered together on Wednesdays as 'The Psychological Wednesday Society.' This was the nucleus of an expanding group renamed, in 1908, the Vienna Psychoanalytical Society. By then much had happened. In 1904 Eugene Bleuler, Professor of Psychiatry in Zurich, wrote to inform Freud that he and his staff, most notably his Chief Assistant, C. G.

Jung, had been making use of psychoanalytic ideas for the past two years. (In particular, Jung had applied them in his word-association tests.) By 1906 Freud and Jung were corresponding, and in 1907 Jung visited Freud in Vienna. The friendship grew rapidly and when, in 1910, the International Psychoanalytic Association was formed, Freud asked Jung to be President. Jung's bearing, intellect, qualities of leadership, psychiatric background, and dedication seemed suitable qualifications. Freud was attracted by his personality and regarded him as his 'son and heir.' Jung was greatly impressed by Freud's penetrating intellect. The rise and fall of their relationship is chronicled in their correspondence (McGuire 1974).

Otto Rank had joined the group in 1906; and Karl Abraham, a major figure in the psychoanalytic movement, had long been fascinated by Freud's work when he visited him in 1907. Again, the correspondence between the two gives a vivid picture of their relationship; it continues until Abraham's premature death in 1925 (Abraham and Freud E 1965). In 1907, too, Sandor Ferenczi visited from Budapest, establishing himself the following year as a major figure in the discipline. With the visit of Ernest Jones in 1908, and Hans Sachs in 1910, Freud had a close circle of friends and collaborators.

In 1908, Jung organized an international conference in Salzburg. Freud's work was now discussed widely, in Europe, the USA, and Australia. In 1909 Freud lectured at Clark University, Massachusetts, accompanied by Ferenczi, Jones, and Jung. In 1910 a second international congress was held at Nuremberg, organized by Jung. But internal dissent soon surfaced. In 1911 Adler defected: to Freud's dismay, he refused to try to resolve their conceptual differences. Stekel, gifted, charming, but scientifically unreliable (Jones 1955) left about the same time. Although Freud disliked leadership, he was a fatherly figure for his young colleagues, and bickering and rivalry, especially among the Viennese (cf. Jones 1955) threatened stability. Freud's obvious preference for Jung was resented. But by 1912 Jung was showing signs of disaffection. Many Swiss psychiatrists denounced Freud's theory of sexuality, and, during a course of lectures in the United States Jung omitted any reference to it. Personal relations between the two men cooled, but it was not until 1914 that Jung left the movement on the grounds of incompatible views. The story of the rupture is complex: the Freud/Jung letters and the account by Jones (1955) repay study.

Freud's continuing productivity defied these dissensions. He addressed the problem of the sexual enlightenment of children (Freud 1907), discussed children's sexual theories (Freud 1908), and considered the relationship of the character traits of orderliness, parsimony, and obstinacy to anal eroticism—a paper greeted with indignation when it appeared (Freud 1908). He tried to show that psychoanalysis could contribute to the understanding of art in discussions of

Jensen's *Gradiva* (Freud 1907) and of the relationship between creative writing and day dreaming (Freud 1908). He wrote many other papers in these industrious days.

Two extensive clinical studies appeared in 1909. The first (Freud 1909) describes the very first analysis of a child, though one undertaken by proxy. The successful treatment of 'Little Hans,' who had developed a phobia of horses, was carried out by his father, under Freud's supervision. Hitherto, the childhood roots of neurosis in adults had been understood through a process of reconstruction; with Little Hans those sources could be identified at the time they were operative. Freud believed that the analysis could not be conducted by a stranger, and that the affection and authority of the father (in this case, a physician, too) made treatment possible. Child analysis as a speciality was yet unborn. It was many years before the possibility of directly analysing young children, under favorable conditions, was recognized.

The second patient suffered from an obsessional neurosis (Freud 1909). The symptoms included fears that harm would befall his father and a woman he admired; compelling impulses, one of which was to cut his throat with a razor; and self-imposed irrational prohibitions. He was horrified but attracted by an account of a punishment in which rats ate their way up the victim's rectum. The unconscious sadism underlying his 'fascination' with the torture was among the features on which the analysis cast light. A deeper psychoanalytic formulation of obsessional neurosis emerged from the treatment. Later critics of this case report, and that of Dora, have suggested that Freud neglected the role of the mother in the genesis of the disorders. But Dora's treatment was brief, unfinished, and took place when clinical analysis was still in its infancy. In the case of the Rat Man, the criticism, when sound, is largely based on hindsight.

Another case study (Freud 1911) concerned a subject whom Freud had never seen. Dr. Schreber suffered from a paranoid state, and was under care for 6 years. He later wrote his *Memoirs of My Nervous Illness*, though Freud read them only in 1910. The illness fell into two phases: distressing delusions of persecution preceded delusions of grandiosity. Freud made an ingenious and fascinating reconstruction of the course of the illness. His work stimulated much clinical research. Psychoanalytic theories of psychotic illness fall into two broad groups: either it is part of a neurosis–psychosis continuum, or, unlike neurosis, it involves the loss of higher psychic functions and the re-emergence of more primitive ones, hitherto kept in check by the lost capacities. Many claim that Freud supported the first (unitary) theory; others the second (discontinuity theory). The controversy deserves close attention and is summarized elsewhere (Yorke et al. 1989).

In 1910 Freud (1910) published a study of a childhood memory of Leonardo da Vinci, and the first

of three essays on the psychology of love. In 1911, the first of a series on psychoanalytic technique, and from 1910 to 1912 some short papers on theory that paved the way for later and larger works. An excursion into social anthropology, *Totem and Taboo*, was written between 1912 and 1913. Before war broke out in the summer of 1914, Freud's works included a history of the psychoanalytic movement (Freud 1914), giving his version of the disagreements with Adler and Jung; a fascinating paper on the *Moses* of Michelangelo (Freud 1914); a discussion of the scientific status of psychoanalysis (Freud 1913); and a wide ranging paper on narcissism from which so many ideas were later developed (Freud 1914). These were productive years indeed.

During the war Freud was anxious about two of his sons involved in it. Martin fought in Galicia and Russia; Ernst against Italy after that country entered the conflict. Martin was decorated for gallantry. Medical reasons prevented Oliver's acceptance by the army. Optimism about the outcome diminished after 1915. In 1916 the food shortage began to bite and got worse as the war continued. Freud had few analytic patients. Contact between analysts faced obstacles, some severe, even in the central powers.

For all the difficulties, Freud continued to write. He wrote 12 papers on the theoretical basis of psychoanalysis between 1914 and 1917: only five were published, and a sixth manuscript was found in 1983. There is no trace of the others. *Thoughts for the Times on War and Death* (Freud 1915) anticipated the correspondence with Einstein (Freud 1933) *Why War?* At the University, in the winter terms of 1915–6, and 1916–7, Freud gave a total of 28 lectures on psychoanalysis, and wrote them down, from memory, later (Freud 1916–7). Important changes were made in the *New Introductory Lectures* (Freud 1933), but, taken together, the two series offer an excellent entry into Freud's psychological thinking. The most extensive of Freud's case histories (the *Wolf Man*), written in 1914, was published much later (Freud 1918). In 1919 the baffling problem of masochism (sexual pleasure in pain), and a psychoanalytic look at 'the uncanny' (Freud 1919) were among the many subjects Freud addressed.

The return of many old colleagues to Vienna in 1919 ended wartime isolation. For some time life was hard, but psychoanalysis continued to grow worldwide. In 1919 Martha Freud contracted influenza leading to pneumonia and was ill for many months; the following year Sophie Freud died from a similar cause. Freud grieved deeply.

In 1923 Freud's heavy cigar smoking seemed responsible for a growth affecting the jaw and palate, removed surgically. This was the first of many operations for cancer that Freud survived over the next 16 years, bearing discomfort and pain, often severe, with fortitude. But he continued to work. In that same year, he set out major changes in psychoanalytic theory

(Freud 1923). He had already felt obliged to give aggression (more accurately, destructiveness) the same status as libido. For clinical and theoretical reasons the structure of the mental apparatus was redefined. The ego was now the executive mental agency, holding a balance between the conflicting demands of reality, the id, and the superego. The id strove for immediate drive gratification; its mentation followed the primitive primary process; and its content was dynamically unconscious. But it intruded into an unconscious part of the ego where it encountered checks and controls against inappropriate discharge. The superego was thought of as a greatly extended conscience, based on internalized but modified parental aims and proscriptions, but a substantial part of its operations were unconscious. Its functions included that of the earlier censor. With the aggressive drives of the id partly at its disposal, it put pressure on the ego to withstand those inner urges that ran counter to its prohibitions, aims, and ideals. It was responsible for the sense of guilt, conscious, and unconscious. It must be added that higher mental functions such as conscious thinking and reflection (secondary process), reality testing, and judgment were functions of the ego.

Freud continued to elaborate and modify this model (it should not be reified). He made radical changes in his theory of anxiety (Freud 1926); extended his work on masochism (Freud 1924); and in the field of social psychology added to his earlier study of the psychology of groups (Freud 1921) the far reaching *Civilization and its Discontents* (Freud 1930). The work of his female colleagues and his own clinical experience led him to re-examine the many problems of female sexuality (Freud 1931, 1933). This work aroused opposition, particularly among feminists: Eissler (1977) countered some of these criticisms, but there have been many subsequent developments. It is worth remembering that Freud's close friendships included many women (see, e.g., Freud and Andreas-Salome 1972); and many found his work did much to reduce guilt about sexuality. In *Analysis Terminable and Interminable* Freud (1937) emphasized the therapeutic limitations of psychoanalysis, but he was apprehensive about the possible reception of *Moses and Monotheism* (Freud 1939), which extended his inquiries into early social organization (*Totem and Taboo* 1912–3, *Group Psychology* 1921).

8. Exile: England

In 1938 the Nazis entered Vienna. Freud's books had already been burned in Germany (Freud thought this more advanced than burning him). Through the good offices of Princess Marie and Ernest Jones Freud, together with Martha, their daughter Anna, and others, were allowed to leave for London. Freud was quite ill and tired by the journey, but was pleased by the warm reception that awaited him. The British

Psychoanalytical Society gave him a house at 21 Maresfield Gardens in Hampstead. Anna Freud was his devoted nurse. His remarkable *Outline of Psycho-Analysis* (Freud 1940) was written there. It was there, too, that that death ended his considerable pain and suffering on September 23, 1939. His ashes remain at Golder's Green Crematorium.

Of his many honors, he particularly valued the award of the Goethe Prize for Literature (1930) and his Corresponding Membership of the Royal Society (1936).

9. *Freud's Impact on Twentieth-century Thought and Culture*

There is still a widespread view that Freud's impact on twentieth-century thought, on the arts, sciences, social attitudes, and beliefs, has been far-reaching, even immense. Almost every intellectual discipline, it is said, has been influenced by his ideas. The importance of unconscious motivation is acknowledged widely. Furthermore, many of his concepts—such as the 'Freudian slip' of pen or tongue—have passed into the common language of everyday social intercourse; and his views on sexuality have had a liberating impact on social attitudes and broadened sexual mores.

This view is by no means universal. Freud is undeniably a household name, but more than any other major figure, is the subject of widely varying and conflicting claims. These differences may arise in part from the nature of his subject, for it may be said, with a certain truth, that every man is his own psychologist. They may also arise from an investigative method difficult to understand without personal acquaintance. Freud's neuroscience aside, his principle field of inquiry was subjective and internal, and not readily open to methods appropriate to objective and external research. Many academic psychiatrists and psychologists consider that both Freud's clinical method and his theoretical constructs lack empirical support: in this, they generally equate empiricism with mensuration.

This fact stands in the way of dispassionate assessment even for those actively and intelligently involved in debate. The casual bystander, faced with controversy on a substantial scale, may be simply bemused or follow an opinion in line with personal appeal. And if the intelligent and industrious layman turns to Freud's own writings, he will still encounter significant obstacles. Freud's ideas cannot be picked up piecemeal, but comprehensive reading is difficult without informed guidance. Moreover, reliable introductory works are hard to come by. So it seems unlikely that the forces behind the 'Freudian slip,' and the distinctions between the preconscious and the unconscious, are understood widely. (The term 'subconscious' is more likely to be heard—a word Freud never used except by way of criticism.) Finally, while

the liberalization of sexual attitudes may owe something to Freud, social, economic, and political forces are surely of greater importance. These include the availability of reliable contraception.

Indeed, Freud's views on sexuality, when they are not bowdlerized, are misunderstood widely. But the wider point to be made is this. Most people, in all sections of society, who have any interest in Freud, do not know what he really said. They only know what they think he said. And that is just as true for most critics and commentators who seemingly write with authority, including psychologists, 'hard' scientists, sociologists and art critics, whether the views they express are positive or negative. The viewpoint expressed here may at first seem novel. It was presented in extended form at a meeting of the *Psychoanalytic Heritage Foundation* on October 6, 1992, when it became evident that many Freud scholars were thinking on similar lines. At the recent Conference in London (see below), Douglas Watts stated from the platform that psychoanalysts needed to do more to make the general public more familiar with Freud. 'At present all they have is a caricature.'

For reasons that are not dissimilar, though highly complex, even psychoanalysts have widely diverse approaches to both theory and clinical practice and to the weight they attach to basic Freudian principles (Yorke 1995). Psychoanalysis is avowedly pluralistic (Wallerstein 1988, 1990). And although psychotherapy is often said to derive from the 'talking cure,' similar considerations apply.

In a few instances, Freud's influence, directly or indirectly, on other disciplines is evident, though localized. Disciplines not already mentioned include: education (e.g., many members of the Montessori movement); criminology (The Institute for the Study and Treatment of Delinquency in London); family law in relation to children (e.g., liaison between the Child Study Center and the Law School at Yale University). Properly understood, Freud's work and its true derivatives is capable of fostering advances in many intellectual and sociological fields.

It is pleasing to end on a positive note—in relation to Freud's first love, neuroscience. Freud always hoped that the underlying basis for mental activity in terms of the functioning brain would, one day, yield to investigation. For the greater part of a century that hope seemed slim indeed. But the last few years have brought startling developments. Solms (1997), for example, in a fascinating series of experiments, showed convincingly that the neuropsychology of dreaming was very much in line with the argument set out in *The Interpretation of Dreams*. Work on the neuropsychology of affects, for example, attracted interest from an increasing number of psychoanalysts, and in 1999 a new scholarly journal, *Neuro-psychoanalysis*, was founded. In the first issue, Solms and Nersessian (1999) demonstrated, in a wide-ranging survey, the extensive nature of Freud's contributions to affect

theory. On July 21–3, 2000, the first annual Neuropsychology Conference was held in London entitled *Neuropsychology and Psychoanalytic Perspectives on Emotions*, addressed by the world authorities Jaak Panksepp, Antonio Damasio, and Mark Solms, and introduced by Oliver Sacks. The meeting was a heartening success, and the compatibility between the findings of the two disciplines was seen to be remarkable.

All references to Freud, other than those in the bibliography, are to the *Standard Edition of the Complete Psychological Works of Sigmund Freud* (1953–74) Strachey J (ed.) 24 Vols. Hogarth, London. For specific volumes and page numbers see Vol. 24.

Friendship, Anthropology of

Friendship is an informal social relationship. Contrary to kinship, it is based on choice and voluntariness: friends are sought and must be won. Friendship is an acquired not an ascribed status. The relationship is often viewed as affective. However, the 'emotional content' of friendship can vary strongly (Paine 1969, p. 507). Mutuality, concerning interest in the relationship, appears to be one important requirement.

In fact, in some societies there exist asymmetrical friendships, sometimes being difficult to distinguish from patronage. Friendship is based on sharing: besides matters of material value friends share their time, their problems, plans, hopes, and thoughts. Therefore, trust and loyalty are basic requirements for friendship (Kennedy 1986, 128 ff.). But this aspect also involves dangers: if friends share secrets, and the friendship is eventually broken off, it can lead to gossip and enmity. Some authors note that generally no fixed role expectations are attached to friendship. But in fact many societies do have well-defined expectations.

From the perspective of comparative social and cultural anthropology it is obvious that besides common core aspects, notions of friendship are highly variable. To this day there is a lack of data concerning the different meanings friends and friendship can have in different societies, and even within one society. Most languages have many terms for friends (in English among others: *pal*, *chum*, *buddy*, *bosom friend*, *old friend/chap*, *acquaintance*, etc.), which differentiate between kinds and meanings of social relationships called 'friendship.' One also finds different concepts of friendship within one society relating to sex, age, social status, as well as the different places or contexts in which friendship takes place, e.g., neighborhood, school, or place of work. The 'growth' of friendship has also been an underestimated aspect in research. A friendship does not only change in the course of time, it also changes due to the period of its existence: after 20 years a friendship, like all other emotional relationships, is no longer the same as it was in the beginning. As Sarah Uhl (1991, p. 90) states, friendship is a type of 'noninstitutionalized institution' distinguished from blood-brotherhood and fictive kinship—overlooking the fact that with a new stage in a life cycle, friendships may be transformed to other more institutionalized relationships like co-parenthood.

1. Anthropological Interest in Friendship

Uhl (1991) states that research on friendship is difficult due to the fact that despite its being a public phenomenon, friendship is viewed as private. But the same can be said of marriage, and marriage has been one of the most important topics in anthropology since its beginnings. More probably anthropologists have focused too strongly on kinship (see *Kinship in Anthropology*), thus becoming unaware of sometimes even overlapping concepts of friendship.

Until now most empirical research has been conducted in industrialized societies, and basically there are only few studies by cultural anthropologists. If anthropologists have studied friendship at all, they have concentrated on formal relationships with well-defined mutual obligations such as ritual kinship, exchange, trade, or working relationships. These

anthropological studies—most of them conducted in Southern Europe—overemphasized male friendships and neglected friendships between females (Boissevain 1974, Gilmore 1975). For a long time it was supposed that adult women in particular form their most important social relationships inside the family and with relatives. Different forms of friendship between men are on the other hand an important part of public life. These factors have contributed to the lack of research concerning friendship between women, with the exception of some more recent studies (e.g., Kennedy 1986).

One finds very little information on meanings of friendship in nonindustrial societies. One exception is Thomas Kiefer's work, who in 1968 published a major article on institutionalized friendship and warfare among the Tausug of Jolo, in the Philippines. The Tausug perceive strangers and all people not related by kinship as potential enemies. In this context friendship—formally sworn to by oath on the Koran—is very important for forming alliances between kin groups, as well as, on a higher regional level, between local leaders. These can be former or—should the oath be broken—future enemies. This formal friendship in Tausug society derives its meaning from enmity—friends are allies against common enemies (Kiefer 1968). However, Kiefer's study once again focuses on highly formalized male friendship patterns. Institutionalized and formalized friendship patterns, trade and exchange partnerships, like the bond friendship' (*tau soa*) in Tikopia described by Firth (1967), are still today given priority in studies by cultural anthropologists. On the level of intercultural comparison (including more traditional societies), it would be of importance to investigate the assumed declining significance of kinship and the possibly growing importance of friendship.

2. Themes and Methods

Within the realm of anthropological research different dimensions of friendship have been stressed. Eric R. Wolf differentiates between 'emotional' and 'instrumental relations,' which both satisfy a deficit of some kind in each participant of the dyad (1966, 10 ff). The labels emotional/instrumental are somewhat misleading, because both types have a quite instrumental quality. Wolf's approach links friendship with wider societal forms: societies produce different deficits, which different types of friendship respond to. His conception is a useful starting point for further research, embedding friendship in a wider theoretical frame. In that way it differs from Robert Paine's (1969) above-mentioned conception of an emotional, more inward-turning modern middle-class friendship.

Jacobson's approach to research on friendship emphasizes the situational aspect. He is not only concerned with constant friendship and its character-

istics but 'with the labelling process itself, that is, with the situations in which a person gives and takes away the label of "friend".' (Jacobson 1975, p. 225). Both friendship and affiliation with an ethnic group can change depending on the situation. In combination with an examination of group identities, research on friendship could lead to important results in the investigation of interethnic relationships. Friends can be made across ethnic boundaries; besides binding themselves by marriage, people can form alliances between different ethnic groups. An example of the discussion of interethnic relationships in folklore about friendship is given in a story about a Kipsigis and a Masai, who exchange honey and arrows, cheating each other in the process (Dundes 1971, pp. 176–7). Dundes explains that the topic of making and breaking friendship in African societies is a common motif in narratives. In a story about a crippled and a blind person, for example, who join forces during an attack by enemies, the latter takes the first on his back and runs, while the crippled person directs him. No matter whether the failing of a friendship or its advantages are the central theme, exchange is always the constituent core of the described relationship. The different motifs in African narratives show the conflict between social norms and actual behavior. This discrepancy between a value system and behavior is another aspect of friendship that has not yet been thoroughly studied.

Reina (1959) discusses two concepts of friendship, existing parallel to one another among Indians and Ladinos in Guatemala. The Ladino term *cuello* means taking up many relationships and alliances, which can change under different circumstances. The Indian concept of friendship implies having only very few friends, who are made during adolescence. This example shows that divergent notions of friendship can prevent close relationships between members of different ethnic groups. But without more detailed descriptions of intraethnic concepts of friendship, studies about cultural differences and interethnic friendship are impossible.

In early network analysis the issue of friendship played an important role (Bott 1957). Network analyses seemed to be appropriate for research about weak institutionalized social relationships in complex societies. Friendship is one possible content of such social relations, but until now research has been restricted mostly to Western industrialized societies (e.g., Allan 1989, Fischer 1982). Analysis of networks of friends in more 'traditional' societies must be preceded by studies which describe who is referred to as a friend, and what kind of different categories of friends exist within a given cultural context. As shown above, it cannot be taken for granted that concepts of anthropologists and informants are congruent. With a better knowledge of the meanings and terms attached to the notion of friendship, network analysis and other quantitative methods might also be applied in inter-

ethnic situations. From the interplay between participation in everyday life, an evaluation of one's own experiences, and a systematic investigation, a more differentiated picture of the ambiguous term 'friendship' could emerge.

3. Fieldwork and Friendship

Friendship is not only an important research topic, it is also an important relationship during fieldwork (see *Fieldwork in Social and Cultural Anthropology*). The situation regarding friendship between anthropologists and people with whom they live, often for long periods of time, is hardly documented, even though it is quite probable that these are very relevant personal experiences during fieldwork and in some cases they are even the precondition of fieldwork. Exceptions being the articles by Friedman Hansen (1976), Hendry (1992), and Reina (1959). Friendship formed in the course of fieldwork has neither been treated very honestly, nor has it been dealt with systematically in anthropology to this day. Most anthropologists note having made many friends during their fieldwork. In publications it is obligatory to thank all 'friends,' without whom research would have been impossible. In most cases the nature of this friendship is not described, nor is the significance it had for the fieldwork. Therefore, the question of how anthropologists cope with unfamiliar concepts of friendship is left open. Most studies do not make explicit what is meant by friendship, and few authors relate whether friendship with informants is called so from the perspective of the fieldworker or from the emic view. Other intercultural forms of friendship—those between anthropologists and informants are only one special case—have gone unstudied.

In the literature on fieldwork, friendship is sometimes depicted from a very one-sided angle: 'Informants become friends. This creates another dilemma, for it leads to a very instrumental, and often dishonest, approach to friendship. The interest of science demands that you milk your informants. You do this by making them your friends, by exchanging confidences, giving presents, talking for hours about subjects that bore you. Are these friends or scientific objects? The subjects themselves often realize that they are being used. For some fieldworkers the scientific ends justify the means. They have no moral problem. For many others, however, the dilemma remains.' (Boissevain 1985, p. 273)

Other authors warn against making friends with informants on the grounds of possible role conflicts. Spradley, for example, advises anthropologists, repeating the same questions over and over again on their endless quest for explanations, to refrain from bothering their friends with this boring task. Apart from this, however, he has no objection to making friends during fieldwork (Spradley 1979, p. 28).

An exceptionally good account of friendship in the course of fieldwork has been published by Joy Hendry (1992). In detail she describes the changes within the relationship to her Japanese friend that spanned nearly two decades. She also compares, at least marginally, to what extent concepts of who is related to as a friend, as well as expectations regarding how friends should relate to one another, correspond in Great Britain and Japan. Hendry mentions that in Japan it is not possible to bring inequality in line with friendship. As long as she did research in rural Japan, similarities and equality dominated the relationship to her friend Sachiko, who also did not come from a rural area. Later, influenced by their respective cultures, their lives developed differently from one another. Apart from individual changes due to the respective transformations in their lives, i.e., from being students to married mothers of school children, the actual research project nearly caused a breaking off of their friendship. Conflicts arose when Hendry began to study manners of communicating in Sachiko's *nakama* (reference group). She integrated her into the project, which caused Sachiko to have role conflicts within her own *nakama*. However, the author gathered more insight out of this conflict than out of any other contacts with Japanese women. She evaluated her fieldwork experience as one aspect of participant observation—it having been, on the one hand, scientifically successful but personally nearly having led to a loss. The situation became more relaxed when Hendry left Japan, after enough time had elapsed, and she had analyzed and discussed the experience with Sachiko in a number of letters.

The example concerning Guatemaltecan Indians equally shows that friendship in the context of fieldwork may cause problems due to an initial unawareness of cultural differences between notions of friendship. Guatemaltecan Indians have clearly defined expectations regarding friendship, exclusiveness being one criteria for friendship. Ruben E. Reina states that not only his informants, but also those of his wife, terminated relationships, because both anthropologists had also formed contacts to other informants, thus not meeting the expectations of exclusiveness. Only through detailed explanations of why anthropologists carrying out fieldwork must speak to more than one person was the problem solved (Reina 1959, p. 48).

Role conflicts are one of the major topics discussed in writings by anthropologists on friendships formed in the context of fieldwork. In an article by Judith Friedman Hansen (1976), role conflicts are mentioned as the central problem. This is hardly astonishing, since not only during fieldwork but also in other work-related situations friendship can cause conflicts regarding loyalty, possessiveness, and role expectations. At home anthropologists have to play different roles within their families, partnerships, and within academia as well—thus, cross-cutting and intersecting

friendship patterns are not typical of fieldwork alone. The problem is only more obvious and perceived more consciously during fieldwork. Coping with these conflicts requires time, much talking, patience, and a deeper understanding of the rules of the other culture.

Friendship: Development in Childhood and Adolescence

Most children and adolescents have friends. Friendships are characterized by mutual liking and expectations that friends spend more time with one another than acquaintances, that cost–benefit balances in the social exchanges between friends are favorable, and, among older children and adolescents, that friends are loyal, trusting, and intimate (Bukowski et al. 1996). This article deals with friendships during the first two decades of life and their developmental significance.

1. Incidence

Infants and toddlers sometimes show preferences for one another although it is not always easy to compare these relationships to the friendships of older children. The word ‘friend’ begins to be used by children during the third and fourth years and, by that time, about three-fourths of children are involved in reciprocated friendships. Proportions rise through middle childhood (when about 85 percent of children have a best friend and usually several good friends) and decline slightly during adolescence. Only about 10 percent of older children and adolescents have no friends (Hartup and Stevens 1997).

Friendship networks are small among young children, averaging about 1.7 friends for boys and 0.9 friends for girls during the preschool years. These numbers increase to 3.0 to 5.0 best friends during middle childhood and adolescence, depending on whether one includes unreciprocated choices as well as reciprocated ones. Time spent with friends changes with age too, being greater in middle childhood and adolescence than at any other time (29 percent of time awake among teenagers).

2. Friendship Expectations

Friendships are understood by children and adolescents (especially) to provide the individual with companionship and intimacy more frequently than parent–child relationships, but less frequently with experiences of compliance and control. Most dramatically, friendships are understood to differ from parent–child relationships in power sharing (Furman and Buhrmester 1985). Overt affection is provided less frequently to children by friends than by parents but nurturance in general is understood to be provided by both.

Differences between children and adolescents in the ways that they describe their friends occur mainly in the number, complexity, and organization of information and ideas about these relationships (Rubin et al. 1997). Among young children, for example, friend-

ship expectations are most likely to emphasize common activities and concrete reciprocities as well as the ‘here and now’ (‘We play’). Among older children, friends are described as sharing values and rules about loyalty and trust; friends also expect to spend time together and engage in constructive conflict resolution. Among adolescents, friends are expected to share interests, be understanding, and empathetic; similarity between oneself and one’s friends is especially important among teenagers. These developmental changes have sometimes been interpreted as reflecting changes in the child’s understanding of reciprocity or mutuality (Youniss 1980). Indeed, the emphasis on mutuality in these expectations at all ages suggests that the meaning structure underlying these relationships is ‘symmetrical reciprocity.’

3. Behavior with Friends

Children spend more time with their friends than with nonfriends. Some researchers, in fact, have used time-sharing as a means of identifying friendships (Hinde et al. 1985), although most investigators prefer validation by the children themselves or an outside observer (a parent or a teacher).

The social exchanges of friends and nonfriends are different in four major respects (Newcomb and Bagwell 1995): *positive engagement* (friends talk, smile, and laugh together more frequently than nonfriends); *task activity* (friends are more task-oriented and spend more time on-task than nonfriends); *relationship mutuality* (friends are more affirmative with one another, more mutually oriented in their interaction, and more likely to emphasize equality in their exchanges than nonfriends); and *conflict management* (friends use disengagement and negotiation as opposed to power assertion proportionally more often than nonfriends). Mutuality and symmetry thus mark the social exchanges of children and their friends as well as adolescents; these results are another reason for suggesting that reciprocity and symmetry are the behavioral hallmarks of friendship during the first two decades of life.

4. Similarity between Friends

Children and adolescents are more similar to their friends than to nonfriends. Greatest similarity is evident between friends in gender, race, and age—extending from early childhood through adolescence. School-aged children are more similar to friends than to nonfriends in prosocial behavior, antisocial behavior, shyness dependency, depression, and social acceptance/rejection. Friends also share biases in social perception, although it should be recognized that these similarities do not mean that friends are carbon copies of one another (Hartup 1996). By

adolescence, friendship similarities vary according to attribute, with greatest similarities occurring in school-related attitudes, aspirations, and achievement along with life-style behaviors that include smoking, drinking, drug use, and sexual activity. Generally, friends are not very similar to one another in personality traits measured with paper and pencil tests—either in childhood or adolescence. Similarities between friends are multidetermined. Owing to the manner in which schools and neighborhoods are organized in most industrialized countries, children are more likely to come together with children who are like themselves than who are unlike them. Once in the same school or neighborhood, they are more likely to be exposed to the same socialization agents (e.g., teachers). Beyond these sociodemographic conditions, children are also more attracted to children who are like themselves rather than different; children and adolescents also become more like one another as an outcome of mutual socialization. The relative extent to which mutual selection and socialization contribute to the similarity between friends depends on many conditions, including characteristics of the children themselves, the nature of their interaction, and the behavioral attributes being measured (Urberg 1999).

5. Gender Differences

One of the most notable characteristics of friendships in childhood and adolescence is their gender concordance. Opposite-sex friendships are relatively rare, even among preschoolers. Boys and girls do not differ in the proportion who have friends, although friendship networks are likely to be somewhat smaller among girls than among boys (Rubin et al. 1997).

Everyone knows that the activities of boys and their friends differ from the activities of girls and their friends. Certain interpersonal provisions also differ. Girls, for example, expect to be provided with greater affection, intimacy, and instrumental help by their friends than do boys. Intimacy concerns are more common in girls' talk about their friendships than in boys' talk; self-ratings of girls' friendships are more intimate; and self-disclosure between girls and their friends is more common than between boys and their friends. These gender differences are recognized and accepted by both boys and girls. Not well studied, however, are gender differences in intimacy when the construct is defined in terms of camaraderie and shared mastery rather than in terms of empathy and self-disclosure.

6. Children Who Have Friends vs. Those Who Do Not

Children who have friends are more likely to evince better adjustment over time than those who do not. Research supports this conclusion in that: (a) children

and adolescents who have friends are better adjusted than those who do not; (b) children referred for clinical treatment are more likely *not* to have friends than children who have never been referred for treatment; and (c) youngsters who have friends feel better about themselves and are less lonely than youngsters who do not (Hartup 1996). These results have been widely reported, but they are difficult to interpret. First, 'having friends' usually means having 'good friends' in the sense that the relationships in question are harmonious and mutually supportive. This confounding is important since research with adults shows that *not* having problematic friendships is more closely related to good adjustment than actually having supportive and intimate ones (Hartup and Stevens 1997). Second, correlational results cannot be used to support causal interpretations: having friends may contribute to individual well-being but the reverse may also be true. Third, existing data may not be adequately refined: having friends may be associated with certain behavioral adaptations (e.g., self-esteem) but not others (conduct disorder).

Longitudinal studies assist in sorting out these issues when adequate assessment of early status is included in the research design and multiple measures are used to assess outcome. Accordingly, certain studies show that having a friend increases self-esteem and decreases psychosocial difficulties among preadolescents during changes from lower to middle to high school. Also, having friends in middle childhood predicts young adult feelings of self-worth, family attitudes, and the absence of depression, but not sociability, school performance, educational aspirations, and job performance (Bagwell et al. 1998). These results indicate that merely having a friend contributes selectively rather than generally to developmental outcome.

One other consequence of having friends during childhood should be mentioned—success in early romantic relationships. Having same-gender friends during middle childhood forecasts having romantic relationships during adolescence. Having friends in middle childhood also enhances success in early romantic relationships, even when the quality of early parent-child relationships is factored out (Sroufe et al. 1999). These results conform to theoretical predictions that childhood opportunities for intimacy in an asexual context are necessary precursors to heterosexual adaptation.

7. Characteristics of One's Friends

Considerable weight in determining developmental outcome is carried by characteristics of the child's best friends. In many instances, more can be learned by knowing who children's friends are than by knowing merely that they have a best friend. For example, following divorce or remarriage (both stressful events), having socially skilled friends who have few behavior problems promotes resilience whereas having imma-

ture friends who have many behavior problems does not (Hetherington 1999). Conversely, considerable evidence shows that friendships between antisocial children increase the risk of antisocial behavior among both children (Coie and Dodge 1997).

What socialization experiences between friends contribute to these outcomes? Although observational learning (modeling) may make a contribution, it is also the case that the interaction between friends varies according to the characteristics of the children involved. Overtly aggressive boys, for example, are more contentious and conflict-instigating with their friends than nonaggressive boys are, and engage in more deviant talk (Dishion et al. 1995). 'Relationally aggressive' children, who hurt others by exclusion or doing things that damage the victim's relationships with other children, have friendships that are intimate and exclusive but, at the same time, marked by frequent displays of relational aggression (Grotper and Crick 1996). One can easily guess how this admixture of intimacy and relationship-oriented aggression incites conflict and uncertainty, as well as provides instruction in how to draw others into dysfunctional relationships.

8. Friendship Stability

Children who have friends at one time are likely to have friends at other ages. Changes in partners are common, although friendships are more stable than is sometimes appreciated (Hartup and Stevens 1997). Preschool-aged children often maintain these relationships for many months. Friendship stability, however, increases with age until about 70 percent of adolescents report that their friendships last for a year or more; the majority of 13- and 14-year olds who have friends report that these relationships have lasted between one and five years.

Stability varies according to child characteristics: friendships between aggressive, antisocial children are less stable than friendships among nonaggressive children (Dishion et al. 1995). Disabilities and psychosocial difficulties are also associated with reduced friendship stability. In these instances, stability is reduced as a consequence of limitations on the child's ability to regulate emotion and other deficits in social skills.

Friendship stability has considerable developmental significance. Kindergarten children, for example, who maintain friendships across the school year show improvement in attitudes toward school and other school-related behaviors, whereas children who do not maintain their friendships show poorer adaptations. In other instances, friendship stability is correlated with outcome according to characteristics of the child's friends: stable friendships with children who have conduct problems, for example, increase children's own behavior problems, whereas stable rela-

tionships with children who are socially withdrawn do not increase the children's social withdrawal. Friendship stability thus affects children differently according to the behavior in question and other aspects of their relationships (Berndt et al. 1999).

9. Friendship Quality

Friendships among children and adolescents vary in their social and emotional qualities. Some relationships are supportive and intimate, some conflict-ridden. One can differentiate among these relationships in terms of reciprocity, self-disclosure, overt hostility, and covert hostility. Friendship structures have been most commonly described, however, simply as 'positive' or 'negative' (Bukowski et al 1996).

Supportiveness between children and their friends is positively correlated with school involvement and achievement while being negatively correlated with school-based problems. Supportiveness between school-aged friends is positively correlated with self-esteem in early adulthood, as well as negatively correlated with later identity problems (Bagwell et al. 1998). Friendship quality is associated with most developmental outcomes, however, in combination with child characteristics and friendship stability. For example, boys with very low-quality friendships and who are delinquent at age 13 to 14 escalate more over the next year in delinquent activity than either delinquent or nondelinquent boys in better relationships (Poulin et al. 1999). Other results show that sociability increases most and social withdrawal increases least across the transition from elementary school to junior high school when friendships are *both* high quality and stable (Berndt et al. 1999). Although causal direction has not been established in these data, the weight of the evidence suggests that good developmental outcomes are most likely when a child has friends, those friends are socially skilled, and these friendships are supportive and stable. Friendships between children who are not well socialized are mixed blessings.

10. Conclusion

Friendships are developmentally significant from early childhood through adolescence and beyond. Friendships are cognitive and affective resources, fostering social problem solving, self-esteem, and well-being. Friends socialize one another (sometimes for better, sometimes for worse). Supportive and intimate friendships generally are developmental advantages, whereas contentious relationships between individuals at risk generally are disadvantages.

Even so, friendships are not all alike. Children differ in the company they keep and in the social and affective qualities of their relationships. Developmental assessment is more complete when one knows who

a child's friends are and what these relationships are like. Developmental outcomes need to be better understood, however, especially in terms of children's involvement in relationships that can place them at risk. Particularly needed are studies of the manner in which friendship experience combines with temperament and early experience, social skills, family relationships, and the social context (especially the child's encounters with stress) to affect developmental outcome. One must also consider that childhood friendships may be more important in accounting for developmental outcome in some individuals than others.

Frontiers in History

Frontiers are as ancient as the state and the history of frontiers begins as far back as Herodotus, but the frontier as a myth is a recent invention. In Europe, the word 'frontière' first appears in French in the fourteenth century to indicate a facade in architecture or a military order of battle and only gradually came to mean the limits of state control. It passed into English and was widely used in the sixteenth century to mean a barrier against attack. In the thirteenth century the Slavic word 'greniz' or 'granitsa' was applied, particularly by the Teutonic Order, to the area of contact between Germans and Slavs, and replaced the Gothic term 'mark'. In the scholarly literature, definitions of frontiers have shifted from line and place to process, symbol and mythology as the disciplines involved—anthropology, geography and history—interacted creatively with one another under the general influence of the contextual approach. This has not been a linear evolution; nor has it been uniformly accepted, least of all by advocates of geopolitics, who still perceive frontiers as constituting a power grid, even when they have been determined by cultural or ideological factors.

1. Frontiers and the Historical Sciences

It is just over 100 years since Frederick Jackson Turner published his famous essay that still serves as the main frame in a triptych of historical approaches to frontiers in history (Turner [1893] 1921). Given the large number of American historians and their methodological restlessness, the comparative historiography of fron-

tiers has been dominated by their revisions of Turner. Flanking Turner's frontier on one side is a different spatial concept tied to the rise and consolidation of the centralized state that developed out of the French experience, as interpreted by the Annales school. On the other side a third panel represents the symbolic geographies, that is, the construction of imaginary borders between civilizations, as exemplified by the classical dualism of Europe and Asia, and the trialism of the Cold War: the West, the Communist Bloc and the Third World.

Anthropologists came later than historians to frontier studies, but then arrived in considerable force. In the 1950s they began to engage in extensive fieldwork on the margins of sedentary and nomadic societies (Khazanov 1994). Their insights were rapidly absorbed by historians, who had already been seriously exploring frontiers for over half a century. Finally, geographers based in local history and influenced by cultural studies began to redefine the ideas of space and frontiers in terms of linguistic and social contexts (Godlewka and Smith 1994). As a result the current state of research on frontiers is multidisciplinary and comparative.

2. Types of Frontiers

Frontiers may be separated into three basic types: consolidated state frontiers; dynamic frontiers of advancing settlements; and symbolic frontiers. On occasion, features of two or even three of these types coincide with one another. Each has a variety of subtypes. All are characterized by the existence of zones of influence and exchange on both sides of the real or imaginary line that presumes to divide them.

2.1 State Frontiers in Antiquity

The earliest historical evidence of frontiers expresses the needs of the state to define the limits of public authority, as in the empires of ancient Mesopotamia and Egypt, or later of private property in the Greek city states. In both cases, boundary markers were endowed with a sacred character and their removal signified the victory of a conqueror (Foucher 1991). The Athenian and Roman Empires and, independently, the Chinese Empire introduced two additional features: the construction of walls or defensive lines, and, second, the definition of peoples beyond the frontiers as culturally inferior, that is, barbarian. The attempts of the Roman and Chinese emperors to establish fixed frontiers repeatedly broke down under the pressure of migration, raiding and the development of extensive cultural and economic exchange. In the case of the Chinese-steppe frontier, the process of acculturation, transculturation and assimilation, sometimes simplified to 'trade or raid,' worked in

both directions long before the Great Wall was constructed and continued into the twentieth century. Relations between the Romans and peoples on the periphery of their control varied greatly according to location over centuries. Even the walls (limes), especially in the UK and Tunisia, were designed less to exclude, and more to control the movement of people and goods. The collapse in the West is increasingly regarded as a process of mutual accommodation of Romans and barbarian tribes through the emergence of a new military elite of the warlord type (Whittaker 1994).

2.2 Islamic State Frontiers

The Ottoman Empire represents a subtype of state frontier, intermediate between the ancient empires and the modern European state system. Embodying the precepts of Islam, it did not recognize until the late eighteenth century the concept of state frontiers in the European sense, but rather a division of the world into two cultural spheres: the Dar ul-Islam, the abode of Islam, and the Dar ul-Harb, the abode of war. But even this rigid division could not be strictly maintained. For example a contested space occupied by nomads opened up all along the Islamic-Byzantine frontiers during the relative stability of the tenth century. By the thirteenth century, there had arisen a culture of holy warriors (gazhis) with a corresponding type on the Byzantine side (Akritai), at first composed of Greek, and then of Turkomen tribesmen. This intermediate zone where war and trade often alternated facilitated the penetration and conquest of the Byzantine Empire by the Ottomans (Witteck 1938). At the western end of Ottoman power, an even more complex military frontier emerged where three empires, the Ottoman, Habsburg and Venetian (triplex confinium) confronted and co-existed with one another for three centuries (ca. 1500–1800). Small wars, population transfers, natural disasters and deeply rooted uncertainties shaped a border society that invented a variety of survival strategies, from cross-border trade and blood brotherhood to religious conversions, and gave rise to a variation of the ghazi warrior culture in the form of the Christian Uskoks (Kaser 1997, Roksandic 1998). Along the northern Ottoman frontier, similar conditions existed at the meeting ground of both the Poles, Russians and Ottomans in the Ukraine, and of the Russians, Ottomans and Iranians in the Transcaucasus, which also produced a warrior culture of Cossacks. Curiously, Ottoman specialists have yet to make the frontier experience the central theme in the history of the empire.

By the nineteenth century, the Ottoman frontier societies became more sharply divided by fundamental cultural conflicts. As Ottoman power receded in southwestern Europe and along the Black Sea, littoral

new state boundaries were drawn by international negotiation (first with Russia in the Treaty of Kuchuk-Kainardji, 1774) and great power intervention. Later, both the idea of rigid linear frontiers along national lines and the power to enforce them came from western Europe.

2.3 West European State Frontiers

A very different kind of frontier emerged in Western Europe during the transition from the feudal fragmentation of political power to the centralized absolutist monarchy. France, which set the pace frontiers as the limit of state power, evolved from a military to an ideological, financial and linguistic line accompanied by a more scientific cartography; in 1815, the French government produced the first map in the world drawn on a geodesic triangulation. Propagandists of the ancient regime and men of the revolution both claimed for France its 'natural frontiers', first in the form of the four rivers (Rhône, Saône, Meuse, and Scheldt), and then invoking Strabo and Caesar, the quadrilateral limits of ancient Gaul, the Rhine, Alps and the Ocean. To these myths the revolutionaries added another, the exact correspondence between 'natural' and 'national' frontiers before it was entirely clear who or what constituted the nation. It took another century before the administrative, customs and juridical instruments were sufficiently firmly established to enforce the claim (Bergeron and Revel 1989). In the process, the national territorial boundary was shaped as much by the local, frontier societies as by the central state, and as a result, the inhabitants retained their sense of place, even as they accepted their identity with the nation (Sahlins 1989).

The French (or Jacobin) model that the frontiers of a state ought to correspond to the natural and the national with one language and one culture was internationalized, at least for France, in the treaties of Vienna of 1815. Subsequently, it was widely diffused throughout Europe, Latin America and—with the participation of the British—Africa and the Middle East with mixed results.

One subtype of the French model emerged in the late nineteenth and early twentieth centuries in the small successor states of central, southeastern and eastern Europe. But there the prolonged existence of multicultural societies (Habsburg, Ottoman, and Russian) shaped by dynastic interests delayed into the twentieth century the shift from historic to linguistic (national) frontiers with dire consequences. By this time, internal migration, colonization, forced resettlement, and expulsions had created a kaleidoscope of peoples which could not be neatly compartmentalized by drawing linear frontiers.

Redrawing the map of southeastern Europe as the Ottoman power gradually receded was a cartographic nightmare, the result of a series of unhappy compro-

mises between the conflicting interests of the great powers and the aspirations of the subjugated peoples striving not only for independence but also for frontiers based on historicist claims—Greater Serbia, Greater Croatia, Greater Romania, Greater Hungary, Greater Bulgaria, Greater Greece, etc.—claims that were mutually irreconcilable.

German frontiers represent another subtype, sharing elements of the consolidated state and the dynamic moving frontier. In the north, west and south, the German frontiers evolved along the lines of the French model. But in the vast eastern space of the German-Slavic encounter, the discrepancy between sovereignty and settlement remained unresolved for 1000 years. For German statesmen, publicists and intellectuals from the eighteenth to the mid twentieth century, the task of consolidating a fixed state frontier with the Slavic east became a profoundly disturbing sociopsychological as well as political problem producing its share of historical myths (Demandt 1990).

3. The Dynamic Type of Frontiers

The second type of frontier may be characterized as an advancing line of settlements engaged primarily in agricultural or mixed economy, confronting a seminomadic and/or technologically less developed culture. In the modern period, three subtypes may be distinguished: the United States, the former British dominions and the Imperial Russian and Chinese Empires. The United States was the only former British colony where, once it had achieved independence, the frontier experience became both a national myth and a dominant historiographic theme. The other former British dominions constitute another subtype, where geographical and political factors placed the idea of the frontier in a different context. The continental expansion of Russia and China constitute a third subtype where the advance of the two societies brought them into direct contact and competition with one another.

3.1 The American Frontier as a Subtype

Neither the revisionists in American historiography nor the comparativists on an international scale have been able to free themselves entirely from the Turnerian concept of the frontier, even as they demolished its tenets one by one. What Turner did was to establish the frontier as a historical problem and to ask what it meant to be an American. The complexity of his approach guaranteed its longevity even as a foil. He combined elements of economic geography, social structure and ideology even though he was not always clear or consistent in drawing the relationship between them. His brilliant essays added up to something less than a full-blown theory and left the way open for

multiple interpretation, extensive revision and critical refutation. Like many great theses in historiography, its importance lies more in the literature it generated than in its original propositions. The debate over his legacy took place in two arenas, the national (American) and the comparative (global).

In American historiography, the revisions and reformulations of the Turner thesis radiate around two conceptual poles: new methodologies, particularly anthropology and environmental studies, and fresh interpretive perspectives reflecting the shifting concerns of a restless society in search of itself. At present, as in so many other areas, the task of charting the currents of the debate has itself become a minor cottage industry (Nash 1991). Turner's frontier as an advancing line of settlement has given way, in the work of the regionalists, to a multiplicity of locations. But Turner's tendency to conflate the frontier as a line and 'the Great West' as a region continues to be a source of confusion. There has also been a trend away from spatial to cultural definitions of the frontier, that is, from place to process. Turner's concept of the frontier as dividing 'savagery from civilization' or, alternatively, as a forward movement into 'empty lands' has, under the influence of anthropologists, yielded to the idea of the frontier as a zone of interaction involving two or more previously distinct societies that engendered a variety of cultural and commercial 'frontier exchanges' between Native Americans and colonists. Turner's concept of the West as an environment that bred rugged individualism and privileged self-reliance was challenged by historians and sociologists who gave equal billing to social collectivities, and uncovered a darker side of the frontiersman in the persistence of a gun culture and the cult of violence. Environmentalist historians exploded Turner's arcadian picture of natural harmony on the frontier by exposing the depredations, manipulations and 'species shifting' impact of the western advance (Cronon et al. 1992). Turner's insistence on the defining role of the frontier experience in building American democratic institutions was counterbalanced by the contributions of urban life and the antecedent values the pioneers brought with them. At one end of the historiographical spectrum, Turner's thesis lies in ruins and even the term 'frontier' is rejected or excoriated. At the other end, attempts have been made to synthesize the newer ideas on race, class, gender and region, in order to rescue once again the importance of the frontier in American history. The persistence of interest in Turner, marked more often by invoking his 'ghost' or 'spirit' rather than the body of his work, lies in large part with the power of his explanatory theme to explain American national identity. Pluralistic interpretations have never conveyed the same emotional force. Turner's thesis has passed into the realm of historical myth and nowhere is this more evident than in the realm of mass culture.

The commercialization of American history found

the perfect vehicle in the frontier. The transformation of the frontier into a popular myth and its subsequent permutations was a function of changes in both the medium and the message. New social and environmental concerns left their mark on Turnerian stereotypes. In film and television, the heroic cowboy in the white hat, the intrepid farmer fighting off the Indians, the cavalry arriving at the last minute became more ambiguous figures. Black cowboys and troopers, environmentally sensitive Native Americans, even women gun-slingers challenged the dominant white male image. The Marlboro Man made his last stand on American billboards.

3.2 *The British Empire as a Subtype*

An analysis of subtypes of the dynamic frontier cannot be treated without reference to the comparative approach largely inspired by, if not always accepting, the Turner thesis and its revisions. The influence of the debate over the Turner thesis has been felt most keenly in the historiographies of the former dominions of the British Empire, and the Russian and Chinese Empires. Historians of North America and South Africa have produced a particularly well-designed comparative analysis of their respective frontiers (Lamar and Thompson 1981). It sought to achieve theoretical clarity and consistency by establishing a universal definition rather than adopting the USA experience or Turner thesis as a model, even though the original inspiration remained clear. Three elements in defining frontier societies are considered essential: first, the geographical-territorial, conceived as a zone rather than a line with different carrying capacities, attractiveness and resources; second, the cultural, in terms of the interpenetration between two previously distinct societies, one indigenous and the other intrusive; and third, the operational, the process of opening and closing, the former dated by the arrival of representatives of the intrusive society and the latter, more complex stage because it was variable and potentially reversible, as it indeed proved to be in South Africa, by the establishment of a single political hegemony through extermination (Tasmania), expulsion (Trans-Mississippi), subjugation (South Africa) or incorporation (Brazil). Specific comparisons of the USA and South Africa reveal more differences than similarities, although the white communities in both mythologized the frontier experience as formative. Before the recent reversal in South Africa, the critical difference appeared to be the different relationship of the indigenous people in the USA and South Africa to capitalism.

Comparative studies, with Turnerian overtones, of the frontier experience in Canada, Australia and New Zealand suggest that despite superficial similarities with the USA, geographical factors and the prolonged tutorship of the metropolitan center in the UK

prevented the rise of a mythology of frontier exceptionalism (Nugent 1994). In Canada there were close parallels between the farming frontier in Ontario and Saskatchewan, and in North Dakota and Montana. But the expansion west was delayed by the physical barrier of the Canadian shield. When it came, it was promoted by Royal Governors established national police (the Royal Mounties) before mass immigration and negotiated settlements with the Blackfoot tribes thus heading off the local violence and large-scale white-native American wars that characterized the American west. To an even greater extent, the geography of Australia, dominated by a vast arid region in the center, 'a hinterland but no heartland,' relegated the bulk of the population to the cities on the east and south coast while royal land policy did not favor the small farmer in competition with the large sheep ranges. Yet even here there are regional similarities between the semi-arid fringes of California and Victoria. And Australia had its frontier folk hero in the form of the bush-ranger, although he was connected to the convict life rather than the freebooter born in an open society. The Northwest Frontier of India was the only zone of encounter between the British colonial expansion and a seminomadic population where the odds were rated even. The character of this military frontier resembled more that of the great older empires, the Roman, Chinese and Ottoman, confronting a persistent threat to security along one or several of their peripheries. The British inherited the problem from their predecessors the Moghuls, who, like the founders of several Chinese dynasties, were originally 'eastern barbarians' before they came to settle in the fertile river valleys of the south. Although the Northwest Frontier could hardly be said to have dominated British colonial politics, there was a constant tension between the proponents of a forward policy to anchor the frontier on the Hindu Kush and the advocates of 'masterly inactivity' (Fraser-Tytler 1950). And there was concern and debate over the Russian advance behind the tribes. The British crossed the frontier in force three times to fight the Afghans without settling much of anything. It was a classical military frontier zone exhibiting sporadic warfare, trade, smuggling, movement of peoples and a mythology of heroism immortalized by Kipling. Today, the Northwest frontier between Afghanistan and Pakistan has lost nothing of this except its glamour.

3.3 *The Imperial Russian and Chinese Empires as a Subtype*

The long, porous and shifting Eurasian frontiers of Russia and China have also attracted comparativists who employ Turner's thesis and its revisions as a point of departure in their analysis. However, even before Turner, nineteenth-century Russian historians, like S. M. Solov'ev and V. O. Kliuchevskii, stressed the

central role of colonization and frontier in shaping the history of their own country, and drew from many of the same formative influences as their American counterpart (Bassin 1993). By contrast, though, their interpretations emphasized the negative effects: the draining of resources from the center, the unfavorable conditions of climate and soil, the threat of nomadic incursions. Historians in the early Soviet period added to this list the exploitation of the conquered people. A strong reversal set in only after World War II when the new state school of Soviet historians extolled the Russian peasant colonizer as a heroic figure and employed the specialized term 'merging' (sblizhenie), a form of assimilation, to signify the civilizing mission of the Russian people. A third turn has been taken only recently by the emerging regional (Siberian) school of historians who, in readjusting their focus to the specific features and values of the periphery at odds with those of the center have, nonetheless, acknowledged their debt to Turner.

Meanwhile, Western scholars, mainly Americans and British, assumed the mantle of the pre-revolutionary Russian historians and invoked Turner's thesis, in order to draw parallels and contrasts between the Russian conquest and colonization of Siberia and the American western expansion. The earliest attempts to apply the Turner thesis to the Russian experience lagged behind the extensive revisionist literature in the USA that had already forced a re-evaluation of its central tenets. However, since the 1980s a new generation of American and British students of Russian colonization have incorporated new ideas borrowed from the historiography of the USA, rather than from direct comparison with the American experience. Multiple locus and process have replaced conquest and resistance (Barrett 1995).

On the Chinese side, after more than six decades the dominant figure in frontier studies remains Owen Lattimore. His earliest work combined the keen first-hand observations of the linguistically competent, experienced traveler with historical and anthropological training (Lattimore [1940] 1951). Studded with comparative insights (Roman Empire, American West, Northwest Frontier Province), its central thesis was to establish that frontiers, as distinct from boundaries, were the outer limit of zones on the margins of a socioeconomic systems that represented their 'optimal limit of growth.' While admitting that Turner was 'an acute observer' he added that 'what he saw so clearly he saw standing on his head. In large measure, when he thought he saw what the frontier had done to society, he was really seeing what society did to the frontier' (Lattimore 1962). By comparing the social and economic character of Chinese and Russian empires, he was able to distinguish between their different 'margins of expansion.' The study of Chinese frontiers has increasingly focused on the long-term sinefication of the frontier provinces: Manchuria, Inner Mongolia, Sinkiang, and Tibet.

4. Symbolic Frontiers

The frontiers of symbolic geographies focus on the meeting ground of distinctive civilizations. The attempt to define and defend these frontiers was a feature of both the Greco-Roman and Chinese empires, the first to identify the boundary between civilized and barbarian. It was continued by the Islamic and Christian (European) traditions which were contemporaneous and contiguous hence more conflictual. But religious fissures (Sunni-Sh'ia on the one hand and Eastern Orthodox and Latin on the other) created intercivilizational frontiers that proved just as difficult to cross. Within Europe, a significant shift in symbolic geography occurred in the eighteenth century when the philosophers realigned the main cultural divide between the enlightened and the backward from a south–north to an west–east axis (Wolff 1994). But the exact demarcation line was much disputed, especially when confused with the symbolic frontier between Europe and Asia as Metternich's famous quip, 'Asia begins at the Landstrasse,' well illustrates.

In the twentieth century, the Soviet rhetoric of frontiers infused the ancient 'sacred' concept with an exclusionist ideological meaning enabling another rhetorician, Churchill, to coin the phrase 'Iron Curtain,' which retained its symbolic power long after events demonstrated its imprecision and inadequacy. The collapse of the Soviet Union and the Communist bloc overturned the theory of stable state frontiers, which had dominated American political science from 1950–90 (Anderson 1997). It also spurred a recurrent debate about the cultural line dividing western and eastern Europe and the West from other civilizations. Both during and after the Cold War there were divergent attempts to locate the historic origins of the dividing lines. Some held that Latin and Orthodox Christianity constituted a single civilization for 1,000 years until the communists rang down the curtain and arbitrarily split it along the Oder–Neisse line (Halecki 1950). Others, like Arnold Toynbee, drew the frontiers of civilizations along religious lines and argued that totalitarian Russia had its roots in Eastern Orthodoxy. After 1989, several émigré and former dissident intellectuals in the region resurrected the idea of a different more westerly and long-established cultural frontier between 'central Europe,' which was equated with liberal democracy and the spirit of capitalism, from 'eastern Europe' associated with the authoritarian state and cultural backwardness. Only in this context is it possible to measure the enormous psychological impact on the people of the region of being accepted or rejected for membership in NATO or the European Union, real institutions which, nevertheless, constitute the new symbolic frontiers of civilization.

Functional Brain Imaging

Since the 1990s the field of cognitive neuroscience has emerged as a very important growth area in neuroscience. Cognitive neuroscience combines the experimental strategies of cognitive psychology with various techniques to actually examine how brain function supports mental activities. Leading this research in normal humans are the new techniques of functional brain imaging: positron emission tomography (PET) and magnetic resonance imaging (MRI) along with event related potentials (ERP's) obtained from electroencephalography (EEG) or magnetoencephalography (MEG). This article focuses on PET and MRI.

1. Antecedents of Functional Brain Imaging

1.1 Neuropsychology

Early discussions of the 'mind-brain problem' treated the brain largely as a 'black box.' Then, in 1861, French surgeon and anthropologist Pierre Paul Broca described a clear relationship between a patient's difficulty speaking and an injury to a specific part of the patient's brain due to a stroke. Since this seminal observation, a vast body of scientific literature has accumulated implicating various parts of the human brain in specific aspects of human behavior, including language. This approach to the study of human brain function has achieved a remarkable level of sophistication and represents an important tool in neuroscience.

The features of brain organization arising from the study of patients with brain injury nevertheless raise some questions of interpretation. The size and location of brain injury varies greatly from patient to patient, making a precise correlation between damage to a particular area of the brain and the function normally served by that area sometimes difficult to determine. Furthermore, each patient may be assumed to have some features of brain organization that are unique to him or her. Finally, it remains uncertain whether one can simply attribute a lost or disrupted function to a particular area of injury. Because of the interconnected nature of areas of the brain, injury in one area is likely to have effects on other areas that cannot necessarily be predicted from the location and size of the injury. Thus, as valuable as our insights concerning the

organization of the human brain have been, from the study of patients with stroke and other types of brain injury, it has remained an open question exactly how this information relates to the normal organization of the human brain.

Only recently have scientists interested in this question had the opportunity to explore it analytically—to peer inside the black box as it functions normally. This ability stems from the developments in imaging technology since the 1980s, most notably PET and MRI. These techniques can now capture localized changes in blood flow in the normal human brain associated with behaviorally induced changes in brain cellular activity (Raichle 1998).

1.2 Blood Flow and Brain Function

The quest for an understanding of the functional organization of the normal human brain, using techniques to assess changes in brain circulation, has occupied mankind for more than a century (for a historical review see Raichle (2000)). An enduring theme throughout this work has been that changes in the cellular activity of the normal brain of humans and laboratory animals is invariably accompanied by changes in the blood flow to the region of the brain affected.

1.2.1 Early quantitative blood flow measurements in humans. At the close of World War II, Seymour Kety and co-worker opened the first chapter in quantitative studies of brain circulation and metabolism in humans and laboratory animals. Working with Lou Sokoloff and others, Kety developed the first quantitative methods for measuring *whole* brain blood flow and metabolism in humans. The introduction of an *in vivo* tissue autoradiographic measurement of regional blood flow in laboratory animals by Kety's group (Kety 1960, Landau et al. 1955) provided the first glimpse of quantitative changes in blood flow in the brain related directly to brain function.

Soon after Kety introduced quantitative methods for measuring whole brain blood flow and metabolism in humans, David Ingvar, Neils Lassen, and their Scandinavian colleagues introduced methods applicable to man that permitted regional blood flow measurements to be made using scintillation detectors arrayed like a helmet over the head (Lassen et al. 1963). They demonstrated directly in normal human subjects that blood flow changed regionally during changes in brain functional activity. The first study of functionally-induced regional changes in blood flow using these techniques in normal humans was actually reported by Ingvar and Risberg at an early meeting on brain blood and metabolism (Ingvar and Risberg 1965) and was greeted with cautious enthusiasm and a clear sense of its potential importance for studies of

human brain function by Kety (Kety 1965). However, despite many studies of functionally induced changes in regional cerebral blood, which followed, this approach was not embraced by most neuroscientists or cognitive scientists at the time. It is interesting to note that this indifference was to disappear almost completely in the 1980s, a subject to which the article will return.

2. Introduction of Modern Imaging Techniques

The modern era of medical imaging began in the early 1970s when the world was introduced to a remarkable technique called X-ray computed tomography, now known as X-ray CT or just CT (for review see Kevles 1997). South African physicist Allan M. Cormack and British engineer Sir Godfrey Hounsfield independently developed its principles but it was Hounsfield who constructed the first scanner successfully.

2.1 X-ray Computed Tomography (CT)

CT takes advantage of the fact that different tissues absorb varying amounts of X-ray energy. The denser the tissue, the more it absorbs. A highly focused beam of X-rays traversing the body will exit at a reduced energy level depending on the tissues and organs through which it passes. A beam of X-rays passed through the body at many different angles through a plane provides sufficient information to reconstruct a picture of that body section. It was crucial to the development of CT that clever computing and mathematical techniques emerged for processing the vast amount of information necessary to create the images themselves. Without the availability of sophisticated computers, the task would have been impossible to accomplish.

CT had two consequences. First, it changed the practice of medicine forever, because it was much superior to standard X-ray techniques. For the first time, physicians could safely and effectively view living human tissue such as the brain with no discomfort or risk to the patient. Second, CT immediately stimulated scientists and engineers to consider alternative ways of creating images of the body's interior using similar mathematical and computer strategies for image construction. These efforts went beyond the picture of human anatomy to focus on function.

2.2 Positron Emission Tomography (PET)

One of the first groups to be intrigued by the possibilities opened by CT consisted of experts in tissue autoradiography, a method used for many years in animal studies to investigate organ metabolism, biochemistry and blood flow. In tissue autoradio-

graphy, a radioactively labeled compound is injected into a vein. After the compound has accumulated in the organ under investigation, the animal is sacrificed and the organ (e.g., the brain) removed for study. The organ then is sectioned carefully, and the individual slices are laid on a piece of film sensitive to radioactivity. Much as the film in a camera records a scene as it was viewed originally, this X-ray film records the distribution of radioactively labeled compound in each slice of tissue.

When the X-ray film is developed, scientists have a picture of the distribution of radioactivity within the organ and hence can deduce the organ's specific functions. The radioactive compound injected determines the type of information. A radioactively labeled form of glucose, for example, measures brain metabolism, because glucose is the primary source of energy for the cells of the brain. Central to functional brain imaging with PET is the measurement of brain blood flow, which is accomplished by the injection of radioactively labeled water.

Investigators adept at tissue autoradiography were fascinated when CT was introduced. They suddenly realized that if they could reconstruct the anatomy of an organ by passing an X-ray beam through it, as CT did, they could also reconstruct safely the distribution of a previously administered radioisotope. One had simply to measure the emission of radioactivity from the body section. This realization was the birth of autoradiography of living human subjects.

One crucial element in the evolution of human autoradiography was the choice of radioisotope. Workers in the field selected a class of radioisotopes that emit positrons, which resemble electrons except that they carry a positive charge. A positron produced with the tissue almost immediately combines with a nearby electron. The positron and the electron annihilate one another in this interaction, emitting two high-energy gamma rays in the process. Since the gamma rays travel in nearly opposite directions, radiation detection devices arrayed in a circle around the organ of interest can detect the pairs of gamma rays and, with the aid of computers, locate their origin with remarkable precision. The crucial role of positrons in human autoradiography gave rise to the name positron emission tomography or PET (Phelps et al. 1975, Ter-Pogossian et al. 1975).

2.3 Magnetic Resonance Imaging (MRI)

Finally, another technology emerged contemporaneously with PET and CT. This was MRI. MRI is based upon yet another set of physical principles that have to do with the behavior of hydrogen atoms or protons in a magnetic field. These principles were discovered independently by Felix Block and Edward Purcell and colleagues in 1946 and expanded to imaging by Paul Lauterbur in 1973 (for review see Kevles 1997).

Initially MRI provided superb anatomical information but inherent in the data also was important metabolic and physiological information. An opening for MRI in the area of functional brain imaging emerged when it was discovered that during changes in neuronal activity there are local changes in the amount of oxygen in the tissue (Raichle 1998). By combining this observation with a much earlier observation by Pauling and Coryell (1936) that changing the amount of oxygen carried by hemoglobin changes the degree to which hemoglobin disturbs a magnetic field, Ogawa et al. (1990) were able to demonstrate that *in vivo* changes in blood oxygenation could be detected with MRI. The MRI signal (technically known as T2* or 'tee-two-star') arising from this unique combination of brain physiology (Raichle 1998) and nuclear magnetic resonance physics (Pauling and Coryell 1936, Thulborn et al. 1982) became known as the blood oxygen level dependent or BOLD signal (Ogawa et al. 1990). There followed quickly several demonstrations of BOLD signal changes in normal humans during functional brain activation (Kwong et al. 1992, Ogawa et al. 1992) giving birth to the rapidly developing field of functional MRI or fMRI.

It is important to keep in mind that when a BOLD signal is detected blood flow to a region of brain has changed out of proportion to the change in oxygen consumption. When blood flow changes more than oxygen consumption, in either direction, there is a reciprocal change in the amount of deoxyhemoglobin present locally in the tissue changing the local magnetic field properties. As you will see both increases and decreases occur in the BOLD signal in the normal human brain.

3. Functional Brain Imaging

3.1 The Strategy of Functional Brain Imaging

As a result of collaboration among neuroscientists, imaging scientists, and cognitive psychologists, a distinct behavioral strategy for the functional mapping of neuronal activity emerged. This combination of disciplines and the strategies resulting from it probably account for the remarkable success and the resulting acceptance of functional brain imaging in cognitive neuroscience. The general strategy of functional brain imaging is based on a concept introduced by the Dutch physiologist Franciscus C. Donders in 1868 (reprinted in Donders (1969)). Donders proposed a general method to measure thought processes based on a simple logic. He subtracted the time needed to respond to a light (say, by pressing a key) from the time needed to respond to a particular color of light. He found that discriminating color required about 50msec. In this way, Donders isolated and measured a mental process for the first time by subtracting a *control state* (i.e.,

responding to a light) from a *task state* (i.e., discriminating the color of the light).

One criticism of this approach has been that the time necessary to press a key after a decision to do so has been made is affected by the nature of the decision process itself. By implication, the nature of the processes underlying key press, in this example, may have been altered. Although this issue (known in cognitive science jargon as the *assumption of pure insertion*) has been the subject of continuing discussion in cognitive psychology, it finds its resolution in functional brain imaging, where changes in any process are signaled directly by changes in observable brain states. Events occurring in the brain are not hidden from the investigator as in the purely cognitive experiments. Careful analysis of the changes in the functional images reveals whether processes (e.g., specific cognitive decisions) can be added or removed without affecting ongoing processes (e.g., motor processes). Clearly, some areas of the brain active at one stage in a hierarchically designed paradigm can become inactive as task complexity is increased. Even more surprising, areas of the brain active in the resting state can also become inactive during certain cognitive states (Raichle et al. 2001). While changes of this sort are hidden from the view of the cognitive scientist they become obvious when brain imaging is employed.

A final caveat with regard to certain cognitive paradigms is that the brain systems involved do not necessarily remain constant through many repetitions of the task. While simple habituation might be suspected when a task is tedious, this is not the issue referred to here. Rather, when a task is *novel* and, more importantly, conflicts with a more habitual response to the presented stimulus major changes can occur in the systems allocated to the task. Such changes have both practical and theoretical implications when it comes to the design and interpretation of cognitive activation experiments. Functional brain imaging obviously provides a unique perspective that is unavailable in the purely cognitive experiment.

3.2 The Assumptions of Functional Brain Imaging

It is important to point out that the underlying assumptions of current brain-mapping studies with PET and fMRI do not embrace a modern version of phrenology. The phrenologists of the nineteenth century posited that single areas of the brain, often identified by bumps on the skull, uniquely represented specific thought processes and emotions. In contrast, modern thinking posits that single areas of the brain each contribute quite simple mental operations that form the elementary components of the observable behaviors. Observable behaviors and thought processes emerge through the cooperative interactions of many such areas. So, just as diverse instruments of a large orchestra are played in a coordinated fashion to

produce a symphony, a group of diverse brain areas, each performing unique elementary and unique mental operations, work together in a cooperative fashion to produce human behavior. The prerequisite for such analyses is the conviction that complex behaviors can be broken down into sets of constituent mental operations. This is not a new view. In 1909, the great neuroanatomist Korbinian Brodmann commented that ‘With regard to the infinite variety and richness of the psyche one should rather envisage the situation that in each particular case supposed “elementary functional loci” are active in differing numbers, in differing degrees and in differing combinations. One must further accept that specific complex processes occur mainly in one locality and others mainly in another. One must therefore also assume a certain regional preference for higher activities, sometimes more in occipital and temporal areas, sometimes more in frontal. *Such activities are, however, always the result (and not merely the sum) of the function of a large number of suborgans distributed more or less widely over the cortical surface; they can never be the product of a morphologically or physiologically independent “center”*’ (Brodmann 1909, 1994).

3.3 The Future of Functional Brain Imaging

Functional brain imaging took a major step forward with the introduction of fMRI. This resulted not only from the improved spatial resolution of the technique and the wide availability of MRI scanners, many now appearing outside of hospitals in departments of psychology, but also the ability to obtain information on the response of the brain to individual stimuli (Buckner et al. 1996). Earlier studies with PET required that stimulus types be ‘blocked’ in order to accommodate the time necessary to make a single measurement of blood flow (usually about 1 m). With fMRI stimulus types can be randomized in ways that are identical to those used traditionally by cognitive psychologists. Thus, following the completion of the study, image data can be sorted according to stimulus type or response characteristics (Brewer et al. 1998, Wagner et al. 1998), providing a much more sophisticated analysis of brain function in relation to behavior or stimulus type.

Even with the introduction of fMRI we still do not have an adequate description of the temporal dimension of responses occurring within the brain. We know from direct measurements of the responses of neurons in the brains of laboratory animals that information is processed among areas of the brain with time differences in the range of tens of milliseconds. This is far too fast to be captured with fMRI. Electrical techniques such as the EEG and MEG do capture this temporal dimension but do so with very poor spatial resolution. The hope, therefore, is to combine eventually the spatial dimension of responses

captured with fMRI with the temporal dimension provided by EEG or MEG. This combination of techniques remains a technically challenging problem but progress has been made (Liu et al. 1998, Rosen et al. 1998).

Those readers interested in a general survey of the current state of functional brain imaging work might wish to consult a variety of new books that are appearing regularly (Moonen and Bandettini 1999; Toga and Mazziotta 1996, 2000).

Functional Data Analysis

Most statistical analyses involve one or more observations taken on each of a number of individuals in a sample, with the aim of making inferences about the general population from which the sample is drawn. In an increasing number of fields, these observations are curves or images. Curves and images are examples of functions, since an observed intensity is available at each point on a line segment, a portion of a plane, or a volume. For this reason, we call observed curves and images ‘functional data,’ and statistical methods for analyzing such data are described by the term ‘functional data analysis’ (FDA), coined by Ramsay and Dalzell (1991). Though the individual methods and techniques are important, functional data analysis is also a general way of thinking, where the basic unit of information is the entire observed function rather than a string of numbers. A few illustrations will be offered in this article, but Ramsay and Silverman (1997) may be consulted for many more examples and methods, for consideration of the underlying philosophy, and for further references to the literature.

The goals of functional data analysis are essentially the same as for other branches of statistics, and include the following:

- (a) to represent and transform the data in ways that aid further analysis,
- (b) to display the data so as to highlight various characteristics,
- (c) to study important sources of pattern and variation among the data, and
- (d) to explain variation in an outcome or dependent variable by using input or independent variable information.

We shall illustrate the nature of functional data, these goals, and FDA tools available or under development, through a series of examples.

1. Human Growth Data: Looking at Velocity and Acceleration

Figure 1 shows the growth patterns of 10 Swiss boys involved in the Zurich Longitudinal Growth Study (Falkner 1960). Each boy’s height is measured at 29 separate ages, but it is more instructive to think of this as a sample of 10 growth curves or functions than as a set of 290 numerical observations. Of particular interest in the study of growth is the way that growth speeds up and slows down at various stages of

Figure 1

The heights of 10 Swiss boys measured at 29 ages
Notes: Points indicate unequally spaced ages of measurement; solid line is a function fitted to these data by monotone smoothing.

Figure 2

The estimated accelerations of height for 10 Swiss boys
Notes: Heavy dashed line is cross-sectional mean. This is a rather poor summary of the curves because of the presence of the timing of the pubertal growth spurt, called phase variation.

development, and this is much better illustrated by studying the velocity and acceleration of height. Figure 2 gives estimates of the acceleration or second derivative of these 10 height functions, and shows that around puberty there is a strong pulse of acceleration in growth, followed by sharp deceleration. This is the pubertal growth spurt (PGS), and there is also often a smaller spurt, hardly visible in Fig. 1 but obvious in Fig. 2, at around age 6.

2. The Mean Function and the Registration Problem

How would one estimate an overall acceleration curve to quantify the size of these spurts? The dashed curve in Fig. 2 is the average acceleration over the sample at each time point, but the PGS for this average is smaller in size and longer in duration than that of any of the individual spurts. Averages are supposed to look like typical observations; so what went wrong?

The problem is that the curves vary in two ways, termed amplitude variation and phase variation. Alternatively, these are called vertical and horizontal variation, respectively, since amplitude concerns the height of a function at a given point, and phase the location in time of a feature such as an acceleration peak. In short, the actual acceleration peaks in the PGS vary in both size and timing. An artificial example demonstrating these two sorts of variation is presented in Fig. 3. The phase shift displayed in this figure is constant across the timescale, but many data sets require more complicated and nonlinear transformations of the time axis in order to align curve features like the peaks and valleys in Fig. 3. The presence of phase variation arises in FDA because many processes involve a system time, or in this case biological time, that does not unfold at the same rate as clock time. In this case, the biological clock of each boy marks off time at its own unique rate.

A key part of the FDA methodology is time-warping or registration of the data curves to align specific features or to minimize variability, since estimating the mean and most other analyses are thrown off by the presence of phase variation. The time-warping functions may be simple constants, linear functions, or more complicated, nonlinear

Figure 3

Figure 4

Time-warping functions taking chronological age on the horizontal axis into biological age on the vertical axis

Figure 5

The height acceleration curves in Fig. 2 aligned or registered by measuring height with respect to the biological time shown in Fig. 4

Notes: Heavy dashed line is the mean acceleration. This provides a much better summary of the actual curves than Fig. 2

functions. The amount or shape of warp may be of great interest. See Ramsay and Silverman (1997, Chaps. 5 and 8). Figure 4 shows time-warping functions and registered height acceleration curves for the growth curves of Fig. 1 estimated using a method developed by Ramsay and Li (1998). The time-warping curve for each individual shows his maturation pattern. A warping function consistently above

the diagonal dashed line implies that clock time lags behind development, and therefore development is late in clock terms. If height is measured relative to biological age, the curves in Fig. 2 are aligned as shown in Fig. 5. Differences in height acceleration after registration correspond to pure amplitude variation in growth patterns. The mean of the registered curves in Fig. 5 is a much better summary than the mean of the unregistered data in Fig. 1.

3. The Nondurable Goods Index and More Derivatives

Valuable information may be gained by plotting one derivative of a functional observation against another, a technique called phase/plane plotting. The US index of nondurable goods production is an important economic indicator, and considerable insight may be gained by plotting the acceleration of this index against its rate of increase. If the index had a smooth trend plus a sinusoidal seasonal variation, this plot would be approximately circular with suitable choice of scales. The typical year 1970 in Fig. 6 has three main cycles, of which the spring cycle is rather smaller than the summer and fall/winter cycles. Comparisons of plots for different years is instructive. During the stable period 1964–6, there is little year-to-year change, but the period 1973–5 in Fig. 6 shows considerable instability, due primarily to the end of the Vietnam War. A typical plot for a more recent year, 1994, shows that the whole pattern has changed, indicating structural changes in the methods and economics of production. For further details, see Ramsay and Ramsey (2001).

4. Functional Principal Components Analysis

Many FDA methods are adaptations of classical multivariate methods such as principal components analysis (PCA), linear modeling, and analysis of variance (see *Linear Hypothesis* and *Multivariate Analysis: Overview*). Functional PCA demonstrates the way in which a set of functional data varies from its mean, and, in terms of these modes of variability, quantifies the discrepancy from the mean of each individual functional datum. Figure 7 (fig. 6.2 in Ramsay and Silverman (1997)) shows the first four principal component weight curves for temperature records for 35 Canadian weather stations. The first mode of variability is overall temperature, but with larger effects in the winter; the second corresponds to variation in annual range of temperature; the third partly to a time-shift of the overall cycle, and the fourth to short, hot summers and long, mild winters, or vice versa. Individual weather stations can then be

Figure 6

A phase/plane plot of *US index of nondurable goods production*. Each panel plots second derivative on vertical axis against first derivative on horizontal axis. Plots show structure of seasonal variation in index, and how structure varies with time

characterized according to their scores on these four criteria. The interpretability of the components can often be improved by a suitable rotation of the original principal components; see Ramsay and Silverman (1997, Chap. 6).

5. A Functional Linear Model and Regularization

An example of functional linear modeling is provided by the study of the dependence of the acceleration of the lower lip (*lipacc*) in speech on neural activity, as measured by electromyographical (EMG) recording. It is reasonable to suppose that the neural activity at time s continues to affect lip movement for only a short period of time, which we denote by δ and this leads to a model of the form

$$\text{lipacc}(t) = \alpha(t) + \int_{t-\delta}^t \text{EMG}(s) \beta(s, t) dt + \varepsilon(t),$$

developed by Malfait et al. (2000). The bivariate function $\beta(s, t)$ plays the same role as the regression coefficient in standard linear regression, and quantifies the relationship between the independent functional

variable EMG, and the dependent functional variable lip. One particular issue is the appropriate choice of the time lag δ the length of time within the model that neural activity can continue to affect movement. Models for increasing values of δ correspond to nested linear models, and in this case a study of the amount of variation explained demonstrates that there is little effect beyond a lag of about half a second.

An important theoretical and practical issue is the necessity or otherwise of incorporating some form of smoothing or regularization into a functional analog of a classical multivariate procedure. In principal components analysis, the principal components, such as those displayed in Fig. 7, are smoothed or regularized and in some procedures, such as canonical correlation analysis (see *Multivariate Analysis: Overview*) or certain types of linear modeling for the lip/EMG data, regularization is necessary to give any meaningful results at all; see Leurgans et al. (1993), and Ramsay and Silverman (1997, Chaps. 11, 12).

6. Modeling with Derivatives: A Central Theme

It is the smoothness of the processes generating functional data that differentiates this type of data

Figure 7

A principal components analysis of mean temperature curves for 35 Canadian weather stations

Notes: Solid line is the mean curve taken across all stations. The effects of adding (+) and subtracting (−) a suitable multiple of each component are also shown.

from more classical multivariate observations. This smoothness means that we can work with the information in the derivatives of functions or images. We looked at acceleration in the growth data, found something interesting in the joint variation of the velocity and acceleration of nondurable goods pro-

duction, and used derivatives to define roughness penalties; see Ramsay and Silverman (1997, Chap. 4) for the weather data.

We may also use derivatives to construct models for data. Such models are called differential equations, and are part of the standard model-building toolkit in

Figure 8

Observations of the tip of the pen while writing the word 'statistics' in Mandarin

Notes: Dots indicate 2400 observations; solid line is an approximation based on a second-order linear differential equation.

the natural sciences and engineering. Differential equation models are often called dynamic models, since they are especially effective at representing processes unfolding in time. Ramsay (2000) developed a linear differential equation for handwriting involving velocity, acceleration, and the third derivative of the tip of the pen. Figure 8 shows a sequence of pen positions during the writing of the word ‘statistics’ in Mandarin, and also shows as a solid line its approximation on the basis of the dynamic equation estimated from 50 such samples of Chinese script. The equation not only captured the essential features of this particular sample, but was also able to model a fair amount of the sample-to-sample variation as well. And, finally, it also provided an excellent account of the velocity, acceleration, and jerk functions at the same time. Ramsay and Silverman (1997, Chaps. 13, 14) take up this topic of dynamic modeling with functional data, including an account of a technique called ‘principal differential analysis,’ developed by Ramsay (1995).

7. Relationships with Other Branches of Statistics

Of course, statisticians have been exploring curves for a very long time, and there are many older statistical methodologies that can continue to inform and enrich an FDA. First of all, FDA usually begins with some kind of nonparametric regression (e.g., see *Exploratory Data Analysis: Multivariate Approaches (Nonparametric Regression)*) in order to replace discrete and possibly noisy curve values by smooth, continuous functions. Density estimation also involves data smoothing. Typically, time series analysis (Brillinger 1981, Box and Jenkins 1994) considers long sequences of curve values corresponding to equally spaced time values that are more or less stationary; that is, the data show little overall trend, and the covariance among neighboring values does not change much from one time region to another. However, methods for non-stationary processes are also under active development, and there are strong structural links between times series methods such as state-space modeling and FDA methods such as smoothing. Longitudinal data analysis or multilevel modeling (Diggle et al. 1994, Searle et al. 1992) usually looks at shorter sequences of curve values sampled over many cases, and studies the structure of between- and within-curve variation. It seems likely that this field and FDA will merge in a number of useful ways. Multivariate statistics has many methods developed specifically for functional data that have preceded FDA, but which have not explicitly exploited the smoothness of functional data or made other uses of derivatives (see *Probability Density Estimation; Longitudinal Data; Multivariate Analysis: Overview*).

8. Conclusion

By the smoothness of a functional observation we have meant the possibility that one or more derivatives, such as velocity or acceleration, may be examined or used in the modeling process. Otherwise, FDA makes only minimal assumptions about the structure of variation within and between curves. We have seen, however, that teasing apart amplitude and phase variation is a central issue, and one that has largely been ignored until recently. Certain types of models considered to be fairly routine and well understood in multivariate statistics, such as linear regression, have many more variants in the functional domain, and are being researched actively. Software for FDA is also being developed, and it is likely that FDA will soon be considered as a routine item in a data analyst’s black bag of instruments and nostrums. Further information on FDA and related issues may be obtained in Pinheiro and Bates (2000), Ramsay and Silverman (1997), and Simonoff (1996).

Functional Equations in Behavioral and Social Sciences

Theories in the behavioral, social, and natural sciences are often formalized by equations involving unknown functions, i.e., by functional equations. For instance, a theorist may be reluctant to make specific assumptions regarding the form of functions involved in a mathematical model, but the qualitative formulation of the model itself may impose constraints on the initially unknown functions. Such constraints often reduce the possibilities and occasionally are so severe that they restrict the possible forms to a few. A recent general reference to functional equations is Aczél and Dhombres (1989) where references to earlier and still useful surveys are given.

In the simplest cases there is one unknown, real-valued, function ϕ . An example, named after the famous French mathematician A. L. Cauchy, is the Cauchy equation $\phi(x+y) = \phi(x) + \phi(y)$, where x, y are in the set of real numbers $\mathbb{R}$. More restrictive domains are sometimes studied. With no further restrictions, the solutions to the Cauchy equation can be wild. But assuming that ϕ is monotonic, or continuous, or bounded over a finite interval, the solution reduces to $\phi(x) = cx$ for some constant c . By taking $\psi = \exp \phi$, we get $\psi(x+y) = \psi(x)\psi(y)$, which is the so-called 'lack of memory property' and it is easy to see from the previous case that the strictly monotonic solutions are $\psi(x) = e^{cx}$, $c \neq 0$.

A celebrated psychophysical example is the connection between empirical just noticeable differences and G. T. Fechner's hypothesis that sensation corresponds to subjective differences being equal. By one interpretation of what he meant, one is led to the family of functional equations, named Abel equations after the famous Norwegian mathematician N. H. Abel, $\eta[x+g(k,x)] - \eta(x) = h(k)$, where the variable x and the parameter k are in the set of nonnegative real numbers $\mathbb{R}_+$. For the special case of Weber's law where $g(k, x) = (k-1)x$, this equation reduces to $\eta(kx) - \eta(x) = h(k) = \eta(k) - \eta(1)$, i.e., with $\phi(z) = \eta(\exp z) - \eta(1)$, $k' = \log k$, $x' = \log x$, we have $\phi(k' + x') = \phi(k') + \phi(x')$, which if k' is treated as a variable is Cauchy's equation. The restriction of strict monotonicity yields $\eta(x) = a \ln x + b$, $a \neq 0$, b constants, as the solution. For references and a general discussion of closely related issue see Falmagne (1985, Chap. 4).

Sometimes a functional equation has multiple, qualitatively different solutions. Yet the scientist arriving at the functional equation has the strong intuition that only one of these solutions is really appropriate for the scientific problem in question. Whenever this happens, the challenge is to discover additional behavioral properties that seem to be empirically correct and that serve to isolate the desired solution. A reason for fully determining the several solutions is that the same functional equation may arise in an entirely different empirical context and, for that context, one of the previously unacceptable solutions may be appropriate. So the complete characterization is clearly of interest.

As will be seen, functional equations arise in the social sciences in at least three main ways. One occurs when one knows how to measure numerically the same attribute in two different ways, which is the case more often than not. Then the two measures are related by an unknown strictly increasing function. An empirical law linking the two underlying measurement structures manifests itself as an equation restricting that unknown function.

Functional equations also arise when some invariance condition holds. The Fechner hypothesis above is an example. Others are given later.

Economic aggregation problems are a third source of functional equations. Consistent aggregation both rules out some *ad hoc* aggregation functions and leads to families of functions that are indeed consistent. Despite the intuitive appeal of additive aggregation, that assumption is inconsistent with the most common production functions used in economics. Examples are given of production functions and of permissible aggregation rules.

1. Independent Measures of an Attribute

1.1 A Physical Example: Mass Measures

Consider mass measurement where one decides which of two objects x and y is more massive by observing which arm of an equal-arm beam balance drops (in a vacuum). This provides a mass ordering. One can construct a numerical measure m of mass, unique up to multiplication by a positive constant (ratio scale), by placing pairs of objects, denoted by $x \circ y$, on the pans. Under reasonable, empirically-testable assumptions m is additive over the operation of combining, i.e., $m(x \circ y) = m(x) + m(y)$. One can also construct a measure unique up to power transformations (log-interval scale) by varying the velocity of objects and determining which has greater momentum. Under empirically reasonable assumptions, the measure of momentum is multiplicative in powers of a mass and a velocity measure, i.e., $\alpha m'(x)^\beta v'(x)^\beta$, where $\alpha, \beta > 0$ but are otherwise unspecified. It can be shown that the two

measures m and m' preserve the same mass order, and so they must be related by a strictly increasing function ξ . A natural question is: What is the form of ξ ?

The following qualitative distribution property is empirically justified. Suppose (x, v) denotes the object x moving at velocity v and that $(x, v) \sim (x', v')$ means the two objects have the same momentum. Suppose also that $(y, v) \sim (y', v')$. Then, distribution asserts $(x \circ y, v) \sim (x' \circ y', v')$. This condition forces ξ to be multiplicative in the sense of satisfying $\xi(rs) = \xi(r)\xi(s)$, where the variables are real numbers with $r > 0, s > 0$. By setting $\xi = \exp \phi(\ln)$ we see from the strictly increasing solutions of the Cauchy equation that $\xi(r) = r^\beta$, $\beta > 0$. Thus, one mass measure is a power function of the other one. See Luce et al. (1990, p. 125).

1.2 Preferences Among Gambles

Something quite analogous occurs in studying people's preferences among uncertain alternatives, often called gambles. A binary gamble $(x, C; y, \bar{C})$ means that x is the consequence if event C occurs and y otherwise when a chance 'experiment' with possible outcomes $E = C \cup \bar{C}$ is conducted. The preference order over gambles, which is assumed to be connected and transitive, is denoted by $\succsim$. We assume there is a status quo e , and a consequence x is said to be a gain if $x \succsim e$ and a loss if $e \succsim x$. A well developed theory of preferences over gambles, which generalizes subjective expected utility (Savage 1954), was worked out during the 1980s (see Quiggin 1993). It establishes that under certain conditions a utility function U over gambles and a weighting function W over chance events exists such that for gains x, y , and $g = (x, C; y, \bar{C})$

$$U(g) = \begin{cases} U(x)W(C) + U(y)[1 - W(C)], & \text{if } x \succsim y \\ U(x)[1 - W(\bar{C})] + U(y)W(\bar{C}), & \text{if } x \precsim y \end{cases} \quad (1)$$

$U(g) = U[(x, C; y, \bar{C})]$ is usually written just as $U(x, C; y, \bar{C})$, which is a minor abuse of notation. Because we assume $x \sim (x, C; x, \bar{C})$, U on gambles is also on consequences as well. This representation is called rank-dependent utility because the weight used in the average depends upon the ordering of the consequences. The model can be extended to cover losses and mixed gains and losses, but we do not go into that here (see Luce 2000).

One can also consider having or receiving pairs of valued consequences and gambles. Suppose g and h are gambles (including, as special cases, pure consequences) and let $g \oplus h$ denote having or receiving both. This binary operation $\oplus$ is called joint receipt. Assume that the preference order $\succsim$ extends to the domain of joint receipts. It is plausible that, for gains, $\oplus$ and $\succsim$ satisfy the same formal properties as does mass where no change from the status quo, e , plays the

role of an identity. Thus, there is a real-valued 'value measure' V that preserves the order $\succsim$ and is additive over $\oplus$, i.e., $V(x \oplus y) = V(x) + V(y)$.

A natural question is: How do U and V relate? Luce and Fishburn (1991) considered the following linking hypothesis (or putative 'law') called segregation: For all gains x, y and events C

$$(x, C; e, \bar{C}) \oplus y \sim (x \oplus y, C; y, \bar{C}) \quad (2)$$

Note that both sides yield the same thing under the same conditions, so this is a highly rational property. If we introduce the notation $G(u, v) = U[U^{-1}(u) \oplus U^{-1}(v)]$ one can show that segregation implies that for $u = U(x)$, $v = U(y)$, $w = W(C)$ and $u \geq v$

$$G(uw, v) = G(u, v)w + v(1 - w) \quad (3)$$

For commutative the solution to this functional equation (Luce and Fishburn 1991) is that for some real δ

$$G(u, v) = u + v - \delta uv \quad (4)$$

From this equation one can show that U and V are related as follows. If $\delta = 0$, then $U = \alpha V$. If $\delta \neq 0$, then either $U_+ = 1 - e^{-\kappa V}$ or $U_+ = e^{\kappa V} - 1$, where $U_+(x) = |\delta|U(x)$, $x \succsim e$. Thus, if one knows how V depends on the consequences, then one knows up to a constant how U_+ does also. Conditions are given that determine the form of V over money and W over probability. [In like manner, a theory for losses is possible with constant δ' and $U_-(x) = |\delta'|U(x)$, $x \precsim e$.]

From these expressions and the additivity of V over $\oplus$ one can deduce formulas for the utility U over $\oplus$ and for gambles when the consequences are a gain and a loss. Some interesting non-bilinear expressions arise (Luce 2000).

Recently, Luce and A. A. J. Marley (summarized in Luce 2000) have suggested a generalized representation of binary gambles over gains, namely, for $x \succsim y \succsim e$,

$$\phi_0[(x, C; y, \bar{C})] = \phi_1[u_1(x)w_1(C)] + \phi_2[u_2(y)w_2(\bar{C})] \quad (5)$$

where $\phi_1(0) = \phi_2(0) = 0$. The ranked-additive decomposition in this form has been axiomatized by Wakker (1991, 1993) and the separability of u_1w_1 can be defended axiomatically for the first component (Luce 2000). Assume, as seems reasonable,

$$x \sim (x, E; y, \emptyset) \quad (6)$$

$$y \sim (x, \emptyset; y, E) \quad (7)$$

$$x \sim (x, C; x, \bar{C}) \quad (8)$$

where $\emptyset$ denotes the null event and E the universal one underlying the gamble. Then noting $w_1(E) = 1$, $w_2(\emptyset) = 0$, the first indifference yields $\phi_0(x) = \phi_1[u_1(x)]$. If we set $y = x$, $v = u_1(x)$, $w = w_1(C)$, $w_2(\bar{C})$

$= Q[w_1(C)] = Q(w)$, then the second of the above conditions implies $x \sim (x, \emptyset; x, E)$, and so $\varphi_1(v) = \varphi_0(x) = \varphi_2[u_2(x)]$ or rewriting $u_2(x) = \varphi_2^{-1}[\varphi_1(v)] = \psi(v)$. Thus, setting $\varphi = \varphi_1$ the third yields the functional equation

$$\varphi(v) = \varphi(vw) + \varphi(\psi^{-1}[\psi(v)Q(w)]), \quad v \in [0, k], w \in [0, 1] \quad (9)$$

where the unknown functions φ, ψ are strictly increasing, and Q is strictly decreasing. Aczél et al. (2001) have determined all solutions to this equation. From these results, Luce and Marley (see Luce 2000) showed the following utility representation: For $x \succcurlyeq y \succcurlyeq e$, there exist constants $c > 0$ and $\mu > -1/k^c$ such that

$$U(x, C; y, \bar{C}) = \frac{U(x)W(C) + U(y)[1 - W(C)] + \mu U(x)U(y)W(C)}{1 + \mu U(y)W(C)} \quad (10)$$

where $U = (u_1)^c$ and $W = (w_1)^c$. If, however, one supposes that segregation holds, then one can show that $\mu = 0$, which of course is just the rank-dependent model.

2. Invariance Principles

2.1 Value Function for Money

Section 1.2 left open the question of how V depends upon money. The most obvious assumption is that if x, y are sums of money, then $x \oplus y = x + y$. Thus, $V(x) + V(y) = V(x \oplus y) = V(x + y)$, which is Cauchy's equation. Because V is strictly increasing, V is thus proportional to money. Some empirical work suggests that, in general, this hypothesis may be too strong (Thaler 1985). An alternative assumption is that $\oplus$ is invariant under proportional changes in money, i.e., for any $\lambda > 0$,

$$x \oplus y \sim z \Rightarrow \lambda x \oplus \lambda y \sim \lambda z \quad (11)$$

Using the additivity of V ,

$$V^{-1}[V(\lambda x) + V(\lambda y)] = \lambda z = \lambda V^{-1}[V(x) + V(y)] \quad (12)$$

For $x, y \geq 0$, functional equation arguments lead, through multiplicative functions, to $V(x) = \alpha x^\beta$ and $x \oplus y = (x^\beta + y^\beta)^{1/\beta}$, for some $\alpha > 0, \beta > 0$. This result, combined with those of Sect. 1.2, gives U to within one additional free parameter β (note that κ of U_+ and α are not separately identifiable).

2.2 Prelec's Weighting Function

Section 1.2 also left open the question of the form of the weighting function W . When the gambles are

characterized in terms of probabilities $p = \Pr(C)$, much empirical work shows that in general for some p_0 in $]0, 1[$

$$W(p) \begin{cases} > p, & \text{if } 0 < p < p_0 \\ = p, & \text{if } p = p_0 \\ < p, & \text{if } p_0 < p < 1 \end{cases} \quad (13)$$

with W strictly increasing initially concave, and then convex. Such weighting functions are described as inverse S-shaped. Until Prelec (1998), suggestions of the mathematical form have not been derived from behavioral principles. He provided a somewhat complex behavioral invariance condition leading to $W(p) = \exp[-\gamma(-\ln p)^\alpha]$. Gonzalez and Wu (1999) showed that the Prelec form fits empirical data remarkably well. Not only is this function inverse S-shaped for $\alpha < 1$, but for $\alpha = 1$ it includes the 'rational' weighting function that arises from the conditions that gambles of the form $(x, p; 0)$ have a separable representation $U(x, p; 0) = U(x)W(p)$ and that $((x, p; 0), q; 0) \sim (x, pq; 0)$ holds.

Luce (cited in Luce 2000) gave a simpler condition, called reduction invariance, equivalent to Prelec's function which generalizes a property of the rational condition to the non-rational case: For all gains x and p, q, r in $[0, 1]$,

$$((x, p; 0), q; 0) \sim (x, r; 0) \text{ implies, for } N = 2, 3, \text{ that } ((x, p^N; 0), q^N; 0) \sim (x, r^N; 0) \quad (14)$$

From this, one first shows that the right side holds for N replaced by any real exponent $\lambda > 0$. Then, using separability, one arrives at the functional equation

$$(W^{-1}[W(p) + W(q)])^\lambda = r^\lambda = W^{-1}[W(p^\lambda) + W(q^\lambda)] \quad (15)$$

Note that with $V = \ln W(\exp)$, $x = \ln p, y = \ln q$ this reduces to the same functional equation as that for the value of money.

2.3 Additive Conjoint Weber Laws

Consider stimulus pairs (a, x) such as a tone of intensity a in a background noise of intensity x . Denote by $P(a, x; b, y)$ the probability that a subject perceives a in x more easily than b in y . Theoretical psychophysicists wish to understand the mathematical structure of such families of probabilities.

To do so, they explore various regularity or invariance conditions. For example, a homogeneity condition called a 'conjoint Weber law' assumes that for all real $\lambda > 0$

$$P(\lambda a, \lambda x; \lambda b, \lambda y) = P(a, x; b, y) \quad (16)$$

That is, the probability is invariant under multiplication of all four intensities by any positive number λ . A second important hypothesis is that of 'additive probability' in the following sense: There are con-

tinuous functions f strictly increasing, r strictly decreasing, and H strictly increasing in the first and strictly decreasing in the second variable such that

$$P(a, x; b, y) = H[f(a) + r(x), f(b) + r(y)] \quad (17)$$

In place of the last equation, Falmagne and G. Iverson (see Falmagne 1985, pp. 289–91) assumed the weaker condition

$$P(a, x; b, y) = H[q(a, x), g(b, y)] \quad (18)$$

of simple scalability where H is as above and g is strictly increasing in the first and strictly decreasing in the second variable, and the variable pairs (c, z) lie in subsets closed under multiplication by any $\lambda > 0$. They showed that then P must be of one of two forms:

$$P(a, x; b, y) = M \left[\frac{T(a/x)x}{T(b/y)y} \right] \quad (19)$$

or

$$P(a, x; b, y) = Q\left(\frac{a}{x}, \frac{b}{y}\right) \quad (20)$$

where $T > 0$, M , and Q are continuous, T and M are strictly increasing, and Q is strictly increasing in the first and strictly decreasing in the second variable.

In particular, they determined the form of all representations that are both additive and satisfy a conjoint Weber law as follows. The last equation when rewritten as

$$P(a, x; b, y) = Q(e^{\ln a - \ln x}, e^{\ln b - \ln y}) \quad (21)$$

is additive with

$$H(u, v) = Q(e^u, e^v), f(a) = \ln a, r(x) = -\ln x \quad (22)$$

The first homogeneous, simple scalable form is additive if and only if

$$M \left[\frac{T(a/x)x}{T(b/y)y} \right] = H[f(a) + r(x), f(b) + r(y)] \quad (23)$$

Holding $b = b_0$, $y = y_0$ constant and letting

$$K(t) = T \left[\frac{b_0}{y_0} \right] y_0 M^{-1}(H[t, f(b_0) + r(y_0)]) \quad (24)$$

we get

$$K[f(a) + r(x)] = T \left[\frac{a}{x} \right] x \quad (25)$$

Thus, for all $\lambda > 0$,

$$K[f(\lambda a) + r(\lambda x)] = \lambda K[f(a) + r(x)] \quad (26)$$

This functional equation and its method of solution is similar to but somewhat more complicated than those in Sects. 2.1 and 2.2. Moreover, it has two distinct sets of solutions:

$$f(a) = Aa^\beta + B, \quad r(x) = Cx^\beta + D \quad (27)$$

and

$$f(a) = A \ln a + B, \quad r(x) = C \ln x + D \quad (28)$$

Accordingly, for all homogeneous, additive, conjoint Weber laws, the probabilities are of one of the following three forms:

$$P(a, x; b, y) = Q \left(\frac{a}{x}, \frac{b}{y} \right) \quad (29)$$

$$P(a, x; b, y) = G \left(\frac{a^\beta + \gamma x^\beta}{b^\beta + \gamma y^\beta} \right) \quad (30)$$

$$P(a, x; b, y) = G \left(\frac{ax^\beta}{by^\beta} \right) \quad (31)$$

where Q is as above, G is continuous and strictly increasing, and $\beta > 0$, $\gamma \neq 0$ are constants.

Results of this character are useful both in understanding the implications of general invariance principles and in suggesting to experimentalists how to plot and analyse their data.

3. Aggregation

Consider an industry with m producers using n inputs. Denote by x_{jk} the amount of inputs k used by producer j . Let $y_j = F_j(x_{j1}, \dots, x_{jn})$ denote the output of producer j and $z_k = G_k(x_{1k}, \dots, x_{mk})$ denote the total consumption of input k . Consistent aggregation holds if there is a macro production function F and macro input function G such that

$$\begin{aligned} F(z_1, \dots, z_n) &= F[G_1(x_{11}, \dots, x_{m1}), \dots, G_n(x_{1n}, \dots, x_{mn})] \\ &= G[F_1(x_{11}, \dots, x_{1n}), \dots, F_m(x_{m1}, \dots, x_{mn})] \\ &= G(y_1, \dots, y_m) \end{aligned} \quad (32)$$

This equation is called $m \times n$ generalized bisymmetry. Although a full treatment deals with general domains (see, e.g., Aczél and Maksa 1996, Aczél 1997), here it is assumed that all of the variables and functions lie in the set of non-negative real numbers $\mathbb{R}_+$. Assuming

that all functions are strictly monotonic and continuous, Maksa (1999) has proved that there are continuous functions α_k , β_{jk} , γ_j , and φ , $j = 1, \dots, m$, $k = 1, \dots, n$ such that

$$F(z_1, \dots, z_n) = \varphi^{-1}[\alpha_1(z_1) + \dots + \alpha_n(z_n)] \quad (33)$$

$$F_j(x_{j1}, \dots, x_{jn}) = \gamma_j^{-1}[\beta_{j1}(x_{j1}) + \dots + \beta_{jn}(x_{jn})] \quad (34)$$

$$G(y_1, \dots, y_m) = \varphi^{-1}[\gamma_1(y_1) + \dots + \gamma_m(y_m)] \quad (35)$$

$$G_k(x_{1k}, \dots, x_{mk}) = \alpha_k^{-1}[\beta_{1k}(x_{1k}) + \dots + \beta_{mk}(x_{mk})] \quad (36)$$

Aggregation functions of this quasi-additive type had been obtained earlier, but under stronger regularity conditions (for a survey see Aczél 1997). Maksa's achievement was to get the same results under appreciably weaker conditions.

One way to interpret this result is that if the variables and functions are 'properly' measured, i.e., as $\varphi(F)$, $\varphi(G)$, $\gamma_j(F_j)$, $\alpha_k(G_k)$, $\alpha_k(z_k)$, $\beta_{jk}(x_{jk})$ and $\gamma_j(y_j)$, then aggregation is additive. This is, however, very different from assuming that the 'raw' inputs and outputs are related additively. Consider the following examples. Two commonly used production functions are the Cobb-Douglas (CD) function

$$F(z_1, \dots, z_n) = az_1^{c_1} z_2^{c_2} \dots z_n^{c_n}, \quad a, c_k > 0 \quad (37)$$

and the Constant Elasticity of Substitution (CES) Function

$$F(z_1, \dots, z_n) = (c_1 z_1^b + \dots + c_n z_n^b)^{1/b}, \quad c_k > 0, b \neq 0 \quad (38)$$

Aczél and Maksa (1996) have shown that if any one of the aggregation functions is simple addition at the level of the 'raw' inputs or outputs, then it is impossible for any production function to be either CD or CES with $b \neq 1$. This does not say that inputs (or outputs) cannot actually be additively aggregated. Rather, it says that such additive aggregation is not consistent with common and realistic production functions. (One can prove that it is consistent only with linear production functions.)

Another question addressed is: If the F_j functions are in some sense of the same form, does that dictate that the macro F is also of that form? This is called the representativeness problem. The answer depends upon exactly what one means by 'the same form.' In a trivial sense, the answer is 'Yes' since the F and F_j 's in the above quasi-additive solution have roughly the same structure. A somewhat more sophisticated answer is that it need not be so. For example, if all of the F_j are CD functions, then

$$\gamma_j(y) = \ln \left(\frac{y}{a_j} \right), \quad \beta_{jk}(x) = c_k \ln x \quad (39)$$

Or if they are all CES functions, then

$$\gamma_j(y) = y^b, \quad \beta_{jk}(x) = c_k x^b \quad (40)$$

Neither conclusion restricts φ and α_k in any way. Thus one may choose F to be CD or CES or neither.

So the general conclusion from solving the aggregation problem is that consistent and even representative aggregation is possible only for appropriately chosen functions. In general neither is possible if the aggregating functions are preselected in the 'wrong way.' The implications for the possibility of macro production models are considerable.

Related ideas and results concerning aggregation of probabilistic models of choice, with results for Luce's choice model as a special case, appear in Aczél et al. (1997).

4. Conclusions

For many static questions in the behavioral and social sciences, functional equations serve as a powerful tool in understanding theoretical constraints. Three types of constraint have been illustrated: (a) the linking of measurement structures that have a common qualitative attribute; (b) the imposition of invariance principles of various types of which three were illustrated; and (c) the question of whether one can aggregate over inputs and separately over industries and arrive at the same macro conclusion.

Functional Explanation: Philosophical Aspects

Functional explanation has received a great deal of philosophical attention in recent years, partly as a consequence of a surge of interest in the philosophy of biology, and partly as a consequence of attempts to make functions and functional explanation central to issues in the philosophy of psychology. In both of these areas there has been some controversy over what the correct account of functional explanation is, with the contending accounts splitting into two main camps. Both camps agree that functional explanation is dependent on an account of functions, but disagree on what the correct account is. Within evolutionary biology the favored view is that functions emerge over time as a consequence of evolutionary processes, so a certain feature of an organism will only have a function if it has a suitable history. The opposed view is that the operation of a system can be analyzed into the way in which parts of the system function to make the system behave in that manner. This version has many names, but is perhaps best known as a ‘systems’ or ‘Cummins’ account of functions and functional explanation, but it has also been called ‘causal-role’ functionalism. In what follows both of these views will be examined; in addition the controversy over what it is that functional explanations explain will be outlined.

1. Functions and Systems

The ‘systems’ account of functions takes as its starting point the fact of (biological) complexity and proposes to understand the complex functioning of a biological entity (or system) in terms of the working of its parts. The fact of complexity suggests that the systems are goal directed, and if this is taken for granted one can recover what is distinctive of many explanations in biology, that they invariably cite the effects of causes as explaining why the cause is there. It does this by specifying how a part of the system operates in the production of the aimed-at goal.

The best known account of how such an explanation operates is given by Cummins (1975, 1983). He distinguishes explanation of changes, which is done by ‘transition’ theories, from explanation of properties. Transition theories are suitable for explaining ‘What caused S to acquire P?’ whereas a property theory explains what it is for S to instantiate P. This is best done by constructing an analysis of S, such an analysis adverting to the properties of S’s components and their organization. So the kinetic theory of gases explains what it is for a gas to have temperature via an account of the properties of the molecules contained within the gas. Cummins calls the analysis of such a system compositional analysis: the analysis of a dispositional property being called functional analysis. The general claim is that in science the ascription of a function to something is to specify a capacity, such a capacity being identified by its role in enabling a system to operate in a certain manner. Thus, in biology the capacities of an organism are explained by analyzing them into a number of systems (circulatory, digestive, etc.), such systems having a particular task to perform. How these tasks get performed is in turn explained by functional analysis, such an analysis citing the capacities of parts of these systems. Such capacities are the functions of the parts, so we get the Cummins-style definition of function:

X functions as an *F* in *s* (or: the function of *X* in *s* is to *F*) relative to an analytical account *A* of *s*’s capacity to *G* just in case *X* is capable of *F*-ing in *s* and *A* appropriately and adequately accounts for *s*’s capacity to *G* by, in part, appealing to the capacity of *X* to *F* in *s* (Cummins 1975, p. 762).

This account clearly does not restrict the attribution of functions to biological organisms; one can recognize the attribution of this type of function to parts of societies within sociological and anthropological functionalism. Here the system was seen as a society or culture, and the parts were the subsocietal structures or the recurrent patterns of behavior, the function of which was to maintain the structural continuity of the whole. The fact that this account of functionality is applicable to any system has given rise to two criticisms of this approach, one seeing a problem in how to specify nonarbitrarily which behavior or capacity of the containing system is relevant for the

functional analysis to analyze, the second seeing a difficulty in producing a sufficiently determinate notion of a 'system' for which a functional analysis is appropriate. The problem is that the choice of both a capacity and a system may seem to depend upon our decisions in a way which could make the functional analysis of any capacity or system seem justifiable. The pertinent question here concerns the explanatory gain made by the appeal to functional analysis. There seems to be no explanatory pay-off in some cases where functional analysis may be applied. Take the 'system' which is my study, which includes as parts various items of furniture, books, and me. The property of the room that we want explained is its temperature. Say my presence in the study raises the temperature of the room by $1/2$ a degree. One does not gain any insight into the working of this system by attributing to me the function of enabling the room (the system) attain its present temperature.

Cummins was aware of this trivialization of functional analysis, and suggested constraints on the choice of a system and capacity that could be analyzed illuminatingly. One problem with the above analysis is that the capacity to be explained via functional analysis, the temperature of the room, is similar in kind and complexity to the property doing the explaining, my body temperature. One gets an explanatory pay-off when the analyzing property is both less complicated than, and different in kind from, the analysandum. This suggests the third constraint imposed by Cummins: one is not going to get a less sophisticated property doing all the explanatory work in showing how a complex system operates. The analysis will have to appeal to the operation of component parts and their properties, their combined action producing the complex behavior of the system. It is through the organization of interdependent parts that simplicity generates complexity, and functional analysis succeeds when it shows how this can be achieved.

The choice of system and capacity to be analyzed, then, is constrained: functional analysis will be applied fruitfully only to a complex system whose behavior is produced by the action of simpler but well organized parts. It is unsurprising, then, that the systems most often favored as exemplars of systems suitable for functional analysis are those that have been designed. The interdependence of the parts of such systems is often attained by careful planning. The second theory of functions that will now be examined focuses on this 'design' aspect of the systems to whose parts functions can be aptly attributed.

2. Functions and Selection

It is the improbability of complex systems existing by chance that suggests that such systems are generated by design, and so have parts which function so as to

produce the intended behavior of the system. With artifacts it is easy to see how functionality can be ascribed: the complex system is designed intentionally to have the capacity to produce certain effects, and the parts are chosen for their ability to contribute towards that goal. They are selected for that task. This type of functionality is derived from intentionality. The achievement of Darwin and Wallace was to provide a nonintentional explanation of how such complexity could originate, and they did this via the theory of natural selection. The major strength of the historical account of functions is that it ties attribution of functions to 'design' by natural (nonintentional) selection. The essential features of this account are dependent upon the idea that to attribute a function to an item is to say that the item has that feature or behavior because it has a certain history: in the past that feature produced certain consequences, those consequences themselves having the effect of reproducing items with that feature. It is this latter aspect which makes the account teleological. One can say that the item has the relevant property in order to produce those consequences. It is because of (some of) its effects that the item with this capacity is selected for. What the theory of natural selection does is make respectable the apparent purposefulness of the 'in order to.' It does this by showing how environmental pressures on variable items can produce varied reproduction of those items; those items with certain features will become more prevalent because those features have typical effects on the reproductive capacity of the items which bear them.

The long neck of the giraffe, to take a standard example, is an adaptation and has the function of enabling giraffes to eat the leaves at the top of tall trees. On the historical account, this capacity is the function of the long neck because previous giraffes whose genes produced longer necks than their contemporaries were better producers of offspring, and were so just because of the advantage conferred on those giraffes in the food wars. This results, in the long run, in more long-necked giraffes, until the giraffe is a long-necked species. Put as briefly and generally as possible, the etiological account says that functionality arises because some variants within a group (a mutant gene, for example) have novel features with capacities which are favourable to their possessors' ability to reproduce (i.e., more favourable than the nonpossession of those features by the other members of the group). Such features are transmitted to their descendants, proliferating within the group in the process. The feature of the organism will then, and only then, have as its function the exercise of the favorable capacity.

As with Cummins-style functions, this account of functionality is very general. It applies not just to biological entities, but to all items that have the required characteristics of:

- (a) variability in the items to be selected,

- (b) selection of some of those items, and
- (c) variable reproduction of the items selected for.

Selection cannot take place if there is no initial variation; the same selection forces operating on a homogeneous population will have no effect. For a cause to be there in order to produce certain effects it must also be the case that instances of properties with those causal powers have been selected in the past because they produced those effects. The selection process requires that the causal property interact with salient features of the environment in such a way that other items without that property are seen to 'suffer' some loss as a consequence of their non-possession of the property. Finally, it is because the favored properties are transmitted to descendants of the items having those features that the present items have these properties. Then it can be said that the property is, or was functional, its function being to produce those types of effects which lead to its ancestors reproducing items with the property in question.

As the giraffe example indicates, it is in its forging a connection between function and adaptation that the strength of this account resides. Adaptations are produced historically via the operation of natural selection, so they are functional. A creature may have a feature which renders it 'adapted' to its environment because it so happens that that feature will help it flourish in that environment, but such a feature, lacking the relevant selectionist history, will be adaptive for the creature, but not an adaptation. The historical (etiological) theory of functions claims that it is because adaptations are selected, not accidental, features of organisms that we are entitled to the use of functional explanation.

The historical and systems account of functions are not necessarily competitors. It has been seen that the systems for which functional analysis is appropriate are complex, with the analysis proceeding by showing how the operation of simpler, interdependent parts can produce the relevant capacity of the system. Such systems, it can be claimed, come into being either by intention or by selection, so functional analysis will be appropriately applied in just those cases where some design-mechanism is operating. On this view, functional analysis is an accessory to the historical theory of functions. There are, however, two aspects of the historical conception that render it significantly different from the systems version. The first is a consequence of what has been suggested above: it is probable that complex systems are generated by some design process, but it is not impossible for such a system to emerge by chance. For such a system, a functional analysis would still be appropriate, but the historical version of functions would disallow the attribution of any function to the system or its parts, these not having the appropriate history. Second, the historical theory has the ability to include malfunctions within its purview. On the systems account, if a part 'functions' so as to produce a system with a

different capacity from that expected, that part cannot be said to be malfunctioning. A functional analysis will proceed as usual, with the new capacity being analyzed, and the analysis showing just how it is produced given the nature of the contained parts, and their causal powers. On the historical conception, given a suitable account of reproduction, one can allow for mistakes to be made in the reproducing process, so that the items which are considered to be descendants of some common ancestor need not be perfect copies of that ancestor, and in particular may not have the causal powers for which items of that type have been selected previously. The item may then not do what it is supposed to do—it may malfunction. To appreciate this better, and to make manifest the power of the explanations which the historical theory makes available, that theory needs to be fleshed out in more detail.

3. *Elaborations: Malfunction and Novelty*

An essential aspect of the historical account is that a function results from selection operating over a period of time on items that are descended from each other. What is it to be descended in the relevant sense? Initially one may think in terms of copying, one item being a descendant of another if it is an exact copy of the former, and is so as a result of some law-like process that ensures that such a replica is forthcoming. This is too strict a definition: for one thing, it would be impossible to provide a decent conception of a malfunctioning device if all descendants had to be exact copies of their ancestors. A malfunction involves some mistake, so a device that malfunctions will not be an exact copy of a properly functioning device. One has to allow for an item being a descendant of another even though the copying process is not perfect. One way of making what is involved more precise is due to Millikan (1984, 1993), and it goes like this: individual A is a reproduction of individual B if and only if B has some determinate properties in common with A, and this correlation of properties can be explained by a natural law operating in that environment. These common properties are the reproductively established properties of B, and the devices sharing these properties form reproductively established families (refs.). (Only first order refs. reproduce in this manner. Higher order refs. (horefs.) are produced by first-order refs. My and my ancestors' two-leggedness is the result of common genes, such genes being first-order refs. They have certain properties in common, this being ensured by the laws of genetic inheritance.) Direct proper functions are functions of devices that are members of refs. or horefs.

So how do we get malfunctioning members of refs. or horefs? Millikan suggests that a malfunctioning member of a ref. can be produced provided it has been produced by a device the proper function of which is to produce members of the ref. in question, that it is in

some aspects similar to other members of the ref., and that its production has an explanation which approximates (in some undefined degree) to a normal explanation for the production of members of the ref. Because a particular reproductive process need only approximate the 'perfect' reproductive process it can produce imperfect copies, ones which malfunction.

The historical theory's emphasis on the role of reproduction and selection has given rise to the thought that functional explanation, construed in this way, cannot explain novel behavior. On the historical account it is inheritance from past (selected for) patterns of behavior that gives rise to the present functional behavior. However, to suppose that novel behavior cannot be produced by something whose function it is to produce that behavior is to underestimate the variety of functions. Millikan notes that there can be a relational proper function, which is a function to do something bearing a certain relation to something else. The chameleon's skin-color mechanism has the relational function of making the chameleon's skin match that of its environment (whatever that color may be). Given a specific color to adapt to, the mechanism then acquires an adapted proper function. So when it's sitting on a brown plant the adapted proper function of the device is to produce brown skin. Crucial here is that the brown skin may have never been produced before, so it is not a member of a ref., and the production of it is not a direct proper function of the device. That to which an adapted device adapts is its adaptor (the brown plant being the adaptor in this case). One can extend this picture to include the functions of those who may be consumers of the output of an adapted function. Consider the dance of the bees which acts as a signal to other bees, 'telling' them to go southeast, where the nectar is to be found. This dance is adapted to the location of the nectar, so has an adapted function. The response it calls forth, the flight of the bees to the southeast, is adapted to this adapted function. It is not a short step to extend this approach to the communicative linguistic and other cultural capacities of human beings. Complications abound, but the fundamentals for doing this are in place. For the extension to be seen as a realistic prospect, two important features of these extensions of the historical approach need to be noted. The first is that functional explanation includes a normative aspect: a functional property is there in order to produce an effect, the effect being one it ought to cause, given that the property is instantiated here because past instantiations have produced that effect. Malfunctioning items are not doing what they ought to do. The extent to which functional explanation can account for psychological and sociocultural properties is partly dependent upon whether the normativity intrinsic to these latter properties can be explicated by the norms of functional explanation.

The second is that the above extensions indicate the explanatory reach of that theory. Any items (including

patterns of behavior (e.g., rituals), social structures, ideas, 'memes'), can be the bearer of functions, provided that the basic conditions for this are met: variety, selection, varied reproduction. The reproduction need not be gene-centered, nor even broadly 'biological.' The transmission of bodies of knowledge and ways of behaving across generations is a form of reproduction, and so these items are possible bearers of functional properties. Whether they are or not depends on whether selection operates on these reproduced items, and here it is important to note that selection can take many forms. As behaviorists emphasized, behavior can be molded by painful experience, so pain is one selector. Emotional experience can be another. These have been called 'vicarious' or 'secondary' selectors (Campbell 1960), indicating that they themselves have been selected for by natural selection, their purpose being to be local, less severe eradicators of those types of behavior that are inimical to the flourishing of the organisms which produce the behavior. Given that reproduction and selection can be ubiquitous, it would appear that functional explanation has a much wider reach than once thought.

There have, though, been suggestions both that the explanatory scope of functional explanation has become too broad, that it is being abused by those who tend to see functionality everywhere, and that it is too narrow, not encompassing explanations of items which have no past history of selection, but are nevertheless beneficial to the organism. In the next section these criticisms of the historical theory are reviewed.

4. Difficulties and Additions

4.1 Panglossianism

The etiological theory is supposed to explain the persistence and spread of a trait in terms of its adaptive history, such explanations involving historical claims as to why the feature being explained was adaptive, and then tying this adaptation to its present function. At times it is extremely difficult to trace the relevant history, and the temptation is to ascribe functionality anyway, with the hope that the historical detail will be forthcoming. This has led to the accusation that such explanations are 'Panglossian,' presuming that this world is the 'biological best' world, one in which all features of organisms have some function or other (see Gould and Lewontin 1978). This accusation is particularly relevant to the sociobiological explanations of psychological and social behaviors, as the relevant history supporting these explanations is often unknown. The complaint is a welcome caution against epistemologically unconstrained attributions of function, but does not attack the heart of the historical theory. It simply warns against its abuse.

4.2 *Exaptations*

A related worry about attributing functions incorrectly, also voiced by Gould (Gould and Vrba 1982), concerns a trait that may be adaptive for one reason, but then change function in mid-stream, either doubling up in its functions or (because of environmental change maybe) sloughing off the old function in favor of the new, without any change of structure. Now the present persistence of the trait cannot be explained via its previous adaptive history, as that would give a misleading account of its present function. Such a change in function has been called an exaptation. An example of such an exaptation is the wing feathers of birds, the function of which we now think is to enable birds to fly. A selectionist story, however, would have to say that their function was as a thermal regulator, as that is what they were selected for originally. Clearly some complication of the original selectionist theory is called for, but the complications are hardly unexpected. Causal explanation and accounts of causality in general have difficulties dealing with causal overdetermination, and what we have in the above examples is functional overdetermination. What we need to say, in the functional case, is that the functions of an item are those fitness enhancing effects which advantage (or advantaged) the bearer of the item relative to rivals, and which have been reproduced differentially in the relevant population. With the change of function of feathers from thermal regulation to flight, the stage at which some feathers produced a flight-response would be critical in noting the acquisition of the new function. As soon as the feathered and flighted birds became preponderant, then one can say that the feathers had acquired a new function.

4.3 *Dispositional and Virtual Selection*

Once one notes that selection can be recent, a question arises as to how recent selection can be for functionality to be correctly attributed. To some extent the answer will be vague; there seems no exact stage at which one can say: before now there was no function, but now there is. But given that selection can be recent, a natural suggestion will be that present selection suffices for functionality. The radical proposal is that history can be irrelevant, that the essential component in the historical theory is the contribution of a feature to the reproductive success of the item possessing that feature, and that a trait without any history of selection can be seen to be useful for its possessor in the precise sense of making a (future, or possible) positive contribution to the survival or reproductive capacity of the organism. This 'dispositional' or 'virtual' selectionism involves the recognition that selection does play some role in the attribution of functionality, but it need not be actual selection. Differential reproduction need not have taken place. On this

account, a trait is functional because of its potential contribution to the fitness of the organism possessing the trait, given the environment in which the organism operates.

A weak version of this view can be developed by requiring the environment to engage actively with the trait, so that the trait can be seen to contribute positively to the organism's fitness. On this view, suitably developed, the trait is seen as being currently under a selection pressure. That is, it is seen as potentially contributing to the differential reproduction of those organisms with the trait, where 'potentially' only means 'barring accidents, it will contribute to the differential reproduction of those organisms.' So the weak view agrees with the historical view in all respects except that it allows for functionality prior to differential reproduction. The stronger interpretation does not require actual engagement with the selection-relevant environment; it only requires that there are factors present in the environment that could influence the organism's chances of reproduction and survival.

The crucial question facing these amendments to the historical theory is: what is the advantage in using the notion of function here? What does it add to a simple nonfunctional causal explanation of what is happening? On the historical view, part of the distinctive force of functional explanations derives from the normative elements implicated in attributions of function, the idea that the functional trait is there in order to do something. The selectionist story, cashed out in terms of differential reproduction, makes this normativity naturalistically respectable. Without the selection occurring, this distinctive feature of functional attribution is threatened.

It is clear that these accounts cannot give any functional explanation for the existence, proliferation, or shape of the trait. Take the first generation of long-necked giraffes. The existence of the long-necks (their proliferation) cannot be given an explanation relating to the reproductively beneficial effect which the long necks have had in the past. The only explanation seems to be a straightforward causal explanation in terms of mutations. A suggestion is that one change the explanandum, which is what Pettit (1996) does in his advocacy of virtual selection. The idea is that there can be an explanation of a fact that is not an explanation of its existence or actual persistence, but an explanation of why it would persist in certain nonactual conditions, an explanation of its resilience. This would be an explanation of the robustness of the fact under various hypothesized circumstances. An example given is that of equilibrium explanation, where the explanation of, say, a certain ratio of prey to predator in a given environment need not explain why this ratio (which is in fact an equilibrium) has come about—why it exists—but why, if disturbing influences were brought to bear upon it, it would return eventually to this ratio. It is in this sense that the

resilience of the pattern is being explained. With functional explanation, the thought is that the absence of the operation of the function, the absence of the 'good' effect, may itself initiate certain mechanisms or processes that will reinstate the function's effect. So independently of how the trait performing the function emerged or proliferated, so long as it has this modal property of being re-instatable (in certain conditions) when disturbed, then the attribution of function will be in order. There will be something for that attribution to explain: namely the resilience of the pattern.

The problem for the advocate of functions here is that a normal causal story (perhaps one with feedback built into it) seems adequate to the task of explaining what is going on. The notion of function adds nothing, or at least, the plausibility it has derives only from the systems idea of functions. There is a system here which works so as to maintain an item, or a pattern of behavior, and any subsystemic processes which work so as to maintain the item or behavior 'functions' to that end. There is nothing more that functional explanation does here, and this notion of functional explanation does not have the distinctive normative character that the historical account imparts to functionality.

4.4 The Explanandum

There is some debate about what it is that a functional explanation explains. One suggestion is that, given selection only 'chooses' among the traits which are in existence, favoring some at the expense of others, all it can explain is why there are (so many) items with that feature. The proposal is that selection can not explain how individuals come to have the traits that they do have. The explanation for the traits possessed by any individual would be simply the causal story instantiated in the genetic processes that produced the trait in that individual. Sober (1984) called this latter type of explanation developmental explanation, and the good point he was making was that selection operates on traits already in existence.

One can accept this point, though, and still deny that all that functional explanation can explain is the very general fact concerning the proliferation rates of the causally explained traits. Neander has pointed out that that each such trait will have an evolutionary history, the elaboration of which will show how the trait came to have the form it now has (Neander 1995). Given the falsity of saltationist doctrines, traits such as opposable thumbs or long necks did not emerge fully fledged; there were many mutations, and those which increased, say, opposable thumbness were favored. A restriction to looking at 'selection of pre-existing traits' has almost an air of saltationism about it. It is as though the traits came into existence formed as they now are, and were then selected for on that basis. Ignoring the more gradual, at times almost imperceptible, changes that took place in order to arrive at

the present trait is to ignore a part of the explanation as to why the trait is what it is. It is because functions can be performed by different mechanisms that attending to the historical detail is important in showing how and why this mechanism evolved into its present form. The central point is that although selection does only distribute characteristics, the history of successive distributions shows selection as also molding those characteristics. It is then possible to explain not only why people with thumbs were selected, but also the shape of the thumb, by citing facts about the shapes of its predecessors.

G. Macdonald

Functionalism, History of

Functionalism is a method of sociological analysis which has its roots in nineteenth-century social thought. It originated from the application of methods from biology, the rising science at that time, to the analysis of society. Three features are characteristic of

this orientation toward biology: society is more or less strictly conceived as an organism; its development is understood as an evolutionary process; special attention is given to the relationship between the parts and the whole constituted by them, particularly to functions which have to be fulfilled by the parts for the working of the whole. The parts are institutions such as forms of family life, economic production, government and religion as well as the organizational embodiments of such institutions: families, enterprises, governmental bodies, and churches. The institutions are binding rules which regulate the activities and relationships between people. The functions are, for example, biological reproduction for the family, generating resources and allocating them to needs for economic production, binding decisions for the collectivity for the government or the production of meaning for religion. It is assumed that, for its simple continuation, society needs the subserving of such functions by institutions and their organizational embodiments.

1. *Origins of Functionalism: Auguste Comte and Herbert Spencer*

It was the fundamental change from traditional agrarian to modern industrial society which constituted the background for the rise of functionalism in nineteenth century social thought, particularly in the work of Auguste Comte and Herbert Spencer. Comte (1830–42/1969) carried on the system developed by his former teacher, Saint-Simon, from whom he separated after having served him in his younger years. In his *Social Statics*, Comte conceived of society as a whole which, in its ideal state, is kept in perfect harmony by the balanced contribution of its constituent parts to its working in the process of fulfilling their specific functions. In his *Social Dynamics*, he conceptualized social change as an evolutionary process from lower to higher forms of societal organization. Because he expected science to bring about the perfect organization of social life in its final stage in modernity, he couched the evolutionary process in terms of the evolution of thinking from the theological to the metaphysical to the positive stage shaped by 'positive' science.

The other major source of functionalism in nineteenth century social thought next to Comte is Herbert Spencer (1909). Though he shared the adoption of biological and evolutionary thought with Comte, he demarcated his approach explicitly from Comte's by conceiving society and social development not as a matter of ideas, but as a matter of the objective things, namely the behavior of human individuals. The major process in the development of society is differentiation; functions become more numerous and the tendency is a function that is fulfilled by one specific institution specialized in it. The more society grows in size, the

more differentiated will be its functions and corresponding institutions. The first differentiation occurs between regulative, sustaining, and distributive functions. The corresponding institutions are government, economy, and the infrastructure of channels for transport and communication. With the differentiation of functions and institutions, society works like higher organisms, it becomes more heterogeneous, definite in the demarcation of institutions, and integrated; group life is transformed from the coexistence of groups with the same structure without coherence between them (families, clans) to greater heterogeneity but also greater coherence between groups. The evolution of social life goes from incoherent homogeneity to coherent heterogeneity in the process of specialization and growing division of labor (see *Evolutionism, Including Social Darwinism*).

2. *The Classical Framing of Functionalism: Emile Durkheim*

Among the great classical founders of sociology at the turn of the nineteenth to the twentieth century, it is Emile Durkheim (1893/1973a, 1897/1973b, 1912/1968) who was most influenced by Comte and Spencer and who made a distinctive contribution to functionalism as a method of sociological analysis. From Comte he borrowed the holistic view of society, from Spencer the idea that the growing division of labor is a core feature of social evolution. In his *Rules of the Sociological Method*, Durkheim made a clear distinction between functional and causal analysis and a clear statement that every functional analysis needs to be complemented by causal analysis. He argues that the utility of an institution in serving a need for individuals or in performing a function for society does not suffice to explain its existence.

In his study on *The Division of Labor in Society*, Durkheim points out that specialization and division of labor are tools for the self-preservation of the individual and the society and for integrating society. They help to overcome the struggle for scarce resources. This struggle is caused by the increasing material and dynamic density that results from population growth and the extending as well as denser weaving of ways and means of transport and communication. Nevertheless, serving self-preservation and social integration do not produce specialization and the division of labor by themselves. In Durkheim's eyes, this functional explanation of specialization and division of labor needs a complementation by causal analysis. In doing so, he looks for forces which lead the selection of behavior and individuals in the direction of increasing labor division. He says that emigration, suicide, and crime would have been other possible solutions of the problem besides labor division. He explains the fact that they have not been selected to the same extent by the greater resistance called for by

them. The bonds to one's home country work against emigration, the bonds to one's life against suicide, the sympathy for our fellows prevents us from committing a crime. They are on average stronger and more resistant feelings than the habits which could prevent us from further specialization. The latter had to give way to the pressure toward specialization. In doing so, Durkheim points out the 'functional equivalents' which would serve self-preservation and then gives answers to the question as to the forces which lead human behavior in the direction of one of them. This is his complementation of functional analysis by causal explanation in his study on the division of labor.

In his later work on *The Elementary Forms of Religious Life*, Durkheim draws on anthropological studies on Australian aborigines. Here he makes use of his idea of the circular link between cause and functional effect in the study of ritual practices in which the sacred is strengthened in distinction to the profane and in which the community is regularly becoming conscious of itself. We have another circular link here. People gather because they want to influence the demonic powers positively for practical reasons of a good harvest or hunt, their willingness to come together is, however, supported by their feeling of belongingness and solidarity, which is again strengthened by the ritual itself.

3. *A Paradigm of Functional Analysis: Robert K. Merton*

Durkheim's analysis of tribal societies was continued in the anthropological study of tribal societies, particularly by the leading British anthropologists, Alfred R. Radcliffe-Brown and Bronislaw Malinowski. According to Malinowski (1948), every social phenomenon has to be explained by an indispensable function it fulfills not only for the whole of society, but also for the human individual: biological needs for food, shelter, and reproduction, psychological needs for support, needs for maintaining culture and social organization. Institutions of exchange, decision-making, social control, and education should be explained by such functions. Radcliffe-Brown (1952) criticized Malinowski's emphatic functionalism and preferred to call his approach structuralism. He did not accept the presumption that every social phenomenon exists because of a necessary function it fulfills. In his view, the unity of society was not a postulate claimed for every society, but a hypothesis which allowed a functional explanation of a social phenomenon by its contribution to the persistence of society. One of his examples is the explanation of lineage systems by the fact that they help to avoid conflicts about property rights after the death of property holders and thus contribute to the maintenance of solidarity. It is obvious that such an explanation is nevertheless insufficient in the light of

Durkheim's methodological objections against purely functional explanations.

At this point, it is quite reasonable to turn to the detailed methodological analysis of functionalism contributed by Robert K. Merton (1949/1968) in his paradigm of functional analysis. Merton points out three postulates of functionalism, which all have to be doubted in his eyes. (a) Functional unity postulates that society is one consistent whole and every phenomenon contributes to its working and that there is no division of society into parts with conflicting needs. (b) Universal functionalism postulates that every social phenomenon performs a positive function for the whole of society. (c) Functional indispensability postulates that every social phenomenon performs an indispensable function for the whole of society and cannot be replaced by some other phenomenon. Merton says that all three postulates are unfulfilled by concrete societies, particularly by modern societies, so that functional explanations of social phenomena cannot be based on them.

Instead, Merton introduced a more realistic paradigm of functional analysis with a set of 12 requirements. (a) Only standardized social phenomena like institutions should be analyzed with regard to their functions. (b) Subjective dispositions of actors and objective consequences of their action in social practices should be outlined and distinguished. (c) Positive, negative (dysfunctional) and neutral effects of standardized practices should be discerned. (d) The units for which an item fulfills a function have to be exactly determined. (e) The functional requirements for maintaining a system have to be denoted. (f) The mechanism of their fulfillment must be specified. (g) The functional alternatives have to be enumerated. (h) The structural context needs description regarding the narrowing down of space for functional alternatives. (i) Dysfunctions have to be detected and analyzed with regard to effecting stress and strain with resulting pressures for change. (j) The functional explanations should be validated in comparative research. (k) Functional analysis must be neutral in ideological terms. (l) Functional analysis of a social practice needs to include; (i) the location of participants in the social structure; (ii) alternative modes of behavior excluded by the pattern; (iii) the emotive and cognitive meaning of the pattern for the participants; (iv) a distinction between motivation and objective behavior; (v) behavioral regularities that are part of the pattern but are not recognized by the participants.

A good example of Merton's idea is his functional explanation of the political machine by the various needs it fulfills for the whole of society and for a variety of groups. As an informal network with a boss at its head, it concentrates power and thus makes political decisions possible in the American political system of checks and balances; it also serves as a vehicle for helping the poor and weak, legitimate and illegitimate business, and provides channels for

upward mobility. Thus the political machine becomes stabilized because—according to Merton's requirement—the positive functions outweigh the dysfunctions by far.

4. *Functional Prerequisites and Social Stratification: Aberle et al., Davis and Moore*

In the 1940s and 1950s, functionalism achieved the dominant paradigm of sociological analysis under the name of 'structural functionalism.' The investigative strategy of structural functionalism was the discovery of the functions which have to be fulfilled in order to secure the survival of society and the discovery of the corresponding structures serving these functions (Aberle et al. 1950/1967). Another representative contribution to structural functionalism is the functional theory of social stratification outlined by Kingsley Davis and Wilbert E. Moore (1945) in their much debated article 'Some Principles of Social Stratification' published in the *American Sociological Review* in 1945. Davis and Moore argue that every society needs a system of social stratification for the following reasons. (a) The members of the society share common views on the importance of a certain position needed for the provision of public and private goods and services. (b) To perform the corresponding roles, more or less talent, training and/or effort is required. (c) Thus, positions can be more or less important, the personnel needed for filling the positions more or less scarce. In order to fill the positions there must be a differentiation of rewards in terms of money or prestige according to the importance of the position and the scarcity of the personnel available. The greater the importance and scarcity, the greater the reward. The result is that positions are always stratified. The representative criticism of this functional theory of stratification was formulated by Melvin M. Tumin (1953) in an article published in the *American Sociological Review* eight years later, in 1953. It is couched in terms of conflict theory: the class structure is based on the power of the dominant class, which defines the importance of positions; its major effect is the differentiation of access to the higher positions according to socialization advantages and training of the offspring originating from the dominant class. Rather than contributing to the working and integration of society, the stratification system has disruptive effects so that society is not stabilized by value consensus and stratification, but by the application of power.

5. *Functionalism as an Attempt at Synthesis: from Talcott Parsons' Structural Functionalism to Neofunctionalism*

Five years earlier than Davis and Moore, in 1940, Talcott Parsons published another functional theory

of social stratification, which he revised twice, in 1954 and 1975 (Parsons 1954a, 1954b, 1977). In the perspective developed by Parsons, social stratification has to be explained by the interaction of dynamic and controlling forces of action, interests, and power on the one hand, and solidarities and cultural values on the other. Interests and power determine the access to positions and the enforcement of positional differences and outcomes; particularistic solidarities of family and lineage explain the inertia of class structures because of the tendency of families to secure their offspring remaining in the same class position. The *legitimacy* of the stratification system in distinction to its factual production and reproduction is, however, an effect of the consensus on a grading scale according to which prestige is attributed to positions. Only in as much as such a consensus on a grading scale is achieved will the system of stratification be accepted as legitimate. Otherwise, the definition of the importance of positions and the access to them will be a matter of the war of all against all. In general terms, this is the problem of double contingency.

Other than Merton's deliberate plea for empirical middle range theories, Parsons' program was analytical grand theory. Merton stood for empirical functionalism, Parsons for analytical functionalism (Parsons 1951). He introduced his four-function paradigm as an analytical instrument of analyzing structures as well as dynamic processes with regard to abstract functions (Parsons 1966, 1967, 1978, Parsons and Smelser 1956). By cross-tabulating the instrumental/consummatory and the internal/external orientation of action, he defined four abstract functions: instrumental/external: adaptation (A); consummatory/external: goal attainment (G); consummatory/internal: integration (I); instrumental/internal: latent pattern maintenance (L). For further differentiation, Parsons distinguishes three levels of applying the four-function scheme: social system: economic (A), political (G), community (I), fiduciary (L) system; general action system: behavioral (A), personality (G), social (I), and cultural (L) system; human condition: physico-chemical (A), organic (G), action (I), and telic (L) system. Further differentiation results from the application of the scheme to one of the subsystems. After having developed an analytical action theory in his first work of 1937, *The Structure of Social Action* (Parsons 1937/1968), Parsons established structural functionalism as a link between analytical functionalism and systems theory in *The Social System* in the early 1950s, and extended that link with the introduction of his theory of generalized media of interchange (money (A), political power (G), influence (I) and value-commitments (L) for the social system) and his theory of evolution as instruments for the analysis of dynamic processes of inflation and deflation and social change in the 1960s. With his turn to functionalism, systems, media, and evolutionary theory he did, however, not give up the core position

of his early action theory: the idea that social order emerges from the interaction between controlling and dynamizing forces. In his systems theory, he couched this idea in the double cybernetic hierarchy of conditions and controls. From L to A energy and dynamics in the system increase, while information and control decrease, and vice versa.

Looking at one analytical level, the social system, this system is composed of subsystems which fulfill their specific functions (A G I L) with specific structures (markets A, authority G, association I, and communication L) and specific media of interchange. They build an inter-related set of systems with in- and output processes of factors and products processed by the circulation of the media from one system to the other (interpenetration). Crises in the working of the systems can be analyzed as inflation–deflation spirals of the media involved.

In his theory of evolution, Parsons tries to point out the evolutionary advantage of specific institutions. Religion, communication by language, social organization through kinship, and technology are the first conditions of building human societies. A breakthrough to higher forms of social organization is realized by social stratification according to prestige based on achievement instead of ascription by origin. The rigidity of kinship systems is pushed back in this way. A further step forward is the replacement of tradition by cultural legitimation through general values. The developmental stage of a modern society is realized by the establishment of bureaucratic organizations, markets and money, universalistic norms, and democratic association. In two volumes, he outlines the evolutionary process in four dimensions according to his AGIL scheme: A adaptive upgrading, G structural differentiation, I inclusion and L value generalization.

Evolutionary achievements require breakthroughs in all four dimensions. He points out such breakthroughs in his analysis of primitive societies, archaic societies (Egypt and Mesopotamia), intermediate historic empires (China, India, Islamic, and Roman empires), seedbed societies (Israel, Greece) and, finally, the system of modern societies from ancient cultural roots via the Renaissance and the Reformation to the Enlightenment and the building of modern citizenship, state, and capitalism. The major modern breakthroughs are the industrial, the democratic, the educational, and eventually the 'expressive' revolution of the 1960s and 1970s (Parsons 1966, 1967, 1971).

According to his position that social order always has to reside in some form of consensus and solidarity in order to avoid an unlimited power struggle, Parsons lays special emphasis on the development of citizenship as a core of a modern 'societal community.' It is a modern form of community which has the greatest potential for inclusion, it associates people of the most varied ethnic and cultural origins. In this respect, it is

the cornerstone of modern social organization. He sees the society of the United States farther developed in this respect than the ethnically more homogeneous European welfare states. The modern community of citizens is the core which is complemented by a capitalist economy, democratic government, and universalistic institutions of education, science, professional work, and voluntary religious association. This is the abstract path of sociocultural evolution, which has to be distinguished from concrete historical development that can more or less deviate from this path. There is particularly always the danger of fundamentalist movements against modernity, which originate from the severe tensions caused by the evolution of modern forms of social organization. For Parsons, fascism as well as communism were such fundamentalist reactions to modernity, which have, however, no chance of long-enduring stabilization in his eyes. Therefore, he expected that the Soviet system would crumble some time, an expectation grounded in 'abstract' evolutionary theory which turned out to be very 'realistic' eventually.

The dominant role played by Parsonian functionalism in the 1950s provoked countermovements which concentrated mostly on some particular aspect of social organization, which was relativized within the very general Parsonian scheme. The need for revitalizing the Parsonian approach has called for a new movement, which aims at continuing with the general program of Parsons on the contemporary level of development. This is the movement of neofunctionalism which arose in the 1980s. Neofunctionalism tries to advance the Parsonian legacy by way of learning from new developments in social theory and social research, for example, from advancements provided by Clifford Geertz or Jürgen Habermas. This new movement has contributed fresh interpretations of Parsons' work along with a new reading of the classics, studies on civil society and public discourse, on the evolution of the culture of modernity, on communication society, European integration and globalization (Alexander 1982/83, 1998, Münch 1982, 1998).

6. Functionalism and Modern Systems Theory: Niklas Luhmann

A comprehensive renewal of functionalism has been undertaken by Niklas Luhmann (1970, 1984, 1997). He, too, combines functionalism with systems, media, and evolutionary theory. In his early phase of theory building, Luhmann introduced a turn from structural-functional to functional-structural systems theory. To justify this turn, he claims that the question of function has to be posed in a more fundamental way. Before we ask for the structures of systems which have to fulfill certain functions, we should raise the question as to which function is served by systems-building as such.

What is the problem solved by systems building? This is how he asks his question. His answer is: world complexity which needs reduction so that it can be handled. Systems just perform this function of reducing world complexity.

In his second phase of theory building, Luhmann undertook another turn of his functionalist systems theory: the conceptualization of social systems as autopoietic, self-referential systems. Because there is always the danger of too much complexity, the major problem is systems building and the continued maintenance of systems boundaries, which are boundaries of meaning. Autopoiesis is a form of systemic operation which guarantees the maintenance of boundaries and, at the same time, allows for maximum absorption of environmental complexity. An autopoietic system is operationally closed, but open to any kind of complexity in the environment. Operational closure is guaranteed by a binary code according to which any kind of environmental complexity is processed. The concrete processing is organized by a system's program. Special links to other systems in the environment are stabilized by structural coupling. Generalized media of communication allow for most flexible forms of systemic processing: money, power, law, love, for example. Social systems are built up by communication, they originate from that and continue to exist as long as communication takes place according to the established code. Communication consists of three elements: information, message, and interpretation.

An autopoietic system produces and reproduces all its elements—communication—by itself, that is by systemic communication, but it makes use of environmental complexity. It does not take inputs from the environment to transform them into outputs, but receives impulses from the environment to which it shows more or less response. The system observes events in the environment and absorbs them according to its own code and program. Problems of maladaptation to the environment can be discovered by second-order observation, that is, self-observation and self-description.

Luhmann distinguishes three levels of social systems: interaction systems, organizational systems, and societal systems. According to his theory of evolution, more complex societal systems evolve by variation, selection, and stabilization. There are three (later four) stages of societal evolution which are defined by the form of differentiation of systems: segmentary, estate (later: center/periphery), and functional differentiation.

Modern societies are functionally differentiated and no longer have a center. The economic, political, legal, science, educational, arts systems are more and more differentiated on a world scale and thus transcend their centering around a societal community and/or a state. Thus the nation-state societies are transitional stages on the way to world society. Paying vs. not paying, having power vs. having no power, right vs.

wrong, true vs. false are the binary codes of the economy, polity, law, and science systems. The evolutionary process works toward the establishment of functionally differentiated systems on a world scale, which are linked by structural coupling and by mutually stabilizing co-evolution.

7. Future Need for Functionalism

The question finally is: what will be the future of functionalism after its renewal by neofunctionalism and by Luhmann's functionalist systems theory? Whatever the movements against functionalism have contributed to our knowledge, we cannot say that they can replace the insights of functionalism completely. They have merely emphasized some particular aspect of social reality and some particular question. But they did neither raise nor answer the questions posed by functionalism from Comte and Spencer to Parsons and Luhmann. Because their questions are still legitimate, there is still a place for functionalist theorizing, whatever form it might take in the future.

Functionalism in Anthropology

In its simplest common-sense form functionalism in anthropology describes approaches which purport to explain cultural or social phenomena in terms of the purpose they serve.

Since the 1960s, specialized research into the sociological and historical framing of anthropology has revealed the extent to which discussions of functionalism contribute to analysis of knowledge as culture. As yet, however, it falls short of meeting the criticism that it tends to treat the discipline of

anthropology as a closed discourse, despite calls that it be viewed as part of a larger discursive field in which anthropology operates (Asad, in Stocking 1991; Trouillot, in Fox 1991).

1. The Intellectual History of an Idea

The term ‘function’ was first introduced as a mathematical concept by Gottfried Wilhelm Leibniz in 1714, to refer to a variable considered in relation to one or more other variables in terms of which it might be expressed.

Two main bundles of ideas underlay the concept of ‘function’ that dominated academic anthropology in the first half of the twentieth century: (a) a relation of interdependence and (b) an orientation toward given ends. The first involved reciprocity and reversibility in terms of cause and effect. The ends might be the needs of the individual, as in the utilitarian functionalism of Malinowski (1884–1942) or the needs of society, as in the structural-functionalism of Radcliffe-Brown (1881–1955). Both adopted notions of culture or society in the modern pluralized usage as totalities with a certain unity and integrative character, a notion derived from the German philosopher Johann Gottfried Herder.

In the second half of the century, the premise remained that cultures and societies were structured wholes, now more consistently referred to as cultural or social systems. At this point functionalism’s orthodoxy came under challenge in the aftermath to the Second World War which saw the withdrawal of sovereignty claims over a plethora of colonial territories within the British Empire and the establishment of United States ‘trusteeship’ in Oceania. This spurred British functionalists to address complex ‘new nations’ and provided American anthropologists *de novo* with a laboratory of functioning colonial cultures (Bashkow, in Stocking 1991).

By the 1970s, functionalism (as an achieved, shared paradigm which defined problems and procedures) was seen to be outmoded. It was replaced, amidst repeated calls for anthropology to reinvent itself, by struggle among new modes of discourse, chief among them Levi-Straussian structuralism, Marxism, and symbolic and interpretive anthropology. Nevertheless, echoes of functionalism lingered on into the decentralized, fragmented, pluralizing, flexible, refractive, postmodern world of the new millennium.

2. Functionalism’s Multivocality

A distinction among (a) functionalism as doctrine (or theory); (b) functionalism as method; and (c) functionalism as interest or ideology was a critical feature in Bronislaw Malinowski’s modernist legacy to functionalism (Vincent 1991). This, along with the essential dualism between natural science and the humanities (particularly science and history) that entered mod-

ernist anthropology with Franz Boas's *The Study of Geography* (1897, reprinted in Stocking 1996), goes some way towards ordering the cultural complexity of functionalist knowledge. The scientific tendencies of the physicist who tries theoretically to reduce reality to simple elements and the humanist tendencies of the cosmographer who seeks to comprehend a complex phenomenon as a whole are both contained within the functionalist moment in anthropology.

2.1 Functionalism as Doctrine or Theory

Three cross-cutting anthropological trajectories may be recognized within functionalist anthropology.

2.1.1 Utilitarian functionalism (Malinowskian). Recent research has exposed the extent to which Malinowski's utilitarian functionalism, which dominated British anthropology between the wars, derived from his engagement with the neopositivism of Ernst Mach in his doctoral dissertation—particularly Mach's view that knowledge is a response to biological human needs (Thornton 1985; Thornton and Skalnik 1993). In his last, posthumously published, position paper, *The Functional Theory*, Malinowski takes his stand on two axioms: first, that every culture must satisfy the biological system of needs, and second, that every cultural achievement that implies the use of artifacts or symbols is an instrumental enhancement of human anatomy, and refers directly or indirectly to the satisfaction of a bodily need (Malinowski 1944, p. 171).

Strictly followed, these axioms would restrict cultural anthropology to the economism of the rationalizing individual (human nature), or the ecologism of selective advantage (external nature) (Sahlins 1976), but Malinowski's practice deviated considerably from his theorizing. As with Boas, his sentient functionalism lay immanent in his ethnography; neither man was deemed 'a theorist.'

2.1.2 Hybrid cultural functionalisms (Boasian/Parsonian). This complex functionalist trajectory, triggered by Franz Boas's (1858–1942) 'vaguely functionalist ideas' (Sahlins 1976, p. 71), drew explicitly on German humanist intellectual traditions. It comprised several contradictions which manifested themselves transgenerationally. Initially this took the form of Alfred Kroeber's (1876–1960) functionalist historicism and Robert Lowie's (1883–1957) neopositivist empiricism. A second generation was further divided; it was also developing in the context of the 'British' functionalist paradigm.

Thus, in 1934, Alexander Lesser (1902–82), recognizing functionalism as the most vigorous tendency extant in anthropology, set out to distinguish the particular interests and conceptions of individual

American functionalists from the broader, foundational Boasian functionalist approach. He adopted a Leibnizian mathematical definition of a functional relation, established by observation, while arguing that contemporaneous events associated by the observer might be merely coexistences. Functional historicity recognized that 'institutions, customs, beliefs, artifacts have careers in time, and that their form and character is molded more by what has happened to them in the course of that history than by what particular things they occur associated with at any one time' (Lesser in Mintz 1985, p. 60). Radcliffe-Brown's position paper 'On the concept of function in social science' (1935) was prompted by his taking Lesser's critique personally.

It was actually directed at Lesser's fellow Boasians at Columbia University in New York, Ruth Benedict (1887–1948) and Margaret Mead (1901–78). Romantic holistic sensibility figured most prominently in Benedict's cultural configurations or patterns of culture. Mead, on the other hand (after corresponding with Radcliffe-Brown), designed a framework for the comparative functional analysis of social systems. This was published in *Cooperation and Competition among Primitive Peoples* (1937).

At the same time a more scientific anthroposociological functionalism was being developed at Harvard where sociologist Talcott Parsons (1902–79) joined forces with anthropology to set up a Department of Social Relations. One of its earliest products was arguably the most thoroughgoing functionalist ethnography ever published, Conrad Arensberg and Solon Kimball's *Family and Community in Ireland* (1940). Under the direction of W. Lloyd Warner (formerly Radcliffe-Brown's student) this extended functionalist anthropology from simple/primitive to complex/modern cultures. Later critics faulted the work for presenting as eternally cultural what was no more than a well-observed historical moment in county Clare.

2.1.3 Structural-functionalism (Radcliffe-Brown). Structural-functionalism's core concepts are, in harness, structure and system. Under the auspices of Radcliffe-Brown (1881–1955) it emerged as a clear-cut alternative to hybrid Boasian functionalism and successor to Malinowski's particular brand of economism and radical individualism. It derived not from German and British precursors but mainly from Durkheimian French sociology with supplementary insights from the Russian geographer and anarchist, Peter Kropotkin (1842–1921).

Structural-functionalism emphasized the formal ordering of parts and their functional interrelations as contributing to the maintenance needs of a structured social system. The function of any institution (or 'recurrent social activity') was the part it played in the maintenance of the larger structural whole. This

assumption attributed to social systems an internal integration of parts similar to that found in organisms.

Whereas Malinowskian functionalism was seen to have outworn its usefulness by 1945, and American cultural functionalism remained factionally divided, Radcliffe-Brown's successors, particularly Meyer Fortes (1906–83), Edward Evans-Pritchard (1902–73), and Max Gluckman (1911–75), expanded structural-functionalism to address situation, selection, and history while continuing to work implicitly with equilibrium models of processes internal to the socio-cultural system. Marxisant anthropological analyses of contradictions in structure and function supplemented structural-functionalism with a compatible, historically oriented, approach to competition, conflict, and change.

2.2 Functionalism as Method

Malinowski claimed that the so-called functional method in modern anthropology constituted a specific and necessary method of knowledge production. The relationship between theory and practice was reciprocal. Practice consisted of the intensive fieldwork that had emerged in contradistinction to the scientific survey methods of the Cambridge University Torres Straits Expedition of 1898–9, and the writing up of research findings in monographic form. The 1912 edition of *Notes and Queries*, that Malinowski carried with him into the field, contained W. H. R. Rivers, (1864–1922) delineation of 'intensive' fieldwork in which 'the worker lives for a year or more among a community of perhaps four or five hundred people and studies every detail of their life and culture; in which he comes to know every member of the community personally; in which he is not content with generalized information, but studies every feature of life and custom in concrete detail and by means of the vernacular language' (Rivers 1913, p. 7, quoted in Urry 1993, p. 28). This became functionalism's ideal mode of production.

Functionalism's methods of reproduction (knowledge as culture) included grantsmanship, correspondence, seminars, public events, unpublished and published lectures, oral histories, biographies, and the writing of monographs. Commemorations and conferences held in Cracow, London, and New York to memorialize Malinowski in 1984 (Gellner 1987) and in America to memorialize Boas in 1992 exposed a more complex functionalist heritage than that commonly recognized.

Paradigmatic adjustment was essential to the production and reproduction of functionalism. Thus, the last volume of Malinowski's Trobriand ethnography, *Coral Gardens and their Magic* (1935), documents the extent to which he was beginning to question 'the wholeness of culture,' criticize his neglect of the colonial order and of the inadequacy of the concept of culture contact or acculturation. He noted the possi-

bility of placing his own functional analyses of land tenure in the same frame as political controversy over land rights in Ireland and India (Vincent 1991). But such paradigmatic adjustment was rare. More routinely, it was the thick, detailed ethnographies functionalism engendered that empowered the reader to re-evaluate functionalism long before the textualization of theory became emblematic of paradigmatic change. The perdurance of a romantic ethnographic tradition contributed significantly to the persistence of inherent functionalist notions in anthropology even when the theoretical adequacy of functionalism remained an issue (Gellner 1987).

2.3 Functionalism as Interest: The 'Functionalist Movement'

Functionalism was both a concept and a scientific community contesting the constitution and distribution of cultural capital. Throughout the first three decades of the twentieth century in both Britain and America evolutionism, diffusionism and functionalism represented warring trajectories and interests and the paradigmatic dominance of functionalism was by no means secure (Vincent 1986). Explanations of dominance, as George Stocking has consistently demonstrated, are to be found not in the valency of ideas but in academic power, control, and institutionalization—to which observation must be added strategies of reproduction. In anthropology departments where field materials were presented in seminars (as at the London School of Economics and Manchester) 'field-notes were treated as facts, as concrete things, as sources of authority, as weapons in the struggle to gain the high ground of functionalist debate' (Bond in Sanjek 1990, p. 279).

3. Methodological Issues or Problems in Functionalism

As with other -isms, functionalism has been described most clearly and simply by those with most to gain from detracting interest from it. Yet anthropological functionalism has been characterized by constant immanent critique as well as external challenge. For critics it has been something of a moveable feast. What is noted depends on whose functionalism they are addressing and at what phase in that functionalist's thinking. Broad, generic charges laid against anthropological functionalism relate to positivism and pragmatism, on the one hand, and primitivism, on the other. Specific critiques have been directed against its holism along with its assumption of interdependence of parts, synchronism, homogeneity and the notion of collective consciousness, uniformity and its transgenerational replication through custom. Re-evaluations of structural-functional classics demonstrated that even so-called simple societies/cultures were internally

differentiated and heterogeneity gave rise to conflicting concerns among different sectors of the population. As the paradigm expanded further, new charges were made that functionalism could not accommodate the analysis of power.

4. Conclusion

The radical antipositivism of the 1960s put functionalism on trial. Functional anthropologists who declined to commit anthropology to the scrap heap argued ethnography's value as social history. Others argued its continued relevance for specific subfields such as ecological and applied anthropology.

It is not likely that future theoretical and research problems will follow the trends set by functionalism except, perhaps, in re-evaluations of problems in Foucault's adoption of functional terminology in his conceptualization of 'discourse'; in the work of anthropologists who holistically find instances of cultural resistance to what they perceive to be Gramscian style 'hegemony'; and in the relationship of anthropological functionalism to other modernisms (Webster, in Manganaro 1990).

The main thrust is likely to be the further undercutting of the two pluralized concepts integral to functionalism: 'cultures' and 'societies' (Wolf 1988, Barth 1992). This new emergent paradigm, 'New Critical Theory,' retains functionalism on its agenda, albeit in a literary and historical mode. It promises to further problematize addressed by anthropological historical realism (sometimes in the guise of political economy) and postinterpretive cultural critique. In both instances, functionalism, in anthropology, lingers on (just as evolutionism and diffusionism linger on) not just as situated knowledge ever in the making but as historical ethnography of the operations of culture.

J. Vincent

Functionalism in Sociology

Functionalism is a sociological research program of historical and systematic significance. Sociological explanations in terms of functions are teleological: social phenomena are to be explained by their effects and consequences—chiefly of a beneficial, morally desired or non-intended character—and/or by a circuit of equilibration (a homeostatic loop) which is maintaining a certain state of proper functioning. The notion of (mono-)functionally specialized subsystems of society can be seen as the most important precipitate of functionalist thinking in sociology.

1. Basic Extra-disciplinary Orientations of Sociological Functionalism

Beginning with the renaissance, the quest for a truly empirical analysis in the natural sciences has given the concept of function a crucial leverage in replacing the metaphysical notion of substance (Cassirer 1980). Substance has been recast as the functional interdependence of (minimally two) related variables. In

sociology functionalist thinking has spread with the works of Auguste Comte, Herbert Spencer, and Émile Durkheim, who drew on contemporary physiology and evolutionary biology as the disciplines that offered the most sophisticated notions of functional interdependence so far.

Of crucial significance for the development of sociological functionalism is the work of Harvard University's biochemist and physiologist Lawrence Joseph Henderson, who played the role of a mediator between physiology and sociology as regards equilibrating processes. In his famous seminar 'Pareto and the Methods of Scientific Investigation' (1932–42) Henderson exerted considerable influence on several generations of Harvard sociologists, among them Robert K. Merton and Talcott Parsons, who became leading figures in the movement of functionalist thinking in the USA. The basic ideas of a refined sociological functionalism originate within this context.

1.1 System, Interdependence, Equilibrium

A mixture of ice, soda water, and whisky in a tightly stoppered thermos bottle can serve as an example for an isolated system of different components: water, alcohol, and carbon dioxide are its main components. There are three phases: a solid phase (ice), a liquid phase, and a gaseous phase. All three components exist in the liquid and the gaseous phase in this system. Concentration, pressure, and temperature form a set of related variables. If one thrusts the stopper more deeply into the neck of the bottle the pressure will increase and there will be a movement of components from the gaseous phase to the liquid phase; there will also be a change in concentration and temperature. All variables that characterize the system stand in a relation of mutual dependency with one another and make up an equilibrated state (Henderson 1935). If the system exhibits a minimal complexity, its internal process cannot be conceptualized as a temporal succession of single cause–effect chains any more. The alternative is the simultaneous variation of interdependent, but relatively autonomous, variables. The two single most important sources of Henderson's analysis of systems are Claude Bernard's experimental physiology—which deeply impressed Durkheim as well—and Josiah Willard Gibbs' research *On the Equilibrium of Heterogeneous Substances* (Gibbs 1948), which decisively extends the applicability of the laws of thermodynamics. On the basis of Gibbs' insights, the biochemical equilibrium of a *milieu intérieur*—of the circulation of blood, for example—can now be given a description in terms of functional equations (Russett 1966). This 'homeostatic process,' as it has been called by Henderson's colleague Walter B. Cannon, provides the systematic starting point for functionalist thinking in sociology. The conceptual

scheme of the social system involves the variation of heterogeneous, interdependent components that can be accounted for in a model of equilibrium—in the ideal case, in the form of a system of functional equations. The facts, that the variables of a social system are not easily quantifiable, and that the system cannot be experimentally isolated, do not detract from the value and applicability of this conceptual scheme.

1.2 The Problem of Teleology

Equilibrating processes are not random processes. They are not the result of deterministic causal mechanisms, and they do not issue from a deterministic process of natural selection, from a 'survival of the fittest.' The internal integration of an organism and its adaptation to external conditions are based on *reciprocal* relations with the environment: as the organism is adapted to the environment, the environment is adapted to the organism; there is something like the 'fitness of environment' which is based on the internalization of the environment's properties within the organism—water and carbon dioxide, for example, play a very important role for the organism in both milieus: the external and the internal (Henderson 1913).

At least *ex post factum* the world seems to be a world of interdependent functional systems and can be described as a process of 'negentropy'; a process of organization. This is the basic assumption on which the teleological character of functionalism is grounded. But commitment to this assumption is not a necessary condition to make use of equilibrium models in sociological functionalism.

2. Structural Functionalism

Structural functionalism marks the phase of dominance of functionalism in sociology, especially in the USA from the 1940s to the 1960s. Structural functionalism does not constitute a single and unified research program. There are simpler versions of functionalism than the refined functionalism already characterized above by its extradisciplinary grounding in equilibrium models. A paradigmatic version of the simpler forms of structural functionalism can be found in the work of British anthropologist A. R. Radcliffe-Brown (1952). The anthropological study of institutions in the context of a social totality can be seen as a blueprint for the procedure of functionalist research: the careful description of structural patterns, i.e., of non-random interrelations between components of a society or a social system that is at the core of this procedure. The *functioning* of these structural patterns secures the adaptation and/or integration, i.e., the persistence of the social unit in question. The structural

patterns are explained in terms of their consequences. Such a structural pattern would be, for example, the repressive law in archaic societies which Durkheim saw as indicative of a mechanical solidarity. Repressive law contributes to the integration of society. Retributive acts revive the feelings on which mechanical solidarity is based. All sociological research tends to exhibit the formal characteristics of functionalism in so far as it is pursued carefully (Davis 1959).

2.1 Simple Functional Explanation

A simple functional explanation follows the following sequence:

- (a) A system S is adapted to its environment/is integrated, if the corresponding functional prerequisite P is fulfilled;
- (b) If the functional prerequisite P is fulfilled, pattern A or its functional equivalents B, C ... exist;
- (c) Patterns B, C ... do not exist in the system;
- (d) System S is adapted to its environment/is integrated, because pattern A exists in the system. This type of explanation does not imply an equilibrium model or a system of variables in the sense of Gibbs/Henderson.

Two questions have to be asked here. First, how can one explain *historically* that pattern A contributes to the fulfillment of the functional prerequisite? The functional explanation has to be linked to a theory adequate to ground the claim that pattern A would not exist at all if it did not make a difference in the fulfillment of the functional prerequisite P or in the adaptation/integration of system S, respectively (Runciman 1990). Second, what is the *origin* of functional prerequisites? Either all consequences of action are functional prerequisites, or a limited set of functional prerequisites has to be justified theoretically and/or empirically. In the latter case a more refined version of functional explanation is called for, which will be taken up in the next step. In the first case an encompassing functional unity of society cannot be presupposed. Here, functionalism advances on an inductive basis. Such a middle-range approach to functionalism is presented by Robert K. Merton, who distinguishes between manifest functions on the basis of intended and recognized consequences of action on the one hand, and latent functions on the basis of non-intended and non-recognized consequences of action on the other (Merton 1963).

Since Merton, functionalism has become associated with a concept of (mono-)functional systems that are the product of an interweaving of non-intended consequences of action and have gained substantial autonomy as against the intentions of actors. The discrepancy between actors' intentions when acting in economic systems and the actual outcome of market processes as an aggregated result of these intentional actions may serve here as an illustration. As Merton demonstrates, the definition of functions on the basis

of consequences of action does not imply any preference towards an existing social order. It is impossible to make the disruption of social order the center of a functional perspective. Merton's repudiation of the commonplace critique of conservatism proves him to be one of the liberal representatives of functionalism.

2.2 Refined Functional Explanation

The greatest danger for functional explanation lies in the arbitrary selection of consequences of action as defining a function—this holds true for both simple and refined functional explanations. A limited set of functional prerequisites could be gained inductively from the empirical comparison of singular societies. The alternative is to justify a limited set of functional prerequisites on theoretical grounds. It has to be clarified, in which sense functions such as adaptation or integration make sense, not only for the organisms of biology and physiology, but for social systems as well.

In particular, the question has to be answered, how an essential change of the system can be distinguished from mere surface variations in its operations. What is missing is a clear analogon in sociological functionalism for the concept of the 'death of an organism' (Döbert 1973).

In his version of structural functionalism Talcott Parsons has provided a theoretical, normativistic account of functional prerequisites: a cultural system of values that is shared by all members of a society constitutes the central criterion for the adaptation and integration of society. The processes of society are functional in so far as they help to realize this common system of values. Parsons cannot introduce this system of values independently from an analysis of contemporary society that makes his theoretical grounding of functional problems a mere affirmation of consequences. At the same time he has to admit, that he is not able to conceive the equilibrating process of society in terms of a system of functional variables, in terms of a Gibbs/Henderson system. In particular, it does not seem possible to explain the *change* of action systems in terms of a functionalist analysis of equilibrating processes, especially processes of a moving or even a dynamic equilibrium.

That leaves Parsons with static, normative structural categories and little difference compared with the 'no frills' strategy of simple functional explanation. The concept of function serves for him as a means for the dynamic interpretation of static categories that can eventually explain no more than a static equilibrium—the boundary maintenance of society and social systems, as they already exist. Parsons sees the concept of function as a logical, but not really satisfactory, equivalent for a system of simultaneous functional equations; structural functionalism therefore is only the 'second best type of theory,' biased for a normatively defined static equilibrium (Parsons

1954, 1959). Since an existing system of values is used here as the grounding interpretation for a limited set of functional prerequisites, the charge of conservatism that has been brought against Parsons is difficult to repudiate. However, it should be clear that the reasons for these shortcomings of Parsons' theory are not political or ideological in character, but due to theoretical deficiencies. Finally, Parsons' normative version of structural functionalism has to be put into the historical context: it is a reaffirmation of the cultural identity of American society during the dramatic developments on the eve of World War II, when the identity of American society indeed seemed to be at risk (Parsons 1973).

The guiding ideal of a Gibbs/Henderson system certainly is an admonition for Parsons to avoid simple analogies and to search thoroughly for a system of interdependent functional equations. This clearly distinguishes Parsons' effort from simple forms of functional explanation, but it is not the only difference. Formally the essential difference is marked by Parsons' use of an equilibrium model (Nagel 1957, 1961). A state of equilibrium E is dependent on the variable contributions of several functions—a case of hierarchical or vertical organization of equilibrium: E is a system's overriding concern. The range of variation of these functional contributions is large enough to endanger the stability of E. If the stability of E is endangered, certain mechanisms intervene to start a process of re-equilibration. A state of equilibrium E can be brought about by several different combinations of the values of the functional variables, but there are also combinations that characterize a disequilibrium: the loss of stability. In contrast to the hierarchical, vertical organization stands the horizontal organization of equilibrium: in a horizontally organized equilibrium functional variables are on a par with each other and constitute a mutual equilibrium.

Of crucial importance for equilibrium models and for the development of functionalist thinking are the mechanisms that regulate the processes of (re)equilibration. There are three different mechanisms:

(a) *Compensatory mechanisms.* The interdependence of the functional variables is based on direct relations between them: a decreasing contribution of the functional variable A directly causes the compensating, increased contribution of the functional variable B. The limits of compensation are given in the functional variables' range of variation. Increasing the pressure in the thermos bottle illustrates a process of re-equilibration on the basis of compensatory relations between pressure, concentration, and temperature.

(b) *Mechanisms of a central control of equilibrium.* The cybernetic self-regulation of machines can provide an example for this kind of re-equilibrating mechanism. The thermostat of a refrigerator is an instance of a central re-equilibrating control.

(c) *Mechanisms of reflexive control.* In this case the

system must be able to observe its own operations and to decide on re-equilibration on the basis of a 'conscious' or self-referential act of taking these observed operations into account.

3. Systemic Functionalism

Parsons' systemic functionalism exemplifies an equilibrium model characterized by a central control. Systemic functionalism replaces the deficient structural functionalism and develops an equivalent to the Gibbs/Henderson system. This theory claims to be able to explain the change of action systems in terms of a model of a moving or even a dynamic equilibrium. Parsons makes temporal process a constituent of his functional variables. The standard reproach directed against this type of functionalism concerns its deductive character. It may be deductive, but the theory is nevertheless empirically grounded in the empirical studies of small groups and interaction processes by Robert F. Bales, who collaborated with Parsons in developing the so-called 'four-function scheme' (adaptation, goal attainment, integration, latent pattern maintenance: AGIL). These four basic functions of social systems are derived from the analyses of processes of problem solution in small groups (Bales 1950, Parsons et al. 1981).

Parsons conceives of society as a functionally differentiated unity consisting of four subsystems: economy, polity, societal community and the cultural, fiduciary subsystem. Parsons reconstructs the interdependence of these functional subsystems in terms of communication or interchange.

Each subsystem has a specialized language of communication at its disposal—generalized media of communication or interchange: money, power, influence and moral appeals (see Fig. 1). In this scheme of

Figure 1

Parsons' four-function scheme, the functional subsystems of society, and the societal media of interchange

interchange relations between the subsystems in terms of these media, Parsons has constructed his final equivalent to a system of functional equations in the sense of Gibbs and Henderson. Moving and even dynamic equilibrium now can be explained in terms of this communicative interchange. An empirical application of this scheme can be found in the study of Parsons and Gerald Platt on the system of higher education in the USA (Parsons and Platt 1973).

All functional processes are regulated in the final instance by a *central control mechanism*: the top system of a cybernetic hierarchy which Parsons has integrated into his four-function scheme since the 1960s. This top system is culture or—on the level of societal subsystems—the fiduciary subsystem. This is a theoretical assumption that perpetuates the ‘cultural determinism’ of Parsonian theory.

4. Functional Structuralism

The theory of German sociologist Niklas Luhmann offers an outstanding example for the ‘reflexive control’ of the equilibrium process. Although Luhmann’s theory has been referred to as a ‘second encoding’ of Parsons’ functionalism, it is really an inversion of Parsons’ structural functionalism. Therefore it may be called functional structuralism: Luhmann is not—as is Parsons—primarily interested in the function of given structures. His inverted theoretical perspective is characterized by the search for equivalent solutions of problems, i.e., for equivalent structures that fulfill given functional prerequisites. The basic assumption of his theory is that for almost all problems there are also other solutions than the ones already selected; every solution is a contingent one. This perspective brings ever-new potentialities and the continuing change of systems into view. The basic functional problem is not the boundary maintenance of systems but the functioning of systems in the face of contingency. There is no culturally defined structure, no program, no code that has to be maintained, executed, or realized to preserve the identity of the system. Luhmann shifts Parsons’ problem of the boundary maintenance of systems radically into the dimension of time, shaking off all the normative connotations of Parsonian theory. This leaves only the continuity of the system over time as a problem—and as a radically purged understanding of persistence in an overly complex world of other possibilities, of other equivalent solutions (Luhmann 1970).

From the 1980s on, Luhmann began to rethink the distinction between system and environment, drawing on the works of Argentinian biologists F. J. Varela and Humberto Maturana and on the so-called ‘second cybernetics’ developed by researchers such as Heinrich von Foerster and Ernst von Glasersfeld. At the core of this process of rethinking stands the concept of the autopoiesis (self-creation) of systems. Even before this rearrangement of theoretical concepts, Luhmann de-

veloped the notion of a self-referential system. Self-referentiality took the strategically important place which the top system of the cybernetic hierarchy, culture, held in Parsons’ theory. This was a first step to introduce a reflexive control of equilibrium process. Even more significant is the concept of autopoietic systems. Autopoietic systems repeat the difference of system and environment internally, within the system. Autopoietic systems use this difference to observe (and to regulate, to condition) their own operations. The distinction between system and environment is transformed, the difference of identity (what belongs rightfully to the system makes up its identity), and difference (what does not belong to the system, what is foreign to it) forms the basis for the system’s operations.

Autopoietic systems produce the typical elements they consist of on their own by observing themselves in the process of production, by using the difference of identity and difference—in a metaphorical sense one could call this the self-consciousness of the system. Autopoietic systems are closed, and operate only under the condition of self-contact, whereas Parsons postulated open systems engaged in processes of mutual interchange. The only way for autopoietic systems to influence each other is in a manner that Luhmann calls the ‘structural coupling’ of systems: mutual irritations and resonance effects which the operations of one system have in the other. In a sense, autopoietic systems discover their own functionality and internalize the process of the search for equivalent solutions (Luhmann 1984). Luhmann’s theory can eschew Anthony Giddens’ criticism that equilibrium process, the self-regulation of systems, eludes an analysis in terms of *reflexivity* (Giddens 1977).

For Luhmann, social systems consist of communications as elements. The differentiation of society into (mono-)functionally specialized subsystems—the economic system, the political system, science, art, religion, love, etc.—is based on the development of generalized media of communication. These specialized types of communications form the elements which autopoietic systems have to reproduce endlessly. The economy, for example, is made up of money communications; payments.

It is observing itself in terms of the difference payment/non-payment (or liquid/broke). The maintenance of liquidity is the single most important functional prerequisite which has to be fulfilled to secure the continuity of the economic system’s operations (Luhmann 1988).

5. Neofunctionalism

Neofunctionalism is a research program that has been founded on the basis of a thorough critique of Parsonian theory, in particular by Jeffrey C. Alexander (Alexander 1985, 1998). Although the name suggests a

close relationship with other forms of functionalism, the central criterion for belonging to the class of functionalist approaches is clearly not satisfied: neofunctionalism does not provide simple or refined functional explanations in terms of the teleological interpretation of consequences of action or in terms of equilibrium models. The only reason that the label 'neofunctionalism' is justified at all can be seen in its renewal of Davis' assertion, that all careful sociological analysis is (neo)functional analysis. As a movement of theory and empirical research, neofunctionalism is a reorientation of sociological analysis from systems and equilibrium to concrete actors and interpretative processes.

Fundamental Rights and Constitutional Guarantees

'Fundamental rights' are typically the protections of individual (and sometimes group) liberties in modern constitutions. International human rights law provides a baseline of minimum protections that all members of the international community ought to observe. Many constitutional orders supplement these minimum protections with additional guarantees.

1. Types of Fundamental Rights

Fundamental rights developed in three stages. Initially governments committed themselves to protect a set of basic civil and political rights, and later began to treat social welfare rights as fundamental. In the later part of the twentieth century, rights to cultural and environmental protection came to be understood as fundamental as well.

The idea that people have constitutional rights makes sense only in the context of accounting for why some exercises of power are arbitrary and unjustified. Postmedieval Western political theory abandoned accounts in which sovereign power was by definition unlimited, and replaced them with accounts of sovereign power—usually the power of governments, but sometimes the power of individuals over others—according to which there were limits on the justified exercise of power. Initially, the accounts defined a set of rights, which came to be described as 'civil' rights, that people had simply by virtue of the fact that they lived in an organized society (rather than in a state of nature). At the core of this set were the right to own property, the right to dispose of one's property

according to one's personal preferences, and the right to enter into legally enforceable contracts. Protecting these core rights were collateral procedural rights, usually associated with judicial proceedings, to ensure that one could effectively protect property rights and enforce contracts.

Successful popular and elite struggles against arbitrary royal governments led to the creation of institutions to limit government (e.g., parliaments), and to the development of another set of rights. These rights, denominated 'political' rights, arose because people lived in particular societies, each with its own political form of regulating arbitrary power. Civil rights were universal, held by all people outside the state of nature; political rights were held by the people of particular political society, and might vary from one society to the next. As parliamentary, and more generally popular, government spread, the core political right came to be the right to vote. Some rights that became widespread in this first period checked arbitrary power by protecting the institutions of civil society; examples are the press and religious institutions (other than an established church).

Accompanying the development of civil and political rights was the expansion of their distribution among the population. Conceptually, civil rights inured to people simply because they were members of an organized society, and political rights did so because they were members of a particular political order. As the idea that people were entitled to civil and political rights took hold, the denial of those rights to certain groups—women, slaves, men with little or no property—became increasingly difficult to defend. Social movements pressed for the extension of civil and political rights to those groups. Slavery was abolished in western societies by the middle of the nineteenth century. Anglo-American law recognized the rights of married women to hold property and to enter into contracts in their own names through a series of statutes enacted during the same century. Most generally, the franchise was expanded gradually, beginning with the elimination of property-based qualifications for male voting in the United States in the 1830s and 1840s, extending to universal male suffrage from the 1860s through the early years of the twentieth century in the United States and western Europe, and culminating in the elimination of gender-based qualifications for voting from the 1920s through the late 1940s in those regions.

The idea of a generalized right to equal treatment became increasingly credible as civil and political rights were extended gradually. Equal protection of the law was implicit in the theory of civil and political rights, but the manifest denial of equality made it difficult to conceptualize equality as a fundamental right. As barriers to equal protection of the law crumbled, equality as such became a fundamental right. In the contemporary United States and in discussions elsewhere influenced by the US experience,

the term 'civil rights' now refers not to a category of rights, as it did earlier, but to the general right to equal treatment. Controversies over civil rights concern whether rules denying some benefit to specific groups violate their right to equal treatment, not whether access to the benefit is itself a right.

A second generation of fundamental rights, dealing with social welfare, began to emerge in the late-nineteenth century. The rise of socialist parties in western Europe provoked a response from conservatives, such as Germany's Chancellor Otto von Bismarck, and from the Roman Catholic Church. The socialist parties challenged the capitalist order for its failure to secure conditions of material well-being, such as minimal guarantees of shelter, food, and employment. According to the conservative perspective and Catholic social teaching, providing these second generation rights is a basic task of modern governments. The western commitment to social welfare rights deepened during World War II; in the War's immediate aftermath, socialist parties again played a large role in the constitutional restructuring of western Europe. The commitment was extended geographically as well, as former colonies gained independence and incorporated second generation social welfare rights in their constitutions.

The socialist arguments for social welfare rights rested to some extent on the fact that first generation civil and political rights were already viewed as fundamental. They were purely formal protections, because they guaranteed a right to hold property without guaranteeing that a person would actually hold property. In more modern terms, they protected opportunities without ensuring outcomes. Critics argued that first generation rights were empty guarantees. As they saw it, the right to own property was meaningful only to people who actually owned it. More generally, people could really have and exercise certain first generation rights only if they had second generation rights as well.

Social welfare rights were connected to first generation rights in another way. People who lacked guarantees of material well-being were likely to be dependent on others for their lives; they might, therefore, be under the command of those on whom they depended. They might be so consumed by their efforts to reach minimal levels of material well-being that they could not exercise rights to vote or participate in politics. Proponents of second generation rights argued that the fair exercise of formally guaranteed rights could occur only when people had social welfare rights as well.

First generation civil and political rights and second generation social welfare rights generally had a fundamentally individualistic character: They were rights that each person held simply because of his or her status as a human being or as an individual member of a particular society. A third generation of rights became important in the late 1960s and thereafter,

although there were hints of this new category of rights earlier. This group includes rights of national minorities to sustain their own cultures and languages within states dominated by other national groups and, relatedly, rights of aboriginal peoples to obtain support for their cultures and some degree of reparation for their displacement by settler and immigrant communities (see *Aboriginal Rights*). Rights to the protection of the environment may also be included in enumerations of third generation rights.

Although most first generation rights were individual, some had a collective orientation. Rights to religious liberty are individual only under a particular theological view of the relation between individuals and their god(s); they are collective rights when held by a group organized, for example, as a church. Third generation rights expanded the range of rights that were importantly collective in nature. A person can have a right to maintain the language of his or her origin only if, and to the extent that, other people similarly have and exercise that right. Environmental protection benefits society as a unit, rather than any particular member of society.

2. Permissible Limitations of Fundamental Rights

No legal system gives absolute protection to every constitutional guarantee. Doing so would sometimes substantially impair a government's ability to pursue social goals that most people regard as worthwhile. Modern formulations of the power of governments to restrict fundamental rights often resemble the one used in Canada's Charter of Rights and Freedoms (1982), which authorizes restrictions on the rights it protects when such restrictions are 'reasonable limits ... [that] can be demonstrably justified in a free and democratic society.'

Historically, governments asserted the power to limit constitutional guarantees to advance the public interest in such matters as health, safety, and (more controversially) morality. These were called the 'police power' limits on constitutional guarantees. Frequently, governments found it relatively easy to assert reasonable police power interests to support restrictions on fundamental rights. This undermined the status of those rights as truly fundamental.

Constitutional systems, often through their constitutional courts, now restrict the occasions on which ordinary police power interests can justify restricting fundamental rights. In societies characterized by a wide range of views about what constitutes morality, it is now difficult to justify restrictions by reference to morality: the claim that some restriction advances a specific moral goal is met with the response that, in a morally pluralistic society, public policy ought not seek to advance that goal. Most systems require that restrictions on fundamental rights be 'proportional' to the harms the restrictions are designed to reduce.

Many constitutional systems require that when efforts to promote uncontroversial goals such as health and safety impair fundamental rights, those efforts must be justified by showing, for example, that they infringe the fundamental rights no more than is absolutely necessary to advance the police power goal, and that they will be effective in doing so. Terms such as 'strict scrutiny' or 'substantial showing' are common in describing the limits on a government's ability to invoke its police powers to restrict a fundamental right.

Sometimes, constitutional guarantees conflict with each other. A defendant's right to a fair trial may conflict with the press's free expression right to publish information about a crime and with the public's right to know about the conduct of public proceedings such as trials. A person's rights of free expression, when they take the form of hate speech, may conflict with the ability of subordinated groups to achieve true equality.

Constitutional systems address these clashes in two ways. They may give one right substantial priority over others, allowing infringements on the preferred right only when such infringements appear to be the only way to protect the other rights. That is the solution in US constitutional law to the conflict between free speech and fair trial rights: the US Supreme Court allows restrictions on dissemination of information about criminal proceedings only when no other methods of protecting the defendant's right to a fair trial seem likely to succeed. However, the court must provide reasons for choosing the right that has the preferred status, and must explain the fact that such choices may produce intrusions on the subordinated rights that the alternative approach could mitigate.

The other solution is to balance the conflicting constitutional guarantees. Under this approach, a statute prohibiting some forms of hate speech might be acceptable if decision-makers reasonably conclude that the restrictions it imposes are outweighed by the increase in equality that it will produce. While common among constitutional orders, balancing solutions are problematic because they call upon decision-makers to compare interests that are not truly commensurable.

The emergence of third generation rights poses particular difficulties in the theory of rights, because those rights sometimes conflict quite dramatically with first and second generation rights. Some national minorities, for example, may have internal norms that subordinate women in ways incompatible with the exercise by their female members of the full set of first and second-generation rights. A right to individual mobility may undermine the ability of a linguistic minority to sustain its language, as individual members of the minority move away, or simply choose to conduct their affairs in the majority's language. Constitutional orders have found it difficult to address

these sorts of conflicts. The balancing approach seems even more inapt here than it does when there are conflicts between political rights, because the rights at stake so obviously are different. Further, the evolutionary development of rights means that first and second-generation rights have a stronger theoretical basis than third-generation rights, and commitments to first and second-generation rights usually are held more deeply, if only because more familiar. When third-generation rights conflict with others, then, the third-generation rights are likely to yield, making them legally and practically less fundamental and secure than other rights.

3. *Methods of Protecting Fundamental Rights*

Some fundamental rights are identified in written documents, such as constitutions, statutes, or international human rights treaties. Particularly in Anglo-American legal systems, others derive from the unwritten law. It is conventional to regard judicial enforcement as the necessary concomitant of fundamental rights. The means of enforcing fundamental rights are more varied, however. Notably, the institutional mechanisms for enforcing international human rights consist of quite weak judicial institutions and significantly more potent moral and political ones.

Most of the world's nations have signed treaties committing themselves to enforcing international human rights defined as minimum standards universally applicable. Some, but not all, of these treaties also require the nations to submit to adjudication by international human rights courts. Not all states have submitted themselves to these courts, however. An extremely limited number of human rights violations, such as genocide, can be enforced against wrong-doers in *any* court in the world willing to exercise its power, and the 1990s saw the creation of international criminal courts with authority to convict upon finding that a defendant had committed criminal violations of core human rights. Otherwise, the power of international tribunals to enforce international human rights is rather limited.

Fundamental rights can be effectively guaranteed even without judicial enforcement. International human rights, for example, are enforced in part by moral pressure generated by adverse publicity produced by some organs of the international community and by nongovernmental human rights organizations (NGOs), an increasingly potent participant in the international arena. The mere presence in a constitution of a fundamental guarantee may place political pressure on governments to honor the guarantee. Legislatures and chief executives can create committees or administrative units charged with reviewing legislative and administrative proposals to determine whether they are consistent with constitutional rights.

The question of enforcement is particularly pressing in connection with second generation rights. Fully guaranteeing social welfare rights would be extremely expensive in many countries, often far beyond the nation's fiscal capacity. Some constitutions address this problem by describing the guarantees of second-generation rights as 'directive principles of social policy,' a phrase first used in the Irish Constitution of 1937 and then adopted by the postwar Constitution of India. As constitutional 'directives,' second-generation rights are committed to the care of the legislature and sometimes, as in the Irish Constitution, specifically excluded from judicial enforcement. Other constitutional systems, such as the Italian and Japanese, treat second-generation rights as judicially enforceable, but allow legislatures a wide range of discretion in choosing how to go about actually providing those rights.

Modern constitutional systems typically provide some mechanisms for the judicial enforcement of first generation rights. Courts may develop the unwritten (or 'common') law or interpret statutes in ways expressing sensitivity to concerns about fundamental rights, even if they acknowledge that the legislature has the power to alter the law however it chooses (as is the case, at least in theory, in many parliamentary systems). They may find that when executive officials violate fundamental rights, they have acted outside the authority conferred on them by statute, a doctrine known as *ultra vires*.

Sometimes, the mechanisms for judicial enforcement of constitutional rights are so limited in scope or so cumbersome that individuals may be unable to raise claims that their personal constitutional rights have been violated in specific cases. In France, for example, individuals cannot challenge statutes once they have been promulgated; only legislators and a few other high officials have the power to invoke constitutional review, and then only before a statute has become binding law.

Proponents of judicial enforcement of fundamental rights often overlook a serious problem with judicial enforcement. Even when all agree that there is a fundamental right, described in general terms, there may be reasonable disagreement over the precise content of that right and, in particular, over whether a specific statute in fact violates the right. Some legal doctrines take account of the existence of reasonable disagreement of this sort. The European Court of Human Rights, for example, gives states a 'margin of appreciation,' allowing them to adopt interpretations of the agreed-upon rights that other states reject and that the judges themselves might reject if they had the power to specify the content of the right themselves.

Judicial enforcement means that the views of judges concerning the precise content of an agreed-upon right prevail over the views of legislators or of executive enforcement officials that no violation of fundamental rights has occurred. Where disagreement regarding

the precise content of a fundamental right is reasonable, the case for judicial enforcement is weaker than its proponents believe.

Fundamentalism (New Christian Right)

'New Christian Right' (NCR) is the label given to a cluster of US social movement organizations and political pressure groups formed in the late 1970s and early 1980s, of which the best known was the Moral Majority, headed by Baptist fundamentalist pastor and televangelist Jerry Falwell, of Lynchburg, VA.

Unlike such ethnic and nationalist movements as right-wing Afrikanerdom and Ulster Unionism, where religion had long played a part of identifying a people and legitimating their political struggles, the political involvement of American fundamentalism has always focused on sociomoral issues and that engagement has been sporadic. Fundamentalists have alternated between periods of pietistic retreat from the world and attempts to re-assert their values on what was seen as an increasingly secular and immoral public sphere. In the 1920s and 1930s fundamentalists campaigned for temperance and against Darwinian evolution. In the 1950s they were involved in anticommunist campaigns. They were relatively quiet during the 1960s and early 1970s.

The mobilization of the NCR in 1979 was initiated by a group of right-wingers who had previously supported third-party candidates against the liberal Republican establishment. It had two novel features. It made extensive use of direct mailing (using the lists

of those who had contributed to fundamentalist radio and television programs) to raise funds, to spread information, and to create mass pressure from very small acts of commitment. For example, potentially supporters in a state with a liberal senator would be sent a pre-printed and pre-addressed card protesting about some piece of legislation and threatening to vote against the senator should he or she not vote the right way. All the recipient had to do was sign the card and mail it. The NCR also, for the first time, used white fundamentalist churches in a way that the Civil Rights movement has used black churches: to provide a network of contacts and venues for politicization. Where the law permitted a voter-registration booth would be set up in a fundamentalist church and the pastor asked to preach on the Christian's duty to vote.

Although Falwell and other NCR leaders were avowedly nonpartisan, they quickly won more friends among Republicans than Democrats and during the 1980s, the movement evolved into a pressure group within the GOP. In 1987, Marion G. 'Pat' Robertson, a religious broadcaster, Pentecostal minister, and founder of the Christian Broadcasting Network (later the Family Channel) ran for the Republican nomination for the presidency.

Specifically the NCR was opposed to an Equal Rights for Women Amendment to the constitution, gay rights, abortion, divorce, public displays of sexuality and promiscuity, and to the teaching of evolution and 'secular humanism' in schools. It was in favor of public prayer in schools and the teaching of Creationism (which it tried to recast as 'Creation Science'). More generally, it wanted public re-affirmation of the superiority of conservative Protestant culture and identity. Although this was often denied there was also a large amount of racism in the appeal of the NCR. Criticism of liberal welfare state and immigrant policies provided a respectable language for a 'nativist' reaction to Blacks and Hispanics. Support for tax tuition credits for independent schools, although presented as pro-parental choice, was also a way of opposing racial integration.

The NCR had considerable early success in gaining publicity for its cause. Falwell, Robertson, and other religious broadcasters were masters of the mass media. With the technical assistance and experience of right-wing lobbyists, they were able to create an appearance of power far beyond the reality. In this they were aided initially by the credulity of naive commentators who over-reacted to the reappearance of a large constituency which the liberal and cosmopolitan centers of the US had forgotten. Thus, the NCR's claims to have been responsible for the ousting of four leading liberal Democrat senators in 1980 was reported without the qualification that the swing against those four was the same as the swing against the Democrats in states where the NCR had not campaigned actively. The NCR also claimed the credit for the 1980 election of Ronald Reagan to the presidency, even though

Reagan's success owed far more to the appeal of his economic liberalism and his aggressive foreign policy than to his conservative rhetoric on socio-moral issues.

1. The NCR's Record

Despite the 12 years of Reagan and then George Bush in the White House, the NCR conspicuously failed to make much progress on its agenda. In areas where fundamentalists were strong, it won a number of court cases and managed to have state legislatures pass such measures as bills requiring that teaching of evolution be balanced by equal time for creationism, but such gains were always reversed once the issue had been appealed upwards. Appeal courts decided that Creation Science was religiously-inspired rather than evidence-driven science and hence that its teaching in public schools was unconstitutional. Attempts to have any form of instruction that did not specifically promote Christianity regarded as expressions of the 'religion' of secular humanism were rejected repeatedly by the courts. A landmark judgment ruled that teaching children about beliefs and values they did not share was not in itself a form of unconstitutional propaganda. On its most popular issue, opposition to abortion, the NCR made very little headway. Although the Supreme Court was willing to permit very slight constraints (for example, on public funding of information about abortion), it turned down opportunities to outlaw it repeatedly.

The NCR's electoral record was similarly unimpressive in the light of the unprecedented sums that were spent. Being able to deploy groups of highly committed activists allowed NCR groups to win power and promote candidates in some branches of the GOP but such advances were usually reversed by mainstream Republicans. When they were not, movement candidates usually were rejected by the electorate. In particular, the NCR alienated middle-class, women voters who saw the entire conservative agenda as an attempt to reverse their gains in the labor market and in public life.

Where the NCR had some success was in presenting itself as a cultural minority the rights of which had been infringed. It was thus able to reverse a number of overly zealous decisions of the separation of church and state. For example, a Christian student group won back funding that had been denied it while the University funded a variety of equally contentious political and cultural groups.

2. Explaining the NCR's Failure

Idiosyncratic causes of the NCR's failure can be identified. It certainly did Robertson's campaign no good that it coincided with two major television evangelists being exposed as frauds, perverts, and

hypocrites. However the major roots of failure lie in the dynamics of motivation and in US social structure.

Despite the title of Falwell's organization, NCR supporters were never a majority. They could only achieve their goals if they formed alliances with other conservative groups but this created motivational problems because it required alternating between two sets of values. Fundamentalists were encouraged to become politically active by various threats and insults to their socio-moral values, which were derived from their religious beliefs. But to be effective politically, they had to set aside their religious preferences and co-operate with conservative Catholics, Jews, and atheists. While the NCR leadership could separate religion and politics, many of the rank-and-file could not. They either became disillusioned at the compromises involved in pressure group politics or refused to make such compromises and by their anti-Catholicism, anti-Semitism, and racism offended, respectively, Catholics, Jews, Blacks, and Hispanics, groups which had considerable sympathy for aspects of the NCR agenda.

Potential for frustration was inadvertently built into the movement from the start by its flawed explanation of what was wrong with America. Because it saw all that offended it as the deliberate work of militant 'secular humanists,' it supposed that all that was required to 'bring America back to God' was an equal counterforce of militant socio-moral conservatives. The NCR failed to appreciate that many of the changes that concerned it were the accidental by-product of two social forces that, in general, its members supported: prosperity and individual autonomy.

The one sense in which liberals were implicated directly in the failure of the NCR was in successful counter-attack. Once leading scientists realized that they could not take their cultural dominance for granted but had to persuade people, they did so extremely effectively. Organizations such as People for the American Way mobilized very effectively to produce a compelling defence of diversity and toleration. But the liberal counterattack worked because it rested on values that many fundamentalists themselves accepted. Unlike, for example, Islamic fundamentalists, NCR sympathisers were not opposed thoroughly to the division of the public and private spheres or to the principle of toleration. Hence, they were often ambivalent about their own legislative program; while polls repeatedly showed most Americans opposed to abortion, more sensitive questioning showed considerable willingness to make exceptions and some reluctance to impose morality on others. In addition, most voters put socio-moral concerns relatively low down their list of priorities and attempts by NCR-supported candidates to stress such matters reinforced the impression that they were single-issue candidates who would not be effective politicians. The result was that the NCR failed to turn the very large constituency of born-again Christians into committed supporters.

What was clear from opinion polls and voting patterns in the southern states in Pat Robertson's election campaign is that even many who shared Robertson's religion were unenthusiastic about supporting a conservative and fundamentalist pastor for the presidency.

While it is easy to assess the NCR's record on specific agenda items and conclude that it failed, it is less easy to assess its more general and long-term effects. Given that the proportion of women in full-time employment, divorce rates, and abortion rates have continued to rise, we may conclude that the movement failed in its more general objectives. The one sense it can claim to have succeeded is in making sociomoral issues extremely contentious and emotive. Although the commonly used phrase 'culture wars' is an exaggeration, the NCR has contributed to the development of an extremely acrimonious tone in American public life signaled, for example, by murderous attacks on the staff of abortion clinics.

3. Conclusion

Although interesting in its own right, the career of the NCR allows us to understand some basic features of modern democracies. While the more ethnically and culturally homogenous and smaller states of Europe tend to have centralized and closed systems of political power and public administration, the size and diversity of the US has resulted in an open, federal structure that allows sizable minorities considerable opportunity to initiate debate and promote their agendas, and to win some local victories. However, those issues of central importance to the operation of the state are

dealt with in a centripetal structure that prevents even well organized and highly motivated minority movements carrying the day. In electoral politics and in the formulating of legislative programs, the NCR could press its case but then suffered repeated rejection at higher levels as that case was scrutinized by politicians answerable to wider constituencies. Similarly victories in lower level courts were reversed in various levels of appeal.

What is clear from the decisions of such influential elite groups as Congressional politicians and judges, and from the voting patterns of ordinary Americans, is that there is widespread implicit understanding that the protection of individual liberty and the preservation of social harmony in a culturally diverse democracy require a division of the public from the private and that, while considerable liberty can be permitted in the private sphere, the public sphere has to remain religiously neutral.

Gaia

In the early 1970s, the English chemist, James Lovelock, and the American microbiologist Lynn Margulis postulated the Gaia hypothesis that life on Earth is part of a self-regulating system that binds the atmosphere to the continents and oceans in a quasi-physiological process (Lovelock and Margulis 1975). The ideas behind Gaia were developed as part of NASA's efforts to find life on other planets (Lovelock 1965). As a theory of evolution, Gaia holds that life forms have co-evolved with their environment in such a way that environmental conditions are held steady in the face of a continual influx of energy and matter. Gaia posits first that life on Earth is a planetary phenomenon, and second, that living organisms have to regulate their planetary environment otherwise the forces of physical and chemical evolution would render it uninhabitable (Lovelock 1979).

The evidence put forward for Gaia draws attention to the fact that the chemical composition of the Earth's atmosphere has stayed remarkably constant and quite unlike the composition that would be expected in the abiological steady state of a lifeless planet. The geological record suggests that neither global freezing nor boiling conditions have ever prevailed. Mean surface temperature has probably never departed from the range 5–50°C (Lovelock and Whitfield 1982). The Gaian perspective has spawned new avenues of scientific inquiry aimed at furthering the understanding of biogeochemical cycles, especially in the atmospheric sciences. For example, the importance of methane in climate change came to be taken seriously with the recognition that biological organisms play a vital role in regulating the atmospheric environment.

Lovelock (1988) coined the term geophysics to denote an emerging systems approach to earth science that might assist in furthering understanding of the implications of human intervention into biogeochemical cycles in a way that distinguishes situations which threaten the planetary operating system from those that do not. By using the term geophysics, Lovelock distanced himself from teleological criticisms and the mysticism that has come to surround the notion of Gaia. For Lovelock, Gaia is a quasi-living entity that has the capacity for global homeostasis operating according to cybernetic principles, which like a thermostat does not require will or sentience.

Gaia caught the public imagination in the 1980s, along with an emerging conviction in the scientific

community that the global environment was being seriously affected by human action (Joseph 1990). For environmentalists, Gaia became a symbol of the need for promoting an ecocentric view of the world around us, in contrast to the dominant anthropocentric view. For many, Gaia became also an argument that cooperation rather than competitiveness was needed to unite humanity in the face of threats to the global environment and an argument for alternative ways of living.

It is important to distinguish between the Gaia hypothesis of earth science, and Gaia, the popular symbol of environmentalists, which underpins a call for an ecological egalitarianism to end all forms of human domination of nature (Serafin 1988). A considerable literature has developed exploring Gaia both as a scientific concept and as an ethical, philosophical, and sociological proposition. Debates in the literature about Gaia have been set increasingly in the historical context of an emerging science of the biosphere. Gaia is seen as an elaboration of ideas put forward by the Englishman James Hutton who first proposed the Earth to be a living system in 1785 and the Russian Vladimir Vernadsky who realized the importance of life in transforming geology in the early part of the twentieth century.

R. Serafin

Galton, Sir Francis (1822–1911)

Francis Galton was born in Birmingham on February 16, 1822, the third son of Samuel Tertius Galton, a wealthy banker whose fortune was mainly derived from his father's musket manufactories. Francis was also the grandson of Erasmus Darwin, in whose scientific and evolutionist footsteps he was later to follow. However, he was originally destined for a career in medicine. Aged 16, at his father's behest, Francis enrolled as a medical student at the Birmingham Free Hospital, from where he moved to King's College, London to study medicine in 1839, and to Trinity College, Cambridge in 1840 to read mathematics. Having achieved only a pass degree at Cambridge, largely due to the first of the mental breakdowns that punctuated his career, Galton continued with his medical instruction despite a growing aversion to it. Coming into a substantial fortune on the death of his father in 1844, he immediately abandoned medicine and spent several indolent years 'hunting, fishing and shooting.' Then, in 1850, he led and financed an exploratory expedition to South-West Africa (modern Namibia). On his return, in 1852, Galton was lionized by the scientific establishment. And having achieved this entrée into the scientific community, gradually he established himself as one of Victorian Britain's most respected men of science. He was knighted in 1909.

Francis Galton is now remembered chiefly for his innovations in the field of statistics and for advocating the practice of eugenics. But his interest in both of these areas initially arose from an attempt to provide scientific evidence for the inheritance of human mental attributes. In fact, Galton devoted most of his professional energies to investigating varied aspects of heredity, a predilection largely inspired by reading Charles Darwin's (his half-cousin) *The Origin of Species* in 1859. Throughout his career, Galton's views of mind and morality were unequivocally materialist and evolutionary. In 1865, he published an article in two parts, under the heading 'Hereditary talent and character,' that were later expanded into his first book on the subject of mental heredity, *Hereditary Genius* (1869). In each of these publications he sought to show that the pedigrees of geniuses contain considerably more forebears of high social distinction than the lineages of those with mediocre parentage. Galton was aware that any positive results might instead suggest

the importance of nepotism and unequal access to education. But on the basis of several ingenious—albeit less than convincing—arguments he insisted that for the highly intelligent neither education nor preferment are necessary for the fulfillment of their inborn intellectual potential. This permitted him to interpret any instance of relatedness among the eminent as being due to shared heredity.

Having presented detailed pedigrees for several hundred eminent men Galton calculated that 50 percent of illustrious individuals have at least one distinguished relation. On this basis he concluded that heredity is the primary determinant of intellectual ability. He also devoted a section of *Hereditary Genius* to estimating, in terms of the overall stock of hereditary intelligence, the 'comparative worth' of different nations and races. Galton reproduced the typical mid-Victorian conception of a racial hierarchy stretching from the Caucasian to the Negroid, although he argued that the ancient Athenians were appreciably more intelligent on average than any modern civilized nation.

During the 1870s, Galton continued his researches into human mental heredity. In 1874 he issued questionnaires to leading men of mid-Victorian science, hoping to shed light on the relative importance of 'nature and nurture' in their choice of vocation. Predictably, his data interpretation was prejudiced in favor of a hereditarian explanation. In 1875, although he had no conception of the modern distinction between monozygotic and dizygotic twins, Galton turned to the phenomenon of twinning as a means of delineating between heredity and environment. He collected the life histories of pairs of like-sexed twins and sought to determine if those that were similar at birth and in childhood became unlike upon leaving their similar home environments. He also asked if like-sexed twins that were dissimilar at birth subsequently became more similar in the shared home environment. In both cases Galton concluded that character had been formed prior to birth and had thereafter shown only limited flexibility in response to environmental pressures.

On the basis of his studies of heredity, Galton proposed the peremptory regulation of human breeding so as to maximize the biological quality of the nation. In 1869 he recommended the confinement of the socially undesirable in 'celibate monasteries or sisterhoods,' and the creation of incentives for the intellectual elites to reproduce more frequently. The term 'eugenics' was coined in 1883 by Galton from the Greek *eugenes* meaning 'good in stock.' Yet, eugenics was widely considered impracticable during the 1860s and it was only during Galton's last decade that he began championing the idea. By then, foreign challenges to Britain's industrial and mercantile hegemony, and fears of an increasingly volatile urban underclass had rendered eugenics an appealing notion to many *fin-de-siècle* Britons. In 1908, after initial

reluctance occasioned by his advanced age, Galton became President of the newly formed Eugenics Education Society.

Political considerations bulked large in Galton's advocacy of eugenics. Running through his work on heredity and eugenics, and becoming more pronounced with time, was a strongly elitist conviction that the vast majority of the lower classes were sexually profligate and irremediably inferior to the higher social classes. Accordingly, he expressed the fear that the lower classes were out-breeding the 'respectable' classes. Moreover, Galton's predilection for studying intelligence and his commitment to enhancing the reproductive rate of the most intelligent are symptomatic of his upbringing as a member of the Victorian professional middle class. This was a social stratum that set great store by intellectual accomplishment and produced many of the century's foremost social reformers, commentators and scientists: Galton unconsciously celebrated the core values and accomplishments of this important social group. In advocating eugenics he was also influenced by the widely held belief in the possibility of human perfectibility—of which his grandfather Erasmus Darwin had been a leading exponent—and by the potent mid-Victorian ideologies of human and social progress advanced most forcefully by his friend and colleague Herbert Spencer. Lastly, Galton's eugenic thought reflects the growing impetus among Victorian life-scientists for making their discipline practically useful to the state.

In the context of studying the inheritance of human mental and bodily traits, Galton emerged as an innovative statistician. His maxim was 'Whenever you can, count,' and his researches suggest a man with an almost obsessive compulsion to do so. In *Hereditary Talent and Hereditary Genius*, Galton became the first person to employ the Gaussian error curve in classifying human *mental* attributes. Although his use of statistics was at this stage rudimentary, he accomplished the important step of measuring—and focusing almost entirely upon—statistical variation. This aspect of the normal curve had not received much attention from his contemporaries (with the exception of the Belgian astronomer and statistician Adolphe Quetelet), many of his predecessors regarding variation from the mean as 'error' rather than a natural phenomenon worthy of investigation. All of Galton's major statistical insights stemmed from this concern for statistical spread as opposed to averages alone. In particular, his work was pivotal in the development of both the correlation co-efficient and regression analysis. Galton formulated a graphical method to measure correlation in 1886 by plotting the distributions of both variables, and two years later he devised an 'index of co-relation.' In fact, his computational procedures for 'co-relation' involved measuring the slope of the regression line and producing a measure of the regression coefficient. The mathematical underpinnings of correlation were developed more fully by

his admirer and first biographer, Karl Pearson. From Galton's idea of regression, Pearson also developed a statistical system for the linear production of two continuous variables.

Galton's role in the development of regression analysis is more ambiguous. As a means of studying the mathematics of hereditary variation, during the late 1870s Galton began to breed sweet peas. He found that the F_1 generation peas were, on average, only a third as extreme in any given quality as the parental generation. Thus, through his breeding experiments, Galton had stumbled upon the statistical principle of regression. However, he always assumed that the phenomenon of regression related to a fundamental physiological process, and his explanation for it was biological rather than statistical. Galton asserted that each individual is composed of distinct hereditary units derived both from parents and from earlier ancestors. In each generation a random selection of the ancestral and parental hereditary material is made, such that only some of the total complement of hereditary units are actually expressed in each offspring. Galton believed that, from a purely probabilistic point of view, the entire hereditary material—stretching back several generations—would on average be close to the population mean. However, because only a random selection of hereditary units gain expression, it is possible for more extreme characteristics to be produced. Regression occurs when, as is likely, the more mediocre hereditary units regain supremacy in the following generation. This conception of the nature of heredity led to Galton's formulation of the 'ancestral law of heredity,' a law stipulating that any two parents together contribute approximately one-half of the total hereditary material of the offspring, the four grandparents one-quarter, and so on until the proportions become vanishingly small. Galton believed this law to describe the actual hereditary composition of each individual and the model formed the basis of his statistical treatment of heredity in *Natural Inheritance* (Galton 1889). During the twentieth century, 'Galton's law' would be eclipsed by the advent of Mendelian genetics.

'Galton's law' may not have long survived the rediscovery of Mendel's work, but Galton has been credited with anticipating August Weismann's concept of the continuity of germplasm. Unlike Darwin and the majority of his contemporary life-scientists, from as early as 1865 Galton was largely dismissive of the notion of the inheritance of acquired characteristics. During the early 1870s he experimentally tested Darwin's theory of 'Pangenesis'—according to which bodily tissues throw off the germ cells from which offspring are produced—by transfusing blood among different varieties of rabbit. His predictable conclusion brought no pleasure to Darwin, and Galton's 1871 rejection of Pangenesis in *Nature* elicited from him a swift rebuke. Subsequently, Galton's resistance to the inheritance of acquired characteristics hardened. In

the models of hereditary transmission he published during the first half of the 1870s, he claimed that the 'patent' hereditary units that become bodily structures only rarely return to the reproductive organs to be transmitted to progeny. In contrast, the 'latent' elements remain in the testes and ovaries ready to be transmitted to the next generation. In this rather circumscribed sense his hereditarian model did foreshadow Weismannism.

However, aside from the many technical inconsistencies between Galton's and Weismann's concepts of heredity, it is important to note that after 1875 Galton departed significantly from the position outlined above. He gradually came to appreciate that his case for the continuity of traits between parents and offspring was weakened if it were assumed that the latter inherited only the former's latent elements and very few of their patent elements. As a result, by the late 1880s Galton was writing of patent and latent elements as being equally heritable. Whilst he remained only mildly sympathetic to the notion of the inheritance of acquired characteristics, he had abandoned his earlier emphasis upon the near-absolute separation of bodily from reproductive cells.

Galton's dual fascination with heredity and quantification also generated an interest in anthropometry, the measurement of bodily morphology. During the 1870s, appalled that so little was known about the physique of the British people and fearful that a biological decline was already in progress, Galton sought to obtain anthropometric information on children from different social classes. Subsequently, he became a member and later chairman of a British Association committee investigating occupational disparities in size and weight. Throughout his involvement with this committee Galton was convinced that heredity was the chief determinant of anthropometric variation. As a means of procuring raw data from which to study hereditary transmission in humans, in 1884 he set up an elaborate anthropometric laboratory at the International Health Exhibition in London. Equipment was installed to measure the height, weight, breathing-capacity and, *inter alia*, the strength of pull of members of the public. Also measured were such qualities as keenness of sight, hearing, and color discrimination.

These last tests reflect Galton's interest in what he dubbed 'psycho-physics,' the scientific investigation of mental phenomena. Generalizing his earlier conviction that individual nurture is a subordinate force to heredity, he emphasized aspects of unconscious cerebral function in which the 'will' seems to play little if any role. In his 1883 *Inquiries into Human Faculty*, Galton described and, where feasible, quantified a range of unconscious and sensory phenomena, including number forms, visual imagery, color associations, visions, and sensory awareness among the blind. He also documented the results of his introspective investigations into the power of the individual

will. In the course of these studies, Galton devised the method of 'word-association' with which to demonstrate his claim that very few thoughts or actions are ever the spontaneous product of the will but relate to desires, ideas and associations of which we have little conscious awareness.

In addition, Galton was a pioneer in the design and employment of composite photography. He hoped that through superimposing numerous photographic portraits on top of each other he would be able to discern the common hereditary features shared by families or groups. His main work in this area involved an attempt to discover the physiognomical indices of different forms of criminality from a series of photographs supplied by the Inspector of Prisons. To his disappointment, Galton found no evidence of distinctive criminal types. However, this interest in hereditary variation, measurement and their relevance to criminal investigations also culminated in his extensive study of fingerprints. Galton was not an innovator in this field but his several publications on the subject drew attention to the enormous value of fingerprints as a means of personal identification.

Although it is clear that most of Galton's scientific work stemmed from his early fascination with heredity, his scientific curiosity was nonetheless polymathic in breadth. Over the course of half-a-century's involvement with the Royal Geographical Society, he was able to make significant contributions to the expeditions of such explorers as R. Burton, J. Speke, and J. Grant, and he worked hard to place geography on a more scientific footing. As an active meteorologist he was instrumental in the construction of weather maps and was responsible for discovering the 'anti-cyclone' in 1862. Finally, he was an enthusiastic advocate of establishing scientific activity as an occupation of dedicated, professional and, if necessary, salaried, researchers. Alongside T. H. Huxley, John Tyndall, Joseph Hooker, and others, he campaigned vigorously to free science from the limitations imposed by religious orthodoxy. To this end, many of Galton's works carried thinly veiled attacks on theology and the Church, most strikingly his 1872 attempt to prove statistically that prayer is inefficacious.

In retrospect, there can be little doubt that Galton gave an important impetus to the scientific study of heredity and the development of psychometric testing. Despite the shortcomings later revealed in his own work, he was the first to subject human intellectual attributes to systematic numerical analysis. With the aid of W. F. R. Weldon and Karl Pearson, he was also intimately involved with establishing a statistical approach to the study of evolution. Perhaps Galton's most lasting contributions to science arose from his statistical breakthroughs of the 1870s and 1880s. Statistical procedures derived from his initial insights are now indispensable to both the natural and the social sciences. More practically, his private wealth enabled him to set up a Eugenics Research Office at

University College London in 1904. He honored and extended this commitment upon his death (on January 17, 1911) when he created the Galton Professorship of Eugenics and named Karl Pearson as the Chair's first holder.

Any summary of Galton's legacy must recognize that eugenic ideas were implemented after his demise with horrific consequences, and that the hereditarian ideologies he promoted have often been used as means of social, sexual and racial oppression. In the wake of the Nazi atrocities of the 1930s and 1940s, and of the civil rights movements of the 1960s and 1970s, Galton's stock as an important scientific figure has declined rapidly. However, in the interests of a proper understanding of the past, it should be pointed out that to implicate Galton in the rise of twentieth-century eugenic practices is to over-personalize a complex series of events and set of national circumstances. Eugenic measures were linked to a wide range of social, economic and political factors against which Galton's advocacy is scarcely more than trivial. Furthermore, even in 1865 the notion of selective human breeding was far from novel: Galton's originality lay only in buttressing the idea with apparently rigorous scientific research.

Game Theory

1. Introduction

Game theory is the mathematical study of situations of conflict of interest. It is applicable to military

situations, but has also been applied to economics and other social sciences, and even to biology.

We think of game theory as the fourth in a sequence of paradigms, explaining how people attempt to achieve goals; call these type I, II, III, and IV thinking: in type I thinking, the question is whether a goal can be met. In type II thinking, the decision maker, satisfied that the goal can be met, tries to meet this goal in the most efficient way possible (at minimal cost); alternatively, having decided that the goal cannot be met, he tries to come as close as possible to meeting the goal. In type III thinking, the decision maker realizes he is faced, not by nature, but by other decision makers whom he can influence. He therefore tries to influence them so that they (acting according to type II thinking) will carry out actions helpful to him. In type IV thinking, the decision maker realizes that he is faced by other individuals whose actions can affect him, and who in turn are trying to influence his actions. Thus he will generally try either to outsmart the others, or to cooperate with some or all of them. It is this last type which represents game theory.

A game is any situation in which two or more agents (players), not having identical interests, can affect the outcome. We assume that all players seek to maximize their individual utility. There may or may not be random moves.

Games can be noncooperative or cooperative. In the noncooperative case, we are mainly interested in the strategies chosen by each player. In the cooperative case, we are also interested in the process of bargaining and coalition formation. Games may also have complete or incomplete information. In case of incomplete information, there is interest in the process of learning, as players elicit information during the play of a game.

Essentially, given a game situation, game theory tries to answer the following questions:

- What strategies should each player use?
- Where there are gains to be made from co-operation, how should the players bargain?
- Where there are many players, what coalitions should form?
- What information can be deduced from other players' actions?

2. Extensive and Normal Forms

There are several ways of representing a game. The simplest perhaps is to draw a graph, with nodes representing the several positions in the games, and arcs representing moves. This is the extensive form of the game. For example, consider the simple game of matching pennies:

Example 1. Player I puts a coin on the table, with either heads (H) or tails (T) up. Player II, not seeing the coin, calls either H or T. If II has called correctly, she wins \$1 from I. If the call is incorrect, I wins \$1 from II.

Figure 1
The game of Matching Pennies

Figure 2
The game of Matching Pennies, modified

This game is represented by the graph in Fig. 1. Play starts at node A, which 'belongs' to player I (it is his turn to play there). Depending on I's choice of H or T, play then moves to either node B or node C, both of which belong to II. After II makes her choice, play terminates at one of the nodes D, E, F, or G, all of which are terminal nodes of the game. Numbers are assigned to the terminal nodes: they are payoffs for the game. Thus, at D, the payoff $(-1, 1)$ means that, since II guessed H correctly, I must pay a dollar to II. Similarly at the other terminal nodes.

Note the connection (shade) between nodes B and C. This is meant to represent II's lack of information when she moves here: she knows the position is either B or C, but cannot distinguish between them. Thus B and C are said to belong to the same information set.

Example 2. Suppose, in the previous example, II were allowed to see how I had placed the coin. Otherwise, assume the game is unchanged. In this case, we obtain the graph shown in Fig. 2. The difference between the two figures is that nodes B and C are now in different information sets. II, when moving here, can distinguish between these two positions.

Alternatively, it is frequently more convenient to represent a game by means of its strategies. A strategy is a rule that tells a player what to do in each conceivable situation, i.e., at each of his information sets. Thus, in example 1, each player has two strategies, namely H and T. In example 2, Player I still has only two strategies, H and T. Player II, however, has two information sets (vertices B and C) at each of which she has two alternatives. This gives her a total of four strategies, which we might call S(HH), S(HT), S(TH), and S(TT) (where HT means 'call H in position B, T in position C,' etc.).

For a given choice of strategies (one strategy for each player), the outcome of the game is determined except for the effect of random moves. Assuming that the probability distributions at chance moves are well defined, and known to the players, it is quite straightforward to obtain expected payoffs for each choice of strategies. The function which assigns to each n -tuple of strategies these expected payoffs is known as the normal form of the game.

For the game of example 1, above, the payoff is given in the form of a table or, more precisely, a 2×2 matrix, in which the rows correspond to Player I's choice of strategy, and the columns to II's choice. The entries are pairs of numbers, representing the payoffs:

	H	T
H	$(-1, 1)$	$(1, -1)$
T	$(1, -1)$	$(-1, 1)$

For the game of example 2, the normal form is given as a 2×4 matrix, much as in example 1:

	S(HH)	S(HT)	S(TH)	S(TT)
H	$(-1, 1)$	$(-1, 1)$	$(-1, 1)$	$(-1, 1)$
T	$(1, -1)$	$(1, -1)$	$(1, -1)$	$(1, -1)$

3. Two-person Zero-sum Games

3.1 The Game Matrix

In the simplest of cases, a game situation will have only two players, with directly opposed interests. This can be thought of as a closed system in which, whatever one player wins, the other loses. Thus the sum of the two players' utilities will be zero at all times. It follows that it is not necessary to state explicitly Player II's payoff: this is always the negative of that to Player I. The outcome of such a game can be represented, then, by a single number: I's payoff. The normal form of such a game becomes a matrix in which, as before, rows represent I's strategies, and columns, II's strategies.

tegies. The entries are payoffs to I, which I wishes to maximize, and II, to minimize. Thus, for the game of example 1, the normal form becomes the matrix:

$$\begin{array}{cc} -1 & 1 \\ 1 & -1 \end{array}$$

and, for example 2, it becomes:

$$\begin{array}{cccc} -1 & -1 & 1 & 1 \\ 1 & -1 & 1 & -1 \end{array}$$

3.2 Equilibria and Saddle Points

In a desire to 'solve' games, we look for equilibria, i.e., choices of strategies such that no one of the players can gain by a unilateral change of strategy. In a zero-sum matrix game, a pair of strategies will be in equilibrium if the payoff they define is simultaneously the largest in its column and smallest in its row. This is frequently called a *saddle point*, by analogy with the surface of a (riding) saddle.

Example 3. In the matrix game:

$$\begin{array}{ccc} 6 & 1 & 2 \\ -4 & 0 & 9 \\ 8 & -1 & -4 \end{array}$$

the entry in the first row, second column is a saddle point. Similarly, in example 2, above, both entries in the second column are saddle points.

When a matrix game has a saddle point, game theory recommends that the players choose the strategies giving rise to that point. Unfortunately, as in example 1 above, most matrix games will not have saddle points. Another example of a game without a saddle point is:

Example 4:

$$\begin{array}{ccc} 5 & 1 & 0 \\ -1 & 2 & 1 \\ 1 & -3 & 3 \end{array}$$

3.3 Mixed Strategies

If a game does not have a saddle point, it is important to keep one's opponents from learning one's plans. Game theory then recommends the use of a mixed strategy. In a mixed strategy, a player chooses among his strategies (the rows and columns of the matrix,

hereafter called pure strategies) by a randomization scheme. The mixed strategy is then an assignment of probabilities to the several pure strategies. Thus it may be possible for an opponent to compute one's mixed strategy (since this particular assignment of probabilities is chosen in a rational manner), but it is impossible to know the actual pure strategy used in any play of the game. We generally represent a mixed strategy (for a given player) as a vector with m components (m being the number of pure strategies that player has), non-negative and adding to 1.

Suppose, then, that in matrix game A, Player I has chosen the mixed strategy x , while II has chosen y . It is not too difficult to see that, assuming these two randomization schemes are independent, there will be an expected payoff equal to the matrix product xAy . Once again, I wishes to maximize, while II wishes to minimize, this quantity.

The question now is how the mixed strategies should be chosen. A very important theorem, the minimax theorem, discovered independently by E. Borel and J. von Neumann during the 1920s, tells us that, for any matrix game, there exist mixed strategies, x^* and y^* (optimal strategies) and a number v (the value of the game) such that, if I uses x^* , he will always have an expected payoff at least equal to v , no matter what II does. Similarly, if II uses y^* , the expected payoff will never be greater than v , no matter what I chooses. The triple $(x^*; y^*; v)$, consisting of two optimal strategies and the value, is the solution of the game.

As an example, note that, in example 1 above, the optimal strategies are $x^* = (1/2, 1/2)$ and $y^* = (1/2, 1/2)$, guaranteeing the value $v = 0$. In example 4, the optimal strategies are $x^* = (2/7, 4/7, 1/7)$ and $y^* = (1/7, 2/7, 4/7)$, guaranteeing the value $v = 1$.

4. Two-person General-sum Games

In other games, the players' interests will not be directly opposed. Thus cooperation between the two players may well be possible, unless the rules of the game (e.g., antitrust laws) specifically forbid this. We therefore consider two cases: the noncooperative and the cooperative game.

4.1 Noncooperative Games

In the noncooperative case, the emphasis has generally been on equilibrium points, (still defined as pairs of strategies such that neither player can gain by a unilateral change). Much as in the case of matrix games, it can be shown that, when mixed strategies are allowed, every finite n -person game has at least one equilibrium n -tuple of strategies. Unfortunately, equilibrium points are not generally as satisfactory here as in the case of matrix games. In fact, a game might have

several different equilibrium points; moreover, even if a game has a unique equilibrium point, it is not clear that it will be best for players to play in equilibrium.

Example 5. In the two-person (non-zero-sum) game:

(4, 1)	(0, 0)
(1, 0)	(2, 5)

the strategy pairs (row 1, column 1) and (row 2, column 2) are both in equilibrium. Note, however, that Player I clearly prefers the first of these, while II prefers the second. It is not clear how the game should then be played.

Example 6. In the game:

(5, 5)	(0, 10)
(10, 0)	(1, 1)

(usually known as the prisoner's dilemma), the pair (row 2, column 2) is the unique equilibrium point. Note, however, that both players will receive a higher payoff if (row 1, column 1) is used.

4.2 Cooperative Games

In case cooperation is allowed, it is usually possible for both players to gain by profitable deals. Since, however, many such deals may be possible, the question of bargaining comes into play. Essentially, the search in such games has been for a 'fair' arbitration rule, one that takes into account what each player can do for himself (without the other player's help) and what the two of them can accomplish together. J. Nash in 1950 developed an axiomatic model for this. Assuming a set S of possible bargains (represented as pairs of payoffs), Nash looks for an outcome (bargain) which will be Pareto-optimal (it is not possible for one player to gain more without taking something from the other) and individually rational (each player gains at least as much as he could by himself) and which moreover satisfies certain technical conditions. Nash shows that the only arbitration rule which satisfies these axioms is the rule that chooses the bargain which maximizes the product of the two players' increments in utility (over what they could get by themselves).

Example 7. Two players are to divide the sum of \$100; if they do not agree on a division of the \$100, each gets \$0. Assume player I's utility is proportional to the amount of money he receives; for Player II, however, suppose that \$ y represents a utility equal to the logarithm of $100 + y$.

In this case, any division (x, y) with $y \leq 100 - x$ is permissible. This will give rise to any utility payoffs of the form (x, w) , where $w \leq \log(200 - x)$. Nash's solution is the point which

maximizes the product $x(w - \log(100))$, subject to the constraint above. Using differential calculus, it is not difficult to see that this maximum is attained at $x = 54.4$, so that I should receive \$54.40 while II receives \$45.60.

Nash's system of axioms is not the only one possible. Several other systems of axioms, as well as nonaxiomatic approaches, have been suggested. There is, unfortunately, no generally accepted solution to the bargaining problem.

5. n-Person Games

5.1 The Characteristic Function

In case there are three or more players, the cooperative game is further complicated by the fact that each player might choose among several possible coalitions. J. von Neumann and O. Morgenstern (1947) approached these games through the *Characteristic Function*. Let $N = \{1, 2, \dots, n\}$ be the set of all players in a game. For a given coalition S (nonempty subset of N), $v(S)$ is the amount of utility which the members of S can obtain jointly. It is assumed that this utility can be divided among the members of S in any way, if they agree. Thus v , the characteristic function, assigns a number to each coalition. The problem then is to look for a division of the total amount $v(N)$ which is available in the game, in such a way that each player, i , receives at least the amount $v(\{i\})$. Any payoff vector that does this is an imputation of the game v .

Von Neumann and Morgenstern then introduce the notion of domination. Given two imputations, x and y , we say that x dominates y if there is at least one coalition S such that (a) $x_i > y_i$ for every $i \in S$ (so that all members of S prefer x), and (b) $\sum_{i \in S} x_i \leq v(S)$ (so that S is strong enough to obtain x).

5.2 The Core and Stable Sets

One possibility, now, is to look for the undominated imputations. The set of these is known as the core, and is closely allied to the economic concept of market equilibrium.

Example 8. In a three-person game, player 1 owns a horse for which she has no use. Players 2 and 3 would both like to buy the horse; player 2 values it at \$200 while 3 values it at \$100. We will equate money with utility.

It may be seen that any single player can create no utility in this game. Thus $v(\{i\}) = 0$ for $i = 1, 2, 3$. Similarly, $v(\{2, 3\}) = 0$ since the two buyers together can do nothing.

Now, if 1 sells the horse to 2 for \$ x , then 1 gains x (she has exchanged a useless horse for \$ x), while 2 gains $200 - x$ (he has obtained a horse worth \$200 for \$ x). Together, then, they gain 200, and we set $v(\{1, 2\}) = 200$. Similarly, $v(\{1, 3\}) = 100$ and $v(\{1, 2, 3\}) = 200$.

For this game, an imputation is any vector (x_1, x_2, x_3) with non-negative components adding to 200. To be in the core, the imputation must additionally satisfy the conditions

$x_1 + x_2 \geq 200$ and $x_1 + x_3 \geq 100$. This can only happen if $100 \leq x_1 \leq 200$, $x_2 = 200 - x_1$, and $x_3 = 0$. In effect, it seems that 1 will sell the horse to 2 for a price between \$100 and \$200. Player 3 receives nothing, but helps to drive the price up. (Note that, if player 3 were removed from the game, the price could be anything between \$0 and \$200.) We should point out that, in classical economics, such a situation would reach equilibrium with precisely such a price.

In many cases, unfortunately, the core is empty, and von Neumann and Morgenstern thus develop the concept of a solution (now better known as a stable set). A stable set (for a given game) is a set V of imputations such that (a) no imputation in V dominates another in V and (b) every imputation not in V is dominated by at least one in V . For some two decades, it was conjectured that every game in characteristic function form had at least one stable set, but W. F. Lucas (1967) gave an example of a ten-person game with no stable sets.

Example 9. In a three-person game, there is a trunk full of valuable objects, worth 100 units of utility. This trunk is so heavy that no one of the three players is strong enough to lift it; alternatively, any two acting together can carry the trunk and collect the utility.

We represent this game by the characteristic function u , where $u(\{i\}) = 0$ for $i = 1, 2, 3$, and $u(S) = 100$ for any coalition S with two or three members. For this game, we see that the imputations are vectors with three nonnegative components adding to 100. Now, for an imputation to be in the core, each two-person coalition must receive at least 100 units. But this means that the players must receive on average at least 50 units; i.e., the three together must receive at least 150 units. This is impossible since there are only 100 units available, and we conclude that, for this game, the core is empty.

However, it is not difficult to check that the set V , consisting of the three imputations (50, 50, 0), (50, 0, 50), and (0, 50, 50) is a stable set. (This is not the only stable set for this game.)

5.3 The Shapley Value

Both the core and the stable set solution concepts suffer from the fact that (a) the first may be empty, the latter might not exist, and (b) in many cases they contain an enormous number of imputations. Game theorists have therefore looked for other solution concepts. Foremost among these is L. S. Shapley's value.

First developed in 1953, the Shapley value or power index is based on the three axioms of efficiency (if a game is played entirely by a set of players, these players will share the total available utility), anonymity (the value depends only on the players' possibilities, and not on the names given them) and additivity (the value of the sum of two games is equal to the sum of the two games' values). Shapley proved

that there is a unique value scheme satisfying these three axioms over the set of all n -person games, and this scheme assigns to player i , in game v , the quantity $\phi_i[v]$ given by the formula

$$\phi_i[v] = \sum_{S \subset N} \gamma_{n,s} [v(S \cup \{i\}) - v(S)]$$

where the sum is taken over all coalitions, S , and for these, s is the number of players in S , while $\gamma_{n,s} = s!(n-s-1)!/n!$.

As an example, the horse game (example 8) has value $\phi[v] = (116.7, 66.7, 16.7)$. The game of example 9, being totally symmetric, has value $\phi[u] = (33.3, 33.3, 33.3)$.

The Shapley value is also very useful as a measure of voting power in political situations. A voting structure is a game v whose players are the voters, N , and such that, for any coalition S , $v(S) = 1$ if S has enough votes to win an election (or approve a motion), and $v(S) = 0$ otherwise.

Example 10. In a committee with four members, assume member 1 (the chairman) has the power to break ties. In this case, $v(S) = 1$ if S has three or four members, or if S has two members, including the chairman. For this game, the value is $\phi[v] = (0.5, 0.167, 0.167, 0.167)$.

5.4 The Bargaining Set(s)

Of other solution concepts for n -person games, we mention only the bargaining sets, developed by R. Aumann and M. Maschler (1995). Given a coalition structure, $T = \{T_1, T_2, \dots, T_m\}$ (a partition of the set of players) we consider only payoff vectors $\mathbf{x}$ which give to each of the sets T_j (the coalitions which are assumed to form) their total possibility $v(T_j)$ and to each player, i , at least $v(\{i\})$. Such pairs $\langle T; \mathbf{x} \rangle$ are individually rational payoff configurations (i.r.p.c.'s). Now, given an i.r.p.c., a player, i , can object against another player, k , if i can receive greater utility in another i.r.p.c. $\langle U; \mathbf{y} \rangle$ in which she does not have player k as a coalition partner. Of course, k can counterobject if there is yet another i.r.p.c. $\langle V; \mathbf{z} \rangle$ in which he does not need i as a partner, and such that $z_k \geq x_k$. In this case, the objection is unjustified; otherwise (i.e., if there is no counter-objection) the objection is justified.

Now, an i.r.p.c. is said to be stable, or belong to the bargaining set $\mathbf{M}$, if there are no justified objections. Because of different possible relations allowed between the objecting and objected players, i and k , there are several somewhat different bargaining sets. Aumann and Maschler prove that in one case, namely when i and k have to be partners in the original structure $\mathbf{T}$, the bargaining set—here denoted $\mathbf{M}_1^{(i)}$, is nonempty in the sense that, for any game v , and any coalition structure $\mathbf{T}$, there exists at least one $\mathbf{x}$ such that $\langle T; \mathbf{x} \rangle$ belongs to $\mathbf{M}_1^{(i)}$.

Example 11. In the three-person game of example 9, if the coalition structure is $T = \{\{1, 2\}, \{3\}\}$, the only stable payoff vector is (50, 50, 0). If, instead, the grand coalition ($T = \{N\}$) forms, then the only stable payoff vector is (33.3, 33.3, 33.3).

In the four-person game of example 10, if the coalition structure $T = \{\{1, 2\}, \{3\}, \{4\}\}$ forms, then the stable payoffs are of the form $(t, 1-t, 0, 0)$, where $0.5 \leq t \leq 0.67$.

6. Games with Incomplete Information

In some cases, players are unaware of some of the available strategies, or might be uncertain as to the payoffs which correspond to certain choices. In particular, they may be unaware of the utilities which other players assign to certain outcomes (e.g., we frequently do not know whether we are dealing with an honest or dishonest person—an honest person being one who assigns high utility to keeping an agreement). In such situations—known as games with incomplete information—repeated play will often give us further information—a person who does not keep an agreement may simply have made an honest mistake, but if this happens repeatedly, we generally conclude he is dishonest. Of course, a dishonest person, realizing this, will frequently keep some less important agreements so as to ‘lull’ others in preparation for a big scam. In some important work dating back to the 1960s, J. Harsanyi (1977) on the one hand, and Aumann and Maschler on the other, address this problem of learning and deception.

7. Conclusion

Game theory represents an important attempt to give a mathematical basis to behavior in conflict situations. Admittedly, there are elements of human activity which are not easily modeled, and this leads to certain gaps in the theory. Nevertheless, it has served to give a mathematical structure to several well-known ideas (bluffing, bargaining) and to develop new insights into human behavior. As of this writing, it is considered an important mathematical tool for economists and other social scientists.

Game Theory and its Relation to Bayesian Theory

This entry explores some open controversies relating to a contrast between rival decision paradigms. Alas, it cannot be a report on a unified theory of games: such a thing does not exist. The controversies between Bayesian decision theory and traditional Game Theory have a common source, however, which may be identified informally, as follows.

Bayesian decision theory comes in many varieties, Good (1971). Common to all is one rule: the principle of maximizing (subjective) conditional expected utility. Generally, an option in a decision problem is depicted as a (partial) function from possible states of affairs to outcomes, each of which has a value represented by a (cardinal) utility. Where Bayesian decision makers are uncertain about which state of affairs obtains, they assign conditional probabilities to those states, conditional upon the choice of the option. The Bayesian decision rule is to choose an option from the set of available options that maximizes subjective conditional expected utility—assuming a maximum exists, as will be done here. (Some Bayesian theories, e.g., Savage (1954), use a restricted formulation where acts and states are probabilistically independent, and dominance considerations apply. Then the Bayesian decision rule is simplified: maximize subjective expected utility.) Thus, the primary Bayesian decision rule assesses the value of an option by a weighted average of the utilities of potential outcomes, weighted according to the decision maker’s (conditional) personal probability over states (see *Decision Theory: Bayesian*).

Traditional Game Theory, by contrast, requires that rational players choose strategies that form an equilibrium—though which variety of equilibrium they adopt is also a matter of serious debate among game theorists, as noted below. However, under each sense of ‘equilibrium’ that is proposed, a player is required to assess the value of a strategy in terms of a best response that an opponent might make against it. That is, by game theoretic standards, against each available strategy that the player might select, typically

there is one state of affairs, namely the *best reply* that might be chosen by the (collective) opponent(s). That *best reply* is what determines the value of the strategy for the player. When all the players' choices jointly meet the criterion of being best replies, a *Nash equilibrium* results.

At the core of the debate, then, is this conflict. On the one hand is the Bayesian decision rule as that might be applied to games. It is a rule that specifies the value of a player's choice of a strategy in a game as a weighted average over possible replies that an opponent might make. Here, the set of potential strategies available to the (collective) opponent(s) constitute the states of affairs over which the Bayesian player is uncertain, and the weights assigned to these are the player's subjective probability distribution for what the opponent might do. On the other hand, there is the game theoretic rule that uses an opponent's best reply as the primary criterion to determine the value of a player's choice of strategy. Of course, since a distribution with all its weight concentrated on one point—corresponding to the state of affairs that is the opponent's *best reply*—is not precluded by Bayesian theory; sometimes, but usually not, the two approaches agree. But Bayesian theory generally does not privilege the Nash equilibrium solution. Before we examine games where the two approaches give different recommendations, and some recent attempts to mitigate these differences, it is worthwhile to review a few points of shared agreement.

1. Illustrations Where Expected Utility Considerations Are Welcome Within Traditional Game Theory

1.1 Decisions Under Risk

First, in their *magnum opus*, *The Theory of Games and Economic Behavior*, von Neumann and Morgenstern (1944), formalize the assumption that each player's preferences for outcomes in a game can be quantified by a (cardinal) utility. That is, they assume that a player's preferences over outcomes satisfy the expected utility rule applied to decisions under *risk*. Specifically, when options are presented as *lotteries* over outcomes, i.e., when a (simple) probability distribution for outcomes is well defined, then von Neumann and Morgenstern assume that the decision maker's preferences accord with the Bayesian rule of maximizing expected utility. This assumption is critical to the received game theoretic interpretation of *mixed strategies*, whose values are given by expectations over the numerical outcomes of pure, i.e., non-mixed strategies.

That is, the numerical values used to describe outcomes in games depend for their meaning on the application of expected utility in decisions under *risk*. This much of von Neumann and Morgenstern's theory

is in common with Bayesian decision theory, though it involves a game with one player. Of course, Bayesian decision theory, but not Game Theory, extends the rule to maximize expected utility also to decisions under *uncertainty*—where well-defined probabilities over states of affairs are not specified by the assumptions of the decision problem. In particular, Game Theory does not extend the Bayesian decision principle to problems under uncertainty with more than one player where the relevant states of affairs are decisions by an opponent!

1.2 deFinetti's Game of Coherent Previsions

In a seminal work, deFinetti (1937) proposed a game theoretic basis for using subjective expected utility. Here is a simplified version of that game—simplified to avoid important technical considerations involving deFinetti's use of merely finitely additive probability that arise with infinite state spaces.

Let $\Omega = \{\omega_1, \dots, \omega_n\}$ be a finite set of pairwise exclusive and mutually exhaustive states, i.e., Ω is a finite partition of the sure event. Call the elements of Ω the *states*. Let $\{X_i; i = 1, \dots\}$ be a set of random variables defined on Ω . That is, each $X_i: \Omega \rightarrow \mathcal{R}$ is a simple, real-valued function defined on the partition Ω . *Player*₁, whom we call the *bookie* in the game, is obliged to play first and to reveal a set of real-valued quantities, called *previsions* $\{p_i; i = 1, \dots\}$. A set of previsions constitutes a strategy for the *bookie*. (The game requires that the bookie reveals a pure strategy.) *Player*₂, whom we call the *gambler* in the game, plays second and, having seen the strategy chosen by the *bookie* is then allowed to choose a set of real-valued terms $\{\alpha_i; i = 1, \dots\}$, subject to the constraint that only *finitely* many of these terms may differ from zero. (For added simplicity in this presentation, assume that $\sum_i |\alpha_i| \leq 1$.) A set of terms constitutes a strategy for the *gambler*.

Next, consider the (simple) random variable, $Y = \sum_i \alpha_i X_i - p_i$, whose value $Y(\omega_i) = y_i$ is fixed by the state. Given a strategy choice by each player, the payoff to the *bookie* in deFinetti's game is the maximum $\max_i \{y_i\} = y^*$, while $-y^*$ is the corresponding payoff to the *gambler*. Hence, this is a 2-person, zero-sum game in which the *bookie* plays first.

Since the *gambler* may choose all the terms equal to 0, in which case $Y = 0$ for sure, the *gambler* can ensure that the value of the game to the *bookie* is bounded above by 0. Now, either the *bookie's* previsions $\{p_i; i = 1, \dots\}$ form a set of expected values for the random variables $\{X_i; i = 1, \dots\}$, based on a single probability distribution P over Ω , or they do not. deFinetti showed that one of two circumstances obtain, respectively: If there exists a probability P such that $E_P[X_i] = p_i$, then the *gambler* can do no better than securing the value 0 for the game, and the *bookie* is said to have *coherent previsions*.

Aside: This can be seen as follows. When the bookie's previsions are coherent, then $E_P[Y] = 0$ regardless of the gambler's choice of strategy. But a weighted average of terms (y_i) cannot exceed its maximum term (y^*); $0 = E_P[Y] \leq y^*$. Thus, the coherent bookie is assured a value of at least 0.

If, however, the *bookie's* chosen strategy does not agree with the expectations from a probability P , then the gambler may find a reply that insures a strictly negative outcome to the *bookie*: then the *bookie* is said to have *incoherent previsions*. That is, if and only if the *bookie* does not play as though the *previsions* are (subjective) expected values of the random variables, calculated with some subjective probability P , the *bookie* is in jeopardy to suffer a sure loss from a clever choice of strategy by the *gambler*. Thus, though the *bookie's* prudent, equilibrium strategy is to play a coherent set of previsions, just as though maximizing expected utility, which equilibrium from the continuum of coherent sets of previsions is chosen remains unspecified.

Aside: When the random variables are indicator functions for events, i.e., when they are indicators for subsets of Ω , then this result reduces to the familiar Dutch Book Theorem (see *Probability: Interpretations*).

For an original application of deFinetti's prevision game to problems of cooperative decision making among several agents, see Nau's interesting work (1999).

1.3 Admissible Statistical Decision Functions

Wald (1950) proposed a very general theory of statistical decisions where, in effect, the statistician plays a zero-sum game against Nature. The statistician chooses a statistical decision rule and Nature fixes the unknown state of affairs. In outline and simplified for presentation here, Wald's influential program for framing statistical problems uses the following structure. Let θ be a real-valued statistical parameter with parameter space Θ , a partition of the relevant states of affairs. Let X be a random value whose distribution $P_\theta(X)$ depends upon the parameter θ . The statistician anticipates observing $X = x$ and in advance of the observation chooses a statistical *decision rule*, denoted $d(\cdot)$, that may depend upon the value of X to be observed. The result to the statistician of the *terminal decision* $d(x)$ depends upon the unknown parameter θ . The value of that result is specified by a loss function, $L(d(x), \theta)$, understood as the negative (cardinal) utility of the consequence to the statistician of $d(x)$ when θ obtains. In Wald's presentation, typically the loss function is nonnegative. When, for each value of θ the minimum (over the set of terminal decision) of the loss function is 0, the utility for payoffs is then said to be formulated as a *regret* function.

Aside: In Bayesian decision theory, when acts and states are probabilistically independent and utility is bounded—as in Savage's theory—then, without loss of generality, the decision problem may be reformulated with utility represented by a regret function.

Here are key definitions in Wald's theory.

The *risk function* R for a decision rule $d(\cdot)$ is the expected loss of adopting $d(\cdot)$ as a function of the unknown parameter θ .

$$R(d(\cdot), \theta) = E_\theta[L(d(\cdot), \theta)].$$

A decision rule $d'(\cdot)$ is *inadmissible* if there exists another decision rule $d(\cdot)$ such that, for each value θ the risk for d is never greater than the risk for d' , and for some value of θ the risk for d is less. In that case, say that rule d *dominates* rule d' .

That is, for each θ $R(d(\cdot), \theta) \leq R(d'(\cdot), \theta)$, and for some θ $R(d(\cdot), \theta) < R(d'(\cdot), \theta)$.

A decision rule that is not dominated is *admissible*.

Given a probability distribution $P(\theta)$ for the parameter, the Bayes-risk r for a decision rule $d(\cdot)$ is the expected risk with respect to P of adopting $d(\cdot)$.

$$r(d(\cdot), P(\theta)) = E_P[R(d(\cdot), \theta)] = E_P[E_\theta[L(d(\cdot), \theta)]].$$

A decision rule $d(\cdot)$ is *Bayes-admissible with respect to the distribution* $P(\theta)$ if, for each dominating rule $d'(\cdot)$, the set of parameter values where $d'(\cdot)$ has strictly lower risk has P -probability 0.

A decision rule $d(\cdot)$ is minimax for the statistician if it minimizes the maximum risk over the parameter space (see *Decision Theory: Classical*).

The following result (Berger (1985, p. 254) or Schervish (1995 p. 155) helps to explain the relevance of Bayesian expected utility considerations in identifying admissible decision rules.

Theorem: Suppose that the Bayesian statistician's 'prior' distribution $P(\theta)$ gives positive probability to each open interval. Assume that the risk function $R(d(\cdot), \theta)$ is continuous in θ for each decision rule $d(\cdot)$. Then if $d^*(\cdot)$ is Bayes-admissible with respect to P , it is admissible.

The resulting connection of Bayesian decision rules to Game Theory, as first developed by Wald, is indicated by the following (see Berger (1985, p. 353) or Schervish (1995, p. 167)).

Theorem: If decision rule $d(\cdot)$ has constant risk and if it is admissible, then it is minimax.

Thus, if $d^*(\cdot)$ is Bayes-admissible with respect to the distribution P and has constant risk, it is minimax. Also, in that case P is said to be the *worst-case* prior, since it is Nature's (mixed) strategy for achieving a maximin solution in the statistical game. Though the

details are beyond the presentation here, similar results apply to certain limits of Bayes-admissible solutions, obtained by considering a sequence of (proper) priors. (See Wald (1950 Theorem 3.17) for a result showing that every admissible decision rule either is Bayes-admissible for some distribution $\mathbf{P}$ or is the limit of a sequence of Bayes-admissible solutions.) The following illustrates the more general case.

Example: Given the parameter θ , let X have a Normal $N[\theta, 1]$ distribution with $\Theta = \mathcal{R}$. The statistician is required to provide a point-estimate for θ under a squared-error loss function, $L(d(x), \theta) = (d(x) - \theta)^2$. The intuitive rule $d(x) = x$ is admissible with constant risk $E_\theta[(x - \theta)^2] = \text{Variance}[X] = 1$. For the (conjugate) Normal prior $\mathbf{P}$, with $\theta \sim N[0, \sigma^2]$, a Bayes-admissible decision rule is $d(x) = x\sigma^2/(\sigma^2 + 1)$, with risk function $R(d(\cdot), \theta) = (\sigma^4 + \theta^2)/(\sigma^2 + 1)^2$ and Bayes-risk $r(d(\cdot), \mathbf{P}(\theta)) = \sigma^2/(\sigma^2 + 1)$. Consider a sequence of such conjugate priors, $\mathbf{P}_n$, where $\theta \sim N[0, \sigma_n^2]$, with $\lim_n \sigma_n^2 \rightarrow \infty$. The corresponding Bayes-admissible rules are just, $d_n(x) = x\sigma_n^2/(\sigma_n^2 + 1)$. The limiting Bayes-rule is the intuitive rule, $d(x) = x$, which is admissible and has constant risk; hence, it is minimax. From the statistician's point of view, the *worst case prior* is the 'improper' uniform distribution for θ : that is Nature's maximin strategy. (See Schervish and Seidenfeld (1996) for a minimax theorem that applies when the worst case prior is 'improper.') Thus, the intuitive decision rule in this problem, $d(x) = x$, illustrates a case where the game theoretic equilibrium and extended Bayesian expected utility theory (using limits of Bayes-admissible strategies) coincide.

In the preceding example, each of the decision rules $d_n(x)$ is Bayes-admissible with respect to the prior $\mathbf{P}_n$, and is an admissible decision rule as well. Thus, even in this heuristic example we see the tension between the two decision paradigms. The Bayesian statistician may have prior beliefs more accurately depicted by one of the (proper) conjugate priors $\mathbf{P}_n$, rather than by the limiting, worst-case prior. In such a situation, the Bayesian statistician will not be motivated by equilibrium considerations to adopt the game theoretic solution instead of maximizing expected utility with the decision rule $d_n(x)$. This is the tension explored in the next section.

2. Equilibrium Refinements and Maximizing Expected Utility: Rationalizable Strategies, Correlated Equilibrium, and Trembling Hands

What if each player in a game is a subjective expected utility maximizer, models the opponents that way, and these assumptions are common knowledge among the players? That is, though each player is uncertain about what choices opponents will make, nonetheless each player behaves as though he or she holds a (subjective) probability over those unknown states of affairs and maximizes expected utility against that probability

distribution. But, insofar as players think that their opponents also maximize expected utility, their probabilities must be supported by the set of their strategies that maximize their expected utilities. That all the players share these assumptions leads to a modest but interesting restriction on the set of Bayesian equilibria that result.

Bernheim (1984) and Pearce (1984) consider the important cases where the Bayesian players have probability models for each other's play where, regarding simultaneous play, acts and states are probabilistically independent. That is, assume that when the game requires players to make moves in ignorance of (some of) the moves of their opponents, then from the perspective of each player, the opponents' moves are probabilistically independent of choices at that time. The result is the set of *rationalizable* strategies, which carries the following elegant description. A strategy is *rationalizable* if and only if it survives the recursive operation of deleting successively options that are *strictly* dominated by another option not already deleted.

Aside: The reader is alerted to the fact that the recursion mentioned above iteratively changes the set of states of uncertainty for a player, i.e., the set of surviving options available to the opponents, that are relevant to a player when determining whether strict dominance obtains between two available strategies.

For an examination of how rationalizability differs from the traditional criterion of Nash equilibrium, particularly for sequential games in extensive form, see the articles by DeGroot and Kadane (1983) and Kadane and Seidenfeld (1992).

The set of rationalizable strategies in a game, as judged by the common standards of traditional Game Theory, typically makes an uncomfortably large collection of permissible moves, offering too little guidance about how the game should be played. An even more radical departure from the traditional point of view is proposed by Kadane and Larkey (1982) who examine the question of what considerations become salient to a Bayesian game-player who does *not* assume Bayesian-rationality on the part of opponents. They argue that the distinctions that are most important to traditional Game Theory are of only passing relevance under their radical reformulation of the same decision problems. For the practical side of this matter, see *Negotiations: Statistical Aspects*.

In the other direction, Aumann (1974, 1987) proposes a narrowing of the rationalizable strategies by introducing additional components of common knowledge among the players. Specifically, Aumann argues for a theory of rationality in which the Bayesian players share a common 'prior' over all the states of uncertainty that are relevant to choices made in the game. The upshot is a powerful criterion of *correlated equilibrium*, where players' *mixed strategies* form a best reply against each other, while relying on what are

in effect probabilistically *dependent* events. This allows for Pareto gains, where all players do better with a correlated equilibrium compared to their expected gains from a Nash equilibrium, when the mixed strategies of the players use jointly *independent* events only.

The relevant states of affairs over which the players have a common prior in Aumann's theory include the choices of all the players. This leads to the following controversy. Can Bayesian players assign nontrivial personal probabilities to their own (current) choices? Levi 1997 examines this intricacy and argues against the coherence of Aumann's condition.

Another interesting approach to reconciling equilibrium theory with expected utility analysis is found in the important works by Harsanyi (1977), and Harsanyi and Selten (1988). Harsanyi's doctrine is that Bayesian agents ought to use special distributions—oftentimes uniform probabilities—to reflect their ignorance about whatever states of uncertainty are relevant to their choices. (Note the connection with the *worst case* prior of the *Example* given in Section 1.3.) In the joint work with Selten, cited above, their novel proposal relies on the following idea: Though Bayesian players have definite preferences over strategy choices, they can achieve only a *trembling-hand* selection, where some residual probability is invariably assigned to other options besides the one most desired. In short, the players' options are modeled as nontrivial mixed strategies with some residual probability attached to even undesirable choices, and this is common knowledge. Trembling-hand equilibrium analysis examines limits of Nash equilibrium strategies as the trembles diminish. The results underwrite the criterion that choices in extensive form games should obey the principle of *subgame perfection*, i.e., that self-defeating threats are only idle threats. This criterion is particularly significant for application of the rule of *backward induction* in the theory of sequential choices, e.g., extensive form games when these are viewed from the Bayesian perspective.

3. Additional Sources

Luce and Raiffa's (1957) work remains a first-rate source of basic ideas and results contrasting the rival decision theories discussed here. Blackwell and Girshick's (1957) book is an excellent introduction to the interplay of ideas between Bayesian decision theory and traditional Game Theory relating to the design of statistical experiments. Binmore's stimulating textbook (1992) is a rich source of heuristic examples and informed discussion illuminating rival accounts of equilibrium refinements, going well beyond the few varieties alluded to here. Binmore is not shy, commenting openly on some of the more radical attempts at applying Bayesian decision theory to games. Even a casual reading of Binmore's textbook

will convince the reader of the truth of the opening sentences in this article!

Game Theory: Noncooperative Games

Games are mathematical models of interactive strategic decision situations: there are various actors (players) involved that jointly determine the outcome and each tries to obtain that outcome that is most favorable to him. A game is said to be noncooperative if there are no possibilities for commitment (unilateral or multilateral) outside the rules of the game. In contrast, in cooperative games, players can form coalitions with the possibilities for doing so not being explicitly modeled within the rules of the game. Nash (1953) argued that the two approaches are complementary and he proposed building noncooperative models of cooperative games, an idea that is referred to as the Nash program. The article describes noncooperative game models and solution concepts and some applications are indicated (see Aumann 1987 for a more extended overview).

1. The Problem

Imagine an interactive decision situation in which various individuals (players) are involved, whose decisions affect each other. Depending on the decisions that are taken, a certain outcome will result; players have preferences over these outcomes and typically there is a conflict of interest as different players prefer different outcomes. Each player now faces the question what decision is best. As the decisions are interdependent, the answer to the question will depend not only on the player's own preferences, but also on the decisions that the other players take. The player, hence, has to make a prediction about what the other players will do. For an outsider there is the related question of predicting the overall outcome of the game. Based on the assumption of rational behavior of all players involved, game theory offers a set of tools and concepts that provide answers to these questions.

The above mentioned problem arises in a variety of circumstances, ranging from parlor games (chess, poker, bridge) to various economic, political, military, or biological situations. Game theory offers a collection of formal models and solution concepts to analyze these situations. While the history of the field can be traced back to the analysis of the two-person card game *le Her* by James Waldegrave in the early eighteenth century, with important contributions by the French scientists Cournot and Borel in the nineteenth and twentieth centuries (Baumol and Goldfeld (1968), Weintraub (1992)), John von Neumann gen-

erally is regarded as the founder of the field. In von Neumann (1928), he showed that the above mentioned problem allows a solution in the case of two players with strictly opposed interests (zero-sum games). The book *Theory of Games and Economic Behavior* that von Neumann wrote together with the economist Morgenstern (von Neumann and Morgenstern 1944) demonstrated convincingly that the tools developed initially for parlor games could be applied successfully to a variety of social conflict situations.

2. Noncooperative Game Models

The simplest type of model is one in which there is no dynamics: each player has to make only one decision and decisions are effectively made simultaneously as no player has knowledge about the decision that has been made by another player. As an example, one might think of a sealed bid procurement auction: without knowing the bids of the competitors, each player submits their bid in a sealed envelope; the player making the lowest bid is awarded the contract and in turn receives a payment (say) equal to their bid. Such a game is called a game in normal form or also a game in strategic form.

The formal mathematical definition of an n -player normal form game is as follows. Let S_i be the (finite) set of possible decisions (also called actions or strategies) that player i might take. Furthermore, let $S = \times_{i=1}^n S_i$ be the set of strategy profiles, hence, $s \in S$ specifies a strategy for each and every player in the game. Assume that each player's preferences over the set of outcomes of the game can be described by a (von Neumann and Morgenstern 1953) utility function, hence, each player wants to maximize their utility and only cares about expected utility. Von Neumann and Morgenstern (1953) give conditions under which such a utility function can be found; some theory has been developed also without this assumption, but it is convenient to maintain it here. Each strategy profile $s \in S$ produces a certain outcome and right $u_i(s)$ for the utility of player i associated with this outcome. The normal form game is then completely specified by the strategy sets S_i and by the utility functions u_i with $u_i: S \rightarrow \mathbb{R}$, hence $G = \langle S_1, \dots, S_n, u_1, \dots, u_n \rangle$.

Games in which players move more than once, and/or in which moves of different players are sequential can be represented by means of a tree. Formally, such a game is said to be in extensive form. The nodes of the tree correspond with decision points of players, with the arcs at a node representing the decisions that are possible at that node. Each endpoint of the tree represents an outcome of the game and again it is associated with a utility for each of the players. A special type of extensive form game is one in which there is perfect information: when a player has to move, they have full information about where they are in the game and what decisions have been taken

before. Chess can be viewed as an extensive form game with perfect information. So-called information sets are used to represent limited information in a tree: when a player cannot distinguish two nodes in the tree, these are in the same information set. When a player has to move, they can condition their action only on the information set that is revealed to them, not on the actual node. The theory has been developed mainly for games with perfect recall, that is, each player is assumed to fully remember their previous actions and information. Kuhn (1953) provides a formal development. For some recent contributions dealing with imperfect recall, see Rubinstein (1998).

Von Neumann (1928) introduced the fundamental concept of strategy by means of which an extensive form game can be reduced to one in normal form. Formally, a strategy for a player is a full plan of action that specifies for each information set of this player the action that this player intends to take if and when that information set is reached. Clearly, once a strategy has been determined for each player, the outcome is determined as well. Von Neumann argued that, for rational players, there is no loss of generality in forcing them to think through the game in advance, hence, to force them to choose a strategy. Consequently, the extensive form can be reduced to the simpler normal form.

The above description abstracted from randomization. A player, however, might randomize before the start of the game which (pure) strategy they might use during the game. Alternatively, they might randomize to determine which action they will choose once a certain information set is reached. The concept of mixed strategy is used to refer to the former case, the concept of behavior strategy refers to the latter case of local randomization. Kuhn (1953) showed that both concepts are equivalent for games with perfect recall, that is, whatever a player can do with a strategy of one type they can also do with a strategy of the other, and vice versa. Note that since players are assumed to have von Neumann–Morgenstern utilities, replacing ‘payoff’ (utility) by ‘expected payoff’ creates no special difficulties.

The traditional theory has been developed for games of complete information, that is, each player is assumed to know the utility functions of all the players in the game. Frequently, a player will not have all information about their competitors. For example, in the procurement context referred to above, a player may not know how many orders a competitor has in stock, hence, they may not know how much value an opponent assigns to winning the present contract. Harsanyi (1968) showed how to incorporate incomplete information into the model. To represent asymmetric information, Harsanyi introduces an artificial chance move at the beginning of the game that determines which piece of private information each player will have. This piece of private information is also called the player’s type. It is assumed that the set

of possible types and the probability distribution over this set is common knowledge, however, which type realization results for player i is typically only known to player i himself. A normal form game with incomplete information, hence, does not only specify the players and their utility functions, but also their types and the joint probability distribution on players’ types. Formally, such a game is given by a tuple $G = \langle S_1, \dots, S_n, T_1, \dots, T_n, u_1, \dots, u_n, p \rangle$ where S_i is player i ’s strategy set, T_i is the set of possible types of player, i , $u_i: S \times T \rightarrow \mathbb{R}$ is player i ’s payoff function (where $T = \prod_{i=1}^n T_i$), and p is the probability distribution on T . The play of the game proceeds as follows: A type profile $t \in T$ is determined according to p and player i is informed about their type t_i . Based on this information, player i updates information about the types of the others, computing the posterior probability $p_i(t/t_i)$ and chooses an action to maximize the associated expected payoff. Harsanyi’s modeling technique has shown to be very powerful (see *Auctions; Information, Economics of*).

3. Solution Concepts

3.1 Individual Rationality

Concepts of ‘individual rationality’ from decision theory can also be used in a game context. If one strategy s_i of player i is (strictly) dominated by another strategy s'_i of this player (i.e., it yields a lower payoff no matter what strategy profile s_{-i} the other players use, formally $u_i(s_i, s_{-i}) < u_i(s'_i, s_{-i})$ for all s_{-i}) then a rational player i will not use s_i and it should be possible to eliminate s_i without changing the solution. Furthermore, dominated strategies can be iteratively eliminated. Alternatively, a ‘Bayesian’ player will represent their uncertainty about their opponent’s strategies by a probability distribution σ_{-i} on S_{-i} ($= \prod_{j \neq i} S_j$) and they will thus only choose strategies that are best responses against some such correlated strategy σ_{-i} . By using duality theory from linear programming it can be shown that s_i is a best response against some correlated strategy σ_{-i} of the opponents if and only if s_i is not strictly dominated, hence, the two concepts are equivalent. In most of the theory it has been assumed that the fact that players decide independently implies that a player will represent their uncertainty by a profile of mixed strategies of the opponents, that is, the components of σ_{-i} are independent. The set of strategy profiles that remain after all strategies of all players that are not best responses against independent mixtures of opponents have been iteratively eliminated is called the set of rationalizable profiles (Bernheim 1984, Pearce 1984). The set of rationalizable strategies may be smaller than the set of iteratively undominated strategies.

In his theory of the 2-person zero-sum game, von Neumann also used an individualistic rationality concept. If player i uses mixed strategy σ_i then the worst that can happen to i is to receive the expected payoff $\min_{\sigma_{-i}} u_i(\sigma_i, \sigma_{-i})$, hence, player i can guarantee the payoff $\max_{\sigma_i} \min_{\sigma_{-i}} u_i(\sigma_i, \sigma_{-i})$ by choosing their mixed strategy appropriately. Note that a mixed strategy may 'guarantee' a higher expected payoff than a pure strategy. For example, in 'matching pennies' (two players simultaneously show the side of their penny with player 1 (resp. player 2) receiving both pennies if the sides are the same (resp. different) it is obviously better to keep one's side hidden, hence, to use a mixed strategy. Von Neumann showed that, for finite 2-person zero-sum games, there exist number v_1 and v_2 with $v_1 + v_2 = 0$ such that each player i can guarantee v_i . We say that is the security level of player i : against a 'rational' opponent, player i cannot expect to get more than this level. Strategies that guarantee the security level are called optimal strategies and v_1 is also termed the value of the game. Von Neumann's theorem is also called the minmax theorem, it thus shows that there is indeed an optimal way to play a finite 2-person zero-sum game.

3.2 Equilibrium

Nash (1950, 1951) was the first to break away from the individualistic rationality concepts. Rather than focusing on the direct question 'what should a player do' (or 'what should a game theorist advise a player to do'), he approached the problem indirectly and asked 'if the game has a solution, what properties would it have.' In fact, a suggestion to proceed in this way was already contained in von Neumann and Morgenstern (1953), but the authors of that book had not followed it through. Nash assumes that a satisfactory solution of a game exists. He further assumes that the solution is unique. Hence, the solution takes the form of a (mixed) strategy profile σ , recommending to each player i a course of behavior σ_i . Rational players will know this solution and a player will be willing to behave according to it only if it is in their interest to do so, that is, if the strategy σ_i is a best response against the strategy profile of the opponents, $u_i(\sigma) = \max_{\tau_i} u_i(\tau_i, \sigma_{-i})$. A Nash equilibrium is a profile of strategies σ such that this condition is satisfied for each player i . To summarize the argument, a necessary condition for σ to be a satisfactory solution of the game is that σ be a Nash equilibrium.

By relying on fixed point theorems (either the one of Brouwer or the one of Kakutani can be used), Nash proved that every finite game admits at least one Nash equilibrium, albeit possibly in mixed strategies. Indeed, in 'matching pennies' each player should choose each side of the coin with 50 percent probability in the unique equilibrium. In a 2-person zero-sum game, σ is

a Nash equilibrium if and only if it is a pair of optimal strategies, hence, Nash's concept generalizes the solution provided by von Neumann and Morgenstern.

Pursuing the above rationale leading to Nash's solution concept, three questions remain: (a) why does a player represent their uncertainty about the behavior of their opponents by an independent mixed strategy profile? (b) do the requirements determine a unique solution? and (c) is being a Nash equilibrium sufficient to qualify as a satisfactory solution? The first issue is taken up in Aumann (1974) where an alternative concept of correlated equilibrium is developed that allows for more general beliefs. One interpretation is that players discuss before the game and construct a common randomization device, a correlated strategy σ . Upon hearing what pure strategy the device selected for player i , this player updates their beliefs on their opponent's actions; σ is a correlated equilibrium if each player is always willing to follow the recommendation of σ . The answer to the second question is a clear no, it is easy to construct games with multiple Nash equilibria and many games, also some with practical relevance, do have multiple equilibria. Hence, the rationale that has been given for the equilibrium concept appears incomplete, and the question is, whether, in a game with multiple equilibria there is any argument for focusing on any of these. Alternatively, should one look in an entirely different direction for a satisfactory solution, for example, by giving up the assumption that the solution be unique? We discuss these questions below after first having taken up the third question and having shown that that one also has a negative answer: not every Nash equilibrium can be considered as a satisfactory solution.

Consider the following extensive form ultimatum game. Player 1 divides \$10 in any (integer) way that they want; player 2 observes the division and decides whether or not to accept it; if player 2 accepts, each player receives the amount that was proposed, otherwise neither player receives anything. In addition, assume that each player cares only about the amount of money that they receive and that each prefers more money to less, say $u_i(x) = x_i$. Player 1 then knows that player 2 is sure to accept as long as they are offered at least \$1, hence, there seem only two possible solutions of the game—10; accept all—and—9, accept iff $x_2 \geq 1$ (the first number is the amount that player 1 asks for himself). Indeed these two strategy profiles are Nash equilibria, however, there are other equilibria as well, for example, 3, accept iff $x_2 \geq 7$ is a Nash equilibrium. (If player 1 demands 3 for themselves, then player 2's strategy prescribes to accept and that is a best response; on the other hand, if player 2 indeed accepts only if offered at least 7, then it is optimal for player 1 to offer exactly 7.) In this equilibrium player 2 'threatens' to reject a positive amount that is offered to, such as \$5, even though strictly preferring to accept in case \$5 would be offered. The reason the profile is in

equilibrium is that an amount such as \$5 is not offered and, hence, the threat is not called. Player 1 behaves as if player 2 is committed to this strategy, in the extensive form game, however, such commitments are not possible and facing the *fait accompli* that \$5 is offered, player 2 will accept. Player 1 can neglect the incredible threat.

Starting with Selten (1965) a literature developed dealing with the question of how to eliminate equilibria involving incredible threats. Selten (1965) proposed the concept of subgame perfect equilibrium that is based on the idea of 'persistent rationality': everywhere in the game tree, no matter what happened in the past, the player that moves will play a strategy that, from that point on, is a best response against the strategies of the opponents. Formally, a subgame perfect equilibrium is a strategy profile that constitutes a Nash equilibrium in every subgame of the game, a subgame being a part of the game that constitutes a game in itself. For games with perfect information, subgame perfect equilibria can be found by the backward induction (dynamic programming) procedure that was used already in Zermelo (1913) to show that the game of chess is determined completely: starting at the end of the game one work backwards each time reducing the game by substituting a decision set of a player by an optimal decision and its associated payoff. It is worthwhile to remark that this assumption of 'persistent rationality' was criticized in von Neumann and Morgenstern (1944).

Selten (1975) noted that requiring subgame perfection was not sufficient to eliminate all equilibria involving incredible threats and proposed a different solution. He reasoned that, if the problem is caused by nonmaximizing behavior at unreached information sets, it can be eliminated by ensuring that all information sets are reached, if only with small probability. Formally, Selten (1975) defines an equilibrium to be (trembling hand) perfect if it satisfies a robustness test: each player should be still willing to play their equilibrium strategy if each player with some small probability makes mistakes and, as a consequence, every information set is reached with positive probability. In the ultimatum game above, if player 1 makes mistakes, player 2 is forced to accept any positive amount and player 1 will not offer more than \$1 to player 2 in a perfect equilibrium. The robustness test proposed is weak (the strategies are only required to be optimal for some sequence of small mistakes that converges to zero) and this guarantees that each game admits at least one perfect equilibrium. However, at the same time this implies that some equilibria are perfect only because of the fact that the mistake sequence can be artificially chosen, hence, the perfectness concept does not eliminate all equilibria that are considered as 'counterintuitive.' The same remark applies to the closely related concept of sequential equilibria that has been proposed in Kreps and Wilson (1982). This concept requires that, at each information

set, a player constructs beliefs over where they are in the set and optimizes their payoff, given these beliefs and taking the strategies of the opponents as fixed. Kreps and Wilson require that the beliefs be explainable in terms of small mistakes, hence, the close connection between their concept and Selten's.

Intuitively, one would like an equilibrium not to be robust against just some trembles but rather against 'plausible' ones: if there is a good explanation for why the information set is reached after all, then preference should be given to such an explanation. Plausibility is hard to define formally, but, if an equilibrium is robust against all trembles, then clearly it will also be robust against the plausible ones. Unfortunately, equilibria satisfying this strict robustness test need not exist. However, Kohlberg and Mertens (1984) have shown that sets of equilibria with this desirable property exist always. They, furthermore, argue that it is natural to look at sets of 'equivalent' equilibria. For example, if a player is fully indifferent between two of their strategies, there is no reason to make them choose a specific one. Similarly, if the choice only makes a difference if and after another player has played a strictly dominated strategy, one might be satisfied to leave the choice undetermined.

Sets of stable equilibria satisfy several desirable properties, such as being robust against elimination of strategies that are dominated or that are not a best response against any element of the set. The latter property is also called 'forward induction' and it has proved powerful to reduce the number of equilibrium outcomes in signaling games (see *Information, Economics of*). The original stability concept proposed in Kohlberg and Mertens (1984) was of a preliminary nature and was not completely satisfactory. The ideas have been further developed in Mertens (1989) but that concept has not seen too many applications yet as it is difficult to handle. In addition, part of the profession considers this a too demanding rationality concept (see van Damme 1991 for further discussion).

The normative, 'rationalistic' interpretation of Nash equilibrium that has been considered thus far relies on the assumption that the solution to a game is unique, yet many games admit multiple equilibria, even multiple stable ones. The question thus arises about equilibrium selection: how will players coordinate on an equilibrium and on which one? Consider the following simple normal form stag hunt game as an example. Two players simultaneously choose between the numbers 1 and 2. If both choose the same number, they each receive a payoff equal to the number chosen, if they choose different numbers the player choosing the lower number receives 1 from the other. The game has two equilibria in pure strategies: (1,1) and (2,2). The latter yields both players higher payoffs than the former, however, choosing 2 is also more risky than choosing 1: while the latter guarantees the payoff 1, the former might result in a loss of 1. How to resolve the problem?

Harsanyi and Selten (1988) provide a general theory of equilibrium selection in noncooperative games that can be used in these circumstances. The theory can be seen as an extension of Nash's (1953) equilibrium selection theory for bargaining games. The authors start by formulating general properties that a theory should satisfy (such as symmetry, ordinality, efficiency, monotonicity, consistency) but they discover quickly that not all of these can be satisfied at the same time. Indeed, the stag hunt game given in the above paragraph has the same best reply structure as the game in which payoffs are 2 (resp. 1) if each player chooses 1 (resp. 2) and where payoffs are 0 if different numbers are chosen, and in this game the efficient equilibrium involves both players choosing 1. Hence, choices have to be made and, as Harsanyi and Selten admit, different selection theories are possible. One of the major innovations of Harsanyi and Selten (that in some form will probably play a role in these alternative theories as well) is the concept of risk dominance. Intuitively, one equilibrium is said to risk dominate another if, in a situation where attention is confined to this pair, players eventually come to coordinate on the first as they consider the second to be more risky. The formal definition makes use of the tracing procedure, an algorithm (homotopy) that transforms any mixed strategy profile (which represents the players' initial assessment about how the game will be played) into an equilibrium of the game. This tracing procedure is supposed to capture the reasoning process of rational players in the game. If, in a situation of uncertainty about equilibria σ and σ' , the tracing procedure produces equilibrium σ , then σ is said to risk dominate σ' . The concept allows a simple characterization for 2-player 2×2 games with 2 strict equilibria. Let $p_i(\sigma, \sigma')$ be the probability that player i has to assign to σ_i in order to make their opponent j indifferent between σ_j and σ'_j . Intuitively, the larger $p_i(\sigma, \sigma')$, the more attractive σ_j is for player j . In this case, σ risk dominates σ' if and only if $p_1(\sigma, \sigma') + p_2(\sigma, \sigma') < 1$. In the above example, the equilibrium (1,1) risk dominates the equilibrium (2,2).

3.3 Evolution and Learning

The above discussion of Nash equilibrium (and its variants) has been based entirely on the rationalistic interpretation of this concept, viz. that a self-enforcing theory advising players how to play should prescribe a Nash equilibrium in every game. Nash (1950), however, provided also a second interpretation of his concept. When the game is played repeatedly by myopic players who best respond against the current situation, then, if a stable state is reached, that state has to be a Nash equilibrium. In this second interpretation it is thus unnecessary to assume that players know the full structure of the game, or are able to perform complex reasoning processes. On the

contrary, the interpretation applies in a context of limited information where players behave in a boundedly rational way. After Shapley (1964) had published an example showing that a certain dynamic adjustment process need not converge at all, interest in this second approach dwindled for some time, but it was revived in the 1990s. Since then a systematic study has begun under which circumstances a variety of processes will converge and, if they converge, to which equilibria. It is too early to draw broad conclusions, instead the reader is referred to Fudenberg and Levine (1998) for a partial overview. Interestingly, some of the concepts that were introduced in the 'rationalistic' branch reappear in this branch of the literature, in particular this holds for the concept of risk dominance.

Consider the stag hunt coordination game described above and imagine that it is played repeatedly. When a player is called upon to play they 'ask around' to find out what other players in the population that have already played have been confronted with and then plays a best response against the resulting sample. Young (1998) shows that the process will converge to one of the two equilibria. Now imagine that sometimes players make mistakes in implementing their desired action and choose the other one instead. In this case the process may move from one equilibrium to the other through a sequence of consecutive mistakes. Young (1998), however, shows that, if the probability of making mistakes tends to zero, the limit distribution will put all mass on the risk dominant equilibrium as that equilibrium is more robust to mistakes than the other one. Hence, in the long run when mistake probabilities are negligible the process will end up in the risk dominant equilibrium, irrespective where it starts out. The process not only produces an equilibrium, it leads to a very specific one. Research effort is under way to investigate the robustness of this result with respect to both the underlying game and the dynamic process under consideration.

Related to the above is the application of the Nash equilibrium concept in biology. As Maynard Smith (1982, p. vii) writes 'Paradoxically, it has turned out that game theory is more readily applied to biology than to the field of economic behavior for which it was originally designed.' In biological applications the concept of utility is replaced by that of Darwinian fitness (expected number of offspring), human rationality is replaced by evolutionary stability and, according to Maynard Smith, both contribute to making the theory more applicable. Note that in this context it is assumed that there is no conscious choice of strategy at all; strategies exist and individuals are 'programmed' to play certain strategies, an evolutionary process selects those strategies that have highest fitness and in the end an equilibrium results.

To illustrate, one may consider the so called Hawk-Dove game in which two animals are contesting a certain valuable resource. There is a (finite) repertoire of possible behaviors, S , and when an individual

programmed to play strategy s meets another individual playing strategy s' the gain in fitness to the first is given by $u(s, s')$. The situation may then be represented by a game in which there are 2 players, and each has strategy set S and payoff function u , that is, the game is symmetric. The question is which strategy will be selected, that is, which one will survive in the long run. Obviously, if $u(s', s) > u(s, s)$ then s' can displace s so that a necessary condition for survival of s is that (s, s) constitutes a Nash equilibrium of the game. A second necessary condition for selection of s is that, once s has been established, random mutations that enter into the population are selected against, that is, these are driven out again. This will be the case if they cannot spread, that is, if the entrant s' is an alternative best response against s , then the incumbent strategy obtains a higher payoff against the mutant than the mutant gets against itself (if $u(s', s) = u(s, s)$, then $u(s, s') > u(s', s')$). A strategy s satisfying both conditions is called an evolutionarily stable strategy or ESS. One sees that an ESS corresponds to a Nash equilibrium satisfying an additional stability requirement (see Hammerstein and Selten 1994 for further discussion).

4. Behavior

Game theory, at least its traditional variant, relies on the assumption of rational behavior, that is, behavior that is consistent and is motivated solely by the desire to obtain well-defined goals, with, furthermore, no cognitive constraints standing in the way. In contrast, the biological branch of the theory relies on no rationality at all, but assumes long time periods for selection to work. The question, hence, is how the theory is relevant for humans that are boundedly rational and have relatively little time to learn and adjust behavior. Real players have only limited rationality: they face cognitive limitations which may make it impossible to get a full overview of the situation and to consistently evaluate and rank all alternatives, they may decide not to think and instead rely on automated procedures that have proved satisfactory in the past or in other related contexts, and even if rational deliberation suggests a decision, emotional factors may override and produce an alternative decision.

The question, hence, is to what extent a theory that is based on strong rationality assumptions is relevant for actual interactive decision making. For sure, a normative solution can serve as a benchmark to better understand actual behavior, it might point to systematic differences and it might even be that the differences are negligible in certain contexts, such as when players have had sufficient time to familiarize themselves with the situation. Unfortunately, a discussion of the issue of relevance is made difficult by the fact that alternative theories are still undeveloped and since relatively little is known yet about the actual

structure of human decision making (see Selten 1991). Nevertheless, some systematic deviations from the theory that are found in the experimental laboratory may be described (see Camerer 1997 for more details).

First of all, a remark that does not apply that much to the solution concepts, but rather to the modeling aspect. Game theory analyses the consequences of selfish behavior, where selfishness is interpreted as the individual following their preferences. However, it is not assumed necessarily that individuals are selfish in the more narrow sense of being only interested in their own material well-being. The latter assumption would indeed be too narrow. Experiments have shown that, in the ultimatum game referred to above, responding players generally dislike being treated 'unfairly,' hence, they are willing to reject proposals in which they get positive amounts but the distribution is uneven. A relevant game model of the situation should take this into account and as a consequence it may well advise to player 1 to allocate a substantial proportion of the cake to player 2 (see Kagel and Roth 1995 for further discussion on this issue). Suffice it to note here that tests of game theoretic predictions are always combined tests of the underlying game and the solution concept applied, that it is difficult to control the players' preferences, hence, that one should be careful in drawing strong inferences from results observed in the experimental laboratory.

Second, when confronted with an interactive decision situation, real-life players typically construct a simplified model of the situation. The 'mental model' may be an oversimplification and, as a consequence, important strategic aspects may be missed. Furthermore, a player needs to take into account the models constructed by other players: if these do not incorporate certain elements, it does not make sense for the player to signal along these dimensions. Selten (1998) argues that the reliance on superficial analysis may explain presentation or framing effects, that is, the way in which a game is presented to the players may have a strong influence on actual behavior. The basic reason is that the presentation may trigger a certain reasoning process or may make some outcomes more focal than others. Related is the fact that human players do not analyze each game in isolation but rather make use of analogies; a principle that has proved useful in a certain context may also be used in another one. In experiments, for example, it is observed that 2-player games with sequential moves in which the second mover receives no information about the first move may be played as if there was such information, where according to the theory the game is strategically equivalent to the game with simultaneous moves. The discussion of the presentation effect in strategic contexts originates with Schelling (1963), but his concept of 'focal points' still largely awaits formalization.

Where standard game theory assumes that all players are equally rational and, hence, homogeneous, experiments have revealed considerable player het-

erogeneity. Some players are more of the adaptive type and do not approach a game analytically. Instead, in repeated contexts, they make use of *ex post* rationality considerations and move in the direction of better responses against the previous outcome. Players who rely on analytic approaches construct simplified models, as discussed above, and they may limit the 'depth' of their analysis to a couple of steps and, hence, may not reach a game theoretic equilibrium. For example, in the 'beauty contest game' in which a set of players choose numbers between 1 and 100 and in which the winner is the one that chooses the number closest to half of the average of all numbers, the equilibrium is to choose 1 and that equilibrium is reached through iterative elimination of dominated strategies. However, most players choose larger numbers and those that choose the equilibrium number do not win the game. Relatedly, in extensive form games players do not necessarily 'look ahead and reason backwards,' but instead may use a myopic somewhat forward looking process and, as a consequence, the outcome obtained may be different from the subgame perfect equilibrium one.

At present, research is under way to construct an empirically-based behavioral game theory that steers a middle ground between over-rational equilibrium analyses and under-rational adaptive analyses, but it is too early to survey this field (see *Behavioral Economics*; *Experimental Economics*).

5. Conclusion

The space allotted has not allowed a discussion of any applications in depth, however, as Aumann (1987) has argued forcefully, the models and solution concepts from game theory should be judged by the insights that they yield. In addition to the entries of this Encyclopedia already referred to above, we may point to the areas of finance (market microstructure), industrial organization, and antitrust and regulation, in which ideas from noncooperative game theory have been influential and are used widely.

Gangs, Sociology of

The term, ‘gang’ is both a theoretical construct and an object of varying definitions in legal statutes, legal and social agency policy, and common discourse. Although the term defies precise measurement, it is the subject of a large scholarly and popular literature.

1. Historical Background of Scholarly Research on Gangs

‘Gang’ and other terms (mob, syndicate, outfit, etc.) have been applied to many types of groups, including those associated with organized and professional crime and incarcerated felons. Scholarly attention, however, has focused primarily on youth gangs. Frederic Thrasher’s *The Gang: A Study of 1,313 Gangs in Chicago* (1927) was the first attempt to survey the extent of youth gang activity in a major city, and perhaps the first in any jurisdiction. The project involved census and court records, personal observations, and personal documents collected from gang boys and from persons who had observed gangs in many contexts. Studies by Clifford R. Shaw and his collaborators provided even more information about the collective nature of youthful delinquency, offering consistent documentation that most boys who were brought before the juvenile court committed their delinquent acts in the company of others. Case studies documented patterns of friendship, the association of younger with older offenders, and the influence of organized crime and other forms of adult criminality in communities with high rates of juvenile delinquency (Shaw et al. 1929, Shaw 1930, Shaw and McKay 1931, Shaw and Moore 1931). Ecological studies located delinquency in space and in relationship to urban development, documenting economic and institutional contexts within which urban lives were lived, and identifying forces that shaped the ability of communities to aid in the socialization of children and exercise control over misbehavior.

Theoretical insights from these studies continue to be important in thinking about youth crime. Fore-shadowing ‘labeling theory,’ for example, Shaw’s Jack-Roller—reflecting on his confinement in a reformatory—noted that he was no longer ‘just a mischievous lad, a poor city waif, a petty thief, a habitual runaway,’ but ‘a criminal’ (Shaw 1930, p. 103). Conversely, both Shaw and Thrasher noted that incarceration and criminal notoriety often had positive value among gang members, as it does today: ‘... res-

idents in the vicinity south of the stock yards were startled one morning by a number of placards bearing the inscription ‘The Murderers, 10,000 Strong, 48th and Ada.’ In this way attention was attracted to a gang of thirty Polish boys, who hang out in a district known as the Bush’ (Thrasher 1927, pp. 62–3).

Thrasher’s Murderers were involved in a good deal of criminal activity, but their primary pastimes ‘were loafing, smoking, chewing, crap-shooting, card-playing, pool, and bowling.’ Their ‘rudeness and thievery’ were ‘an awful nuisance’ to local shop keepers and neighbors (Thrasher 1927, pp. 62–3). The arcane language notwithstanding, these excerpts highlight similar patterns among contemporary and earlier gangs involving ‘hanging out,’ minor and more serious criminal behavior.

The most important impact of earlier gang research was its contribution to social disorganization theory. Youth gangs were found overwhelmingly in communities with high rates of crime and delinquency, poverty, and population heterogeneity and turnover. Social disorganization theory, hypothesizing that such communities lack both effective institutions and local informal means of control, continues to be refined by recent research. Thus, Sampson and his colleagues (2000) find that intergenerational closure (the linkage between adults and children), reciprocal local exchange (interfamily and adult interaction with respect to children), and expectations that community residents will share child control responsibilities, are associated with the ability of local communities to exert effective control over violent and other forms of criminal behavior.

Midway between the publication of Thrasher’s classic work and the turn of the century, the book was abridged and reissued. Social changes had vastly altered the gang landscape, and gang research, heretofore largely descriptive, was changing in response to seminal theoretical proposals by Cohen (1955), Cloward and Ohlin (1960), and Miller (1958). Competing explanations for the origins of the delinquent subculture (Cohen), variations in delinquent subcultures (Cloward and Ohlin), and the role of lower-class culture in producing gang delinquency (Miller) stimulated a large body of empirical research and subsequent theorizing.

By the last decade of the twentieth century, however, events that could hardly have been anticipated by earlier researchers had overtaken both theory and research. Whereas midcentury theories had outstripped available data, modest theoretical advances and related empirical research were overwhelmed by the rapid proliferation of gangs in the USA and their spread to many other countries (Klein 1995, Klein et al. 2000, Moore and Terrett 1999). In the USA sophisticated firearms became more readily available to young people (Blumstein 1995), often turning what previously had been ‘non-zero-sum’ contests between gangs into lethal confrontations (Short and

Strodtbeck 1965, Anderson 1999). Weakened conventional economic, political, and family institutions lost legitimacy, contributing to rising crime rates (LaFree 1998); and the technological revolution in electronic communication and entertainment media created heretofore unknown problems for institutions of social control.

2. *Change and Continuity*

It is possible, nevertheless, to note both changes and continuities in knowledge concerning the collective forms taken by the delinquent and criminal behavior engaged in by the young.

(a) Youth gangs are more prevalent in many countries than previously. Law enforcement agencies in all large US cities (over 250,000) reported the presence of youth gangs, as did many suburban counties, small cities and rural counties, where gang prevalence is quite recent (National Youth Gang Center 1998). European and UK researchers have identified variations in youth gang organization and behavior, some of them patterned after US gangs (Klein et al. 2000).

(b) Gangs in the US, Continental Europe, and the UK are comprised predominantly of youth who are marginalized in mainstream society by virtue of race, ethnicity, or economic status. In the USA these are predominantly African-American and Hispanic, but with increasing numbers of new Asian immigrant children and children of immigrant parents. In Continental Europe and the UK they tend to be the children of refugees from other countries or migrant workers. Gangs comprised of majority population youth, nearly always white, sometimes form in opposition to these marginalized groups, thus becoming marginalized themselves.

Youth gangs are comprised overwhelmingly of young males, and the experience of females who associate with male-dominated gangs, or in all-female gangs, is quite different from the gang experience of males (Chesney-Lind and Hagedorn 1999).

(c) The distribution and patterning of collective youth crime reflect the ecology of the places where they are located. In the USA and many other cities, these are inner-city areas, much as they were in Thrasher's and Shaw's day. Where public housing projects are located outside central cities, gangs of loosely structured, ethnically mixed groups often 'commute' to central city areas where they engage in carousing, 'smash-and-grab' hits on stores, rolling drunks, and robberies.

Large aggregations of gang 'nations' emerged in a few large US cities, most notably Chicago and Los Angeles, during the 1960s. Local gangs—wherever they are found—are primarily 'home grown,' but the influence of gang nations is widespread through mimicry and migration of gang members. Many—

probably most, systematic data are lacking—gangs begin as nondelinquent, friendship groups, 'hanging' groups, or groups formed around particular non-delinquent activities (sports, singing, dancing, etc.) (see, e.g., Schwendinger and Schwendinger 1985, Hagedorn 1988, Sullivan 1989, Schwartz 1987, Short 1997). The primary distinguishing characteristic of all youth gangs is that they are self-determining with respect to membership criteria, group structure and behavior, and—most importantly—they are unsupervised by adults.

(d) A variety of studies suggest that such unsupervised youth groups become violent, and otherwise delinquent, as a result of one or more of the following processes:

(i) escalation of the natural rough-and-tumble punching and wrestling that occurs among most male groups, and the association of status with fighting prowess;

(ii) competition with rival groups involving status-enhancing activities or economic motivations;

(iii) conflicts based on racial/ethnic differences;

(iv) definitions of groups as gangs, by others, and behavior toward them that pushes a violent identity on the group;

(v) group processes that create or reinforce group cohesion based on violent or other delinquent behavior.

Street gangs are diverse in behavior, organization, continuity across generations, and in their relationships with other gangs and with their communities. They change, as members age and move into adulthood. The age range of many gangs has expanded in many countries, in response to the lack of attractive legitimate jobs. This change often is accompanied by increased violence, as gang members have turned to selling drugs and other illegal activities in order to support themselves, and often their families (see Fagan 1996, Fagan and Wilkinson 1998, Hagedorn 1998).

These changes tend to blur distinctions between street gangs and a variety of types of youth and young adult collectivities, such as 'wilding' groups, 'skin-heads,' and perhaps the mass shootings that have occurred on school properties. Although differing among themselves, these groups have in common their hate of 'outsiders,' based on racial, ethnic, or other exclusionary criteria, as, also, do crowds that gather to attack community outsiders, usually members of minority groups. Violence and other delinquent activities often occur, also, in 'staging' areas in which young people gather with friends and others simply in order to escape adult supervision (Schwartz 1987, Anderson 1999).

Drug and other 'working' gangs are organized primarily around revenue-producing activities, such as drug selling, stealing, fencing stolen goods—all activities requiring greater organizational skills and structure than is characteristic of traditional street gangs. Also unlike street gangs, 'bikers,' 'punks,'

and sports fanatics and 'hooligans' are organized around their specialized interests. Except for the latter (most of whom appear to be disadvantaged socially, rather than economically), these groups are comprised primarily of youth who have been marginalized by minority ethnic and/or economic status, and who have poor prospects for integration or social mobility within dominant majority societies. The excessive behavior of bikers and sports hooligans also appears to be motivated in some measure by resentment of minorities.

3. *Youth Culture*

Virtually all youth are heavily influenced by the development, rapid growth, and diffusion of youth culture. Peddled by media advertising, and augmented by large social and economic forces that fail to provide meaningful roles for young people but cater to their distinctive fads, appetites, and currency, youth culture and gang culture together underly the excesses of consumption and violence perpetrated by gangs.

Youth culture developed rapidly during the 1960s, especially in the USA. Young people born during the 'baby boom' following World War II shared in the general level of affluence in the country, thereby creating a youth market with great economic power; the period of education prior to entering the labor market was extended; increasing numbers of women joined the workforce, further separating mothers from youth in the home and in the neighborhood; increasingly, adults worked in large organizations away from young people; and the mass media greatly expanded and focused their attention on the youth market (see Coleman et al. 1974, pp. 114–19). These changes accelerated as the century wore on, expanding their influence throughout the world.

Field researchers document the pernicious seductions of media-advertised products among less affluent young people, leading often to thefts and assaults. Anderson (1999) describes the 'zero-sum quality' that pervades the 'code of the streets,' in the search for respect—often associated with items of clothing such as shoes and jackets—among young African-American men in the ghetto. Sullivan identifies 'mutually valorizing cultural symbols' (clothing, drugs, alcohol, and recreational artifacts and activities) that cut across racial and ethnic boundaries, often resulting in invidious comparison, confrontation, theft, and assault (Sullivan 1989, pp. 248–9).

Observers of youth groups everywhere note that status differences within and between them are extremely variable and highly refined. Status criteria within a group, or between one group and another, may be based on race or ethnicity, relative economic affluence, skills in valued activities, public appearance, school performance, or most importantly, on lifestyle differences. These bases of stratification typically also

become criteria of inclusiveness and exclusiveness which, in turn, create opportunities for both friendship and rejection.

Adolescence is a period of especially intense identity formation, intense relationships, and shared feelings of friendship, acceptance, and respect. Conversely, feelings of rejection and disrespect also are especially intense, and often the basis for group and subcultural formation.

Next to families, schools are perhaps the most important contexts for adolescent friendship, achievement, and recognition. Because of this, school contexts (including the journey to and from schools) are the settings for much adolescent behavior, including delinquent and criminal behavior. On occasion they have also been the setting for the most extreme forms of violence (e.g., mass killings by students or others alienated from their fellows or from mainstream institutions in general). Although the specific causes of such extreme alienation are complex, it seems clear that schools have been especially targeted precisely because of their importance in the lives of adolescents, as symbols of rejection by both peers and an adult world that seems far removed from adolescent concerns. The ready availability of guns at times transforms normal adolescent turmoil and conflict into deadly confrontation.

More than ever before in history, young people, targeted for commercial exploitation and isolated from mainstream adult roles and institutions, confront economic conditions beyond their control. Economic decline, severe unemployment, and the unavailability of 'good jobs,' are associated not only with street gangs, but with their transformation into 'economic gangs' (including drug gangs), and with ethnic, racial, and class-related identities and antagonisms that lead to other types of collective violence (Hagedorn 1998 Pitts 2000). These same forces alter both intergang relationships and relationships between gangs and their communities. Relationships between adults and young people, shaped by generational backgrounds and community cultures, 'translate' these and other macrolevel forces at the local community level.

4. *Research Needs*

Research and theory concerning gangs, and effective means of controlling the violence and crime associated with gangs, are hampered by the lack of a viable typology of youth groups and groups comprised of young adults that would situate the many observed variations of gangs and gang-like groups within even broader collective forms of behavior. Comparative research in many countries suggests that distinctions among and between such groups vary a great deal, and that the meaning and the function of behavioral variations lack universality.

Varying definitions, meanings, and behaviors have consequences. To the extent that gangs and gang membership confer 'master status' on groups and individuals—among law enforcement personnel, in media portrayals, and among the general public—they contribute to the deterioration of relationships between economic, racial, and ethnic groupings and between the generations. Reification and demonization of gangs, by media, law enforcement, the public, and occasionally by scholars, for example, may contribute to gang problems rather than to their solution.

J. F. Short Jr.

Garbage Can Model of Behavior

The garbage can (GC) model is a framework for analyzing decision making in 'organized anarchies'—organizations characterized by problematic preferences, unclear technologies, and fluid participation (Cohen et al. 1972). The model conceives of organizations as conglomerates of semiautonomous decision arenas or 'garbage cans' through which problems and solutions flow as independent streams. Decision outcomes are sensitive to the precise mix of problems and solutions represented in a garbage can at the moment of decision. This mix, in turn, depends on the number of decision arenas, the structure of access to them, the overall organizational load of problems and solutions, and the allocation of energy and attention across arenas.

1. A Challenge to the Rational Model of Organization

The GC model may be understood as an important step in a developing critique of the rational model of organization by the so-called 'Carnegie School.' This school builds on Herbert Simon's treatment of organizations as information-processing systems and his argument about cognitive limits on individual

information-processing (see *Bounded Rationality*). Simon (1985) argued that just as individuals could partially overcome their cognitive limits by decomposing complex decisions into simpler choices and routines, so too could organizations decompose complex collective decision making by means of nested hierarchical structures ('nearly decomposable systems'). The subsystems of these nested hierarchies represented relatively autonomous bundles of routines. While Simon's analysis offers a critique of the rational model, he ultimately seeks to demonstrate that problem decomposition and routinization permit cognitively limited individuals and organizations to approximate, if only imperfectly, rational organization. The GC model, in contrast, poses a more fundamental challenge to the rational model.

The GC model goes beyond Simon's analysis by focusing on the ambiguity and loosely coupled nature of individual and organizational decision making. Whereas Simon's model of bounded rationality emphasizes cognitive limits on evaluating alternative courses of action, the GC model argues that the ambiguity of decision making stems from the ill-defined and inconsistent nature of individual and organizational goals (problematic preferences), and the indeterminacy of knowledge and of techniques for achieving goals (unclear technologies). The GC model also problematizes Simon's notion of organizations as bundles of semiautonomous subsystems. The metaphor of the organization as a collection of 'garbage cans' implies a set of semiautonomous decision-making arenas where problems are neither so neatly decomposed nor so well integrated as conceptualized by Simon. Furthermore, the GC model argues that participation in these decision arenas is unstable rather than routine (fluid participation). In making these arguments, the GC model incorporates and extends many of the earlier arguments of the Carnegie school, including insights into the political and symbolic character of decision making, the coalitional character of organization, the sequential nature of decision making, the role of organizational slack, and the tendency of subunits to develop narrow and parochial decision premises.

In seeking to turn the rational model 'on its head,' the authors of the garbage can model sometimes state their alternative assumptions in fanciful ways. For example, they argue that organized anarchies can be understood as 'collections of choices looking for problems, issues and feelings looking for decision situations in which they might be aired, solutions looking for issues to which they might answer, and decisionmakers looking for work' (Cohen et al. 1972, p. 1). This ironic tone may be read as either usefully provocative or as a hindrance to understanding. Stated in the extreme, the assumptions of the model often appear as unrealistic as the assumptions of the rational model. The argument that problems are decoupled from solutions and flow through the organization as

independent streams is difficult to grasp, because it is intuitive to think that the people who formulate problems are typically the ones best positioned to devise solutions to them. Yet if we were to dismiss the GC model because of its implausibility *in extremis*, we would also miss its powerful insights. Shorn of its irony, it is easy to recognize situations in which people become advocates for certain types of solutions and promote them whenever and wherever they can, often without clearly understanding the problems which are being addressed. It is easy to see that people often bring issues and concerns to a decision arena extraneous to the ostensible decision at hand. And it is obvious that decision outcomes are highly sensitive to the mix of issues brought to bear in any decision arena, that this mix is often highly dependent on who participates, and on the range of other decisions being made at any given time. One value of the GC model is that it treats these very intuitive and commonplace circumstances seriously.

2. The Simulation of Chaotic Decision Making

Part of the purpose of stating their assumptions in exaggerated form is that it allows the authors (brilliantly) to transform their analysis of the essentially *ad hoc* nature organizational behavior into a systemic analysis of organizational decision making. They do this by linking together the following ideas. As already mentioned, the model emphasizes the *loose coupling* or *decoupling* of intentions, actions, and constraints. It argues that individual intentions are not tightly coupled to individual action, that collective goals are not tightly coupled to collective action, and that organizations are not tightly coupled to their environments. By conceptualizing problems and solutions as flowing independently through organizations, the GC model imagines organizations to be *demographic systems* in which problems and solutions (via their attachment to individuals) enter and exit particular decision-making arenas. Decisions or nondecisions can then be understood as dependent upon the composition of problems and solutions in a decision arena at any point in time. At the systemic level, this composition is expected to be very sensitive to the issues to which actors happen to be paying attention at any given moment (attention is treated as a scarce resource) and to the structure of access into decision-making arenas. The model is *processual* in that it suggests that outcomes are not easily predicted from starting conditions, but depend rather heavily on the precise interactions between elements of the system. In general, processual theories suggest that interactions are complex, nonlinear, and characterized by the prevalence of unintended consequences. Taken together, this characterization of organized anarchies as loosely coupled, demographic, and processual allows the authors to treat decision making as a *stochastic*

process, introducing elements of probability and randomness into the model. Beginning with the original paper of Cohen et al. (1972), the GC model has encouraged a strategy of simulation modeling in order to capture the dynamics of these stochastic, demographic processes (e.g., Padgett 1980, Carley in March and Weissinger-Baylon 1986).

3. *The Garbage Can Model and Political Institutionalism*

If organizational decision making is often disorderly and fraught with ambiguity, we rarely experience the extreme versions of chaos the GC model may conjure. Yet the model also suggests how disorder and ambiguity may be transformed into relative order and certainty. It is very possible, for instance, that disorder and ambiguity may be tidied up on the output side of decision-making processes: order and certainty then represent *post hoc* rationalizations of essentially *ad hoc* decisions. Yet order and certainty may also be produced during decision making through a process known in current parlance as *social construction*. Ambiguity is transformed into relative certainty by social processes in which individuals develop and institutionalize shared understandings and judgments. March and Olsen elaborate on this constructivist mechanism in their book, *Rediscovering Institutions* (1989), where they situate garbage can theory in a larger theoretical framework of political institutionalism (see *Institutionalism*). Arguing that politics can be understood as the collective interpretation and enactment of meaning, they suggest that institutionalization leads individuals and organizations to act according to a 'logic of appropriateness.' March and Olsen (1989, pp. 69–116) provide a nice example of how garbage can processes, political institutionalism, and social constructivism can complement one another in their historical analysis of the failure of comprehensive administrative reforms.

The GC literature also suggests at least two other mechanisms through which anarchies organize: leadership and learning. With respect to leadership, for instance, this literature suggests that unobtrusive leadership which embraces rather than rejects the disorder and ambiguity of decision making may be successful in steering organized anarchies toward collective purposes (Cohen and March 1974, Kingdon 1995, Padgett 1980). Learning in organized anarchies is problematic because the lessons we should draw from experience are themselves ambiguous. While learning under conditions of ambiguity may lead to superstitious beliefs, the GC literature suggests that organized anarchies may adapt and learn successfully (Cohen and March 1974, March and Olsen 1979). In fact, it is currently fashionable to see a bit of chaos as necessary for producing creativity and innovation. Hood (1999) notes the interesting parallels between

the garbage can model and Mintzberg's model of 'adhocracy,' which is widely promoted as an organizational design for promoting creativity and flexibility.

The GC model has been applied in numerous contexts. As March and Olsen have noted, the theory probably applies to many organizations some of the time and some organizations most of the time. It is often seen as a good fit for educational institutions, especially universities. Sproull et al. (1978) argue that the characteristics of organized anarchies characterize 'most new government organizations, irrespective of their mission, and most agencies operating in social policy domains, irrespective of their age' (Sproull et al. 1978, p. 5). In addition to their book on the National Institute of Education, other studies of political organization inspired by the GC model include analyses of presidential management (Padgett 1980), military organizations and operations (March and Weissinger-Baylon 1986), public-health management in the context of an 'interorganizational garbage can' (Clarke 1989), policy making and agenda setting in the federal government (Kingdon 1995), and foreign policy decision making (Newmann 1998). While these differ in their details, the GC model should also be seen as similar in spirit to Graham Allison's model of bureaucratic politics, to Charles Lindbloom's model of disjointed incrementalism (see *Decision-making Systems: Personal and Collective*), to Norton Long's notion of politics as an 'ecology of games,' and to Jeffrey Pressman and Aaron Wildavsky's theory of implementation (see *Implementation: Political*). Taken together, these models have made a major contribution to our understanding of the limitations of the rational model of decision making and to the possibility of alternative rationalities.

Gastrointestinal Diseases: Psychosocial Aspects

Research in the area of gastrointestinal diseases has focused primarily on biological and medical aspects of these disorders. Little consideration has been given to psychosocial aspects of these medical conditions. However, there has been one general area, namely irritable bowel syndrome (IBS) that has received increased attention in the area of psychosocial aspects over the past few decades. More specifically, IBS has been increasingly conceptualized using a biopsychosocial perspective (Drossman et al. 2000). This perspective provides a framework for understanding the biological and psychosocial components of IBS, and can provide a model for other areas within the digestive system.

The purpose of this article is to offer an understanding of the psychosocial aspects of gastrointestinal illness. Because it is beyond the scope of this article to supply an extensive and detailed discussion of all the specific diseases of the digestive system, we have limited our discussion to psychosocial aspects of IBS since this is where most of the theoretical and empirical literature has focused. The first section of this article will furnish an overview of IBS. The second section will address how a biopsychosocial perspective relates to IBS. The third section will summarize current psychosocial treatments for IBS. The final section will briefly address future directions.

1. Definition and Symptoms of IBS

Functional gastrointestinal disorders (FGID) are characterized by recurrent or current gastrointestinal symptoms that have no identifiable structural or

biochemical basis. The most common functional gastrointestinal disorder is IBS. Recent evidence supports the belief that dysregulation of the brain–gut neuroenteric systems, rather than the presence of structural disease, promotes the development and persistence of IBS (Drossman et al. 2000). IBS is associated with abdominal pain or discomfort for at least 12 weeks or more, that has two or three of the following features: (a) relieved with defecation; and/or (b) associated with a change in frequency of stool; and/or (c) associated with a change in form (appearance) of stool. Symptoms that are associated with IBS include: abnormal stool frequency (more than three bowel movements per day and less than three bowel movements per week), abnormal stool form (hard or loose/watery stool), abnormal stool passage (straining or urgency, feeling of incomplete evacuation), passage of mucus, bloating, or feeling of abdominal distension (Thompson et al. 2000).

2. Epidemiology

IBS is a very common disorder, estimated to affect 9–22 percent of the Western population. However, of those affected, very few seek medical consultation or treatment for their gastrointestinal symptoms (Whitehead et al. 1988). According to Drossman et al. (1997), of those who seek treatment, IBS accounts for 28 percent of gastroenterological practice in Western societies and 12 percent of primary care. IBS is often associated with unnecessary procedures and surgeries. IBS has considerable economic impact since IBS results in decreased work capacity. Next to the common cold, it ranks as the second most common cause of work absenteeism.

IBS is a disorder that is diagnosed mostly in women (Toner et al. 2000). To date, most of our information about IBS has been drawn from female participants. Accordingly, to date, we know little about IBS in men. A review of the literature by Toner and Akman (2000) noted that the majority of studies investigating IBS use only women in their samples. Moreover, of those studies which do include men, few perform a gender difference analysis. Since a major percentage of IBS patients are women, the issue of gender must be integrated into the conceptualization and treatment of these disorders (Toner 1994).

3. Conceptualization

IBS is best conceptualized using a biopsychosocial model. As summarized by Drossman et al. (1999), the biopsychosocial model provides a useful framework to help us begin to understand the connections among psychosocial factors, gastrointestinal function, disease susceptibility, and clinical outcome. Symptoms may be generated from physiological disturbances (enhanced motility and visceral sensation), which are closely

connected to central nervous system activity (via the central nervous system–enteric nervous system axis). The clinical expression of these symptoms (e.g., the decision to take medication or seek health care) is strongly influenced by psychosocial factors. For this reason, the high frequency of psychosocial factors (e.g., psychiatric diagnoses, sexual abuse history) in the absence of modulating factors (e.g., social support, coping strategies) reported among IBS patients may, in part, relate to their self-selection into referral practices. Accordingly, while psychosocial factors are not part of the diagnosis of IBS, they have important effects on gut motility, symptom experience, and clinical outcome.

In light of this information, it is no longer logical that clinicians and researchers try to assess whether IBS symptoms are caused by physiological or psychosocial factors since both are operative and interactive. Rather, the goal is to determine to what extent these factors contribute to IBS and are remediable (Drossman et al. 1999).

4. Psychosocial Aspects Discussed in the Context of Myths Associated with IBS

It is difficult to discuss psychosocial aspects without acknowledging the stigma and myths that have been associated with IBS. Functional gastrointestinal disorders such as IBS are associated with morally pejorative connotations. Patients who have functional gastrointestinal disorders often feel that their problems are treated as ‘not real’ and due to a moral and/or psychological weakness or defect. Thus, when referred to health care providers, persons with IBS may believe that caregivers think that their symptoms are ‘all in their heads’ and not ‘real’ or ‘serious.’ It is important that health care professionals validate the reality of the person’s symptoms. In doing so, health care professionals can challenge the artificial dualism between functional and organic components of illness in general and pain in particular imposed by our Western society (Toner et al. 2000). Dualism leads to a prominent myth which suggests that if pain is severe, there must be an organic cause. This is a common myth that persists as a function of our Western society’s false conceptualization of pain (i.e., if the pain is severe, there must be a structural cause). However, the experience of pain is a consequence of a complex interaction among physical, cognitive, emotional, and behavioral components.

A related myth is that IBS is caused by stress. We now know that IBS is not caused by stress, but that stress may further aggravate bowel symptoms. We also know that stress is associated with bowel symptoms in most people. In fact, over 70 percent of people under stress will exhibit some GI symptoms. However, studies have found that people with IBS are more reactive since they already have a hypersensitive gut

and therefore are more likely to experience more symptoms under any kind of stress including psychological, physical, dietary, or hormonal.

An additional myth is that IBS is a psychiatric disorder or that it is masked depression. Several studies have found that a substantial percentage of individuals presenting with IBS, particularly in tertiary care settings, also have an associated depressive or anxiety disorder. It is unclear why such an association exists, but the following explanations have been proposed. (a) People who also have an associated anxiety/depressive disorder may have more difficulty coping with gastrointestinal problems and may seek specialized help for their pain at higher rates than people with IBS who do not have an associated anxiety or depressive disorder. (b) Anxiety and depression are common in the general population, and their co-occurrence may simply be due to high frequency. (c) Depression/anxiety may be a consequence of living with a chronic, incapacitating disorder such as IBS (Toner et al. 2000).

A final myth is that people with IBS are sometimes described as difficult patients. Physicians and other health care providers are not adequately trained in the conceptualization and/or treatment of IBS. The lack of information coupled with the shame and trivialization associated with having a so-called functional or psychosomatic disorder leads to frustration, further distressing patients. For physicians, such patients may illicit uncomfortable feelings that might lead some health care professionals to feel powerless and frustrated in the situation. Rather than conceptualizing IBS patients as difficult, it is more helpful to conceptualize the disorder as difficult, especially in light of the fact that there is little information and a great deal of stigma associated with IBS (Toner et al. 2000). An open and honest discussion acknowledging the frustration associated with this chronic and debilitating disorder is beneficial. To date, there are no effective medication or cure for IBS and thus the focus of treatment is symptom management and improving coping strategies. As such, it is important to establish a collaborative environment whereby both the person with a diagnosis of IBS and health care provider work together in attempting to understand the most effective strategies in managing these chronic, painful symptoms.

5. Empirical Support for Psychosocial Treatments

Psychosocial treatments for IBS have included dynamic psychotherapy, cognitive-behavioral therapy, relaxation, biofeedback, and hypnosis. In a recent overview of this area, a multinational team including Drossman et al. (2000) reviewed 13 controlled studies to compare psychosocial treatment with conventional medical treatment. Ten of 13 studies showed signifi-

cant superiority of psychosocial over conventional medical treatment in terms of reducing bowel symptoms. Follow-up data were available for only nine studies and of these, eight showed psychosocial treatment to be superior to medical treatment.

However, it is difficult to determine the efficacy of a specific theoretical approach because most of the controlled studies have used multicomponent treatment packages (e.g., cognitive-behavioral, psychodynamic, biofeedback, and relaxation approaches). As such, it is difficult to assess which aspects of the treatments were beneficial and to what extent. Moreover, therapeutic techniques and procedures are not generally described adequately and in specific detail. This makes replications of treatment protocols difficult. Nevertheless, the data thus far seem to indicate that when compared to conventional medical treatment, psychosocial interventions are consistently more effective.

6. Summary and Future Directions

This article has provided a brief overview of IBS with a focus on associated psychosocial aspects. While psychosocial factors are not part of the diagnosis of IBS, clearly, psychosocial factors play an important role in symptom expression and clinical outcome of IBS. Given the significance of these factors, it is important that clinicians respond to psychosocial issues with the same attention and legitimacy that is given to the physical and biological factors associated with gastrointestinal disorders. Conceptualizing IBS from a biopsychosocial perspective allows clinicians to better understand and treat individuals who are diagnosed with IBS in a more comprehensive manner. Future research must examine how biopsychosocial factors influence other diseases of the digestive system.

Research has suggested that psychosocial treatments are effective interventions for IBS. Further research is needed to determine the usefulness of psychosocial interventions for other diseases of the digestive system. Moreover, future studies are required to determine which aspects of psychosocial treatment packages (e.g., relaxation, cognitive restructuring, etc.) account for their effectiveness and determine the patient characteristics which predict response to specific psychosocial treatments. Since this is a chronic disorder, long-term studies must also be conducted. The role of sociocultural factors and gender on IBS must be further explored in both our understanding and treatment of these chronic debilitating disorders.

Gauss, Carl Friedrich (1777–1855)

1. Introduction

The name of Gauss will already be known to many readers for its use in such phrases as Gaussian distribution, Gauss linear model, and the Gauss-Markov theorem, and for its use in the titles of the Gaussian elimination, Gauss-Jordan, Gauss-Doolittle, Gauss-Newton, and Gauss-Seidel procedures, if not for the *Système International* (SI) unit of magnetic induction and the associated terms gaussage and degauss.

Gauss contributed to all areas of science known in his day, notably to astronomy, physics, and geodesy,

but in this article we shall concentrate on his contributions to statistics and numerical methods. For more wide-ranging surveys of his work, see Eisenhart (1968) and May (1972).

2. *Life of Gauss*

Carl Friedrich Gauss (originally Johann Friedrich Carl Gauss) was born on 30 April, 1777 in Brunswick (Germany). He was the son of a bricklayer and gardener who also kept the accounts of a local insurance company. Gauss received his elementary education at St. Katherine's School in Brunswick. However, his humble origins were not allowed to hamper his intellectual development, for, in 1791, his talent for mathematics was brought to the attention of the Duke of Brunswick, who undertook to support his continuing education, at first at the *Collegium Carolinum* in Brunswick and later at the University of Göttingen. Gauss did not graduate from the University of Göttingen but was awarded a doctoral degree *in absentia* by the University of Helmstedt in 1799 for his work on the fundamental theorem of algebra.

In October 1806, the French land forces consolidated the command of German territory that they had established in 1805 in the battle of Austerlitz by defeating a Prussian army under the command of the Duke of Brunswick at Auerstedt (and mortally wounding the Duke). As a consequence, when in 1807 Gauss submitted the manuscript of his future *Theoria Motus* for publication in German, the political situation was such that his publisher felt obliged to insist on its translation into Latin. Consequently, the manuscript which Gauss had completed in 1806 was not published until 1809. (Fortunately, Gauss had an excellent command of Latin, so that this imposition may justly be compared with requiring a modern German scholar to translate his work into English before publication.)

In 1807 Gauss was appointed director of the University of Göttingen observatory and professor of mathematics at the University of Göttingen. He continued to hold both of these positions until his death in Göttingen on 23 February, 1855.

3. *Elementary Fitting Procedures*

Given any number of observations on a lesser number of variables, the linear fitting problem is concerned with establishing the relationship between one of these variables and the remaining variables. Before the middle of the eighteenth century, practitioners were obliged to employ a variety of more or less arbitrary procedures to determine the parameters of such relationships. But between 1750 and 1800 four algebraic procedures were proposed for the linear fitting

problem, namely the method of averages, the method of selected points, the method of least absolute deviations, and the minimax absolute deviation procedure.

In 1805 Adrien-Marie Legendre (1752–1833) published an alternative algebraic procedure which he named the method of least squares. This procedure chooses the parameters of the relationship to minimize the sum of the squared deviations between the observed values and the fitted relationship. For a detailed history of these five algebraic procedures, see Farebrother (1999). Also note that the relevant pages of Legendre's original statement have been reproduced by Stigler (1986, p. 56).

Legendre's approach to the fitting problem was entirely algebraic and had no statistical content. Further, he did not prove many of the optimality properties he claimed for the method of least squares. Indeed, he had not even shown that the values determined by his algebraic procedure actually minimize the sum of the squared deviations function (except in the unlikely case when the fitted relationship is exact). Such a proof was subsequently supplied by Gauss (1809).

4. *Most Probable Value Criterion*

Gauss' first statistical derivation of the method of least squares was based on a combination of the normal or Gaussian distribution with a Bayesian variant of the maximum likelihood or maximum probability optimality criterion. The normal distribution itself was obtained from a preliminary analysis in which the arithmetic mean of a set of direct observations is associated with the maximum value of this optimality criterion.

Gauss was working in a Bayesian context, so there was no need for him to estimate the disturbance variance, but he employed a simple algebraic procedure that we would now associate with the *LDL'* decomposition of a symmetric matrix to obtain measures of relative precision of each of the parameter estimate.

5. *Priority Disputes*

In his 1809 book, Gauss referred to the method of least squares as 'our principle, which we have made use of since the year 1795' and thus sparked off a serious priority dispute with Legendre that ran on for several years. Although Legendre had certainly been the first to publish a description of the method, it is now generally agreed that Gauss had employed a similar procedure in his unpublished work, notably in his 1801 analysis of the geodetic measurements made in France, see Plackett (1972) and Stigler (1999, Chap. 17).

In this context, we should also mention that the distribution named for Gauss had previously been discussed by Abraham de Moivre (1667–1754) and Pierre Simon Laplace (1749–1827); see *Husserl, Edmund* (1859–1938), Stigler (1999, Chaps. 14 and 22).

6. Asymptotic Results

In his *Théorie analytique des probabilités* of 1812, Laplace had made use of a nonrigorous asymptotic argument to establish the optimality of the method of least squares. Gauss (1816) employed a similar technique to establish the relative efficiency of the scaled sums of powers of the absolute disturbance terms when employed as estimates of the variance of their common distribution function. In particular, he found that the scaled sum of the squared disturbances is a more efficient estimator of the variance parameter than is the scaled sum of their absolute values and significantly better than the scaled sums of their third and higher powers.

7. The Most Plausible Value Criterion

In 1818–19 Gauss abandoned his earlier Bayesian derivation of the method of least squares and adopted an alternative approach which he later published as Gauss (1823–28). Farebrother (1999) has suggested that the principal features of Gauss' second approach to the fitting problem may be traced to a careful recombination of certain elements in Laplace's earlier work. Gauss adopted Laplace's decision theoretic approach to the fitting problem, and his restriction to what we would call a class of linear unbiased estimators, but he employed finite sample theory rather than asymptotic analysis, and chose a value for the parameter to minimize the expected value of the squared error of estimation where Laplace had chosen to minimize its expected absolute value.

The principle result to this new theory, now known as the Gauss–Markov theorem, identifies the least squares estimator as the member of the class of linear unbiased estimators with minimum mean squared error.

In this context, it is interesting to note that Gauss' restriction to the class of linear unbiased estimators was an accidental by-product of Laplace's earlier concern with estimators defined by the method of averages, see Stigler (1986) or Farebrother (1999). However, Gauss also showed that the scaled sum of squared deviations is an unbiased estimator of the disturbance variance, but without making any strong claims for the optimality of the result.

Gauss (1823–8) gave a very full account of the subject. In particular, he extended his earlier analysis by considering the effect on the fitting problem of

adding a further observation, or of imposing a linear constraint on the parameters of the model. The resulting updating formulas now form the basis of the Gauss–Doolittle fitting procedure and the Kalman filter of times series analysis. They also define the set of recursive residuals employed in some statistical tests.

8. Solution of Linear Equations

The solution technique now known as Gaussian elimination is a development of the procedures known to Tobias Mayer (1723–62) and the ancient Chinese for solving systems of linear equations with the same number of unknowns. In his 1809 worked example, Gauss employed a solution technique which may possibly be associated with the ancient method, see Farebrother (1999), but in 1811 he outlined the steps of a solution technique that identified the elimination procedure which now goes by his name. This procedure has two phases: in the forward elimination phase the first equation is used to eliminate one of the unknown constants from the other equations; then the second equation is used to eliminate a second unknown constant from the remaining equations; and so on. This yields an upper triangular system which is then solved for the unknown constants in reverse order.

Gauss illustrated this computational technique by a worked example concerned with the least squares determination of the orbit of the newly-discovered asteroid Pallas.

The so called Gauss–Jordan procedure differs from the original procedure in that the array of numbers is diagonalized in the forward elimination phase. This minor modification (which is familiar from textbook descriptions of the simplex procedure of linear programming) leads to a considerable simplification of the second phase, but usually at the cost of some loss of numerical accuracy, see Farebrother (1988).

9. Matrix Algebra

As a by-product of his work in number theory and the calculus of observations, Gauss (1801, 1809, 1823–8) made use of several concepts now recognized as belonging to the theory of matrices. These include linear dependence; linear transformations; the Lagrange LDL' and Cholesky LL' decompositions of a symmetric matrix; the rank-one adjustment of a symmetric matrix; the inverse of a triangular matrix; the inverse of a symmetric matrix; and, possibly, the generalized inverse of a matrix of full rank. He also explicitly proved that the inverse of a symmetric matrix is itself symmetric.

However, despite these early beginnings, the familiar matrix formulation of the least squares problem did not materialize until 1935, and it did not become a

common feature of statistical textbooks until the second half of the twentieth century, see Farebrother (1999).

10. Iterative Fitting Procedures

Gauss (1809) also explained how nonlinear relationships may be fitted by means of an iterative variant of the method of least squares, now known as the Gauss–Newton procedure, in which the fitted relationship is linearized by a Taylor series expansion and fitted by the method of least squares. This process being repeated until a satisfactory level of convergence is obtained.

Despite its early origin, and the publication by Gauss of detailed worked examples in astronomy and geodesy, the Gauss–Newton procedure was not widely adopted for practical work in other areas until the necessary computing equipment became readily available in the second half of the twentieth century. Instead, practitioners avoided the computational burden imposed by the iterative procedure by transforming their nonlinear relationships to a more linear form before estimating the parameters of the resulting equations by a *single* application of the method of selected points, the method of averages, or the method of least squares.

A second iterative procedure usually named for Gauss is the Gauss–Seidel procedure, although Gauss and Seidel were actually not concerned with the procedure that usually goes by this name, but with a distinct fitting procedure known as the method of *relaxation*; see Gauss (1823) for details.

11. Concluding Remarks

The method of least squares and the related statistical procedures known as linear regression analysis and the analysis of variance are widely used in all areas of science. Thus there can be few numerate practitioners of the social and behavioral sciences who have not read research reports that employ these methods to fit linear or curvilinear relationships to data on the variables of interest.

The method of least squares was developed by Legendre, Gauss, and Laplace in the first quarter of the nineteenth century in the context of important practical problems in astronomy and geodesy. But it was not until later in the century that Quetelet (see *Quetelet, Adolphe (1796–1874)*), Galton (see *Galton, Sir Francis (1822–1911)*), and Edgeworth (see *Edgeworth, Francis Ysidro (1845–1926)*) among others adjusted this technique to the needs of the social and behavioral sciences. There was no great shortage of practitioners trained in the use of advanced statistical techniques, but such individuals as were active in this

area were not able to treat their observations with the necessary level of detachment, so that the original source of the observations remained a significant feature of their subsequent analyses.

The method of least squares was absorbed relatively rapidly into psychology, but its rate of infusion into the economic, social, and behavioral sciences (other than psychology) was more gradual. Indeed, applications of this technique were not at all common in these areas until well into the twentieth century. See Stigler (1986, 1999) for a detailed account of the gradual transformation of these subject areas (see also *Quetelet, Adolphe (1796–1874)*; *Edgeworth, Francis Ysidro (1845–1926)*; *Thorndike, Edward Lee (1874–1949)*).

The history of the method of least squares clearly demonstrates that practical scientists with little or no interest in the social and behavioral sciences can make significant contributions to this subject area by developing general analytical procedures that can be adjusted to the particular needs of social and behavioral scientists.

R. W. Farebrother

Gay, Lesbian, and Bisexual Youth

1. Introduction

Youths who identify as gay, lesbian, or bisexual have become increasingly visible during the 1990s. Although constituting only about 2 percent of the adolescent population, these self-identified youths are, in turn, a subset of the much larger population of sexual-minority youths with same-sex attractions who do not adopt a gay, lesbian, or bisexual label. It is this larger group of youths that has been neglected by social and behavioral scientists. By focusing only on ‘out and visible’ youths, researchers, educators, and mental health professionals may have unwittingly created and perpetuated myths about the behavior, attitudes, and mental health of gay youths. Indeed, more recent developmental research that includes the larger category of sexual-minority youths indicate that these youths are often indistinguishable from their heterosexual peers, except in the nature of their sexual desires.

2. Definitions and Prevalence

The term *sexual minority* characterizes a broader class of individuals than those who identify as lesbian, bisexual, or gay. This is a particularly important consideration because during adolescence, youths frequently explore issues related to their sexuality that extend beyond traditional identity labels. Their sexual attractions, fantasies, and behavior may have no easy categorization. Thus, for researchers and lay people alike, the issue of *sexual identity* labels is a difficult

one. Most people are familiar with the labels ‘heterosexual,’ ‘gay,’ ‘lesbian,’ and ‘bisexual,’ but not ‘unlabeled,’ ‘bi-lesbian,’ and ‘not straight’—terms that current cohorts of youth, particularly young women, are likely to assume (Savin-Williams and Diamond 2000).

Included under the rubric of sexual minority are individuals who reject, for personal or political reasons, cultural definitions of any sexual category. Perhaps they believe that no term can adequately describe their attractions (‘unlabeled’), are uncertain as to the nature of their sexual attractions (‘questioning’), have a mixture of bisexual and lesbian attractions (‘bi-lesbian’), are without sexual attractions (‘asexuals’), use markers other than sex of person as the basis for their sexual attractions (e.g., personality, age, sexual behavior), or do not consider themselves to be traditionally heterosexual (‘not straight’).

Another contemporary sexual-minority group increasing in visibility is comprised of transgender individuals, who may be of any sexual orientation or identity. *Transgender* is an umbrella term for those who believe that they do not meet traditional definitions of masculinity or femininity consistent with their biological sex.

One simple resolution to defining who is ‘gay’ would be to eschew sexual labels altogether and rely on descriptions of behaviors, desires, or attractions. Rather than focusing on a particular sexual identity label, researchers should be asking questions about the existence, number, and proportion of sexual behaviors, attractions, or romantic relationships that an individual has with males and females.

Given cultural prohibitions against sexual minorities claiming their identity, it is not known with certainty how many youths experience same-sex attractions. Yet this number is likely to be far greater than the number of youths who identify as gay, lesbian, or bisexual. Three recent surveys illustrate this point. In a national, representative sample of adults, Laumann et al. (1994) reported that 1.4 percent of women and 2.8 percent of men identified as lesbian, bisexual, or gay. Far more, however, reported having thought about having sex with someone of their own gender—5.5 percent of women and 6 percent of men—or having experienced same-sex attractions at least once—7.5 percent of women and 7.7 percent of men. Second, a Youth Risk Behavior Survey of Massachusetts high schools (Goodenow and Hack 1998) reported that 2 percent of students self-identified as gay, lesbian, or bisexual; however, an additional 2 percent reported having engaged in same-sex behavior despite eschewing a sexual-minority label. Finally, in the National Longitudinal Study of Adolescent Health, a comprehensive, representative study of adolescents, 8 percent of males and 6.6 percent of females reported that they had same-sex romantic attractions or had been in a same-sex romantic relationship (Russell and Joyner 1998).

These findings indicate that far more youths experience same-sex attractions, romantic desires, sexual behavior, and romantic relationships than report that they are lesbian, gay, or bisexual. Thus, many 'potential' sexual-minority youths do not identify as such during adolescence and therefore fail to be included in research studies of sexual minorities. Hence, the overwhelming body of research on youths with same-sex attractions samples a select, likely nonrepresentative minority of this population. This conclusion is consistent with McConaghy's (1999) recent assertion about the most important 'unresolved issues in scientific sexology.' Too often researchers assume that sexual attractions are distributed categorically rather than dimensionally, rendering invisible the 'nongay majority with homosexual feelings.'

Although the reasons many youths with same-sex attractions decline to adopt a lesbian, gay, or bisexual label have not been investigated empirically, it is likely linked to negative cultural attitudes and beliefs about same-sex attracted individuals. The associated stigma causes many youths to forego altogether or to delay identification as a sexual minority. It is not known the ways in which those who adopt a sexual identity label differ from the much larger population of same-sex attracted individuals; however, some evidence suggests that they may be psychologically less healthy (see below).

Clearly, many youths who know that they are not heterosexual are unprepared, either developmentally or politically, to attach themselves to a culturally defined sexual category that, as currently constructed, carries profound psychological and social ramifications. To be gay implies belonging to a class of individuals who are subject to hate crimes, prejudice, and stereotypes. Unfortunately, youth often do not realize that embracing this label also opens the door to a community of like-minded individuals who can provide understanding, acceptance, and support for one's central sense of self. Given the perceived consequences of a gay identification, it is to be expected that some adolescents prefer to describe their sexual desires or attractions (e.g., 'I'm attracted to women.') rather than embrace a specific, stigmatized identity label.

3. Myths and Counter Evidence

Relatively little is known about this class of individuals who experience significant and persistent sexual attractions and fantasies for same-sex others. Until recently, researchers have ignored such individuals and behaviors, in part due to *heterocentrism* (the assumption that the universe is heterosexual) and *homonegativity* or *homophobia* (negative attitudes, beliefs, and behaviors toward those with same-sex attractions). Other reasons for this inattention include the belief that because youths are fickle with yet unformed sexuality, as evidenced by the frequency of

adolescent sexual exploration, it is not worthwhile investigating the correlates and consequences of adolescent same-sex experiences. Finally, there is the common belief that researchers should not ask sexual questions because sexuality is highly private and that inquires about sexuality would not be permitted by parents, research institutions, or funding agencies. Traditional social and religious organizations sometimes fear that by raising the issue of homosexuality, they increase the 'risk' of youths engaging in same-sex behavior and identifying as gay. As a result of this negligence, many myths about sexual-minority youths have taken root. Three prevalent myths are reviewed briefly.

3.1 Youths Develop Their Sexual Identity Through a Series of Coming-out Stages

During the 1970s and 1980s, social scientists and clinicians made sense of these young lives by proposing a number of ideal or typical 'coming-out' models (e.g., Cass 1979). These structural models were cast in a somewhat 'one-size-fits-all' mold that outlined an orderly series of stages based on a particular theoretical understanding of human development. The life histories of sexual-minority youths were proposed to follow a series of stages, from first awareness of being different, sexual exploration, and self-labeling; to first disclosures, romantic relationships, and self-acceptance; and to political/social activism and integration of a sexual identity with the rest of one's life. With few exceptions, the empirical basis for these models remains extraordinarily weak, largely because researchers have not investigated the complexities of these models, studied youths over time, developed appropriate research tools to assess youths' 'fit' with the models, or included diverse, under-represented populations of youths. Given these limitations, it should come as no surprise that recent studies found that only 10 percent of young men followed these developmental stages and that the number of young women adhering to this hierarchy is even less (Savin-Williams 1998, Savin-Williams and Diamond 2000).

3.2 Parents React With Horror and Reject Their Sexual-minority Child

Popular advice books for parents often portray the child's act of disclosure as necessarily creating a crisis within the family that may never be fully resolved. Lesions in family relationships are inflicted, wounds that may not withstand later attempts to amend or overcome, and parents encounter unique developmental issues. This literature promotes the view that the disclosure of same-sex desires by children to their parents inevitably and uniformly places youths at psychological and physical risk. Disclosure may result

in youths being disowned, thrown out of the home, or emotionally or physically harassed. Because parents may feel that their child has rejected them and everything the family stands for, family relationships may be irrevocably damaged.

Empirical research, however, does not support these dire predictions. Around 5 percent of youths suffer physical harm from parents or are thrown out of the home once they are open about their sexuality (Savin-Williams 2000). For example, in a sample of Chicago support group youths, only 3 percent reported that they had been thrown out of the home and were living in shelters or with friends (Herdt and Boxer 1993). In another study, parental rejection and anger were the two least common reactions to the youth's disclosure of same-sex sexuality, both one week and six months after the event (Ben-Ari 1995).

3.3 Sexual-minority Youths Experience Mental Health Problems, Exemplified by High Rates of Attempted Suicide

The prevalent cultural image of gay youths is that they are suicide attempting, prostituting, drug-abusing runaways who are HIV positive. Encouraging outcomes of this depiction include sympathy and support from mainstream society, financing of community support groups and research, and conversations about homosexuality in the public school system (usually in health classes). However, the long-term effect may be disastrous—convincing some youths that the only way to be young and gay is to be disordered, unhappy, and problematic. The pervasiveness of this erroneous, degrading representation has re-pathologized gay youths, almost three decades after mental health professionals removed homosexuality from the annals of psychiatric illness.

Empirically, it is clear that some youths, especially young men, who identify as a sexual-minority early in life are at risk for mental health problems. This is particularly the case for those who seek the assistance of support groups (e.g., Hershberger and D'Augelli 1995, Remafedi et al. 1998). However, these researchers have noted that support group attending youths are also the individuals most likely to be raised in dysfunctional families, subjected to barrages of peer ridicule, and to be sex-atypical in their behavior and interests. More importantly, it is often overlooked that even among these high-risk populations, the vast majority of youths who identify as gay, lesbian, or bisexual did not attempt suicide, abuse drugs, pierce their bodies, or have unsafe sex.

Here the distinction between claiming a sexual identity label and experiencing same-sex sexual attractions or behavior becomes particularly important. Although many reports in the literature document that gay youths are three to 10 times more likely to attempt suicide and that 30 percent or more of all adolescent suicides are by gay youths (Fergusson et al.

1999, Garofalo et al. 1998, Goodenow and Hack 1998, Hershberger and D'Augelli 1995, Remafedi et al. 1998), there are reasons to suspect that these numbers overstate the prevalence of suicidality among the larger population of same-sex attracted individuals. For example, Russell and Joyner (1998) found that youths who reported romantic attractions and relationships with same-sex others—a much more inclusive category of sexual minorities than those who identify as gay—were twice, rather than three or 10, times more likely to report suicide attempts as heterosexual youths, and that these sexual-minority youths constituted 15 percent, rather than 30–40 percent, of reported suicide attempts. A study of college students indicated that the proportion of young women (10 percent) and men (11 percent) with same-sex attractions who attempted suicide was no greater than a matched sample of heterosexual women (8 percent) and men (2 percent) (Savin-Williams 2000). This sample is likely to be more representative of the general population of same-sex attracted individuals because it included individuals who identified after high school and because recruitment was based on sexual attractions, not sexual identity.

4. Conclusion

Social and behavioral scientists should consider two facts about the lives of sexual-minority youths. First, they are essentially similar to all youths, independent of sexual desires, in their biology, behavior, beliefs, attitudes, socialization, and mental health. This should be a basic assumption in empirical investigations, educational programs, and clinical interventions. For example, youths of all sexualities want parental acceptance and support, are preoccupied with peer status, desire love and sex, and wonder about their future. Although these concerns can be flavored by sexual orientation—it is far more difficult to date a same- than an opposite-sex peer in most high schools—they are nevertheless adolescent tasks, ultimately to be negotiated by all youth.

A second point to be recognized—and expected given basic developmental theory—is that sexual-minority youths also vary among themselves based on particular distinguishing characteristics. Indeed, on some domains a subset of sexual-minority youths mirror heterosexual youths more than they do other sexual-minority youths. For example, young women with same-sex attractions are often more akin to heterosexual young women than they are to gay male youths. They are less genitally oriented and more likely to value and pursue romantic relationships and to use these occasions to define their sexual attractions (Diamond 1998, Savin-Williams and Diamond 2000).

A dual focus on the ways in which sexual-minority youths are similar to all other adolescents and how they vary among themselves as the result of their

sexuality, personality characteristics, biological heritage, and other developmental processes should infuse all considerations of their lives. This more comprehensive perspective is now possible because a larger and more diverse sample of contemporary youths is willing to be counted as 'not heterosexual.' As these youths become increasingly visible it will become easier for scientists to include them in research that documents their diverse and similar developmental trajectories. Although investigators of sexual-minority youths have not yet adequately sampled from this newly visible population of youths with same-sex attractions, this will most likely occur when definitions of what constitutes a sexual minority extend beyond sexual identity labels to include all youths with same-sex attractions and behavior.

This dual focus can also be seen in the lives of sexual-minority youths. From the perspective of this contemporary generation of youths, a new world has emerged regarding what it means to be a sexual minority. Consequently, it is no longer rare to disclose the nature of one's sexuality earlier than in any previous generation—while still living at home and attending the local high school. Neither is it mandatory to partake in the 'counter culture'—the 'misfits' and disenfranchised youths—of the local school or community in order to receive support and a sense of community. Whereas 'gay liberation' once characterized the only available social or political organizations for teens, Gay/Straight Alliances, school-based clubs consisting of sexual-minority youths and their allies, now populate hundreds of high schools throughout the US. These allow a youth opportunities to discover others with same-sex attractions; a place to 'hide' until ready to self-disclose; and a means to obtain support, respect, and acceptance. Even though these youths tend to blend in with many others in their junior and senior high schools and in their communities, their issues must not be neglected.

Gay/Lesbian Movements

For a movement to occur there needs to be a sense of common identity or purpose and sufficient political and economic space to organize. It is not surprising that gay/lesbian movements are very much the products of modern liberal democratic and capitalist societies, nor that the globalization of these concepts had led to a rapid expansion of gay/lesbian identities across the world.

1. The Emergence of 'the Modern Homosexual'

While homosexual behavior has existed in most societies at most times in history, the creation of a

specific identity based upon homosexual behavior is a far more recent and limited phenomenon. The term 'homosexual' was coined in 1869 by the Hungarian doctor Karoly Benkert, but there is some evidence that people defined by a shared sexual attraction to the same gender had already formed loose social groupings in several European cities. More common however was a range of understandings of sexuality and gender which saw homosexual behavior as part of an undifferentiated range of possible sexual behaviors, and an equal range of acceptance and condemnation of such behaviors. Such understandings were always heavily gendered, and often ignored the potential for female homosexuality.

By the end of the nineteenth century the idea of the homosexual existed to a sufficient extent that it became possible to imagine the creation of both social and political organizations for those people who identified with the term. The first overtly political organization, the Scientific-Humanitarian Committee, was founded by the German Magnus Hirschfeld in 1897 and campaigned for the decriminalization of homosexuality.

Hirschfeld believed that homosexuals constituted a 'third sex,' and therefore were inherently different, and no more deserving of condemnation than, say, someone born left-handed. However, against the idea of the 'third sex' Freud postulated a universal 'polymorphous perversity,' so that childhood experiences determined whether or not one developed a primarily heterosexual or homosexual orientation. While many psychoanalysts developed a strong antipathy to homosexuality, seeing it as a pathology to be cured through therapy, another tradition, which would emerge in the 1960s, used Freud's works to argue against the idea of a heterosexual norm.

After World War I both Europe and the USA saw the development of small homosexual social groups in major cities, most famously Paris and Berlin. Hirschfeld's organization was ended brutally by the Nazis, and it was not until the aftermath of World War II that new organizations emerged—COC (originally the Shakespeare Club) in the Netherlands; *Arcadie* in France; *der Kreis* in Switzerland. COC remains, by far the longest lived gay/lesbian organization in the world. In the USA the first groups were established in the 1950s (the Mattachine Society in 1951, Daughters of Bilitis in 1955) but these groups remained largely underground, although some overt political protest began in the early 1960s (d'Emilio 1983).

In Europe and North America the dislocations of World War II meant that millions of people came in contact with underground gay and lesbian worlds, and although the post-war organizations remained very small, homosexual communities developed in most major western cities through the 1950s and 1960s (d'Emilio 1983, Kennedy and Davis 1993). It was the presence of both social and commercial networks

which allowed for the rapid emergence of a new sort of gay/lesbian movement in the aftermath of the major social and political upheavals in most liberal democracies from the end of the 1960s.

2. *The Development of the Gay/Lesbian Movement*

The contemporary movement was in a sense born out of the political, social, and cultural changes of 'the sixties,' symbolized by the growing freedom which surrounded discussion of sexuality, the rebirth of feminism, and the student movements of 1968. In France and Italy it was the events of May 1968 which led to the emergence of a radical gay movement; in the USA the turning point is usually assumed to be the riots which followed a raid on the Stonewall Inn in Greenwich Village, out of which the New York Gay Liberation Front was born. The gay/lesbian movement of this period saw itself as part of a larger radical assault on hegemonic cultural and political ideas and institutions, and was closely linked to various elements of New Left theory (Altman 1971). Small gay liberation groups also appeared in Canada, the UK (Weeks 1990), Scandinavia, Australasia, and some Latin American countries: Argentina in 1969; Mexico in 1971; Puerto Rico in 1974. The first Israeli gay/lesbian organization was established in 1976.

The post-1968 movement differed from its predecessors in its willingness to assert a new sense of gay/lesbian identity which demanded complete equality, at both an individual and a communal level. Although the original use of the term 'gay' included both women and men, tensions quickly emerged along gender lines, in part because of the strong interconnection between radical lesbianism and feminism, which had no equivalent for gay men (Faderman 1981, Rich 1980). During the 1970s there was increasing divergence between lesbian and gay male organizations, as a growing commercial gay world opened up new ways of living as a homosexual, particularly for men. As one novelist wrote: 'Almost through an act of will, I had made myself embrace this new identity of mine and never look back. I had gay friends. I ate at gay restaurants. I went to gay bars. I had my apartment near DuPont Circle' (Russell 1994, p. 231).

While 'gay ghettos' such as that described here only developed in a few cities outside the USA—or, as in the case of Paris's Marais, developed a decade later—the growth of gay and lesbian commercial space has been a feature of almost all western countries from the 1970s on. In many capitalist societies the 'pink dollar' has become seen as an important niche market, and this has made possible a flourishing gay press and an expansion of businesses and professional services aimed at a specifically gay and lesbian market. By the 1990s government authorities in a number of countries

were promoting services for lesbian and gay travelers, and Sydney's Gay and Lesbian *Mardi Gras* was recognized as one of Australia's most successful tourist attractions. The gay/lesbian press, originally an expression of the political movement, has become increasingly preoccupied by 'lifestyle' issues and the need to attract 'mainstream' advertizers.

Meanwhile women developed a parallel if sometimes overlapping world, and developed a set of social institutions which allowed room for a 'women-centered' politics, sometimes extended to a rejection of anything that could be seen as male-dominated (Stein 1997). In some countries links were maintained between women and men through common political organisations such as the National Gay (later Gay and Lesbian) Task Force in the USA. The Task Force's commitment to working through mainstream institutions underlines the various splits around gender, political style, and class which became apparent in the movement during the 1970s and 1980s. As the radical energies of the early 1970s dissipated, so too did organized lesbian and gay politics, though the trajectory of the movements is rather different in different countries (Adam et al. 1998). Even in the western world there were significant differences between the English-speaking democracies, where decriminalization of homosexual behavior seemed the top priority; the countries of northern Europe, especially the Netherlands and Denmark, where social acceptance seemed most assured; and those of southern Europe whose laws were less repressive and where a language of universal rights was often used to argue against any sort of identity politics.

The 1970s and 1980s saw a rapid shift in most western countries in attitudes towards homosexuality, with growing recognition of gay men and lesbians as constituting legitimate communities with a certain political influence. Openly lesbian and gay legislators were elected in Norway, Canada, and the USA, and almost all western countries abolished remaining laws which decriminalized homosexual activity. (The great exception was the USA, where homosexual acts remain illegal in a number of states, in part because of a decision by the Supreme Court in 1986 which upheld Georgia's sodomy laws.) The rate of change was particularly rapid in cases such as Spain which democratized during this period, a shift which would be echoed in Latin America in the late 1980s and some parts of Eastern Europe in the 1990s (Long 1998).

The rapidity of changes in attitudes towards homosexuality meant a corresponding backlash from moral conservatives, which was most pronounced in the USA. The mobilization of religious conservatives by groups such as the Moral Majority led to bitter attacks on homosexuality, both in the political arena and, not infrequently, in direct violence. While there were examples of similar reactions elsewhere, such as the Thatcher government's prohibitions on 'the promotion of homosexuality,' it is probably true that the

gains for gay and lesbian rights was rapid and irreversible in most western democracies.

3. *The Impact of HIV/AIDS*

The first reports of what was to be named 'AIDS' (acquired immune deficiency syndrome) came with severe illnesses among young homosexual men on both American coasts, and for a short time the new disease was known as 'gay-related immune deficiency syndrome.' Within a few years two major discoveries were made: the syndrome was transmitted through sexual and blood contact, and in many parts of the world the bulk of sexual transmission was heterosexual. Nonetheless the epidemiological link to homosexuals in the rich world has a continuing impact on how the epidemic is perceived, and has had a major impact upon gay organization. The first responses to the new disease came from gay communities in major western cities, with the Gay Men's Health Crisis in New York (founded in 1982) becoming a model for groups such as the various Australian state AIDS Councils, the Terrence Higgins Trust in Britain and the *Deutsche AIDS Hilfe*.

During the 1980s the need to lobby governments, to provide information and preventive education, and to develop home-care and emotional support for those with HIV/AIDS, dominated gay movements in most western countries, and sometimes involved considerable numbers of lesbians as well. As the epidemic was discovered to be growing very rapidly in Africa and parts of Latin America, AIDS was to be the focus for a new wave of homosexual organizing in a number of 'developing' countries. Groups such as Pink Triangle in Malaysia or Triangulo Rosa in Costa Rica came into existence as *de facto* homosexual organizations because of the epidemic (Altman 1994). The development of People With AIDS groups built on the earlier gay movement concept of 'coming out.'

The impact of AIDS on the movement varied from country to country, but overall it meant a much closer relationship between the state and gay organizations, particularly in countries such as Denmark, Switzerland, Canada, and Australia where the epidemic remained largely due to homosexual transmission and national strategies incorporated community responses. At a global level the development of international responses through the Global Program on AIDS and then UNAIDS saw some institutional support for community organizations, including gay ones.

4. *The 'Queer Movement'*

One of the successes of the movement was the development of 'gay and lesbian studies,' particularly in the Netherlands and the USA. In the case of the latter the development of post-modern theory led to

new ways of conceptualizing homosexuality which sought to move beyond fixed notions of identity and to destabilize assumptions about the relations between sexuality and gender. At an academic level this was expressed in the notion of 'queer theory,' which was played out politically in two major ways: the development of a new radicalism and the extension of the movement to include issues of bisexuality and transgenderism. One might note these were both elements of the gay liberation movement of the early 1970s, which had tended to vanish in the mainstreaming of the movement in the 1980s. (See *Masculinities and Femininities; Queer Theory*.)

In the USA, and to a lesser extent in the UK, the movement has extended itself to recognize 'bisexual and trans-gendered' people as well as 'gay and lesbian.' Elsewhere this move has been more hotly contested, as in battles around membership criteria for Sydney's Gay and Lesbian *Mardi Gras*. Yet despite the rhetoric, the gay and lesbian movement has continued to function as do most pressure groups in western societies, using a judicious mix of popular protest, lobbying, media propaganda and in some cases direct participation in the electoral process.

In the USA two issues dominated mainstream gay and lesbian politics in the 1990s: the place of gay men and lesbians in the military and arguments about same-sex marriage. The first became a major embarrassment for the Clinton Administration in 1993, when the President's pledge to remove discrimination from the military ran into considerable Congressional opposition. The resulting 'don't ask, don't tell' policy was far weaker than the policies in a number of other western countries.

The first national recognition of same-sex partnerships came in Denmark in 1989 and arguments about state recognition of homosexual relationships have now extended to almost all of Europe. A law proposed in France in 1998 would have recognized cohabiting couples (both hetero- and homosexual) 'who cannot or do not wish to marry,' and was bitterly opposed by the right. The following year the Senate amended the proposal to cover only heterosexual couples. The idea of 'gay marriage' became a major issue in the USA in 1996, following a case in the Hawaii Supreme Court which seemed likely to recognize same-sex marriage as constitutional, following which Congress passed—and President Clinton signed—the Defense of Marriage Act, which would have refused recognition in other states of such a ruling in Hawaii.

5. *The Development of an International Gay/Lesbian Movement*

In 1978 the International Gay (later Gay and Lesbian) Association (ILGA) was formed at a conference in Coventry, England. While ILGA has largely been

driven by northern Europeans, it now has member groups from over 70 countries and has organized meetings in several southern cities. Other networks, often linked to feminist and AIDS organizing, have been created in the past two decades, and emerging lesbian and gay movements are increasingly likely to be in constant contact with groups across the world. Such networks argue for a certain universality of homosexual identity, and their major strategy has involved appeals to universal norms of human rights to oppose persecution and discrimination against homosexuals across the world. It is difficult to avoid a certain amount of neo-colonialism in such universalist arguments, as Ann Ferguson has pointed out (Ferguson 1990, pp. 82–4). What is perhaps striking is that while the dominant image of gay and lesbian identity and culture is undoubtedly American, the development of international networks has owed comparatively little to American leadership. On the other hand, the two largest international gay/lesbian 'networks' are probably those based around the Metropolitan Community Church and the Gay Games, both American in origin.

It may be that a political movement is the least likely part of western concepts of homosexual identity to be adopted in many parts of the world, even as they enthusiastically embrace the mores and imagery of western queendom. The particular form of identity politics which allowed for the mobilization of a lesbian/gay electoral pressure in countries like the USA, the Netherlands or even France may not be appropriate elsewhere, even if western-style liberal democracy triumphs. The need of western lesbians to engage in identity politics as a means of enhancing self-esteem may not be felt in other societies. Nonetheless there has been a rapid growth of lesbian and gay organizing during the 1990s in countries as dissimilar as Nicaragua, Slovakia, India, and the Philippines.

The western lesbian/gay movement emerged in conditions of affluence and liberal democracy, where despite other large social issues it was possible to develop a politics around sexuality which is more difficult in countries where the structures of political life are constantly contested. Writing of contemporary South Africa, Mark Gevisser notes: 'Race-identification overpowers everything else—class, gender and sexuality' (Gevisser 1999). In the same way basic questions of political economy and democratization will impact on the future development of gay/lesbian movements in much of Asia and Africa. Yet in Latin America and Eastern Europe gay/lesbian movements have grown considerably in the past decade, and there are now signs of their emergence in some parts of Africa, for example in Kenya and Zimbabwe where President Mugabe has consistently attacked homosexuality as the product of colonialism. The twin impact of globalization and the discourses of international human rights are likely to see a strengthening of both gay/lesbian identities and rights in the future.

D. Altman

Gellner, Ernest (1925–95)

Ernest Gellner was born in Paris on December 9, 1925 and spent his childhood in Prague. The family moved to England in 1939 ahead of the Nazi invasion. At Oxford, where his studies were interrupted by military

service in the Czech Brigade, he specialized in philosophy. After teaching philosophy for two years at Edinburgh, he joined the Department of Sociology at the London School of Economics (LSE) in 1954. Here, stimulated also by his discovery of social anthropology in the department established by Malinowski, he formulated in *Words and Things* (1959) a withering and controversial critique of the linguistic philosophy that was dominant in Oxford at the time. In 1962 he obtained a doctorate in anthropology, based on fieldwork in Morocco. *Thought and Change* (1965) outlined many of the themes that he followed up in later years, including his theory of nationalism. In 1984 Gellner succeeded Jack Goody in the Chair of Social Anthropology at Cambridge, where he was elected to a Fellowship at King's College. In 1991 he returned to Prague to launch the Centre for the Study of Nationalism at the newly established Central European University. He died in Prague on November 5, 1995.

Gellner's interests ranged well beyond the conventional boundaries of the subjects in which he held academic posts. His prolific and diverse writing was securely anchored in his early philosophical studies, particularly in Hume and Kant, augmented later by his reading of Weber, Durkheim, and Malinowski. In short, he drew on classical sources in several disciplines. Negative influences were equally important. Marxism was rejected because of its economic determinism, though much of Gellner's own work emphasized a materialist standpoint and he maintained an enthusiastic curiosity for Soviet Marxist anthropology. Above all, he rejected the relativism of the later Wittgenstein.

Gellner's combination of philosophy and anthropology was far from the continental genre of philosophical anthropology. Rather, he hailed Malinowski as the innovator who made empirical observation in the course of long-term fieldwork the revolutionary basis of modern anthropological knowledge. His fascination with Malinowski led Gellner, late in his career, to explore the founder's intellectual roots in late Habsburg Cracow and to an illuminating (posthumously published) contrast with Wittgenstein (Gellner 1998).

Alongside the functionalist holism of Malinowski, Gellner was also influenced by A. R. Radcliffe-Brown's positivist insistence on the comparison of social structures. His own work prioritized pattern and system, rather than close-up ethnographic analysis of the flux of events. He was interested in all kinds of systems of ideas, and especially in linking ideologies to long-term evolutionary change and to the distribution of economic and political power. Gellner's manner of explicating societies by means of elegant structural models or ideal types was at odds with most of his contemporaries, who stressed interpretation and local knowledge. More controversially, he insisted that *one* culture, that of the modern west, based ultimately upon premises of individualism and ration-

ality, was technologically and ‘cognitively’ more powerful than all others. This anthropological philosophy (1975, 1985a) was complemented by a three-stage philosophy of history (1991). How to explain the dominance of the west and how best to spread the benefits of that superiority were central themes throughout his work.

Among the more specific research themes addressed by Gellner, the most significant in his lifetime was his theory of nationalism. In reaction to his LSE colleague Elie Kedourie, Gellner emphasized not the dissemination of the nationalist idea, but the functional needs of a modern industrial society, which requires a highly mobile labor force and educational institutions to promote literacy in a single ‘high culture.’ This model, elaborated in several variations over more than three decades, was not primarily supported with fieldwork materials but with vivid imaginary sketches, notably that of ‘Ruritania’ (1983). These were evidently much influenced by his own Central European roots, and perhaps by earlier scholars with a similar background, such as Hans Kohn and Karl Deutsch. Gellner’s ‘modernist’ emphasis on the uneven spread of industrialism does not offer a fully satisfactory explanation for the actual spread of nationalism outside Europe, or even within plausible Ruritania. It offers little help in predicting the circumstances in which national sentiment becomes ‘hot.’ It remains, however, as even critics have acknowledged, the best general theory of nationalism that any twentieth-century social scientist has devised (Hall 1998).

In his studies of Islam, Gellner supplemented an abstract model with data from many years of fieldwork in the High Atlas Mountains. His monograph, *Saints of the Atlas* (1969), an analysis of the role played by charismatic religious specialists in the maintenance of political order in the absence of state power, is a classic of the British school. Intellectual inspiration was drawn not only from the segmentary lineage theory of the French pioneers and from Evans-Pritchard, but also from the cyclical models of tribal–urban interaction developed centuries earlier by Ibn Khaldun. Gellner’s generalization of the ‘pendulum swing model’ to the wider Moslem world (1981) has not been widely accepted, while even in the Moroccan case his application of segmentary theory has been criticized by later fieldworkers (see Munson, in Hall and Jarvie 1996). However, his schematic view of Islam, with its text-based high culture, as the most modern of the great religions, gave perceptive insight both into the relative absence of nationalism in these countries and the rise of ‘fundamentalism.’

The Marxist–Leninist régimes of twentieth-century Eurasia were another form of social organization of abiding concern to Gellner, for reasons that connect closely with his biography. Although he visited the Soviet Union frequently and spent a year in Moscow at the height of *Perestroika*, most of his fieldwork in this case was textual. He delighted in reading between

the lines of ethnographers’ adaptations of Marxist theories in order to see what light these might throw on Soviet society (1988b). Though he did not predict the demise of the socialist system, his first-hand observations of socialist disenchantment helped him to get to the heart of the matter: no ideology that promised salvation here on this earth was likely to endure if the utopians could neither satisfy accelerating consumer expectations nor control corruption and widening inequalities. In his last years he found the concept of ‘civil society’ particularly useful in defining a blueprint for a modern democracy that would avoid both the disasters of totalitarian central planning and the tribal ‘tyranny of cousins’ (1994).

Testimony to Gellner’s influence in his lifetime can be found in a remarkable multidisciplinary collection of essays, to which he was able to reply shortly before his death (Hall and Jarvie 1996). Part of the explanation for this fame lies in the topicality of the subjects he treated: nationalism, Islamic fundamentalism and socialism all were vital problems of the age. Another element in his appeal is the allure of a scholar who was not merely radically disrespectful of disciplinary barriers but who consistently opposed the most influential intellectual currents of the day. His critique of Oxford philosophy was followed by equally disrespectful dismissals of many other ‘churches,’ including Parisian structuralism, Frankfurt neo-Marxism, psychoanalysis (1985b), the ‘Orientalism’ paradigm of Edward Said, and every variety of ‘postmodernism’ (1992). Even his relationship with social anthropology, the discipline in which he came closest to finding a home, was often uneasy. He remained basically loyal to the canons of ‘structural-functionalism’ long after these were abandoned by the profession, yet he combined this with an even more unfashionable sympathy for evolutionist agendas. There were sharp disagreements, for example with Rodney Needham over the ‘concept of kinship’ (1974) and with Clifford Geertz, whom he recognized as the leading contemporary exponent of the erroneous relativist–idealistic concept of culture.

It is not therefore surprising that neither anthropology nor any of the other disciplines to which he contributed has a Gellnerian school. His diffuse impact owes much to his forthright stance in defence of ‘modernist’ enlightenment ideals in a century in which these foundations have seemed increasingly fragile to the great majority of the West’s social scientists. His temperament and essayistic, aphoristic style were well suited to this role, which of course in the eyes of those he attacked became the role of bogeyman. This stubborn defender of Cartesian ideals of rationality, clarity and *truth* delighted in controversy and had a preference for striking images and analogies over more prosaic social science techniques; but these were an integral part of his appeal. He is best seen not as a backward-looking defender of European traditions, but as a scholar who strove to

adapt a European liberal heritage to reach a better understanding of all the problems of the modern world. Caricatures such as 'enlightenment fundamentalist' are wide of the mark (even if he himself regularly suggested such labels). Despite his criticism of Wittgenstein and of the relativist trend in anthropology, he was no more willing than Malinowski to dispense with the concept of culture. He insists on the uniqueness of modern western cognition because it is stronger than any other, but he does not claim that it is *better*. Compared to Popper and Hayek, this Central European is painfully aware that decent human communities require stronger social foundations than those which liberal individualism has been able to provide. It is this balancing act and the suggestiveness of his ideal types which make Ernest Gellner a continuing source of inspiration.

Gender and Cancer

Incidence rates for cancer, a group of diseases characterized by the rapid and uncontrolled multiplication and spread of abnormal cells, differ for men and women. Explaining this variation requires consideration of the role of both sex (biologically determined factors) and gender (socioculturally determined factors) in the onset, progression, and treatment of the disease. Although cancer etiology and treatment are complex and multidetermined, there is clear evidence that sex differences in anatomy, physiology, and hormone exposure and gender differences in health-related behavior, environmental exposure, and access to health care play central roles.

1. Cancer Incidence Rates for Women and Men

The neoplastic process can occur in any part of the body, with rates of occurrence differing substantially by anatomic organs, between women and men, and across nations. For example, breast cancer is by far the most frequently diagnosed cancer in women worldwide, due largely to high rates of breast cancer in industrialized countries. Cervical cancer, the site with the second highest incidence rate in women, is diagnosed primarily in women from developing countries, who have much lower rates of breast cancer. Lung cancer is the most common site of cancer in men, whereas it is fifth in frequency among women (Boyle and Maisonneuve 1998). Tables 1 and 2 provide the range in rates of the most common cancers for women and men, indicating where the highest and lowest incidence occurs. The prevalence of cancer in sex organs and the wide international variation within sex suggest that both sex and gender are important.

2. Problems in the Research Literature

It is difficult to ascertain the precise contributions of sex- and gender-related variables to the etiology and treatment of cancer for two sets of reasons. First, these variables have rarely been the focus of careful scientific investigation. Until very recently, subjects in research with both animals and humans have been predominantly male. Many studies included only males and, when both sexes were included, they were typically combined into one sample such that the data from the much larger proportion of males were assumed to generalize to females (Sechzer et al. 1994). The very

Table 1

hormonal and physiological differences that appear to be central to some forms of cancer in women were considered unwanted sources of experimental error. The second set of problems is inherent in the questions of interest. Even with increasing attention being paid to sex, and to a lesser extent to gender, it is difficult to identify clear causal relations because of the complex interactions between and covariation of biological sex and sociocultural gender roles. Animal models cannot adequately explore gender, and there is little opportunity to isolate specific effects in human populations. It is difficult to make blanket statements that are accurate for all cultures and all cancers. Cultural values and constraints regarding gender roles differ substantially across societies, and cancers at different sites vary greatly in terms of incidence and mortality rates, epidemiology, risk factors and causes, and treatments (Harras et al. 1996).

3. Etiology and Prevention

In addition to the obvious relevance of sexual anatomy to several of the most common forms of cancer, other sex-related variables are involved in cancer etiology

(Meyerowitz et al. 2000). Sex hormones often play a central role in the onset and progression of cancers of the reproductive organs and breasts, as well as other sites that have receptors for sex hormones, such as colorectal and laryngeal tissue. Also, the normal physiological variations between women and men in the functioning of virtually all systems of the body have implications for cancer (Legato 1998). For example, the slower colonic transit time and lower excretion of bile acids in women account in part for colon cancer in women, one of the few sex-neutral sites of cancer for which incidence rates for men are not higher than rates for women.

Socioculturally determined factors appear to play an even more important role in cancer etiology than hormones and physiology. It has been estimated that as many as 75 percent of cancer deaths are attributable to behavior, particularly tobacco use and diet (Boyle and Maisonneuve 1998). Women tend to lead healthier lives than men in areas that have been associated with cancer risk. They use less tobacco, drink less alcohol, eat more fruit and vegetables, consume less animal and dairy fat, and apply sunscreen more regularly than men (Meyerowitz et al. 2000). When women's health habits shift to approximate those of men, the gap

between male and female cancer rates shift as well, as seen in the dramatic increase in both smoking and lung cancer rates among non-Hispanic white women in the US over the past few decades.

There are also gender differences in cancer risk due to exposure to environmental carcinogens and, possibly, stress-inducing life circumstances. Occupational segregation in many sectors of the workforce means that women and men are exposed to different toxins and other workplace hazards (Krieger et al. 1993). For example, gender differences in exposure to second-hand smoke in hospitality jobs such as waiting on tables in restaurants or to industrial toxins in factories will vary depending on cultural norms regarding whether these are viewed as primarily jobs for women or for men. Sedentary jobs also have been associated with increased risk of some forms of cancer (Meyerowitz et al. 2000), potentially placing women in clerical jobs at higher risk than men in more physically active lines of work. Additionally, there is growing evidence that stress can influence natural killer cell activity and other aspects of immune functioning that may, in turn, effect cancer onset or progression (Cohen and Herbert 1996). Psychosocial variables that have been associated with immune suppression—inhibition of emotional expression, passive and avoidant coping, lack of social support, and multiple life stressors—can all be influenced by gender-role expectations and cultural values. For example, proscriptions against seeking social support in men and stress associated with filling multiple roles in women have been suggested as important gender differences in the US (Good et al. 2000, Sechzer et al. 1994).

In addition to their individual influences, sex and gender can interact in cancer etiology. The most salient example is cervical cancer, for which a sexually transmitted virus, Human Papilloma Virus (HPV), appears to be a primary causal agent (Boyle and Maisonneuve 1998). Women who have unprotected sex with multiple sex partners or with men who have multiple sexual contacts are at substantially increased risk of contracting the disease. Thus, social norms regarding sexual behavior for women and men and regarding women's rights to demand safe sex practices from their partners will influence cervical cancer rates.

4. Early Diagnosis and Treatment

Once a neoplastic process has begun, survival is dependent upon early diagnosis and effective treatment. Given that women are more likely than men to fall below the poverty line, their access to adequate care can be severely limited in countries where a fee-for-service health care model prevails. Even when finances are not a limiting factor, cultural values about the appropriateness of obtaining care can play a role, as is the case in some cultures where it is up to male relatives to determine whether women should receive medical care. Data regarding gender differences in the

extent to which individuals who do have access to care adhere to medical recommendations for cancer screening and treatment are mixed, although most studies seem to indicate lower adherence rates for men (Good et al. 2000). Rigid adherence to strictly traditional gender roles for either masculinity, such as an unwillingness to accept physical vulnerability and dependence, or femininity, such as passivity in the face of medical authority or pressures to maintain a caregiver role, can impede optimal care (Good et al. 2000, Sechzer et al. 1994). Even when the individual does not hold these values himself or herself, gender roles can have an influence either through policy decision or implicit biases. For example, male physicians have been found to be less likely than female physicians to recommend breast and cervical cancer screening, whereas they are equally likely to recommend sex-neutral screenings such as blood pressure tests (see *Cancer Screening*).

In addition to the influence of gender roles on diagnosis and treatment, there is some evidence to suggest sex differences. Rates of cancer survival differ between men and women, with women having the survival advantage for most cancer sites (Legato 1998). There also is growing evidence that the pharmacokinetics and drug toxicities of some chemotherapeutic agents differ between women and men, indicating the need for sex-specific prescribing standards (Legato 1998).

5. Quality of Life

Psychosocial adjustment to the diagnosis and treatment of cancer is another area in which gender issues are likely to play a role in cancer outcomes. Until recently, almost all of the relevant literature has assessed quality of life among women, with the few studies with men focusing on physical symptoms and functional abilities rather than the emotional or social aspects of adjustment (Meyerowitz and Hart 1995). Therefore, it is not possible to draw clear conclusions regarding the role of gender in adjustment, and further research is required (see *Chronic Illness: Quality of Life*).

6. Conclusions

Clearly, values and standards regarding the appropriate behaviors and roles for men and women, both at the level of the individual and the larger society, influence cancer onset and progression. The precise nature of the influence is likely to vary by cancer site and by culture.

Relatively little research has considered the biological, behavioral, and healthcare pathways through which gender plays a role. Methodological and conceptual refinements are needed in order to allow future research to expand beyond simple description to

consider multiple causal pathways within a multidisciplinary biopsychosocial model.

Gender and Cardiovascular Health

Despite the decline in heart disease in most Western industrialized countries, the disease remains a major health problem and has reached epidemic proportions

in many countries of Eastern Europe, particularly among men (Bobak and Marmot 1996, Weidner et al., in press). Typically, the category heart disease includes nonrheumatic heart disease, hypertension, and coronary heart disease (CHD). The latter comprises the major subgroup (at least 80 percent of heart disease). The focus of this article will be on this major subgroup of heart disease (see *Coronary Heart Disease (CHD): Psychosocial Aspects*).

1. The Gender Gap in CHD

Data from the Framingham Heart Study indicate that the lifetime risk of developing CHD at age 40 is one in two for men and one in three for women (Lloyd-Jones et al. 1999). Recent international CHD mortality data confirm that CHD is lower in women than in men, yielding female:male ratios ranging from 0.1 to 0.6, depending on country (Jackson et al. 1997). At first glance, this universal female advantage in countries differing in heart disease rates and lifestyles points to protective factors of a biological nature (i.e., estrogen) (see *Gender and Physical Health*). However, several studies have cast doubt on the role of sex hormones in the protection from CHD in women (Barrett-Conner 1997). Furthermore, the differences between countries are larger than the difference between the sexes, suggesting that 'male anatomy is not destiny' with regard to CHD. Also, male excess mortality from cardiovascular disease has not always been present throughout history (Nikiforov and Mamaev 1998). Finally, the recent epidemic of cardiovascular disease among young and middle-aged Eastern European men has widened the gender gap over a very brief time span. All these phenomena indicate that nongenetic factors influence the gender gap in heart disease (Weidner 1998).

2. Why Do Men Get More Heart Disease?

2.1 The Role of Traditional Risk Factors

Considerable progress has been made in the identification of physiological and behavioral risk factors for CHD. The major risks are elevated plasma cholesterol, low HDL-cholesterol, hypertension, diabetes, cigarette smoking, and abdominal obesity. Generally, men's levels of these risk factors are less favorable than those of women's (Barrett-Conner 1997). This raises the question of whether gender differences in traditional risk factors can explain the observed gender difference in CHD mortality. Analyses of data from the World Health Organization coordinated MONICA Project and the US Atherosclerosis Risk in Communities Study indicate that only 40 percent of the variation in the gender ratios of CHD mortality in 24 countries could be explained by gender differences

in five major CHD risk factors (i.e., high plasma cholesterol, low HDL-cholesterol, high blood pressure, cigarette smoking, and general obesity; Jackson et al. 1997).

In this regard, it is of interest to note that the traditional risk factors are not good candidates to account for the cardiovascular disease epidemic in Eastern European men either. For example, Kristenson et al. (1998) compared traditional and psychosocial risk factors of 50-year-old Swedish men with age-matched Lithuanian men, who are four times more likely to die from CHD than their Swedish counterparts. There were hardly any group differences in traditional risk factors. However, Lithuanian men were more likely to report greater psychosocial strain (e.g., depression, low social support, job strain) than Swedish men. This raises the possibility that psychosocial coronary risk factors do not only contribute to the recent increase in CHD among men in Eastern Europe, but may also account for some of the variance in the gender differential in heart disease.

2.2 The Role of Psychosocial Risk Factors

The impact of psychosocial factors on the etiology and prognosis of coronary heart disease has been summarized recently (Hemingway and Marmot 1999, Rozanski et al. 1999). These factors include coronary-prone personality attributes such as Type A and hostility, job strain, lack of social support, negative emotions (particularly depression), and low socioeconomic status. Gender-specific associations with CHD for these variables have been summarized previously (Weidner 1995, Weidner and Mueller 2000, Orth-Gomer and Chesney 1997, respectively).

Overall, men appear to be at a disadvantage when considering psychosocial risk factors. For example, they score higher on Type A behaviors and hostility than women (see *Coronary-prone Behavior, Type A*). Both of these attributes are characteristics of the male ('macho') gender role, which has been linked to behavioral risk factors, such as smoking and excessive alcohol consumption (Waldron 1997) as well as other health risks (Courtenay 2000).

Men not only report less social support than women, but also appear to have fewer sources of social support, thus increasing their dependency on a single source (see *Social Support and Stress*). The Male Aging and Women's Health Studies in Massachusetts examined sources of social support among mid-aged women and men, including support from spouse, relative, friend, and co-worker. Men were more than twice as likely as women to name their spouse or their partner as their primary provider of social support (65.5 percent vs. 26.4 percent). Furthermore, 24.2 percent of men (but only 6.1 percent of women) said this was their only source of support! These data may, in part, explain why men's health is more seriously affected by partner

loss through separation, divorce, or widowhood. Finally, men were twice as likely as women to report no supporters (9.2 percent vs. 4.3 percent; New England Research Institutes 1997).

At first glance, gender differences in negative emotions appear to favor men (see *Emotions and Health*). In most studies, women report more negative emotions such as depression than men (although this is not consistently found in populations where women and men have similar roles, such as among college students). Although women may report more depression, they appear to be coping more effectively than men. Generally, men are more likely to use avoidant coping strategies, such as denial and distraction, whereas women are more likely to employ vigilant coping strategies, paying attention to the stressor and its psychological and somatic consequences (Weidner and Collins 1993). Which style is more adaptive depends largely upon the situation. Most stressful experiences consist of uncontrollable daily hassles, which are short-lived and typically of no great consequence. Here, avoidant strategies would be more adaptive ('what I cannot control and what can't hurt me, is best to be ignored'). Thus, men's strategies are likely to pay off for these types of events, contributing to their lesser experience (or report) of emotional discomfort or distress. But what if disaster hits? Avoidance of uncontrollable events—such as divorce, loss of a job or a loved one, sudden financial crisis and economic decline—may not be adaptive in the long run. Here it may be women's greater vigilance that is more adaptive: preparing for the crisis, seeking help, advice, etc. Consistent with this reasoning are recent data from the Hungarian population showing that women tend to accept their negative mood as a disorder to be treated, whereas men are more likely to engage in self-destructive behavior, such as excessive alcohol consumption (Rethelyi et al., in press). Similarly, research on how people cope with disasters (e.g., hurricanes and tornadoes) supports the notion of men's maladaptive coping: increases in alcohol consumption and depression were related to personal disaster exposure among men, whereas no such direct relationship was evident among women (Solomon et al. 1987). Thus, in addition to an unfavorable traditional coronary risk factor profile, men's psychosocial coronary risk factors seem to further enhance their susceptibility to CHD.

2.3 Gender-specific Associations Between Risk Factors

Another major question concerns the interrelationship among traditional, behavioral, and psychosocial risk factors. It is conceivable that gender-specific associations among risk factors may be stronger among men than among women, that is, an increase in one factor may elevate another factor in a gender-specific fashion.

There is some indication that this indeed may be the case. For example, job strain appears to be associated with increases in health-damaging behaviors (e.g., cigarette smoking, excessive alcohol and coffee consumption, lack of exercise) among men, but not among women (Weidner et al. 1997). Similarly, men respond with exaggerated cardiovascular reactions to a wider range of environmental stressors than women. A male ('macho') sex role orientation is associated with decreased motivation to learn stress management skills in men, but not in women (Sieverding 1997). Socio-economic deprivation and depression are more closely related to mortality in men than in women (Kopp et al., in press).

In contrast, men appear to benefit more from social support (i.e., decreased cortisol response to stress) provided by their partner than do women (Kirschbaum et al. 1995, also see Orth-Gomer and Chesney 1997). Similarly, the association between physical activity and CHD appears to be stronger for men than for women. This latter finding, however, may be due to the use of questionnaires designed for men, which focus on sports and neglect physical activities associated with house work (Barrett-Connor 1997).

3. Conclusions

Women score better on traditional and psychosocial coronary risk factors when compared with men (see *Men's Health; Women's Health*). There is also some indication that associations between risk factors may be stronger among men than among women. While gender differences in traditional risk factors appear to contribute substantially to the gender gap in heart disease, we currently do not know to what extent psychosocial risk factors contribute to this gap. Most population studies do not include detailed assessments of psychosocial coronary risk factors, which make analyses of the sort conducted by Jackson and his colleagues impossible. It is likely that gender differences in psychosocial risk factors will explain additional variance in the gender ratios of CHD mortality. Furthermore, currently ongoing research on 'new' coronary risk factors, such as abdominal obesity, cardiovascular stress reactivity, and mechanisms related to antioxidant state in women and men promises to further illuminate factors contributing to the gender gap in heart disease (Weidner et al., in press).

G. Weidner

Gender and Environment

The environment is very much a product of the interplay between societies and the natural world they inhabit. Simply by existing, human beings affect and modify this natural world and render it useful (or otherwise) to society. However, society is notoriously segmented and it follows that different sectors of society will experience the environment differently and will have different degrees of control and influence over it. Entries on environment and development, environmental justice, sustainable development, and environmental social movements explore how differences in race, ethnicity, class, and state of development shape individuals' and communities' relationships with the environment. This section extends this analysis to focus on how gender influences that relationship.

Society is powerfully structured by gender relations that conspire to render women less powerful than men. (The entry on gender defines what the term means and the importance of recognizing its social construction.) These social relations, which are explained variously by reference to class and to patriarchy, result in different, and hierarchical roles for, and opportunities available to, women and men, and structure their relationship with the environment, as well as with each other. Whilst these relationships have persisted, little has changed in structure, if not magnitude, through time. They have only been made explicit in the latter part of the twentieth century, largely due to intersecting debates on development, ecology, and feminism since the 1970s. This article will explore these intersections to show how gender affects the relationships between individuals and communities and the environment, at a variety of scales.

1. Feminist Research

Feminist scholarship has exposed inequalities between men and women which result in an uneven distribution of resources. This relationship has consigned women to the domestic (unpaid) sphere, where they enjoy little economic and political independence. This sphere is notoriously undervalued, with no recognition given to the economic and social value of unpaid work in national accounting procedures (Waring 1988). However, while women are increasingly entering the paid labor force, they do so in a multiply disadvantaged position, which has implications for their relationship with the environment. Most women are paid less, pro rata, than men, through a system of horizontal (through the gendering of different sectors, such as mining or teaching) and vertical (through the gendering of jobs within sectors, such as clerical or managers) occupational segregation, as well as through promotion inequalities. In addition, women engage in this work (full-time and part-time) in addition to their domestic responsibilities, which men have been less willing to share.

Class is often used to explain economic and occupational inequality, and Marxist analysis suggests that women have formed a reserve army of labor which is maneuvered in and out of the labor market in tune with demand. However, this explanation does not sufficiently explain inequalities in the home, nor do they explain systematic male violence towards, and control over women; factors which might better be accounted for by patriarchy. These two systems of domination (class and patriarchy), however, are increasingly being seen as interacting and mutually reinforcing (McDowell 1986).

1.1 Implications for Gender–Environment Relations

This 'double bind' of relatively low paid work outside the home, and responsibility for most domestic tasks within it, exposes women to a number of environmental problems. People on low incomes and in relative poverty are more likely to be exposed to high levels of pollution and other negative environmental effects (see *Environmental Justice*), and since women comprise a majority of adults in poverty, they are more likely to experience environmental problems. For example, DDT, banned in the West, is still used in 2001 as a pesticide in the developing world where women undertake the majority of agricultural work (80 percent worldwide—although women hold title to only 1 percent of the world's land). This chemical accumulates in body fat and is passed from mother to her breastfed children causing, amongst other things, breast cancer, endometriosis and reduced fertility in female offspring. Research in parts of Central Asia found that the Republic of Karahalpakistan (close to the heavily polluted Aral Sea) experienced the highest levels of infant mortality in the former Soviet Union.

Poor diet and hygiene, concomitant with poverty, were found to be contributory factors to mortality and infant anemia (Gabizon 1998).

DDT and other hormone disrupters provide a disturbingly clear example of how environmental manipulation can have a profound effect on the nature of sex itself. Estrogen (produced naturally, by the excretion of estrogen-based contraceptives, but most intensely by PCBs, surfactants used in cleaning materials, and phthalates used in the manufacture of flexible plastics) is being associated with a major drop in fertility and an increase in reproductive disorders. Transsexuality and hermaphroditism in fish is being considered as a direct result of estrogen pollution.

The task of social reproduction accorded to women (unlike the paid tasks of production) are given no value or recognition by national economies (for example, in GNP or GDP) or by the United Nations, which specifies components of national accounting systems (Waring 1988). (Gross national product (GNP) comprises gross domestic product (GDP) plus net income from abroad. GDP is an agdmonetary measure of the value, at market prices, of goods and services produced within a national economy over a given period of time, usually one year (Johnston et al. 2000)). Yet such tasks are made increasingly difficult by environmental exploitation. In the 'Global South' or Third World, in addition to undertaking most of the agricultural work, women are the main water collectors, which can involve journeys on foot of up to four hours each day. Practices that deplete water sources (such as cash crop irrigation) increase this time and energy burden on women, as does deforestation (for commercial farming, mineral extraction, and infrastructure development) for women who can spend four to five hours each day collecting fuel wood when once they would have done so every four or five days (Dankleman and Davidson 1988). In addition, women are carrying increasingly heavy loads of up to 35 kilograms, which is up to 15 kilograms over the acceptable limit laid down by the International Labor Organization Maximum Weight Convention.

In the South, women are exclusively responsible for food preparation, on which they can spend four hours each day. Cooking with firewood (the most common cooking fuel in rural areas) causes inhalation of chemicals equivalent to inhaling the smoke of twenty packs of cigarettes a day. Pollution is even greater when cooks are forced to rely on firewood substitutes, such as husks, straw, and dung, because of the commercial degradation of forests.

In the West, while women do not have the burden of collecting fuel sources and water, they are still primarily responsible for food provision and preparation and, therefore, are more directly concerned with food safety issues such as genetically modified ingredients, BSE, and pesticide use. This is illustrated by the proportion of local environmental and health

campaigners who are women. (Joni Seager (1993) estimates that 60–80 percent of grass-roots environmental activists are women, although this proportion drops drastically for paid/professional appointments in environmental nongovernmental organizations [NGOs].)

In addition to social roles, cultural practices create an additional burden on women in societies in which sex can determine survival. The Chinese practice of limiting families to one child in an attempt to keep within the state's environmental carrying capacity, has resulted in a high female fetus abortion rate and the abandonment of girl children (Bandarage 1997). Likewise, in food deprivation situations Dreze and Sen (1989) have found that women are most likely to go without food. Other research has noted that women are also least likely to receive warm clothing and medical assistance and has confirmed that even pregnant and lactating mothers are last in food priorities (Bandarage 1997).

Because women have largely been confined to the domestic sphere, they have had little formal input into the way in which societies' relationship with the environment has been structured. The practice of science has been particularly masculine, both in that it is undertaken by men, and in its underlying principles aiming to control nature, although this approach is increasingly challenged with science. Even at the start of the twenty-first century, the majority of scientists and science students are men and, it could be argued, this continues to shape the subjects studied (for example, military applications) and the methodologies used (Harding 1986, Haraway 1988).

Other environmental professions, such as planning, civil engineering and architecture, political decision making fora, and business, continue to be male-dominated and masculinist and so women have few opportunities for challenging or contributing to decisions made which have profound implications for the environment itself, and for gender–environment relations, which are then perpetuated.

2. *Ecofeminism*

Feminist politics and scholarship have widely aired aspects of this debate, particularly around inequalities of income and opportunity, the uneven division of labor, and the lack of regard for unpaid work. Linking this feminist debate with environmental issues, and their differential impacts, is the ecofeminist movement that emerged in the 1970s out of the parallel social movements of feminism, ecology, and peace/nuclear disarmament. Its initiators were concerned that economic and political gender equality, without due regard for ecological concerns, would result in doubling the burden the environment would have to bear as women emulated men's behavior. The incorporation of women into 'a man's world' would be unlikely to

challenge research priorities, management practices, social values, or consumption patterns. Instead, ecofeminists argued, society needs to reassess its practices and values and particularly to value the more feminine principles of cooperation and care.

Although the term 'ecofeminism' was coined by a Frenchwoman, Francoise d'Eubonne, the thinking behind it has developed across Europe, North America, and Australasia as both an analysis of socio-economic relations and a prescription as to how these relations can be transformed (Mary Mellor (1992) Carolyn Merchant (1996) and Val Plumwood (1993) respectively). There are two broad strands of ecofeminism: cultural or essentialist (which tend to be more enthusiastically pursued in North America) and social or constructivist (which dominates European thinking).

Cultural ecofeminism celebrates a powerful and positive link between women and nature, arguing that women are more closely in touch with nature through their reproductive potential or capacity. This connection is then thought to better place women (as opposed to men) as advocates for nature. Social ecofeminists do not believe that the essence of what is female (if such an essence actually exists) makes women inherently closer to nature than men. However, they argue that because women are subjugated by a society dominated by men (which also dominates nature), this experience of domination, and consignment to roles and jobs which are less abstracted from nature, and by their dominated status which exposes them more to environmental hazards, places them closer to nature than men who, conversely, are more likely to take on roles and jobs which distance themselves from nature.

These positions, both broadly underpinned by conceptual frameworks based on patriarchy, have led to a debate about the legitimacy of essentialism (Biehl 1991), the need to transcend dualisms of maleness versus femaleness to create a partnership ethic with nature (Merchant 1996, Plumwood 1993), the need to distinguish between different groups of women, and to challenge the unity of their experience (Jackson 1993).

3. Gender and Development

A third key influence on the development of gender and environment as an important relationship has emerged from the Development literature and experience, some of which has already been referred to. This is gradually replacing the arguably tokenistic 'women in development' approach to development project planning. The 'women in development' approach tended to 'bolt' women's concerns on to existing policies rather than questioning these policies and the complex social interactions between women and men which underpinned them. This inevitably affects environment/development projects. Taking these social interactions into account has resulted in a

number of projects and initiatives, such as the Grameen Bank and other microcredit schemes primarily for women in poverty, which also have the potential to improve society-environment relations. Such microcredit schemes are being identified, not only as economically empowering for women, but as giving women more control over their lives in other ways, such as fertility control. Such experiences are slowly penetrating organizations which have the power to impact on society/gender relations, such as The World Bank and the United Nations, and are beginning to affect their lending policies and practices.

4. The United Nations and Sustainable Development

The United Nations, particularly through the *United Nations Conference on Environment and Development* in 1992 and the *World Conference on Women* in 1995, argues that there is a close relationship between the status of women and the state of the environment. It has signaled that the education of women, and the eradication of poverty (targeted at women) are both critical for improving women's status and to reduce societies' impact on the environment. *Agenda 21*, agreed at UNCED 1992, dedicated a chapter (Chap. 24) to the need to bring women into environmental decision-making. This is because women are disproportionately affected by negative environmental impacts due to their social and domestic roles and their greater tendency to be in poverty. UNCED acknowledge that these roles lead to a closer relationship with, and knowledge of the environment, whether as farmers, food and meal providers, or primary health carers. There is, however, little evidence as yet that there are any substantial changes in decision-making locally as a result of this global agreement.

5. Conclusion

Any discussion on gender and environment demands an understanding of the ways in which society is structured along gendered lines. In turn, this requires an understanding of how society creates, reproduces, and mobilizes gender differences. The 'gender and environment' relationship, therefore, is a contested concept which turns on various understandings of gender and gender relations and brings into question the ability to totalize the concept of gender. Whilst this entry has focused on the modernist explanatory concepts of class, and particularly, patriarchy as underpinning gender-environment relations, these relations can be further problematized by recognizing the difficulties in defining gender as a single, undifferentiated, entity. Some critics of ecofeminism draw on the literature of post-modernism to question the validity of treating all men and all women similarly, arguing that class, race, ethnicity, age, disability,

sexuality, and parenthood all cut across gender to render it inadequate as a single explanatory tool. It is important to remember the differences within as well as between genders. Research consistently shows that, while there are clearly differences in income, occupation, and opportunity depending on other factors, the relative differences between most men and most women in many societies are still significant enough to warrant concern about gender inequality and therefore the gendered impact of, and on, environmental issues.

Gender and Feminist Studies

'Gender,' as the term is used in the social and behavioral sciences, refers to all of the ways in which being a male or female, or being socially classified as such, affects one's life. The focus is on the social, political, or economic arrangements that relate to gender. Some gender differences stem from biological differences, and are studied by biologists or others focusing on evolutionary theories. Many facets of gender inequality flow from social norms, beliefs, laws, and institutional practices. Even gender differences rooted in biology will have different consequences depending on the social environment. For example, the fact that children are born from women's bodies is a biological reality, but societies and time periods vary greatly in the consequences of this fact. The consequences depend upon whether birth control is widely available, whether women can use contraception without men's permission, how much fathers participate in the care of children, how much the state collectivizes the costs of rearing children, the extent to which jobs accommodate the demands of parenting, and other factors.

The topic of gender was largely ignored in the social sciences until the 1970s. When relationships and inequalities between men and women were studied in earlier decades, many scholars 'naturalized' existing social patterns. This was true even among social scientists who advocated social explanations for most other forms of social differentiation and inequality. Since 1970 there has been a flowering of scholarship on gender. The increased interest in the topic flows in part from the increased representation of women among social scientists; although there are both women and men among prominent scholars of gender, proportionately more women than men have dedicated research careers to the topic of gender.

The term 'feminist studies' has many meanings in the social sciences and humanities. Some proponents (as well as some opponents) of feminist studies see the term to imply adopting women's point of view. Opponents believe this implies that feminist scholarship is more biased against finding the truth than conventional scholarship. In contrast, most feminist scholars believe that scholarship on gender, men, and women has been, and often still is, distorted by androcentric (male-centered) bias. Some people see the appropriate corrective as an adoption of women's

standpoint; those who view it this way doubt that there is any way the scientific method can insure objectivity. Others see feminist studies as correcting androcentric bias, not by adopting women's point of view, but by taking a less biased and broader view than conventional scholarship.

Feminist theory is a similarly broad and contested term. (See *Feminist Theory*) It generally refers to theories of women's experience and of the subordination of women by men. It is commonly taken to include both what philosophers call 'positive' and 'normative' claims. The positive claims are descriptions and explanations of how gender systems work; they are the conceptual and theoretical part of empirical gender studies. Normative claims answer philosophical questions about how gender arrangements ought to be; they deal with questions of ethics and social justice. Philosophers (including political theorists) wrote much of the normative feminist theory of recent decades.

This essay discusses three prominent themes in gender and feminist studies. Scholars have contributed positive and normative theorizing and empirical scientific research on each. They are illustrative of work in the area rather than being a summary of the field. The three themes are the exclusion of women from well-rewarded positions, the devaluation of activities and qualities associated with women, and the intersection of gender with inequalities of class, race, and nation.

1. *Women's Exclusion from Positions of Power and Resources*

The concentration of men in positions that bring them power and resources is an important theme in gender studies. Women and men typically hold different positions. The fact that relatively few men engage in typically female activities and the fact that relatively few women engage in typically male activities are both constitutive of gender differentiation. However, research has focused on the latter. In most societies, men have monopolized positions that give their incumbents the highest status, power, and rewards. Understanding the forces that keep women out of these positions is crucial for understanding sources of gender inequality. Social scientists from several disciplines have studied determinants of women's entrance into 'male' spheres. Anthropologists studying pre-industrial societies have concluded that cultures that are more competitive and combative are more likely to exclude women from positions of power (Sanday 1981). Economists contend that rising wage rates during the twentieth century increased female employment and lowered fertility, because higher potential wages made employment more lucrative for women (Bergmann 1986). When higher wages are available to women, their incentive to be employed is greater; the opportunity cost of staying at home is higher.

Although women's participation in paid work has increased in all industrial societies; jobs have remained somewhat sex segregated. (See *Sex Segregation at Work*.) Some economists explain the exclusion of women from male jobs in terms of 'statistical discrimination.' This term refers to using an easily observable characteristic such as sex to make inferences about harder-to-measure qualifications. The idea is that employers have some knowledge of average gender differences in the population, and, based on this information, treat all women as if they were like the average woman. For example, if the average woman doesn't have the skills to be an auto mechanic, employers may assume that this is true of every woman, and be unwilling to consider even qualified women. Social psychologists add to this that perceptions may be systematically biased. Most people exaggerate the size of gender differences. Sociologists have focused on other discriminatory barriers to women's entry into jobs typically held by men. These include harassment of women entering male jobs, as well as political maneuvering to ensure policies that will keep women out of their fields. Sociologists, anthropologists, and psychologists point out that cultural beliefs and socialization throughout the life cycle encourage both men and women to enter stereotypic jobs for their own sex. In some periods and places, laws have prohibited women's entry into many positions of power.

Liberal feminist theory focuses on this exclusion of women from well-rewarded positions. (See *Feminist Theory: Liberal*.) This focus follows from the classical liberal value placed on equality of opportunity. The exclusion of women from male spheres is a clear violation of equality of opportunity. In Western thought, philosophers had traditionally justified the exclusion of women from powerful, esteemed positions in the economy and polity by arguing that women are innately inferior to men. Liberal thought locates the basis of rights to equal treatment in rationality and autonomy, seen as the most valuable human qualities. The traditional view saw women as less rational and autonomous than men. Liberal feminists, then, argued for women's equal rights by arguing that women were as capable of rationality and autonomy as men were if given the right socialization and opportunities for education.

A key tenet of liberal thought has been a dichotomy between the public and private spheres, and a belief that, due to individual rights, the state should not intervene in what is private. In this view, justice only applies in the public sphere. But the location of the boundary between public and private is continually under dispute in both theory and real politics (Jaggar 1983). Gender relations in the family were excluded from the public sphere by the early liberal writers (Benhabib 1987). With a few exceptions, early liberal feminists did not dispute this. Rather, they focused on women's equal rights in public matters, such as

education, politics, and careers. Exceptions to this include instances of liberal feminist support for laws against rape or violence by men against their wives, or support for laws mandating that employers give parents the job flexibility they need to combine being parents with employment (Okin 1989).

While part of the liberal tradition is *laissez-faire* and opposes state intervention in the economy, another part emphasizes the need for state action to achieve equality of opportunity by class, race, or gender. It is this second camp that is now called 'liberal' in popular discourse, but both are descendants of classical liberalism. The emphasis in egalitarian liberalism has been on equality under the law, equality of opportunity, or equality of treatment, not on equality of outcomes. The application of the egalitarian strand of liberalism to gender has led to advocacy of laws against discrimination in employment, credit, and educational opportunities. Encouraging more women in elected political positions and in the military has been another priority.

In both politics and research, the emphasis has been on what will get women into male-dominated enclaves. Less consideration has been given to what would increase men's participation in traditionally female spheres such as child rearing, paid caring labor, and other female occupations. Researchers, like the general public, think of egalitarian gender role-change largely in terms of women's movement into male spheres. But this overlooks the fact that women are unlikely to achieve equality in jobs and politics unless men share the burden of household and child-rearing work. But men seldom do; sociological research has shown that even in couples where the woman has a demanding career and earns about as much as the man, men typically perform much less household work than women. (See *Time-use and Gender*) Similarly, occupations cannot desegregate without some men taking up what have been women's jobs as well as more women moving into male fields. The failure to see that gender equality is unlikely unless gender-related change is more of a two-way street may result from an unrecognized devaluation of the traditionally female sphere. Precisely because work and qualities traditionally associated with women have been deprecated, men have had little incentive to enter them. This devaluation of everything associated with women is now a theme in its own right in feminist theorizing and in research on gender.

2. *The Devaluation of Roles and Qualities Associated with Women*

Much of feminist theory contests the claim that women are inferior to men. The liberal feminist tradition, discussed in Sect. 1, contests the claim that women are innately unqualified to fill well-rewarded public roles such as politician, soldier, scholar, manager, or wor-

ker. Liberal feminists point out that many women meet the qualifications for these positions, and many more could if provided with the same education and informal socialization men receive. Some thinkers, called radical or cultural feminists, make a different critique. (See *Feminist Theory: Ecofeminist and Cultural Feminist*; *Feminist Theory: Radical Lesbian*) In their view, the sexism in our society is not just a failure to give women the preparation to live up to the proper standards, or to judge fairly whether they meet these standards. Rather, they argue that the standards themselves are androcentric. They see sexist bias in our notions of what qualities people need to be in important positions, and the values determining which positions are rewarded most. In this view, what is seen as valuable has been socially constructed around what is seen as masculine. Examples of traditionally male characteristics highly valued in our culture include independence, abstract rationality, and repression of emotion. Contesting the valuation of these characteristics over traditionally female characteristics, these feminists ask why patriarchal and liberal views have elevated the spiritual or rational (which they associated with men) over the physical or emotional (which they associate with women)? (See *Rationality and Feminist Thought*) Where patriarchal views revere the bravery of risking one's life in hunting, sport, or war, the cultural feminist reveres nurturing for its preservation of life. Whereas patriarchal thinkers, classical liberals, and some Marxists have revered humans for their domination over nature, cultural feminism reveres harmony with nature.

The traditionally female characteristics that cultural feminists believe our culture has undervalued include nurturing, nonviolence, emotional sensitivity to the feelings of others, unselfishness, kinship with rather than domination of nature, acceptance of our physical bodies, humility, flexibility rather than rigid adherence to abstract principles, and intuition of wholes. People have always benefited from women's practice of these skills and values, but this benefit is seldom acknowledged in patriarchal societies. Rather, these virtues have been seen as weakness, lack of proper individuation, or lack of rationality; and social roles that center on these virtues (such as mothering, paid child care, nursing, teaching) are not allocated high rewards. (Examples of feminist works with this theme are Held 1993, Keller 1986, Nelson 1996, Starhawk 1987, Tuana 1993.)

When feminists argue for a valorization of women's traditional virtues and roles, this is often confused with advocating a return to traditional roles. If we see the value of the work that women have traditionally done as nurturers, this does not imply that women should stay at home and be full-time mothers. It implies that we should respect whoever does nurturing, men or women, encourage the development of these skills in all humans, and esteem and reward those who do the work of caring. Respecting traditionally female work

is entirely consistent with this work being shared by men. If the culture values and rewards traditionally female characteristics, why would it make sense to teach these things only to girls or save these roles for women? The radical and cultural feminists argue that traditionally male values are inappropriate for human behavior by either men or women in either domestic or public roles, at least without greater balance from traditionally feminine values than currently obtains.

Emotional connection and care are often involved in the activities traditionally assigned to women. By contrast, western thought has glorified a 'separative self' that is autonomous. Benhabib (197) traces the ideal of separative autonomy through the liberal political philosophy of Hobbes, Locke, Rousseau, and Kant. All presumed men to be separative and autonomous and presumed women would continue to rear children and provide emotional comfort and sexual satisfaction for men. But the value of women's work went unrecognized, as did the extent to which men were dependent upon women's work rather than autonomous. Such work was seen as 'part of nature' in a metaphysic that denigrated nature. These activities did not count as moral since only exercising autonomy in the public spheres counted as moral. This same bias in favor of individuation is seen in developmental psychology, according to Carol Gilligan (1982). She argued that Freud, Jung, Erikson, Piaget, and Kohlberg all viewed individuation as synonymous with maturation but viewed connection to others as developmentally regressive. They assumed women would do the emotional work of child rearing yet did not acknowledge learning the capacity for intimacy and nurture as part of maturation. This atomistic bias has also distorted neoclassical economics, according to many feminist thinkers (Ferber and Nelson 1993).

Paralleling the theoretical work showing a bias in western thought against qualities and activities associated with women, a body of empirical gender research has documented the low value and reward given to activities associated with women. One example is research associated with the policy issue known as comparable worth. (See *Comparable Worth in Gender Studies*.) Research in sociology, industrial psychology, and economics suggests that the sex composition of jobs exerts an effect on how much employers are willing to pay. If a job is filled largely by women, employers offer a lower wage. That is, after statistically controlling for job characteristics that affect pay, such as requirements for skill or difficult working conditions, researchers find that predominantly female jobs pay less than male jobs (England 1992). Thus, sexism affects earnings not only through keeping women out of high-paying jobs, but also through devaluing the jobs in which women are concentrated.

Sociologists and economists have recently begun to study the part of the economy that involves caring for people. Jobs that entail face-to-face care giving are

especially badly paid for their educational levels. Such jobs include childcare, teaching, counseling, and social work. When children are reared well, there are broad social benefits, including a lower crime rate, a more productive economy, better informed citizens, and better care for the next generation. Many of those who receive these benefits pay nothing to those who did the paid and unpaid work of raising children. This means that the private return that markets will provide for such work will be lower than what is consistent with the broad social return. This is one rationale for government to reward the work more generously, to ensure that enough of these services are supplied, and as a matter of equity. Without this state involvement, and the sort of cultural change that cultural feminists advocate, women are likely to leave care work as other opportunities open up, or those who remain in it will pay a high price (in foregone wages) for doing this work. Whether as mothers or as workers in care work, women bear a disproportionate share of the costs of rearing children (Folbre 1994).

Many modern nations collectivize some of the costs of rearing children, through public financing of education and health care. Most European nations also provide cash family allowances to all families with children. The motivation for these programs was typically pronatalist rather than feminist, but they reduce the extent to which women bear the costs of privately rearing children, and in this sense are in women's interest. However, these subsidies to those caring for children are a relatively small part of the modern welfare state. Scholars studying gender and the welfare state have pointed out that many governments have developed two tiers to their benefits. A 'masculine' set of programs is geared to individuals who make claims as earned rights based on past employment. The 'feminine' programs support single mothers when a male breadwinner isn't present; the programs were seen to compensate for family failures. Underlying the two-tiered benefit system are gender norms that define the home as a female sphere and outside work as a male sphere. Men rely on social insurance schemes for retirement income, disability, and unemployment insurance, and women can make claims on these programs too when they are employed regularly or as wives or widows of earners. But single women with children are segregated into 'female' income-tested benefits, and these programs are more stigmatized and pay much less. (See *Social Welfare Policies and Gender*.) Women are expected to care for children, but this work does not provide as respected or rewarded an entitlement to state help in a time of need as a history of employment. More generally, feminists studying the state have argued that the seemingly gender-neutral notion of citizenship is in fact gendered; it has valorized men's typical activities such as worker and soldier, while failing to give rights and privileges for the parenting work that mothers do.

3. *Intersections of Gender with Class, Race, and Nation*

In the 1970s, gender scholars often wrote as if the subordination of women to men was universal. Depending on which theory one chose, patriarchy was caused by the public/private split, men's ownership of property, employment discrimination, or a combative culture. The idea was that once we found the correct explanation of patriarchy, this would reveal how women could be liberated from patriarchy. So it seemed to many of the upper-middle class white feminists in affluent nations, which were the groups predominating in the women's movement and in academic gender and feminist studies. A challenge to this view emerged from women of color in Western nations and in poorer Southern nations. (See *Feminist Theory and Women of Color; Race and Gender Intersections*.)

These critics argued that the analyses of gender proposed by affluent, white, Western women distorted the way gender affected the lives of many women in the world. The argument was not merely that, for example, the life of an affluent, married white professional woman in America is very different from that of an African-American welfare mother, or a Mexican immigrant to the US, or a middle-class Pakistani woman. That is obvious, since the latter three groups lack privilege on several fronts other than their status as women. The argument was deeper—that 'gender' operates differently for these different groups. The claim was that gender interacts with other axes of subordination. (See, for example, Anzaldúa 1990, Collins 1990, Hooks 1989, Lorde 1984, Stoler 1996.)

For example, ideas constructed by men of a dominant racial group about womanhood in fact often create one conception of woman for members of their racial group and another for the subordinate group. In the American South, during and after slavery, white women were seen as chaste and in need of protection (especially from black men). Yet white men did not see black women as needing or deserving this chivalrous protection. They were seen as naturally sexual. Such a construction served to justify white men's interest in having a group of women who had little power to resist sexual coercion and few claims to white men's help in supporting any resulting children. Here clearly gender and race interacted. Gender oppression differed by race. White middle-class women found themselves limited to the role of asexual, married mother, while women of color were unprotected from sexual exploitation by white men. Similar patterns emerged with the European colonial expansion to North and South American, Africa, and Asia.

Hegemonic notions of manhood often impact men and women very differently depending on their class and race, even when there is agreement across class and race groups on what it means to be a man. When someone says 'Be a man!' the implied notion of

masculinity revolves around power. This notion, while certainly not universal, is shared by men in most class and ethnic groups in modern societies. But men in the dominant ethnic groups have easier access to socially accepted ways of getting power, such as success in school and the labor market. This combination of cultural notions of masculinity as power with class-based or race-based lack of access to 'legitimate' sources of power creates a systemic strain making it likely that poor men will seek power through risky and illegal behavior. The gender-related nature of class and race privilege is illustrated by the fact that what men of less privileged class or race groups may envy about privileged men is that the latter often have power over women of all race and class groups. Women in subordinate class or racial groups may sympathize with the sense of powerlessness that men of their class or race feel. Yet they may also see how disadvantaged they are by the fact that they are the only actors in the social system less powerful than men of their race or class are.

Interactions of gender and nation can lead to complex patterns of identity and collective action. Consider, for example, the Islamic practice of women wearing a veil or the practice of female genital mutilation practiced in certain parts of the world. Clearly these practices are linked to male dominance. Yet, in some settings where indigenous people resent Western imperialism, which has harmed both women and men, women as well as men may see these practices to symbolize nationalist solidarity against what is seen as the decadence of Western individualism and greed. (See *Female Genital Mutilation; Islam and Gender*.)

The lesson from scholars of these intersections is that to understand many facets of the gender system, it needs to be studied in combination with axes such as race, ethnicity, class, sexual orientation, and nation. Yet this can sometimes lead to a rich mosaic of particulars that threaten to make gender and feminist studies descriptive rather than theoretical and explanatory. The challenge is to study gender in a way that does not falsely universalize, while looking beyond the unique aspects of each situation to search for broad patterns that help us understand what explains continuity and change in gender.

Gender and Feminist Studies in Anthropology

The development of studies of gender in anthropology received its impetus from the emergence during the late 1960s and early 1970s in Europe and the USA of what became known as the second wave feminism. This article primarily will review theoretical challenges and critical perspectives contributed by feminist anthropology to both the field of anthropology and feminist studies. The article will address main areas of feminist research and scholarly production such as reproduction, colonialism and postcoloniality, labor and transnational capital, Third World feminisms, and feminist ethnographic writing. Finally, the article will address recent work on masculinity.

1. In Search of Theoretical Frameworks

In anthropology, gender difference had played a crucial role in the theoretical development of the field providing especially during its early history a powerful metaphor for thinking about questions of cultural difference. Many characteristics attributed to 'primitive' societies in the armchair anthropology of the late nineteenth century resembled dominant definitions of femininity in Victorian society, such as nonlogical thinking and excess of emotionality. So too gender difference provided Victorian anthropology with an unquestioned 'natural' model for conceptualizing the notion of race and racial difference which was becoming increasingly central to the discipline. As feminist anthropologists came to argue, the position occupied by the notion of gender in the field of anthropology cannot be separated from the politics of colonial expansion and the development of a theory of cultural difference formulated around the notion of race. This linkage between gender, race, and colonial politics has become an important arena of contestation within contemporary feminist anthropology as this article will show. Not only as a metaphor but also as a theoretical premise, gender difference has been a cornerstone of anthropological knowledge as in, for example, Levi-Strauss' structuralist theory of culture.

While gender difference was crucial to the production of anthropological theory, gender was a

category of analysis filled with uncritical assumptions about the naturalness of inequality between the sexes. Gender was that piece of anthropological theorizing that was unproblematic, because it was conceptualized as natural and as such could provide the support for the study of other cultural variables. Such naturalization of gender difference was challenged strongly in the 1970s by a group of young feminist scholars in a series of foundational texts for contemporary feminist anthropology. Gathered predominantly in two volumes (Rosaldo and Lamphere 1974, Reiter 1975) these texts questioned the naturalness of female subordination. They departed from the premise that gender difference and gender inequality were not the product of biology but were culturally constructed, and attempted to formulate theoretical frameworks that could explain 'the universal asymmetry in cultural evaluation of the sexes' (Rosaldo 1974). These first attempts of feminist anthropology at thinking gender difference and sexual inequality argued that women's subordination was not the product of nature but the product of a number of social factors. Most important among these factors were a social organization dividing private from public domains and the cultural ideology that assigns importance to the public over the private and associates women with the latter and men with the former (Ortner 1974, Rosaldo 1974).

The cultural ideology that sustained this division of private/public social domains was aided by an economic division of labor that undervalues women's work in the reproduction of the species and labor force (Sacks 1974). It was also aided by a family structure that encouraged independence in boys and responsibility for care giving in girls (Chodorow 1974). In their search for theoretical frameworks to study gender inequality, the feminist anthropologists of the 1970s engaged the major social theories of twentieth century—structuralism, Marxism, and psychoanalysis—challenging their gender presuppositions and opening new and exciting avenues of analysis (Rubin 1975). A number of important feminist ethnographies challenged male centered accounts of culture and through the detail of ethnographic cases they showed women as social actors deploying a variety of strategies in their engagements with power, prestige, economic exchange, and other social fields.

2. Beyond Dichotomies

The emergent and vibrant feminist anthropology of the 1970s rested on some assumptions. Much of its theorizing was predicated on crucial dichotomies such as private/public, nature/culture, male/female. Gender was understood primarily in unitary terms as an identity all women and all men shared. At issue was the power difference between male and female. A universalist *Woman* rather than women was the object

of analysis. At the turn of the 1980s the theoretical dualities characterizing feminist theorizing of gender began to be questioned and with them an essentialist conception of *Woman*. This challenge was characterized by an emphasis on history, meaning, and power in the feminist studies of the early 1980s (Ortner and Whitehead 1981, MacCormack and Strathern 1980, Bourque and Warren 1981). Some scholars studied the change in meaning of seemingly unchanging categories such as nature and culture so instrumental in the construction of gender, and argued that gender as a category needed to be examined historically. Another strand of theorizing called attention to power difference among women. New research on the impact of colonialism on women argued that the oppression of women was complicated by their position vis a vis colonial power (Leacock 1980). Thus, while European women could be oppressed as women within a gender hierarchy, they were the agents of colonial domination of native men and women. Feminist studies of colonialism also emphasized the different forms in which colonialism as system of oppression changed the realities of women in ways that were different from those experienced by men. Gender as a system of power relations was inseparable from other relations of power. To complicate things more, another strand of research noted the versatility of gender as sign and symbol (Scott 1988). These researchers affirmed that gender had been historically used to express, conceptualize, or advance other kinds of struggles, whether these were about citizenship, nationalism, or race. The point emphasized by this corpus of research was that gender could not be taken for granted as self-evident reality but had to be examined within a multiplicity of social, political, and ideological contexts as well as in historical perspective. In a path breaking essay greatly influential in the anthropology of gender Joan Scott offered a definition of gender that was both comprehensive and complex, bringing together the various foci of research. Scott (1988, pp. 42–7) defined gender as:

(a) A constitutive element of social relations based on perceived differences between the sexes which involved four interrelated elements:

(i) Culturally available symbols that evoke multiple (often contradictory) representations.

(ii) Normative concepts used for interpreting the meanings of symbols.

(iii) A notion of politics and reference to social institutions and organizations necessary to understand how the normative concepts are used.

(iv) Subjective identity which entail the question of how is gender identity constructed in relation to a range of activities, social organizations and historically specific cultural representations.

(b) Gender is a primary way of signifying relations of power. In other words, gender is a primary field within which or by means of which power is articulated. This understanding of gender as signifier of power

was very influential in feminist ethnographies of colonialism, nationalism and violence. For Scott, concepts of gender structure, not only perception of social life, but its concrete and symbolic organization. Sex related differences between bodies are summoned as legitimization of social relations and phenomena that have nothing to do with sexuality.

In anthropology the study of gender challenged the more canonic fields of social structure, power relations, and symbolic constructions. Gender was not one area of analysis but one that forced a rethinking of the thematic pillars of the discipline.

3. New Explorations in Contentious Domains

During the 1980s there was an explosion of very creative feminist ethnography. This scholarly production was less interested in filling the gap of knowledge about women in the discipline than in the study of women as complex social actors engaged in economic, social, and political fields. An important area of feminist production was kinship. Kinship and reproduction, which had long been a privileged area of research in anthropology, became an important domain of feminist ethnography. Feminist ethnographers challenged male centered analysis of kinship by focusing on the role of women in maintaining or transforming kinship ideologies and structures. They also looked at the ways in which kinship structures and ideologies placed women in disadvantageous positions. Some researchers argued that not only gender but also social class, ethnicity, and sexual orientation had an effect in the way kinship and family were perceived and structured. Studies of kinship among poor African-Americans questioned the theory that the high number of women headed families in this social group was a result of a culture of poverty. Instead, these studies argued that complex kinship networks, articulated around women, played a crucial role in ensuring economic and social survival of large numbers of people in a situation of chronic economic disadvantage (Stack 1974). Research on gay and lesbian families in the Bay area of San Francisco challenged the dominant thesis of an American kinship system based on the ideology of blood connections by mapping the ways in which gay and lesbian people constructed family networks and ideologies not based on blood connection (Weston 1991). In England, feminist analysis of kinship was linked to the emergence of new reproduction technologies and their effect on nationalist ideologies (Strathern 1992). These studies argued that new reproductive technologies were changing not only ideas about women and families, but also ideas about what constituted nature and culture. The association of women with nature that had its support on women's reproductive capacity was challenged with the development of new technologies of reproduction that made reproduction a

highly technological affair but also allowed for a complex array of family forms not based on biological connection. Feminist anthropologists studying reproduction also focused on the ways in which women's bodies were represented in the discourse of biomedicine and the ways in which this discourse excluded women from the control of their own bodies. Approaching science and bio-medicine as cultural discourse some researchers inquired about the gender and race assumptions underlying medical discourses.

Another important area of research during the 1980s was the study of the effects of transnational capital on women. One strand of research focused on the transformations of the role of women in the family and community triggered by the introduction of transnational manufacture in traditional societies of the Third World. Some researchers studying the new international division of labor triggered by transnational capital, argued that multinationals was producing a class of poor, working-class women worldwide. Other researchers focused on the use of traditional beliefs and rituals such as spirit possession to manage the stress and alienation of factory production and capitalist discipline (Ong 1987).

The anthropological research on transnational capital brought to the anthropological agenda new issues about the interrelation between gender and social class, the transformation of traditional societies, and the linkages between new forms of sexual violence and capitalist expansion in the Third World. During the 1990s, the growing industry of sexual tourism has become a new important area of research.

A renewed interest during these years on history and change within anthropology, as well as on the labor politics of transnational capital fueled research on the neglected areas of colonialism and nationalism. Some researchers turned to history to study the cultural assumptions about gender, sexuality, and race that colonial officers and soldiers brought with them to the colonial context (Stoler 1991). A central preoccupation of these studies has been the study of the role of tradition in colonial societies. Tradition is important because it has often been associated to gender identity and used for a variety of purposes. For example, feminist studies of the practice of Sati (the ritual burning of widows in India) show that the practice was subject to a number of contingencies and hardly generalized in precolonial India. The English, however, took this practice as an example of a barbarian tradition that had to be abolished to bring the country to the English level of civilization. In this case an argument concerning violence against women was furnished to legitimize a colonial power relation. In so doing a practice which was not tradition became formalized as such. Once Sati was understood and treated by the British as Indian tradition it began to be associated by some nationalist strands with Indian national identity as well as with a feature of gender relations (Mani 1990). Similar processes concerning

tradition and ethnic identity were at play in colonial Africa in relation to practices of female circumcision. Traditions concerning gender relations produced by colonial scholarship and colonial policy became later on an emblem of national identity. The consequence, almost everywhere, has been a greater control of women and an increase on violence against women. This charged area surrounding the definition of cultural tradition and its relation to ethnic identity has become a central part of contemporary discussions about immigration, race, and citizenship in European countries and the USA. These discussions have been dramatized in the courtrooms and mass media, triggered by charges brought against immigrants performing various forms of genital mutilation on girls. In France, for example, this discussion has confronted feminist activists against cultural specialists. Feminists have argued that female mutilation is a form of violence that violates the right of girls and women to physical integrity and, as an illegal practice, should be prosecuted by the law. Cultural specialists, in turn, have argued that genital mutilation is part of the traditional culture that constitutes the identity of those who practice it. A variety of associated meanings and situations complicate this discussion. At issue is, for example, the fact that those brought to trial are poor immigrants subjected to institutionalized forms of racism in their everyday life. At issue is, too, the forms in which the discourse of human rights has become part of French national identity. The point is that neither 'tradition' nor 'culture' are neutral or self-evident terms, but are terms used to define regulatory practices between men and women and between the state and its people. These practices of power are articulated and symbolized on the bodies of women and particularly Third World women and women of color.

A growing body of feminist anthropology has become preoccupied with the question of how women figure in relation to nationalist identity, nationalist ideologies, and postcolonial nationalist struggles. This line of research has investigated the way nationalist ideologies constrain the lives of women by making them either the repository of national tradition or the passive allegory of the nation. Part of the problem is that colonial discourse often defined colonial subjects in gender codes, attributing them a feminine incapacity for government. To counteract this definition, nationalist movements have often resorted to a reverse gender language that represents the people of the nation as masculine while representing the nation as a female object. When certain women's roles such as motherhood are defined as essential to national identity, such roles are often enforced through legislation, restricting the choice and development of women in other social areas. In postcolonial nations the pressures on women to conform to nationalist demands become complicated by the fact that the new nation represents freedom from the bonds of coloni-

alism. Thus, to rebel against its constraints can be perceived and experienced as national disloyalty. These positions create double bind-like dilemmas for women whose aspirations go against the grain of the national project (Aretxaga 1997).

Notwithstanding its constraints, for women engaged in struggles of liberation such as Palestinian women, nationalism can open a space of social and personal liberation. Research on women in nationalist movements shows that political activism has the paradoxical effect of constraining and liberating women. Women often maneuver between contradictory demands and divided loyalties. At the same time, women's activism in struggles of liberation often leads to reformulation of gender relations but research shows that such reformulation is always precarious and shifting (Peteet 1991). The anthropological research of gender and nationalism has demonstrated that gender identity is never defined in isolation from other forms of identity such as class, ethnicity, or nationality. This research has also brought to light the differences among women showing that the very category of women even within an ethnic group is internally divided. The research on women and nationalism has counteracted a dominant ideology that has represented women in the Third World and women of color as passive victims of authoritarian nationalism or political violence.

4. Third World Women and Women of Color

During the late 1980s and early 1990s women of color in the USA and Europe claimed a specific epistemological and political position within the feminist movement. They criticized the feminist mainstream for silencing the voice of minority women and women of color and contended that the emphasis on women's solidarity had obscured relations of power between and among women of different class, ethnicity, and color. This critique was followed by a critique advanced by Third World women who claimed to be in a subordinated position vis-à-vis western women. Both the notion of 'Woman' and 'Western' were the object of severe criticism. If this moment had a tremendous political impact on the feminist movement worldwide, it had an impact on feminist anthropology as well. Most research on gender and women in anthropology had been produced by Western women studying women in Third World countries or minority women in Europe or the USA. The critique of imperialism launched against white mainstream feminism by Third World feminists cut right across feminist anthropology. The result among feminist anthropologists was a self-critical reflection that emphasized the awareness of the position of power the anthropologist held vis-à-vis her subject and how such position influenced the production of ethnographic knowledge. Feminist knowledge in anthropology became 'situated

knowledge' rather than unmarked universal knowledge. There was a critique of representation and an emphasis on the production of 'subjugated knowledge' (Haraway 1991). Feminist anthropologists turned their attention to questions of experience and self constitution as generating ethnographic knowledge. There was a new emphasis on the role of subjectivity in scholarship which characterized the 1990s. Theoretical production about hybridity, diversity, and partial knowledge rather than universal generalization was at the center of the feminist anthropology of the 1990s.

5. *Writing Gender*

The attempt at presenting rather than representing the voice of minority, subjugated women led feminist anthropologists to experiment with the form of ethnographic writing. Some anthropologists reflected on the difficulty of capturing the subjectivity of women in contexts where women only spoke through the conventions of male oratory. Others found that conventions of ethnographic representation were fundamentally male oriented and inadequate to narrate women's experience. Feminist ethnographers experimented with literary genres and strategies to assert a new form of writing culture suitable to convey hitherto invisible women's experience. Fiction, journal writing, first person narrative, and autobiographical narrative became part of feminist ethnographic writing during the 1990s. Some ethnographers experimented with transcribing women's narratives with minimal interference of analytic voice (Behar and Gordon 1995).

Others juxtaposed the biographical history of the ethnographer to the autobiography of the women they wrote into books, yet others resorted to mixed fictional forms to express the dilemmas of feminist ethnography in a postmodern, fragmented world divided by relations of power and increasingly hybrid. Feminist ethnographies reflected not only on the position of the women they wrote about but on the hybridity of the authors, themselves positioned oddly between the West and the Third World.

For these feminist anthropologists, ethnography in the contemporary world becomes a kind of fiction writing. Their ethnographic stories are composed of stories told in the field by informants, often informally. They freeze a fragment of social life and a fragment of history out of the ongoing unfolding of events. In ethnography, like in fiction, closure is always arbitrary and the goal for feminist anthropology is to capture the dilemmas, complexities, and uncertainties of women's experience. The kinds of questions that traverse experimental feminist ethnography gravitate towards the ambiguities of identity, community, the meaning of home, and fieldwork. In writing about other women, feminist ethnographers reflect on their problematic identity and the kind of home and community that made them feminist ethnographers.

6. *The Anthropology of Masculinity*

Although anthropology had focused traditionally on men, these were represented as universal subjects rather than men whose masculinities were culturally constituted in a variety of ways. During the late 1980s and 1990s, a growing number of ethnographic works have focused on the cultural construction of masculinity. Ethnographies of masculinity have broadened the anthropology of gender often associated with women's studies. However, as Guttman (1997) notes there has been an awkward avoidance of feminist theory by those anthropologists studying manhood. The early anthropology of masculinity focused on how men performed their manhood in a variety of cultural contexts. More recent work analyzes masculinity in relation to a broader number of themes. Guttman (1997) notes several topics of interest in relation to which masculinity has been discussed by anthropologists, such as nationalism, divisions of labor, family, friendship, sexuality, and struggles of power, yet there are no general theories of masculinity produced from anthropology. Part of the problem is the difficulty in defining masculinity which has been taken so much as the norm that it remains conceptually elusive in its specificity. While a number of works have explored performances of manhood in relation to other men, women, and the national identity (Herzfeld 1985), an important contribution has come from the discussion of men's subjective perceptions and feelings about other men.

7. *Conclusion*

Since the 1970s, the anthropology of gender has grown into a complex, diverse, and theoretically sophisticated field. It has gone from a focus on women's studies to include increasing study of masculinity across cultures. Much of the anthropology of gender falls into the rubric of feminist studies and this has posed political as well as epistemological challenges that have resulted in a sophisticated, mature, and rich body of scholarship.

Gender and Feminist Studies in Economics

A feminist approach to economics recognizes the importance of gender in structuring human experi-

ence, including economic life, and seeks economic knowledge for the purpose of combating gender-based oppression. While precursors of such feminist studies go back a century or more, feminist economics did not emerge as a body of thought among academic economists until the early 1990s. The ensuing decade brought an expansion of feminist scholarship not only about women's (and men's) economic status, but also about the gendered structure of economics as a discipline, itself. Can a discipline that seeks for reliable knowledge about economic life *not* be feminist?

1. Defining the Terms

For a branch of scholarship to be considered 'feminist,' it should recognize the importance of gender in structuring human experience, and should be part of a liberatory project to eliminate sexist structures that keep women in inferior and submissive positions relative to men. Work that is simply about women, or by women, but that does not challenge structures of domination, is not feminist in this sense (and hence will not be discussed here). Feminist theories include liberal, Marxist, radical, and other variants (see *Feminist Theory: Ecofeminist and Cultural Feminist; Feminist Theory; Feminist Theory: Marxist and Socialist; Feminist Theory: Psychoanalytic; Feminist Theory: Liberal; Feminist Theory: Postmodern; Feminist Theory: Radical Lesbian*).

Academic economics includes schools of neoclassical, Marxist, institutionalist, post-Keynesian, and Austrian thought. The neoclassical school, however, is clearly the 'mainstream,' as evidenced by its absolute hold on the highest-status institutions and their graduate and research programs, as well as its ubiquitous presence elsewhere. The neoclassical school is paradigmatically characterized by centrality of the question of how self-interested individual agents make rational choices when confronted with scarcity, by a strong belief in the allocative efficiency of markets, by a near-sole reliance on mathematical reasoning as the means of creating knowledge, and by the application of statistical testing to large-scale, often government-collected, data. This neoclassical definition of 'economics' is itself at issue in feminist studies, as will be discussed below. Because of the hegemony of this one school, this article will emphasize work that grows out of and/or reacts against it, although feminist economic studies can also be found within the institutionally weaker heterodox schools, the other social sciences, and popular, nonacademic, economic literature.

Some may doubt that feminist studies have a legitimate place with economics, since they may seem to mix a political agenda into an otherwise value-free, neutral scientific enterprise. Much of the accomplishment of the last decade, however, has been precisely to reveal the value-laden, masculine-biased, and evi-

dence-ignoring aspects of mainstream economic thought, and to begin to envision less biased and more satisfactory means to warranted knowledge.

2. *The Rise of Feminist Studies in Economics*

Feminist studies in economics, as a body of thought, formed in the early 1990s from a convergence of two streams: first, concerns about women's economic status, and second, feminist scholarship on the role of gender in the structuring of science.

Increasingly, in the 1970s and 1980s, concerned women had pointed out the neglect and/or distortion of women's experience in several areas. Marianne Ferber and Bonnie Birnbaum, for example, debated the proposition (put forth by the University of Chicago-inspired 'New Home Economics') that women's exclusive specialization in household work could be explained as their free and advantageous choice (Ferber and Birnbaum 1977). Paula England cast doubt on the empirical validity of the 'human capital' explanation of male–female wage differentials, in which women's lower pay was portrayed as the result of their own utility-maximizing choices of training and occupation (England 1982). Barbara Bergmann highlighted the importance of, and difficulties facing, the movement of women into the labor force (Bergmann 1986). Marilyn Waring pointed out that the United Nations systems of national income and product accounts excluded any consideration of unpaid work by women (Waring 1988). While some scholars took what Sandra Harding has called a 'feminist empiricist' approach, believing that 'social biases [are] correctable by stricter adherence to the existing methodological norms of scientific inquiry' (Harding 1986, p. 24), others began to question the particular forms of scientific inquiry sanctioned by the economics profession. Issues of dependence, interdependence, tradition, social beliefs, power, and oppression did not seem to fit well into mainstream forms of analysis, and feminist scholars began to search for more adequate means with which to understand the fullness of economic life.

During this same period, feminist physical scientists, philosophers, and historians (e.g., Harding) were revealing the gender biases deeply embedded in modern conceptions of science. The identification of objectivity with detachment, and the consequent model of an active, knowing subject exerting control over a passive object of knowledge, are metaphorically connected with images of male/mind activity and female/matter passivity (see *Rationality and Feminist Thought*). Within the economics profession, some attention to the rhetoric of economics (McCloskey 1985) simultaneously helped bring to light the social nature of economic discourse, allowing for the potential discussion of gender influences within the discipline.

Table 1

Contrasts defining neoclassical economics.

Core	Margin
Public	Private
Market	Home
Individual	Social
Efficiency	Equity
Hard	Soft
Fact	Value
Rigor	Intuition
Precise	Vague
Objective	Subjective
Detached	Committed
Self-interest	Altruism
Autonomy	Dependence
Reason	Emotion
Masculine	Feminine

Contrasts such as those shown in Table 1 highlight the gendered construction of neoclassical economics, as those domains, methods, and assumptions chosen to be central to the discipline all have stereotypical masculine associations, while the neglected and denigrated areas are socially considered 'feminine' (see, e.g., McCloskey 1985, Nelson 1992, Jennings 1993). As such a definition of economics can be seen as one manifestation of an identification of feminine associations with inferiority, feminists have sought ways to deconstruct these gender dualisms.

The formation of the International Association for Feminist Economics in 1991 and the publication of *Beyond Economic Man: Feminist Theory and Economics* in 1993 (Ferber and Nelson 1993) signaled the beginning of feminist studies in economics as a body of thought. Continued conferences and the publication of a journal, *Feminist Economics* (started 1995) illustrate the dynamism of the field at the turn of the century.

3. *Major Developments in the Field*

Three major areas have absorbed the attention of many feminist scholars: first, exploration of the definition and methodology of economics; second, analysis of gendered labor market outcomes; and third, inquiries into work traditionally done by women.

3.1 *Definition and Methodology of Economics*

Most feminist work in economics recognizes that the discipline is socially constructed, that is, that it reflects the interests of the people who developed it and the worldviews and prejudices of its formative historical epochs, rather than simply a set of trans-

historical ideals. The dualisms in Table 1, then, reflect social, intellectual, and even psychic biases of the creators of the discipline.

One response might be to think that the point of a 'feminist' economics would be to add more women economists, and, therefore, 'women's ways of knowing.' This emphasis, however, has relatively little support among feminist economists, since it puts the causal story at the level of biology (or sex) rather than at the level of social understandings (gender). Most feminists are less interested in finding 'essential' differences between males and females, and more interested in examining the heavy cultural influences that go into creating observed differences and schemes of categorization. Since, when given the chance, female economists have proven quite adept at the types of thinking required by current disciplinary strictures, a feminist approach looks elsewhere.

The more important point is that the creators of mainstream economics lived in societies characterized by a culture-wide belief in masculine superiority. One graphic tool for working beyond the usual associations between gender and value was proposed by Nelson (1992). A vertical axis marks off the dimension of value, positive (+) or negative (−), while a horizontal axis marks off gender associations, masculine (M) or feminine (F). While sexist thinking recognizes the M+ and F− quadrants, examination of the unusual M− and F+ cells may reveal new possibilities. For example, the idea that economics should be a 'hard' science rests on an identification of hardness with (masculine-associated) strength, and softness with weakness (and femininity). Yet hardness can also mean rigidity (M−), while softness can mean flexibility (F+). Too much effort in economics has been spent on defending the masculine/feminine boundary, and too little on improving the value of economic studies. As a result, the models, methods, and pedagogy of mainstream economics tend to be characterized by rigidity, obsession with mathematical reasoning, detachment from human suffering, and narrow forms of explanation (M−). While recognizing the validity of ambitions to be strong, logical, scientific, and precise (M+), one can simultaneously recognize the value of flexibility, analogical and dialectical reasoning, concern with human life, and richness of analysis (F+).

Avoiding the hyper-rationalist mind/body split implicit in a definition of economics in terms of rational choice, and the marginalization of women's traditional activities implicit in a definition in terms of markets, feminists have suggested a definition of economics as being related to the subject matter of the provisioning of human life. Such a definition in terms of subject matter allows for the use of a larger toolbox of models and methods. Instead of models of individual autonomous in choice, agency is recognized as being limited by physical embodiment and social embeddedness. Rather than identifying knowledge

solely in the forms of theorems and proofs, or statistical tests on second-hand data, the value of more qualitative and even experiential data, and of rigorous attention to the gathering and interpretation of all data, receives increased attention. Objectivity is not guaranteed by strict adherence of an individual researcher to some prescribed model or method, but rather is a characteristic obtainable only through the shared understandings of an expanding knowledge community.

Some feminist economists take this analysis a step further, and, seeing the importance of language and the partiality of positions thought previously to reflect universal truths, conclude that reliable knowledge is not possible. In the extreme deconstructionist postmodern view, the social construction of economics is taken to mean that there is no reality outside of the linguistic structure. While the feminist-postmodernist conversation (see *Feminist Theory: Postmodern*) has influenced feminist studies in the 1990s, such *relativism* is not a necessary consequence of a feminist approach, and most scholars in economics adopt at least a limited form of philosophical realism. That is, while economics is seen as socially constructed, it is also recognized that the external world puts limits on the interpretations that can be supported.

3.2 Gendered Labor Market Outcomes

The movement of women into paid labor in most industrialized countries supplied the raw material for a large literature on gendered occupational distributions and the gap between average male and female wages. Much of the work uses mainstream methods, most notably regression analysis, to determine how much of the wage gap might be attributable to sex *per se*, after taking into account the effects of observable, presumably productivity-related, factors (e.g., education, seniority, etc.). Such analyses typically find these factors to explain about half of the wage gap. Yet mainstream economists who prefer to believe that 'market forces' are stronger than 'social biases' still find ways to avoid interpreting these results as evidence of discriminatory employer behavior. The remaining gap is usually attributed, instead, to variations in some unobserved characteristics of the worker (such as 'effort,' thought to favor men) or at most to 'societal' discrimination that effects the aspirations or dedication that individual workers bring to their (presumably unbiased) employers.

Feminist economists have pointed out the limitations of using a methodology based on an *a priori* faith in markets and a narrow view of economic data (Bergmann 1989). Alternative sources of data such as that available through court cases, interviews, case studies, ethnography, and detailed-level occupational analysis, while less acceptable given mainstream methodological biases, portray a situation of continuing

sex discrimination, and the need for more integrated social and structural analysis of gendered labor market outcomes. Many feminist economic studies along such lines have been done by feminist sociologists (see *Sex Segregation at Work*) and historians.

In studying the newly industrialized countries, feminist scholars have taken a more structural approach, asking how policies of development and trade have created gendered patterns of market work. A rising question in the 1980s was whether the availability of cheap, flexible female labor had led to a pattern of 'feminization' in export-oriented sectors of many of these economies (see *Economic Globalization and Gender*).

Recent work in this area has included more attention to issues of race and sexual preference (see *Lesbians: Social and Economic Situation*) in studies of occupational segregation and wage gaps, and attention to the impact of structural change in industrialized countries.

3.3 Women's Traditional Work

While labor markets are within economists' customary domain of analysis, the historical importance of the nonmarket areas of home and family to women's economic well-being forces an expansion of the domain (Folbre 1994). Taking families as places of interesting economic production and allocation, how can these phenomena be studied? How do home and market life interact? When women move into the labor market, what happens to the tasks that they used to do? Can serious study of traditionally 'feminine' realms also change how we look at markets?

The notion that there could be something called 'home production' filtered into the discipline by the 1970s, usually in reference to constraints affecting women's labor force participation. The early models tended to perpetuate, rather than challenge, gender biases, however, by assuming that women had a comparative advantage in household work, and that the traditional allocations of home and market work reflected rational decisions given unitary 'household' preferences. A few forays into examining the inner workings of households in the early 1980s became a booming literature of bargaining models and intra-household allocation by the late 1990s (Seiz 1991, Agarwal 1997). Recognizing that households are made up of individuals who might have different and potentially conflicting interests, and different well-being outcomes, such models allow at least a limited exploration of the issues of power and perception within households (see *Family Bargaining*). The increased attention within the mainstream to intra-household phenomena may represent the most significant effect on it, so far, of feminist criticism.

In developing countries where formal markets are a smaller part of the economy, women's traditional

work is likely to play an even bigger role in determining well-being (see *Economic Development and Women*). A substantial literature has developed focusing on women's 'reproductive' as well as 'productive' labor (Elson 1991, Benería 1995). In particular, macro-economic and structural adjustment policies have come under feminist scrutiny for their differential impact on women, since the 'reproductive' sector is relied on to cushion the shocks caused by, for example, reduced public spending on health care.

Yet the division between paid and unpaid work is somewhat artificial, and the experiences of most women cannot be adequately analyzed by studying each in isolation. Sex segregation in the labor market, and the relatively low wages paid for nurturing, people-oriented activities (see *Comparable Worth in Gender Studies*), illustrate the way in which traditional expectations of, and domination of, women extends from the household into the market sphere (Hartmann 1976). Women's poverty in industrialized countries is often a combined outcome of low-paying, female-stereotyped jobs and the invisibility of needs for childcare (see *Poverty and Gender in Affluent Nations*). The need for paid childcare (and care of the elderly or ill), while most often studied as a constraint on mothers' labor force participation, is also increasingly looked at in terms of its own characteristics in creating employment—often of women less educated and more likely to be immigrants or of color compared to their employers. The division between paid and unpaid work is often also associated with a stereotypical distinction between presumably self-interested, arms-length relations in the market, and altruistic, intimate relations among family and friends. While the notion of household bargaining stretches this old dualism in the direction of recognizing individual interests within families, recent literature on 'caring labor' (see *Care and Gender*) stretches it in the direction of studying affective and socially significant relationships in the monetized sector. As family and emotional labor becomes less 'invisible' and 'natural,' and more a subject of debate and study, the myth of (male) autonomy becomes more difficult to sustain.

4. The Future of the Field

Spanning a variety of epistemological loyalties, political viewpoints, and geographical continents, feminist work promises to be a dynamic, though not unified, influence on the economics discipline for years to come. With the critique of standard economic schools relatively far along, more scholars are working towards greater development of positive feminist alternatives to the traditional paradigms. Promising routes to the development of a strong alternative to the neoclassical school include cross-fertilization from feminist work in the other social sciences, perhaps in combination with insights from institutional econo-

mics, pragmatist or postanalytical philosophy, and new views of scientific methods arising from developments in the theories of chaos and complexity. Progress is hampered, however, by resistance rooted in the traditional ideologies. While mainstream economists now tend to tolerate more study of women, or the occasional methodological article, or feminist work when it takes place in departments of cultural studies or sociology, the challenges to the core of the discipline make most economics departments and institutes reluctant to provide intellectual or institutional support for feminist studies.

Gender and Feminist Studies in Geography

Gender studies in geography address ways in which the material and symbolic lives of women and men are shaped by aspects of place and spatial relations and, in turn, how considerations of gender are implicated in the creation of place and space. Central within gender studies are feminist perspectives stemming from concerns about inequalities of power between women and men. In seeking points of contact between feminism and geography, Susan Hanson (1992) has identified three core analytic traditions: finding significance in everyday life; appreciating the importance of context; and thinking about difference. Bringing these traditions together, feminist geography has produced a dynamic scholarship which has introduced new themes about women's lives into the discipline, recognized the importance of space and place in understanding gender, and increasingly elaborated its focus to include the intersections between gender and other social inequalities such as those originating in 'race' and ethnicity, class, age, physical ability, religion, and nationality. The sensitivity to context that informs feminist scholarship implies not only that expressions of gender are shaped by context, but also an understanding that the creation and uses of knowledge are 'situated,' that is, they are closely tied to the cultural and political contexts in which the research is located. Given this position, interpretation of gender and feminist studies in geography has to recognize that the field is not unitary but diverse, incorporating multiple perspectives and ways of knowing.

1. The Initiation of Feminist and Gender Studies in Geography

Geographic research on gender began in the early 1970s as an academic expression of the contemporary women's rights movement and its concerns with equality, a phenomenon recognized internationally with the establishment in 1975 of the United Nations Decade for Women. Early publications came from North America, the UK, and The Netherlands, the first widely known pieces appearing in the radical journal *Antipode* in 1973. This writing reflected its political origins, addressing the unequal status of women in society and also drew attention to women's marginal positions within the geographic profession (Zelinsky et al. 1982). Studies reflected the different contexts in which they were created. Whereas Dutch initiatives emerged from student critiques of Marxist writing and relatively quickly turned to the applied and policy-related work that characterizes much Dutch geography, early research in the USA followed empirical, positivist traditions, documenting differences between women's and men's spatial behavior, for example, in daily travel patterns or migration.

From these beginnings, gender studies in geography have become global in scope (Monk 1994). Formal or informal study groups hold meetings and/or produce newsletters in Argentina, Australia, the UK, Canada, Catalonia, German-speaking countries (Austria, Germany, Switzerland), New Zealand, and perhaps other locations; within the European Union, an Erasmus program has linked feminist geographers in Denmark, Greece, The Netherlands, Spain, and England. A strong international network comes together through the Commission on Gender in the International Geographical Union. Within the latter, symposia were organized as early as 1981, a formal Study Group was approved in 1988, and the Commission was recognized in 1992. It links over 400 scholars in more than 50 countries. Feminist work is well represented in a number of mainstream geographic journals, especially in the English-language literature and in Spain (García-Ramon and Caballe 1998). A specialized journal of feminist geography, *Gender, Place and Culture* was founded in 1994. Reviews of current feminist literature also appear regularly in *Progress in Human Geography*. Nevertheless, the field remains barely visible in some parts of the world, notably eastern Europe and east Asia. The range and diversity of participation, however, means that gender studies address numerous topical themes and that research is conducted in multiple paradigms. Still, there are common strands, primarily the understanding of the concept of gender as a complex and varying social, cultural, historical, and geographic construction, not simply a binary biological distinction between women and men, that power relations are implicated in gender relations, and that space, place, and gender are interdependent.

1.1 Feminist Critiques

Important from the beginning was critique of the extent and nature of the masculine assumptions underlying the content, theories, methods, and purposes of most geographic research (Monk and Hanson 1982). Scholars pointed out that research on migration, for example, generally presented men as key actors and decision-makers and women as passive followers, despite an absence of studies confirming how decisions were made. Data also showed women as numerically dominant in migration streams at particular times and places, for example, in rural to urban migration in many Latin American countries. Urban travel models dealt with the journey to work assuming full-time employment (implicitly male), rather than attending to the more complex patterns of part-time (usually female) workers, or people combining responsibilities for household and paid work. Economic geographers usually studied formal economies in which men were the major participants (such as industrial work or export-oriented agriculture), rather

than the service sector, or the informal or subsistence sectors in which women often worked. Feminist geographers advocated attention to arenas more central to women's lives, and introduced issues such as child care, housework, clerical employment, or women's fears in public spaces.

Methodologically, problems were identified with the limitations of secondary data sources such as censuses for their failure to capture women's lives, with primary data collection practices such as interviewing the male 'head' of the household, and with the use of survey methods that did not offer the subjects of research the opportunities to frame their own experiences. Feminist scholars advocated qualitative and in-depth investigations with the hope of learning how women saw their own worlds and in an attempt to modify hierarchical power relations between the researcher and those being studied.

1.2 Theorizing and Documenting Women's Material Lives

Going beyond critique, early theorizing, especially in British geography, elaborated the concept of patriarchy—social control by men originating in the authority of the father—as the source of women's oppression. Included in the arguments about patriarchy were claims that its intersections with capitalism created dual and interlocking sources of oppression. This line of theorizing was compatible both with the socialist tradition in British radical geography, with which early feminists identified, and with the substantive emphasis in research on women's material experiences, especially in urban settings. Distinctions were drawn between the city, as the site of male paid employment and public privilege, and the suburb as the site of domesticity, a private space that served as a basis for women's secondary status. This work begins to show how feminist geographers link the material world with the symbolic and ideological as they strive to understand gender-based inequalities. Though the theorizing initially emphasized the urban scale, other scales were recognized as important. The research also highlighted the importance of place as well as space in the dynamic conjunction of capitalist and patriarchal processes. An enduring piece representing this perspective is McDowell's and Massey's (1984) analysis of ways in which different forms of economic development in four regions of Britain perpetuated male dominance, even as the specifics of economic patterns changed between the nineteenth and late twentieth centuries.

While the theoretical writing emphasized patriarchal and capitalist ideologies, a great deal of the empirical work was undergirded by related concepts useful for understanding the material aspects of labor. Numerous studies have been devoted to documenting and understanding gender divisions of labor and the

ways in which productive and reproductive work were gendered and interdependent. Attention to women's reproductive work brought new subject matter into the geographic literature, for example, on domestic employment, child care, and community-organizing. Research has been conducted in many geographic contexts, for example, on the work of Spanish rural women which demonstrates marked regional differences in its nature and extent (García-Ramón et al. 1991), and especially in the Third World where scholars have identified relationships between the gendering of work and development. This research has brought into gender studies not only scholars from North America, Europe, and Australasia, but has significantly engaged African and Asian geographers (Momsen and Kinnaird 1993). Documenting the details of daily and seasonal space-time divisions of labor in rural settings, they reveal the substantial economic contributions of women, identify relationships between household structures and labor supply and exploitation, demonstrate how the introduction of contract labor schemes, of the rearrangement of work hours, and of development schemes promoting agroforestry or irrigation have frequently increased women's burdens and fostered changes in household and community relations without improving economic outcomes for local people. Research on service and industrial employment at local scales similarly shows that from Malaysia to Massachusetts and Mexico, contemporary labor recruitment practices are implicitly and explicitly gendered with consequences for regional and international flows of migrants, daily patterns of movement, the organization of household work, and the persistence of gender-based occupational segregation (Cravey 1998, Hanson and Pratt 1995, Momsen and Kinnaird 1993).

2. Gender and Women's Agency

Accompanying the focus on women's oppression, disadvantages, and gender inequalities has been research on women's agency in shaping the spaces and places of their lives. Research in political geography and on environment and development provide good examples. Both exemplify ways in which feminist scholarship has contributed to revealing the linkages between not only production and reproduction but also between 'public' and 'private' spaces, questioning the validity of envisioning these as binary divisions. Studies of political struggles in Latin America (Radcliffe and Westwood 1993) show women invoking their 'private' identities as mothers to enter the public spaces to protest against state violence. These women have transgressed in public spaces, for example, seeking out clandestine cemeteries, taking and publishing photographs of the tortured and 'disappeared,' and visiting prisons. Yet they also incorporate tra-

ditional 'private' caring responsibilities of women into their public projects—organizing health and child care services and providing food and clothing for refugees. Similarly, research on Palestinian women under Israeli occupation argues that their resistance in the public political arena has been sharpened by military incursions into the secluded private spaces of the home, and by their needs to defend their children in the streets (Mayer 1994).

The motivations and tactics of environmental protests have also been interpreted in gendered terms. Women's activism may be stimulated by concerns for the health of their children and families; their public protests may draw on domestic symbols in public protests (for example, the Spanish women who nightly banged their *cacerolas* (saucepans) in protest against toxic waste dumps (Bru, in Rocheleau et al. 1996)). However, the feminist geographic literature on the environment reveals complex relationships. In this vein, Rocheleau et al. (1996) elaborated the concept of feminist political ecology. They demonstrate the importance of gender differences in access to and control over resources; how gendered knowledge is reflected in a science of survival; and the gendered nature of environmental politics and grassroots activism that is linked with women's redefinition of their identities and recognition of new environmental problems.

3. Difference, Identity, and Embodiment

In the 1990s, feminist geography has been strongly influenced by interdisciplinary currents, especially by the linguistic turn in the social sciences which has foregrounded discourse analysis, and by theoretical perspectives emanating from postmodernist, post-colonialist, and 'minority' feminist scholarship. Scholars have questioned grand narratives, the presumed centrality of white, Western feminisms, and the essentialism of the category 'woman.' They have focused on destabilizing dichotomous categories, such as man/woman, public/private, self/other, mind/body, and global/local (Duncan 1996). This work is particularly developed in the English-language literature, though is also attracting attention in, for example, Spanish and German-language feminist geography.

The implications of the differences among women on such bases as 'race,' ethnicity, class, sexuality, life stages, nationality, and so on are explored, as are ways in which identities based in these sources of difference are mutually constituted, situationally fluid, formed through discourse and everyday actions, and vary across specific historical and geographic contexts and spatial scales. Research explores hegemonic processes, resistances to them, and the negotiation of identities. Linda McDowell (1999) synthesizes this work, emphasizing life in post-industrial societies. Her discussion

attends to home and workplaces, the public spaces of the street and pleasure, and the nation-state. She challenges naturalized assumptions about gender and about these spaces, for example, depicting the home as simultaneously a place of safety and a trap for women with young children, a haven after work or a place where relations between gender and age have to be continually negotiated; she identifies public spaces of parks and streets as sites that can be liberatory or generative of fear and danger.

This literature recognizes spaces and places, as well as identities as simultaneously open and bounded, within and across geographic scales. How are 'hybrid' identities created, for example, by immigrants who move across international boundaries to settle in specific local places? The fluidity and contingent nature of identity in relation to place is highlighted. While some work looks to the present, past imperialism has received significant attention as the historical discourses of women's travel narratives are re-read. Geraldine Pratt provides multiple examples of the fluid and contextual expressions of identity (Fincher and Jacobs 1998). Among the cases she presents is that of a Victorian British woman traveller in west Africa who is bound by gender at home but enabled by class and race privileges in Africa; in another example, she explores the shifting value positions on ethnicity and expressions of gender roles elaborated by Canadian couples in a multicultural neighborhood in Vancouver as they struggle with making decisions about caretakers (and care-taking locations) for their children; yet again, she speculates on the impacts on the political values of women in Worcester, Massachusetts, of moving daily between homes that are middle class (reflecting their husbands' status) and workplaces where they are side-by-side with women of working class backgrounds.

Perhaps the most notable departure in the 1990s from previous geographic work is the focus on the scale of the body and on links between sexuality and space, especially homosexuality. Research examines ways in which particular bodies—the pregnant, the homosexual, the disabled, and the non-white—are marked in space often in exclusionary ways, and also how 'performances' of gender and sexuality are place-related (Duncan 1996, McDowell 1999).

While this new work introduces exciting possibilities, cautionary notes are sounded. On the one hand, it links feminist geography with other critical scholarship concerned with challenging oppression (Jones et al. 1997). The recent collection, *Cities of Difference* (Fincher and Jacobs 1998), for example, brings together feminist work on gender (inflected by other sources of difference such as life stage) with comparable studies relating to disability, gay male identity, race/ethnicity, religious convictions, and class. On the other hand, concerns exist that decentering gender could lead to a depoliticized relativism in which a hard-won feminist political stance is

silenced. So long as the research retains its focus on inequalities and power relations, however, and seeks possibilities for collaborations and coalition formation, the development may be more effective in achieving feminist goals than concentration on a unitary, and some would argue exclusionary, identity politics.

4. Reflections on Methods and Methodologies

Critical perspectives on the creation of knowledge have been enduring issues in gender and feminist studies. While some discussions address specific issues of methods, particularly the relative merits of qualitative and quantitative research, the fundamental concerns are with the politics involved in creating and representing understandings of the world and the partiality of all knowledge, in both senses of this word—that is, no story is considered complete or objective. Overviews (McDowell 1999), collected essays (Jones et al. 1997) and special sections of mainstream journals have addressed the theme, such as the series of articles in *The Canadian Geographer* in 1993 on aspects of ethnographic methods, in *The Professional Geographer* in 1994 on dilemmas of field research, and in the same journal in 1995 on appropriate approaches to, and the values of, quantitative work. They highlight issues of power and ethics. How does one set a research agenda/define a research question if the goals include being responsive to the people being researched and contributing to the feminist agenda for social change, while remaining constrained by the expectations and conventions of the academy? Rocheleau (Rocheleau et al. 1996) describes her involvement of rural people in the Dominican Republic in a multi-faceted research project on agro-forestry that incorporated both 'top down' and 'bottom up' generation of questions, categories of analysis, and interpretations. Gibson-Graham reports her use of an interactive, dialogic method in which women in Australian mining towns were involved in implementation of the research, engaging their domestic and community politics (Duncan 1996).

Numerous scholars reflect on power issues of their own relationships with 'subjects' especially as their interviews involve people who are of different class, 'race,' ethnic, gender, or sexual orientation from themselves and who may express views that are problematic for the researcher (for example, considering them to be sexist or racist) or who reveal knowledge that could compromise the subject or researcher (Jones et al. 1997, McDowell 1999). While such questions have been widely raised in interdisciplinary feminist literature, as Hanson (Jones et al. 1997) points out, perhaps the distinctive and most interesting contributions from geography concern the roles of location and place within the research process—in

what settings does the recruitment of 'subjects' take place, where are interviews held (homes, workplaces, community contexts)? How does the choice of context shape not only the way subjects present themselves but how they interpret the researcher's intentions and meanings? In a revealing account, Nagar identifies multiple ways that she was viewed and presented herself in research carried out in religiously, regionally, and ethnically diverse social spaces in Asian communities in Dar-es-Salaam (Jones et al. 1997). Overall, these discussions point to the importance of reflexivity that requires researchers to continually evaluate their assumptions and political positions. They also lead to a conclusion that favors combining multiple methods and exploring ways to engage the 'researched' in the validation of one's work.

Discussions about representation also figure prominently in feminist geography—not only asking whose voices are heard in the research, but also how categories are imposed on what we hear, and on where and how research is reported and read. Pulido, for example, writing on the activist group, Mothers of East L. A. (Los Angeles) indicates that while feminist work has identified women's environmental activism with their gender identities, the women involved may not see themselves and their motivations in gendered terms, but rather in relation to ethnic or community identities (Jones et al. 1997). Monk notes the irony of the hegemony of British and US scholarship in the reviews of literature by feminist geographers who simultaneously promote resistance to hegemonic discourses and listening to a plurality of voices (Jones et al. 1997) while overlooking publications written outside their own milieu. One of the most interesting examples of attempts to present research in ways that will speak to different audiences is Pulsipher's analysis of the diverse interpretive texts she has created to communicate her research in historical geography/archeology on a slave plantation in Montserrat to multiple audiences including local project workers and outside volunteers assisting in the research (and especially to engage locals in defining concepts), as well as museum curators and visitors at the Smithsonian Institution. She has also written several fictional accounts using the research material to convey the bodily feelings of life on the plantation to local schoolchildren, community members, outside visitors, and academic audiences (Jones et al. 1997).

Surprisingly rare in these methodological discussions, especially given the proliferation of cartographic metaphors in contemporary post-modern and feminist writing, are reflections on the place of mapping in feminist geography and gender studies, though several feminist atlases (for example, of women in the USA, the *Atlas of Women and Men in India* (Raju et al. 1999), and especially Seager's (1997) world atlas) present examples of the possibilities and difficulties of representing gender themes cartographically. Huffman's critique of the masculine values of traditional car-

tography, and his reading of feminist endeavors, opens up methodological questions, such as the ways maps and other visual representations can present fragmented data, reveal hidden perspectives, and contribute to interpretations of gendered bodies (Jones et al. 1997).

5. Status and Emerging Directions

In little over two decades, gender and feminist studies have become well established in geography despite their marginal origins. In particular, their critical perspectives have contributed to reshaping epistemological understandings in human geography. In addition to the substantive themes mentioned above, work is expanding on gender and the body (including sexuality and health), on gender and human rights, trans-national cultural, political, and economic processes and their intersections, and constructions of masculinity. There is every indication that gender and feminist studies will remain a vital field within geography.

J. Monk

Gender and Feminist Studies in History

Gender history, feminist history, and women's history identify overlapping areas of inquiry whose relationships to each other have become more complex and more contested in the past decade. Emerging as an autonomous subfield by the early 1970s, women's history was a direct outgrowth of the feminist movement in the USA, Canada, Australia, and Western Europe. Certainly, earlier generations of women and of feminists had written on the historical experiences of their sex, but most did so outside the institutions and practices of professional history (Smith 1998). Only in the 1970s did women historians gain access to professional training and teaching positions in colleges and universities in significant numbers and in a sufficient array of countries to nurture this new field of study. A small number of men participated in launching women's history and a growing number employ gender analysis, but women remain the mainstay of the field.

Feminist history was initially conceived as nearly synonymous with women's history in the sense that most practitioners of the latter embraced the politics of the former, including critiques of patriarchal institutions and practices and of maldistributions of power and resources more generally. But feminist history could also define an area of investigation—the origins and development of movements for women's rights and sex equality. Gender analysis appeared as a distinct but related approach to history in the mid-1980s, though a concern with the 'social relations of the sexes' and the relative status of women and men

had certainly been introduced earlier. This approach both complemented and challenged existing work in women's and feminist history by asserting the critical importance of exploring historical changes in individual and collective subjectivities and the centrality of gender in signifying forms and relationships of power (Kelly 1986, Scott 1988, *Gender & History* 1989).

The emergence of gender history as a distinct area of inquiry paralleled and converged with a number of other theoretical and professional developments that assured the transformation of feminist history. These included the rapid increase in women's history scholars, journals, books, and conferences; the resurgence of conservative and right-wing politics around the world; the rise of postmodern, postcolonial, and subaltern epistemologies; and the critique of early feminist frameworks by scholars of color and by historians of the working class, lesbians, and non-western regions and countries (Brown 1992, Meyerowitz 1992, Alexander and Mohanty 1997, Pierson and Chaudhuri 1998).

1. The Rise of Gender History

From the 1960s on, women's and feminist historians had incorporated some gender perspectives in their work. Not until the mid-1980s, however, did the history of gender become a substantial field in its own right. Proponents of gender analysis argued that 'the creation and reproduction of gender is a process, changing over time' and place, and operating 'at every level, and in every sphere' of historical study (*Gender & History* 1989, pp. 2–3). The ubiquity of gender—as a system of symbols and signifiers as well as a cultural construction with implications for society, the economy and politics—demanded 'a theory of meaning that assumes a multiplicity of references, a resonance beyond literal utterances, a play across topics and spheres' (Scott 1988, p. 60). In addition, gender analysis was seen as a critical weapon in transforming traditional historical narratives. Women's history could be accepted as a parallel but separate area of inquiry, but gender history—which recognized gender 'as a key axis of power in society' and provided 'a crucial understanding of how any society is organized and structured'—demanded the recasting of the past *in toto* (Hall 1992, p. 12).

Responding to earlier challenges that feminist history had long been too white, too middle-class and too heterosexual, many gender historians engaged issues of class, race, nationality, and sexuality from the beginning. They asked how class was gendered, how gender was raced, and how nationality was raced, gendered, and sexualized. Davidoff and Hall, for instance, explored the critical role of women and the family in the formation of the British middle class; Brown suggested that jazz and gumbo ya-ya were appropriate models for capturing the multivocal,

relational character of an American women's history riven with race and class differences; and Guy analyzed the ways that fears of 'white slavery,' that is, the international trade in women for sex, shaped notions of citizenship, and nationality in Argentina (Davidoff and Hall 1987, Brown 1992, Guy 1992)

There was considerable resistance, however, to the emergence of gender analysis among some feminist historians. Scholars' emerging fascination with men and masculinities led some to worry that women would quickly be subsumed within this new gender history. Other questions arose when pioneering advocates of gender analysis embraced postmodernism and deconstruction. Postmodernist critiques of grand narratives and the deconstruction of unified subjects and subjectivities posed challenges to fields like women's and feminist history that were seeking to create new narratives by building on the identity politics of the 1960s and 1970s (*International Labor and Working Class History* 1987). Nor was this concern limited to battles among white women historians. Scholars of color, committed to integrating race and nationality into studies of women and gender, were divided over the utility of postmodernism for creating new political insights and practices (Christian 1987, Alexander and Mohanty 1997). Students of sexuality, too, were alternately attracted to and repelled by theoretical perspectives that denied unitary subjects, homosexual and heterosexual alike (Meyerowitz 1992). Critics focused on the political dangers of destabilizing categories of individual and group identity at a moment when identity politics seemed to promise a potent weapon in the fight against racism, sexism, classism, homophobia, colonialism, and imperialism. In a more purely historical vein, the attack launched by postmodernists threatened not only older grand narratives, but also newer ones that celebrated the lives of women, workers, African Americans, indigenous peoples, and anticolonial activists. Yet despite such concerns, gender analysis has increasingly shaped work in women's and feminist history. And taken together, these approaches have begun to transform the study of the past in several significant ways.

2. *The Transformative Power of Feminist and Gender History*

Certain themes and interpretations provide common threads in the history that is being rewoven through analyses of women and gender. Perhaps most importantly, private life, domesticity, reproduction, and sexuality have been reclaimed as subjects. Not only do we now recognize that these topics have a history that parallels that of public life, politics, production, and war, but we also are beginning to see the ways that these two histories are deeply intertwined—private with public lives, domesticity with politics, reproduction with production, sexuality with war.

In recognizing this broader tapestry, studies of women and gender have transformed the meanings of terms central to historical analysis. Politics no longer refers only to the formal institutions of government and law, but also to mass movements, voluntary associations, maternalist campaigns, spontaneous uprisings, and alternative understandings and conceptualizations of power in workplaces, schools, cultural sites, and homes as well as courts, legislatures, parliaments, and partisan arenas. Work is no longer limited to labor performed by men in exchange for land, goods, or wages, but embraces the production of goods and services by women and men, regardless of payment or the system of exchange, and includes the labor of physical and social reproduction and the contributions of informal as well as formal economies. In a similar fashion, studies of war are no longer confined to the battlefield or the arenas of military strategy and diplomatic negotiation, but are instead open to analyses of the homefront, of low-intensity but chronic conflict, and of rape, disappearances, and torture as weapons of domination.

The history of labor—productive and reproductive—offers numerous examples of how attention to women and gender recasts our understanding of the transition to capitalism. For example, women were critical economic agents in many arenas during the medieval and early modern periods, particularly in domestic production, social reproduction, informal sectors, and petty trade. Bennett's (1996) *Ale, Beer and Brewsters in England*, illustrates the centrality of women to the production and sale of alcoholic beverages in the early medieval period, when brewing was a largely local affair. She then analyzes the process by which female brewsters gradually were pushed to the margins as larger markets, new technologies, government regulation, and guild formation turned brewing into a masculine venture. In this transition to commercial capitalism, women remained tied to local, low-paying, low-status work, while the skills they had honed in home-based shops were taken over by men once they proved sufficiently profitable. In similar fashion, Ulrich's exploration of a midwife's contributions to household sustenance and social interaction in a small town in late eighteenth- and early nineteenth-century Maine illuminate the significance of women's labor in maintaining families and communities and its contributions to larger transformations in the gendered economies in which they were embedded (Ulrich 1990). Studies of slave women across time and place and of female service, factory, and home-based workers in the industrial age add to these early portraits of women's place in both formal and informal economies (Berger 1992, Morgan 1997)

In a similar fashion, the study of politics has been transformed by the inclusion of women and of gendered perspectives. Initially feminist scholars shifted the focus away from electoral, parliamentary, and judicial activities, nearly all of which excluded

women—at least formally—until the last half century. Instead women's historians studied the means by which women and other marginalized groups shaped the political terrain through voluntary associations, petitions, food riots, mass demonstrations, and reform and revolutionary movements. Interpretations of the most significant periods of reform in the USA—the 1830s–1850s, the 1890s–1920s, and the mid-1950s–mid-1970s—have now been rewritten to highlight the public activities of women and their larger social, political, and cultural consequences (Hewitt and Lebsack 1993). Scholars of the French Revolution and the revolutions of 1848 across Europe have highlighted both women's participation and the use of women as symbols, alternately, of liberty and degradation. And interpretations of nationalist movements and national liberation struggles in South Africa, India, Spain, Cuba, and other areas of the world are being rewritten to include women activists and gendered images (Landes 1988, Riot-Sarcey 1994, Pierson and Chaudhuri 1998).

In developing new areas of inquiry and new perspectives on traditional subjects, feminist and gender historians have been joined by historians of other groups long marginalized in historical narratives—racial and national minorities, workers, peasants, slaves, and those ostracized for sexual practices or by sexual traumas. Race, class, and sexuality were never absent from women's history, but only from the mid-1980s on did explorations of differences among women gain equal attention with investigations of differences between women and men (Brown 1992, Alexander and Mohanty 1997, Gordon 1999). In recent years, scholars have developed more and more sophisticated analyses of the interplay among race, class, nationality, and sexuality, with a growing number of feminist historians working to reveal their mutually constitutive character. Even studies of feminism and women's emancipation have been recast in terms of race, class, and nationality. In particular, the ways that many white feminists excluded women of color from their ranks and/or wielded racist or ethnocentric logic to advance their own cause has now been sharply critiqued even as historians of women's movements continue to search for moments of alliance and collaboration across these divides (Burton 1994, Pierson and Chaudhuri 1998).

Many fields have been influenced by this attention to race, class, and nationality within women's history. Research on the history of Africa and the African diaspora has been especially important in excavating the intricate links among women's multiple forms of identity. Gendered images of Africa, particularly images of African women as beastly and oblivious of pain in childbirth, justified European conquest, colonization, and enslavement. The skewed sex ratios that characterized the slave trade—with far more men than women being sent to plantations in the Caribbean and the Americas—necessitated transformations in family

life and in productive and reproductive labor and over time shaped new patterns of ethnic, regional, and even religious identity in both Africa and the Americas. Moreover, while acknowledging the overwhelmingly racial character of slavery, historians have now demonstrated the powerful ways that gender shaped the experiences of bondage and of freedom. And in recent years, studies of twentieth-century Africans and African Americans have explored the ways that class, religion, and region as well as gender shaped divisions of labor, movements for social reform and social justice, and struggles for national liberation (Berger 1992, Morgan 1997, Diouf 1998).

As the mosaic of women's and gender history has expanded, a growing number of scholars have turned their attention to conservative women and women on the right. They challenge earlier feminist histories that highlighted women's engagement with progressive, emancipatory, and pacifist struggles or that treated women's engagement with conservative, right-wing, and fascist politics as solely a function of their domination by men. Rather, building on scholars' efforts to reveal women's agency in all aspects of their lives, historians of conservative and right-wing women have insisted that we recognize many women's willing embrace of antifeminist, racist, nativist, and elitist policies and projects. Beginning in the 1980s with works such as Koontz's (1987) *Mothers in the Fatherland: Women, the Family and Nazi Politics*, a number of historians have argued that women who accept traditional family and community roles often feel threatened by efforts to transform their place in society and in response support movements that celebrate motherhood, domesticity, and female subordination (Gravenhorst and Tatschmurat 1990, Sarkar and Butalia 1995). Most of these studies focus on women's engagement with the far right—facism, the Ku Klux Klan, and religious fundamentalism. Only recently, have scholars explored women's participation in more mainstream movements, demonstrating not only their support of conservative political and social agendas but also the ways that that support has undermined feminist claims for women's universal support of peace, social welfare, and other progressive causes (Delegard 1999).

These studies, though their subjects are mainly members of dominant racial and ethnic groups, reinforce claims made by historians of people of color, workers, and lesbians, for the significance of differences among women. They also hark back to earlier work on social reform that demonstrated that women and men who shared economic and racial status often held common views on social order and social change. And they fit neatly alongside more recent studies in which the social relations of the sexes take center stage in analyzing the dynamics of social, political, and cultural change (Kelly 1986, Davidoff and Hall 1987, Guy 1992, Berger 1992, Roberts 1994, Sinha 1995, Bennett 1996, Gordon 1999).

3. Globalization and Revitalizing Gender and Feminist History

The issues raised by gender history were complicated further in the 1990s by the call for more global histories. Certainly earlier work focused on diverse areas of the world. Nonetheless, the increasing globalization of the economy and of communications and the emergence of women's movements and women's histories in a growing number of nations has demanded renewed attention to international and transnational perspectives. Many nations gained their independence in the final decades of the twentieth century, even as they remained financially and culturally colonized by Western industrial powers. The emergence of women's and gender histories in newly independent nations has provided not only additional stories of women's past struggles but has also demanded a rethinking of the roles of women, and feminists, in imperial and colonial politics and culture from the seventeenth century to the present (Davis 1995). Studies of women, gender and sexuality as they shaped colonial relations in South Asia have been especially important in exploring this rich new terrain (Burton 1994, Jayawardena 1995, Sinha 1995).

Interest in comparative and transnational work and in queer theory, which extends postmodernist critiques of unitary subjects into the realm of sexuality and beyond, promise even more complex renderings of women and men, femininities and masculinities in motion around the world (Alexander and Mohanty 1997). Finally, with a profusion of work on women, feminism, and gender now appearing in a wide array of countries and regions and on a broad range of racial, ethnic, national, and sexual communities, differences within as well as between groups of women are increasingly highlighted, making generalizations more difficult even as it often makes comparisons more fruitful. Thus, for instance, differences among women of color rooted in class, color, and sexual orientation, are being explored in greater depth. Similarly, ideological differences among feminists are being analyzed at the same time that their international connections—past and present—are being highlighted and the differences in conceptualizations of women's rights and priorities are being explored in a more global context. The challenges that new and forthcoming work pose to existing interpretations combined with the rich array of research by scholars claiming identities as feminist, women's and gender historians suggests that these fields will continue to have profound effects on the development of history.

Gender and Feminist Studies in Political Science

There are two main issues which feminism continues to pose for political science. The first is the questioning of any conception of social science that sees disciplines as neutral and universal bodies of knowledge. The second, and closely related issue, is the limit of the political. In short, not only have feminists argued that traditional political science was very far from gender neutral; they have also argued that, in order to analyze politics adequately, and incorporate gender issues, it is necessary substantially to extend more traditional political science understandings of what constitutes 'politics.' In the process, feminist work has connected with wider analyses of gender, emphasizing the need to analyze gender politics in terms of the construction of both masculinities and femininities.

1. Political Science as Neutral

From the 1970s on, feminist academics increasingly challenged both the gender neutrality of the focus of political science and the gender neutrality of the discipline itself. As Squires has pointed out: 'until the emergence of feminist theory as a recognized academic perspective, contemporary political theory was largely assumed to be gender-neutral in focus' (Squires 1999). Not only did that neutrality come to be challenged but so did women's largely subordinate position in the political science profession. Giving her Presidential Address to the Australasian Political Studies Association in 1981, Pateman noted that: 'Women's position in the profession of political studies is very similar to our position in other professions and in public life generally; we are marginal participants in organizations that are numerically and structurally dominated by men' (Pateman 1982). While matters have improved in many respects since the time when Pateman was writing, a recent survey of the position of women in the American discipline of political science reported that women held only 21.1 percent of full-time faculty positions in 1997–8 and constituted only 11.2 percent

of full professors. Improving the position of women in the discipline has been made harder by a general decline in tenure-track job opportunities (Sarkees and McGlen 1999). A survey of the impact of feminism on Canadian political science found that fewer than 640 of the nearly 17,770 pages published in the *Canadian Journal of Political Science/Revue canadienne de science politique* in the 22 years since its inception discussed women. Fortunately, the situation had improved markedly in the previous seven years (Arscott and Tremblay 1999).

2. The Limits of 'Politics'

Most challenging of all to conceptions of political science as 'neutral' were the challenges to the subject matter of the discipline. In particular, with the increasing impact of academic feminism, the very subject of the 'political' in political science was thrown into question. Politics, as Pateman had pointed out in her 1981 Address, tended to stop at the garden gate. Traditionally, politics was about government, the state, political parties, and other manifestations in the public sphere. Politics was not about gendered power relations in personal life, domestic labor, or women working in the volunteer welfare sector, or organizations representing sex workers in the third world, or representations of women in the media, or domestic violence or rape. Indeed, Squires has argued that it is the limited subject matter of mainstream political science that has most influenced its androcentric nature: 'The adoption of the narrow institutional or instrumental conception of the political within most dominant renderings of the discipline' is what 'accounts for the fact that the study of politics has been one of the last to take up the challenge of feminist scholarship, and most recently men's studies, and modify the cannon' (Squires 1999). Given the need to move beyond limitations of what has been defined as the political, it is not surprising that the engagement between feminists and political scientists has been continually informed by sociologists, philosophers, historians, linguists, and literary theorists rather than confined to insights generated from within the discipline (see e.g., Butler and Scott 1992).

The archetypal second-wave feminist slogan of 'the personal is political,' therefore, had a particular meaning for political science and challenged the discipline's boundaries. Initially, the tasks of feminist political science seemed relatively straightforward. Neglected areas of women's participation could be documented. The welfare state was reconceived in terms of its role in reinforcing established gender relations rather than merely analyzed in terms of the influence of Keynesian economics or postwar European social democracy. (For example, governments frequently assumed that women who were married or in *de facto* relationships should not be eligible for state

benefits. Rather, it was the job of their male breadwinner to support them.) There could be speculation regarding the possibility of undocumented feminist debates in classical Greece that may have influenced Plato and outraged Aristotle. Leading female political thinkers could be rediscovered and reassessed from fifteenth-century writers such as Christine de Pizan to nineteenth-century writers such as Flora Tristan or Harriet Taylor. Voting studies could concentrate on female voters and analyzing gender difference. The under-representation of women in parliament and the bureaucracy could be documented and critiqued. The lack of provision of services targeted for women, from childcare to women's health, could be highlighted. Feminists could analyze attempts to influence state policy and services, for example, the Australian experiment with 'femocrats,' feminist bureaucratic advisers to government (Eisenstein 1996).

Such tasks still remain a central focus of feminist political science, for example, they are amongst the aims of the *International Feminist Journal of Politics*, established in 1999. They have long been the aim of older journals such as *Women and Politics*. However, it is not a matter of just adding women on to existing analyses; feminists have argued that political science also needs to readdress some of its most fundamental theoretical and analytical underpinnings.

3. The Reassessment of Traditional Political Theory

Many of the issues raised by late twentieth-century feminists were not of course new. As already indicated, predecessors from fifteenth-century Christine de Pizan to better known feminists such as Mary Wollstonecraft had raised issues regarding women's relative exclusion from public life. Nonetheless, from the 1970s on, feminist political theorists along with academics from related disciplines began to reassess traditional political theory. Okin (1979) was one of the first 'second wave' feminists to argue that the fathers of modern liberal democratic thought tended to construct the citizen as a male head of household. The role of women was seen to revolve around the private sphere of the family. Women were to have only limited, if any, involvement in public, political, and economic life. Even liberal supporters of female suffrage such as John Stuart Mill assumed that, while women should be able to choose either a career or marriage, the majority of women will choose marriage. Having made the latter choice, the woman's primary commitment would be to managing the family and rearing children. Such views have led Coole (1988) to argue that, despite tendencies towards egalitarianism, liberal democrats expected women to defer to their husbands on political matters well into the nineteenth century. The issue of marriage also has a deeper significance. Pateman (1988) has argued that the marriage contract

was indissolubly intertwined with the social contract. In other words, when contract theorists postulate an original social contract in which free men, living in the state of nature, joined together and agreed to give up certain individual and collective powers to government, they were telling only part of the story. Underlying the social contract was a marriage contract in which men continued to have power over their wives and their wives' property. The wage contract was similarly gendered as the employee tended to be assumed by both employers and governments to be a male wage earner supporting his family.

While there is debate about how relevant Pateman's analysis of contract is to analyzing contemporary political discourse, there is a widespread feminist view that the citizen subject is still being constituted in masculine terms. Brown (1995) paints a complex picture of how this occurs. She draws on both a conception of ideology as an obfuscating narrative and a conception of discourse as a narrative that is constitutive of a social order. Brown notes that liberalism simultaneously produces gendered subjects whose differences are seen as natural (an ideological moment in her terms), and abstract individuals who appear to be genderless (a discursive moment in her terms). The liberal individual may appear superficially to be gender neutral but is still gendered masculine in crucial ways. As numerous feminist theorists, including Brown, have pointed out, gendered dualisms operate throughout political discourse. For example, in much neoliberal discourse, categories such as self-interest are associated with the masculine, and categories such as selflessness are associated with the feminine. The citizen is meant to be an abstract, self-reliant, and entrepreneurial individual. However, far from the self-interested liberal individual being autonomous and self-reliant he is in fact dependent upon the labor and emotional support of the subordinated female 'other.' It is, therefore, hardly surprising that cutting state welfare services often results in labor being transferred to unpaid female labor in the domestic sphere. For example, as jobs and services are cut in the public sector, it is frequently women who then have to increase their level of care for sick, young, old, or disabled relatives at home. Of course, such problems are not confined to some forms of market liberalism but also appear in some of the classic works of social democracy. For example, Pateman (1996) has argued that T. H. Marshall's classic statement of the 'social' rights to which citizens were entitled was quite literally based on a conception of the citizen as male breadwinner and worker. Here, as elsewhere, women's exclusion from various 'social rights' was not addressed adequately. Not only were married women frequently denied eligibility for welfare payments but 'social' rights were conceived of according to 'male' norms. Rights to services most affecting women such as childcare were neglected. Female under-representation in parliaments and legislatures was not seen as

a major barrier to women's citizenship that needed to be urgently addressed. In short, as Phillips (1991) has pointed out, far from transcending gender, the apparently gender neutral figure is frequently based on a male norm. Feminists have therefore argued that the projects of traditional political theory were often inherently androcentric.

While the situation has improved, feminists argue that many of these problems are still apparent in contemporary western political and social theory. So, for example, Arscott and Tremblay (1999) argue that key Canadian theorists of citizenship such as Jim Tully and Will Kymlicka 'have paid next to no attention at all to gender' despite its relevance and the fact that they do deal with relevant ethnic or indigenous issues.

4. Women and Political Representation

The critique of traditional political science and political theory has had a strong influence on more empirical feminist analyses of women and political representation. It is not just that feminists have studied forms of politics neglected by traditional political science, but feminist analyses have also contributed new insights into mainstream political science concerns such as how politicians are selected. For example, in her analysis of Women National Leaders, Francine D'Amico reminds us that many prominent female political leaders have taken 'the widow's walk,' literally walking into the political leadership job previously occupied by their deceased husbands. Corazon Aquino, former President of the Philippines, would be a typical example. In another form of 'surrogate' politics, daughters have occupied positions occupied by their deceased fathers, for example, Benazir Bhutto, former President of Pakistan. D'Amico points out that traditional studies of political leadership tended to neglect such paths to office because of their emphasis on the 'public' rather than the 'private,' for example, on recruitment of political leaders from a background in business, the military or the professions (D'Amico 1995).

However, concentrating on a few prominent female political leaders should not blind us to the fact that, as of January 2000, only eight countries in the world, Sweden, Denmark, Germany, Finland, Norway, Iceland, the Netherlands, and South Africa had reached the UN sanctioned target of women's share of seats in national parliaments being 30 percent or above. New Zealand had reached 29.2 percent, Australia 22.4 percent, the UK 18.4 percent, and the US 12.5 percent (UNIFEM 2000). Christy has drawn attention to some of the most obvious national differences that can influence women's level and forms of political participation, even where there are not apparently huge cultural or religious differences. For example, as Christy points out in a comparison of Europe and the US, women's attitudes to politics may

be different in countries with more extensive welfare states, where women can easily see the relevance of government provision in areas such as caring for children, the sick, and elderly. Electoral systems that utilize proportional representation, with party listing of candidates, tend to elect more women (Christy 1994). Multimember electorates are, therefore, a particularly important factor (Norris 1994).

The impact of women's increased political representation is still subject to debate, particularly since some prominent political leaders, such as Margaret Thatcher, have been identified with antifeminist politics. Nor can one assume that women will behave 'better' than male politicians. Nonetheless, Conway and co-workers conclude in their study of American politics that the increasing number of women in the legislatures and the political elite has already influenced policy. Female legislators are more likely to emphasize social welfare issues and support equal rights policies. They are also likely to place more emphasis on helping constituents. Their presence has 'probably led' to male members of the political elite being aware that women's issues are important (Conway et al. 1997). The claimed difference in the attitudes of female and male legislators might well reflect the persistent so-called 'gender gap' on issues such as social welfare which a number of commentators have found in longitudinal voting and opinion poll studies (see e.g., the famous study by Shapiro and Mahajan 1986).

5. Analyzing the Politics of Masculinity

While feminism has played a crucial role in exposing traditional political science's neglect of women, it has also drawn attention to the need for political science to analyze the role of the state and political institutions in constructing masculinity. Indeed, one could argue that political institutions are just as implicated in the construction of particular forms of masculinity as they have been in marginalizing women. If, for example, the citizen is being conceived in terms of the male citizen breadwinner, what are the implications of this for conceptions of masculinity? Do such conceptions of citizenship encourage not just a predominantly heterosexual masculinity but also forms of masculinity that emphasize financial self-reliance and paternalism? Do they encourage forms of masculine self-esteem that are dependent upon female subordination? In short, are various forms of masculinity being privileged over others here and what are the implications for men as well as women? Hearn's (1992) study analyzes constructions of masculinity within the hierarchies of patriarchy pointing out that some men oppress other men on the basis of class, race, sexuality, disability, and other categories. Work such as Yuval-Davis's (1997) has drawn attention to the ways in which nationalism is gendered in both masculine and femi-

nine terms. For example, masculinity can be mobilized for national defence while femininity can be mobilized for training children (and even resistant adults) in appropriate cultural values and national identities. However, increasingly, work on the politics of masculinity has also had to deal with the phenomenon of male organizations engaging in 'backlash' politics, as more traditional forms of masculinity are seen to be under threat from feminism (Messner 1997). There is certainly a need for more political science work on the wider normalizing political discourses that help to construct particular forms of both masculinity and femininity. However, it should be noted that mainstream political scientists sometimes have been even less keen to analyze the politics of masculinity than they have been to analyze so-called women's issues. After all, problematizing the self can be even more threatening than acknowledging the other.

6. Analyzing the Politics of Feminism

The analytical tools which feminist theory developed to critique gendered discourses drew on a variety of sources from sociology of gender to French theory's critique of those forms of dualistic thinking that subordinated the feminine 'other.' Increasingly, these analyses began to be turned upon the subject of feminism itself. While early feminist engagements with political science concentrated on documenting women's subordination, marginalization, and exclusion, the issues have now become far more contentious. It is not just the constitution of the 'political' which has been found to be problematic but also the very constitution of categories inherent to feminism such as 'woman.' Difference between women has been emphasized. Feminism itself has become the subject of deconstruction and critique as racial, ethnic, cultural, and class biases in particular versions of feminism have been highlighted. Sometimes, these critiques have a direct impact upon analyses of feminism and political science. For example, the authors of the study on women in Canadian political science (Arscott and Tremblay 1999) note the continued impact of Anglophone and Francophone divisions within the discipline and amongst feminists themselves—many Anglophone scholars rarely citing or teaching the work of their Francophone colleagues. Meanwhile, queer theory raises issues that earlier feminist analyses of traditional political theory tended to neglect such as the extent to which constructions of the citizen as male head of household were not only patriarchal but also constructed the citizen in heterosexual terms. The public/private conception, once so crucial to feminist critiques of traditional political theory, has been criticized for being a Western conception. Women's subordination is now as likely to be seen as being due to the continued influence of gendered binary linguistic categories as being due to more materialistic factors such as the gender division of labor.

Not surprisingly, these issues are also reflected in debates over feminist political practice. For example, there are major debates over whether feminist strategies should revolve primarily around cultural issues of 'recognition' or whether the battles should be over issues of economic 'redistribution.' There are also debates over whether feminist politics has revolved around 'states of injury' which government has then been called upon to redress, rather than upon more empowering political strategies (Brown 1995). Many 1970s' versions of feminism have been seen to result from forms of 'identity politics' which, theorists such as Butler argue, both have strategic importance and can reproduce forms of exclusion. Butler (1991) states that the constitution of the identity of the subject has wider implications since 'identity categories tend to be instruments of regulatory regimes, whether in the normalising categories of oppressive structures or as the rallying points for a liberatory contestation of that very oppression.' Consequently, political scientists such as Dean (1997) have argued for developing reflective political strategies that take issues of difference seriously while negotiating forms of feminist solidarity and political action. Dean's collection on *Feminism and the New Democracy* argues for the importance of increasing democracy not only at the level of the state but also in personal relationships.

7. Feminism, Political Science, and Policy

In short, contemporary feminists are still debating, and stretching, the limits of the political. In Vickers's phrase (1997), feminists need to 'reinvent' political science. However, political science also poses a number of challenges to feminist theory and practice. Key amongst these is the challenge posed by the policy-making process. For example, critiques of the universalizing category 'woman' can be useful in the policy-making process when the resulting sensitization to difference draws attention to the need to develop programs that address a range of women's problems, experiences, and lives. They can be less helpful if the differentiation goes so far that the desirability of feminists establishing women-focused programs is brought into question, or if feminists deny the insights that can be drawn across cultures from old feminist concepts such as gender stereotyping or the public/private divide (Lee 1995, Herrick and Sapieva 1997). Similarly, queer theory can be useful for drawing attention to the ways in which both minority and mainstream identities exclude those who are not seen to belong. The insights of queer theory can be less useful if the need for specifically lesbian advocacy or services is ignored. Arguing for a plurality of interpretations may well be a useful feminist political strategy in the fields of literature or film that prevents gendered meanings being fixed. Eventually, however, policy-makers will need to make definite decisions and implement specific programs. Debates over recog-

nition and redistribution usefully draw attention to the need for programs that address both aspects but are less useful if they lead to the privileging of one aspect over the other. Critiques of dual categories can be useful for drawing attention to the discursive subordination of the feminine but are less useful if dichotomous thinking is seen as the fundamental source of women's inequality that must be addressed. Here, as elsewhere, a combination of judicious eclecticism and sensitivity to difference and multiplicity can be helpful in negotiating the complex engagements between feminism and political science.

The relationship between feminism and political science has also been complicated by the times. The backlash against so-called 'political correctness' in many English-speaking countries has made it more acceptable to not merely dismiss feminist critiques of gender bias but to accuse feminists of silencing and marginalizing men. As indicated previously, the institutions and organizations of gender politics now include various aggrieved men's groups—groups mobilizing over issues of child custody, divorce settlements, and parental support—as well as women's organizations and gay and lesbian organizations. The impact of economic globalization and rapid social and technological change has contributed to an environment in which appeals to nostalgia, including gendered forms such as bringing back dependent stay-at-home Mums and reliable male breadwinners, can be electorally attractive to women as well as men. Meanwhile, the influence of neoliberalism, particularly in English-speaking countries, has undermined those feminist critiques of male dominance and female disadvantage that relied on state action to redress the balance. While there are forms of neoliberalism that attempt to incorporate some women into conceptions of the self-reliant individual, others flirt with forms of social conservatism which privilege more traditional gender relations.

All of this has made the engagement between feminism, gender studies, and political science more complex. It has also meant that analyses must be updated constantly. While appeals to nostalgia ensure that older feminist analyses are unlikely to be totally superseded, there is a need to develop analyses that can deal with the evolving political discourses and practices of the twenty-first century. Earlier feminist analyses concentrated on analyzing the politics of exclusion and marginalization. However, increasingly, feminists may need to develop sophisticated analyses of new forms of political inclusion and incorporation, (and new forms of masculinities and femininities), as changes in gender politics are played out in numerous sites and discourses. In the process, mainstream political science could usefully learn to be as self-critical and reflective as feminism has become.

Gender and Feminist Studies in Psychology

1. The Emergence of a Field

Feminist studies in psychology emerged in the late 1960s, in the context of the second wave of the women's movement (see *Feminist Movements*). A group of activists, mostly graduate students and newcomers to psychology, founded the Association for Women in Psychology in 1969. At about the same time, a group of somewhat more established psychologists worked within the American Psychological Association to create a division for the psychology of women. Divisions on ethnic minority psychology and lesbian/gay psychology were established later.

Division 35, inaugurated in 1973 and now known as the Society for the Psychology of Women, is one of the largest divisions of APA. AWP continues as an activist organization with a collective governance structure and no formal ties to APA, although Division 35 and AWP cooperate on various projects and there is

considerable overlap in membership. Similar organizational development took place in Canada and the UK, where the British Psychological Society now houses a Psychology of Women Section and a Lesbian Psychology Section. For the first time in the century-long history of psychology, the structure of its major professional organizations acknowledges the presence and professional identity of diverse women. The study of women and gender, and women themselves, now have a political and organizational base within psychology.

With these developments came the founding of feminist journals devoted to research from psychology and related disciplines: *Sex Roles* (1975), *Psychology of Women Quarterly* (1977), and *Feminism and Psychology* (1991) are perhaps the most widely circulated. Their founding, along with the growth of interdisciplinary women's studies journals, provided new publication outlets for research on women and gender. In 1974, there was not a single journal article on women and achievement published, although achievement motivation was a lively research field; in 1993, there were 161. Similar growth has occurred for other topics, notably sexual violence and feminist therapy.

The growth of feminist psychology can also be seen in the number of psychology departments offering courses in the psychology of women or gender. Before 1968, there were virtually none. By 1990, 51 percent of departments that responded to an APA survey included such courses, and there were 172 offered at the graduate level. The first two textbooks appeared in 1971; today, there are many in print.

Along with facilitating the recognition of women's presence in psychology, the women's movement gave rise to a feminist critique of psychological theory, research, and practice and to the development of new approaches in all these areas. Organized activism by AWP and Division 35 led to a surge in feminist symposia and papers at APA national conferences starting around 1970. Critical books and journal articles objected to psychology's views of women. Naomi Weisstein, among the first second-wave critics, famously claimed that psychology had nothing to say about women because it knew nothing about women. Carolyn Sherif analyzed how the needs of the cold-war military had shaped psychology's research agenda. Phyllis Chesler argued that clinical psychology and psychiatry were instruments of control directed at women.

These, and the many other voices of second-wave feminist psychology, were not cautious or timid ones. The 1970s feminist critique quite openly challenged psychologists' choice of research topics and methods, their theoretical constructs, and their modes of diagnosis and therapeutic intervention, and it attacked the values underlying them. It had an assertive tone and an activist agenda that probably contributed to its exclusion from 'mainstream' journals. A similar confrontational approach had last been seen some 50 years

earlier, during the first wave of the women's movement, when some of the first American women to receive higher degrees in psychology questioned the biases of the psychology of their day, such as the ongoing search for sex differences in personality and ability. Hollingworth (1916) wrote a powerful critique of the social devices for impelling women to bear children, while Wooley (1910) characterized research on sex differences in mental abilities as 'riddled with flagrant personal bias, logic martyred in the cause of supporting a prejudice ... and sentimental rot and drivel.'

A fundamental aspect of second-wave feminist critique was the claim that psychological knowledge was androcentric, or male-centered. Men were studied much more often than women, and research questions were formulated from gender-biased perspectives. For example, research on violence and aggression focused on male-male aggression ranging from animal territoriality to human warfare. Violence by men against women, particularly in the context of intimate relationships, was overlooked and under-studied.

Theories were constructed from androcentric perspectives, and women's behavior was judged against a (white, middle-class) male norm. Theories of lifespan psychological development, for example, were often derived entirely from research on middle-class men's life patterns. Women's behavior was more likely than men's to be explained in biologically determinist terms, with gender-differentiated social contexts ignored. For example, explanations of the greater incidence of depression in women focused on hormonal causes, not environmental ones like prior physical or sexual abuse. Psychological adjustment for women was articulated in terms of conformity to gender norms. However, because femininity (but not masculinity) was defined in opposition to agency, autonomy, and competence, these norms created many double binds for women. Feminist critics documented gender biases in theories of intelligence, attribution, social influence, learning, memory, thinking, identity, clinical diagnosis, and therapy, among others.

As a result of this critique, psychology began to develop new ways of thinking about women and gender, expand its research methods, and offer more gender-sensitive approaches to therapy and counseling. Contemporary feminist psychology, like most areas of contemporary psychology, is not a unified subject. Meanings are created in a community of practice: they change over time and as members of the community intersect with their other communities. Not all scholarship on the psychology of women is grounded in feminist perspectives, and no single feminist perspective unites all the work that is self-identified as feminist. Rather, an array of political stances is implicit in the scholarship in this area. Feminist psychology means different things to developmental, clinical, and social psychologists; to older second-wave activists and younger people enter-

ing psychology today; to researchers, educators, and practitioners. Most generally, feminist psychology is a form of critical psychology: it interrogates the moral, political, and scientific claims of psychology and attempts to influence the directions of the discipline. Its goal is the systematic analysis of women's psychology and of the impact of gender on human subjectivity and experience.

Subjective definitions are also important. Academic psychologists who self-identify as feminists define their identity in terms of a set of values—respecting women and their experiences, a concern with equality of power, the need for social activism, and the idea of gender as a social construct—and report that they experience feminism as a transformative personal experience.

2. Development and Contributions

One of the important early contributions of feminist psychology was the conceptual distinction between sex (conceived as biological differences between males and females) and gender (conceived as cultural elaborations based on biological differences). The distinction was important because it called into question the naive biological determinism and essentialism of much psychological theorizing. However, this approach later came to be seen as limiting because of its individualism. Although it distinguished social influences from biological ones, it still conceived of gender as a static set of attributes or personality traits, formed by socialization and relatively permanent within individuals. Moreover, the sex/gender distinction rested on the assumption that causation can be determined and is restricted to either nature or nurture, with little allowance for complex interactions of biological and social influences. And it foreclosed the possibility of examining the social construction of biological sex, only to be confronted with the transgender and intersex activist movements. In hindsight, the usefulness of distinguishing gender from sex was that it opened the way to conceiving of gender as a principle of social organization which structures the relations between women and men and governs access to resources. More recent formulations of gender stress its performative aspects; that is, gender is viewed as a set of agreed-upon transactions that are enacted in mundane social relationships.

Another early focus of research was replacing women in the history of psychology. The devaluation, stereotyping and invisibility of women in history had been played out in psychology; indeed, it was the recognition of the 'womanless' state of the discipline that energized the feminist critique of psychological research. Not only were women excluded from the profession, women and their characteristic experiences and activities were thought too unimportant to be a focus of inquiry. Although it originated as attempts to

restore the 'neglected foremothers' of psychology, this line of work catalyzed exploration of the structural and institutional mechanisms of exclusion. An underrepresentation of women in any scholarly discipline points to the importance of gender as a social and political category, prompting questions about how knowledge is sought, validated, and disseminated.

As more research centered on women and gender, new areas of inquiry were developed. Perhaps the most important contribution of feminist and gender studies in psychology is the wealth of new research generated. Uniquely female experiences such as menarche and childbirth have become legitimate topics of study and new feminist perspectives have been applied to them. A feminist critique of autonomy as the endpoint of psychological development grew into theories of the self-in-relation (see *Feminist Theory: Ecofeminist and Cultural Feminist*), and a feminist critique of masculinity/femininity grew into the construct of psychological androgyny (see *Androgyny*). Work on gender socialization, stereotyping, stigma, and objectification proliferated. Violence against girls and women was named and documented. Its causes, incidence, and effects were analyzed (see *Domestic Violence: Sociological Perspectives; Rape and Sexual Coercion; Sexual Harassment: Social and Psychological Issues*). The pervasiveness of gender as a cognitive category, and gender polarization as a cognitive mechanism, were explored. Developmental issues of childhood, adolescence, sexuality, motherhood, midlife, and aging were examined from women-centered perspectives (see *Motherhood: Social and Cultural Aspects; Sexuality and Gender*). New research examined the interactions of multiple roles (spouse, parent, and worker) for both sexes. Sexual identity and orientation were no longer taken for granted, but became active areas for developmental theory-building and empirical inquiry. Women's health issues, long neglected in behavioral and medical research, also became an active site of study. In clinical psychology, a new importance was attached to issues of power in social and therapeutic contexts: the power of diagnosis and labeling, power imbalances in close relationships (including the therapeutic relationship), and the effects of women's social subordination on psychological adjustment. Psychological problems that differed in incidence or characteristic manifestation according to gender (eating disorders, depression, substance abuse, and agoraphobia, among others) received new attention from feminist perspectives.

In interdisciplinary feminist theory there are many variants, including radical, socialist, psychoanalytic, postmodern, and womanist (woman of color). However, in psychology, liberal and cultural feminist approaches have predominated (see *Feminist Theory*). Both these theoretical frameworks are individualistic, leading to conceiving gender largely as a constellation of individual traits. This view of gender as rather static

and internalized has resulted in prolonged debates about the extent, importance, and mutability of sex differences. Liberal feminists have tended to minimize sex differences, arguing that they are small, relatively inconsequential, and easily eliminated with corrective socialization and education. This viewpoint has predominated in debates about cognitive abilities such as mathematics performance. Cultural feminists, on the other hand, have maximized differences, arguing for essential and fundamental divergences between women and men in such areas as identity, relatedness, and moral reasoning.

As the field has matured, there has been a turn away from these debates, which seem intractable, and an increasing interest in gender processes rather than gendered traits. In other words, gender currently is conceived not only as a phenomenon inside individuals but a system of agreed-upon meanings used in social interaction. An increased interest in how gender inequity is recreated and maintained in mundane social interaction is one result, with emphasis on such topics as cognitive bases of stereotype maintenance, gender-biased attributions of others' behavior, tokenism, self-fulfilling prophecies, sex discrimination, sexual harassment, hostile and benevolent sexism, and how the illusion of equity is sustained despite inequalities of status and power (see *Small-group Interaction and Gender*). This reconceptualization has brought social constructionist theory to the forefront and underlies a turn to language and discursive processes, particularly in the UK, where discursive psychology is more developed than in the US.

Feminist psychology has brought about a notable decrease in androcentrism in psychological research, education, and practice. Tangible changes include guidelines for nonsexist research and language in APA publications, the development of courses and curriculum integration resources, and the availability of nonsexist and feminist clinical training. In the US, women now account for 60 percent of Ph.D.s awarded annually in psychology.

There is also an increased presence of women, including lesbians and women of color, in APA's structure and on its policy-making boards and committees. In over 100 years as a professional organization, APA has elected only eight women (all white) to its presidency. The impact of second-wave feminism is evident: six of the eight were elected after 1970. In the UK, the first (woman-organized) psychology of women conference took place in 1987. A decade later, feminist psychology was a theme for the annual conference of the British Psychological Society.

3. Methodological and Theoretical Developments

The characteristic research methods of a discipline reflect its values and the assumptions it makes about its objects of study. Both first- and second-wave

feminists criticized psychology for sexist biases in research, pointing out problems with studying women less often than men, designing research materials from masculinist perspectives, using restricted samples, failing to compare women and men under similar conditions, and exaggerating or overgeneralizing about sex differences. With the second wave, however, came a more fundamental criticism, not of flaws and biases in the use of (otherwise satisfactory) methods, but of the value of the discipline's most characteristic and central methods themselves. Psychology, it was charged, over-relied on experimental methods, which strip behavior from its social context and position the experimenter as an expert manipulator of the participant and situation. Second-wave feminists have also criticized what they see as the naive belief that psychology can discover universal laws of behavior.

There is today considerable variability in the methods used to study women and gender within psychology. The majority of articles published in the two leading US feminist journals, *Psychology of Women Quarterly* and *Sex Roles*, as well as those published in general psychological journals, use quantitative methods such as experimental and correlational designs and meta-analysis. Only the UK journal *Feminism & Psychology* routinely publishes more qualitative and discursive work. However, even outside of feminist studies, psychology has a long tradition of inquiry that transcends laboratory manipulation of isolated variables: field research, observational techniques, content analysis, participant observation, and case studies are a few examples. A significant minority of feminist researchers draws on these traditions as well as newer, postmodern influenced forms of analysis. The feminist call for methodological plurality has had some effects. Special issues of *Psychology of Women Quarterly* have focused on method and theory (1989), transforming psychology (1994), and innovative methods for feminist research (1999).

In contrast to the positivist epistemology that permeated prefeminist research, feminist methodology is characterized by at least three innovations. First, feminist methods are reflexive: they involve recognition of the social identity and involvement of the researcher. Personal reflexivity involves disciplined self-reflection on how one's identity influences one's work and, in turn, how one's work influences the self. Moreover, a broader kind of reflexivity is also apparent—the maintenance of a critical perspective on the discipline and how its dominant paradigms are sustained by powerful institutions.

Second, feminist methods are meant to serve—not drive—the inquiry. There is little methodological elitism, and a great deal of creativity, within feminist psychology. The use of multiple methods within a single research project, and adaptations of methods more characteristic of other disciplines, are emerging practices. These innovations go beyond psychology's traditional concept of convergent validity, in which

different methods of measurement are applied to the same problem in order to strengthen the evidence for a hypothesis by accumulating different kinds of data. Instead, they are ways of creating dialogue between different approaches; they recognize that a method is a theory, and that different methods may lead to different—and incompatible—truths.

Finally, feminist research has a social change orientation. Within feminist psychology, advocacy and scholarship are not viewed as incompatible. Innovative work erodes the polarizations such as basic/applied and theoretical/practical that are maintained elsewhere in psychology. While the original goal of second-wave feminist critics was to eliminate gender bias and make psychology more objective, that feminist empiricist project has evolved into a more sophisticated one. Feminist psychology is no longer merely corrective or oppositional; it is transformative. Science is conceived as a social practice, and the tenets of empiricism, such as objectivity and validity, are subjects of feminist analysis. Alternative modes of research are being developed and recognized, and there is a great deal of practical research oriented toward understanding and resolving social problems.

4. Current Constraints and Future Directions

Despite the growth and gains of feminist psychology, the field has not developed adequately in some key areas. Theoretical initiatives have lagged behind empirical studies. The extended debate between cultural and liberal feminists over the extent and importance of fundamental sex/gender differences delayed recognition of the importance of studying gender as a set of interactional processes and a system of social meanings.

Moreover, despite the wealth of empirical research generated in the last three decades of the twentieth century, the knowledge base of feminist psychology is insufficiently integrated into psychology as a whole. Citation and content analyses indicate that the textbooks, standard courses, and major theories of psychology have been little changed by the availability of its new perspectives. Feminist work is still too easily marginalized and treated as optional.

Feminist psychology has not yet encompassed adequately the diversity of women, despite ongoing attention to this issue. Its research base and its practitioners are still largely white, middle-class, heterosexually identified, and British or North American. And its success in persuading the discipline as a whole to recognize that psychology's claims about human nature and human behavior are culturally and historically situated has been limited.

The relatively successful institutionalization of the psychology of women and gender (and of women) within psychology is not an unmitigated gain. At one extreme, some feminist critics have expressed the fear

that there can be no entity such as 'feminist psychology' without either distorting and weakening feminist commitments beyond recognition, or transforming psychology entirely. They claim that the former, and not the latter, is taking place: that the research that comes to be assimilated is a weak, individualistic 'psychology of women' and decontextualized 'sex differences,' and that there has been a loss of political activism within feminist psychology over time. However, others point to the large variety of topics, methods, and epistemological starting points represented in contemporary feminist psychology. The multiplicity of approaches allows for healthy dialogue and cross-fertilization, and the reflexivity that increasingly characterizes the field assures that the politics underlying the methods, questions, and practice of feminist scholarship will remain open to analysis.

Gender and Feminist Studies in Sociology

When feminists first started using the term gender in the early 1970s, the point was to make a clear distinction between how we are born (sex), from how our society shapes who we become (gender). In the process of studying how we become gendered people, feminist sociologists have changed our sense of both what gender is and of how we can best study social phenomena.

Like all sciences dominated by positivist epistemology, sociology traditionally has assumed that, appropriately conducted, it was objective, that is, had no point of view (see *Inferences, Psychology of*). As feminists began to struggle to make social science

useful for understanding the lives of women, we also began to uncover systematic biases in the tradition we inherited, for example, in the kinds of questions asked, the metaphors underlying governing theories, dominant conceptual frameworks, and the strategies used in gathering and analyzing data. These biases tended to follow a pattern. Sociology (like other sciences) was organizing knowledge from the perspective of the experiences and worldview of racially and economically privileged men (Sprague 1997).

As feminist sociologists have struggled to understand gender from the standpoint of women, we have found that it operates on at least three planes of human experience: as a personality structure, as a set of interactional practices, and as an aspect of social organization. Further, we have moved from seeing gender as something about all women and all men to discovering what gender is, how it works, and, therefore, how we might work to subvert it, varies in different intersections with race and class (see *Race and Gender Intersections; Social Class and Gender*). In sum, we have learned that what might appear to many people as a naturally occurring dichotomy of two opposite sexes is the complex outcome of a great deal of social effort and organization.

1. Gender as Something We Are

Most people who use the term gender probably think of it as an individual attribute, a personality structure that we are socialized into fairly early in life. There is a lot of evidence that we respond to children in gender-specific ways. Parents and other significant adults recognize different qualities in girls than in boys, for example, we tend to see girls as cute and loveable and boys as energetic and mischievous. Since we can only support the development of skills and tendencies that we can perceive, seeing girls as different from boys becomes a self-fulfilling prophecy. In attempting to please children, we give them the toys and experiences that our culture has led us to believe they will like and, eventually, that gender-specific advertising directed at children teaches them they should like. In the process, boys have been more likely to learn to like roughhousing and manipulating objects and girls have been more likely to learn to like taking care of others and dressing up and wearing makeup.

Sociologists operating in the tradition of feminist psychoanalysis (Chodorow 1989) say that the development of gendered personalities in contemporary Western society runs much deeper than developing skills and tastes that gender organizes our very sense of self and how we relate to others. Gendered selves are a consequence of gender beliefs in two ways. First, we assign primary responsibility for care-taking of the young to women and not to men. Second, we have learned to use gender as a key indicator of how we should respond and relate to one another. As a result,

children form their first attachments and develop their basic sense of self and their place in the larger community in very different kinds of relationships depending on their gender.

Boys develop their first attachment in a relationship with someone who has learned to understand herself and her charge as opposite sexes. The sexual opposition propels boys into seeing themselves as separate beings earlier in life and masculinity becomes an important part of how they understand their separateness and identity. As development leads to needs for increasing autonomy, the relative absence of males from primary care means that the people boys most need to separate from are women. Thus, an important means by which boys assert their independence involves rejecting the feminine within themselves.

On the other hand, mothers are not prohibited culturally from seeing girls as extensions of themselves, making the mother-daughter attachment much stronger and keeping it in force much longer. When girls do begin to differentiate themselves from their mothers, it is not as complete as it is for boys. Girls' struggle to develop a sense of an autonomous self is not based on gender identity and does not require a complete break from psychological connection with their mothers.

These gendered psychodynamics can be exacerbated in the learning of social roles. Children spend most of their time in domestic and care-taking sites. If girls learn that their most important roles involve taking care of others, they are in places and sets of relationships in which those roles can be practiced. If boys learn that their important roles occur outside their immediate domestic environment, they must acquire a sense of their adult roles by denying their connection to their immediate context and identifying abstractly with the public roles of their fathers and other men.

Their early experiences can lead to gender differences in how people think about themselves and their orientation to the world. Men tend to develop a highly individuated sense of self, an abstract orientation to the world, and contempt for women in general. Women, in contrast, are more likely to develop a connected sense of self embedded in concrete relationships, a more concrete orientation to the world, and hostility toward their mothers in particular.

The psychoanalytic account of gendered personality structure has given feminist sociologists a good deal of insight on how gender works. It explains why gender has such emotional power; why it generates so much anger, hostility, and fear, both interpersonally and in public debate. Men's psychic need to maintain an individuated sense of self defined by a fairly abstract notion of masculinity suggests why emotional intimacy can be threatening, and why men might be more worried about appropriately displaying (proving) their masculinity. If women have a relational sense of self, founded on a relationship with a female caretaker, we can expect they will seek to form strong emotional

bonds, particularly with other women. And, if our sense of who we are depends on distancing ourselves from a powerful mother, that might explain why women in powerful positions make many of us uncomfortable.

The kind of masculine self-psychoanalysis describes is also consistent with the pattern of conceptual organization that feminists have found runs through the organization of knowledge in Western culture, from religion to science (Harding 1998). Common patterns include organizing phenomena into isolated units, arranging them in hierarchies, particularly dichotomies, privileging abstract universals over contextualized understandings, and adopting explanations that best fit the experience of the privileged.

A major shortcoming of the approach that sees gender as something we are, is that it tends to reproduce these same patterns. It tends to represent masculine and feminine as abstract universals, and people as individual bearers of gendered selves, and it generalizes from the experiences of the privileged. As a result, the picture it gives us of gender is distorted.

While all children in the West and many children elsewhere are inundated with mass mediated messages about gender that reflect the beliefs and values of affluent whites, there is reason to suspect that families and communities in other classes and ethnic communities may communicate competing notions about gender to their children. For example, poor and working-class African-American communities in the US are more likely to teach girls to be strong and self-reliant rather than the dominant view of femininity as passive and dependent. Thus, children growing up in culturally marginalized communities are very likely getting mixed messages about their gender's roles and tastes.

Similarly, the psychoanalytic approach assumes a nuclear male breadwinner/female care-taker family structure, one in which few children in the world and increasingly few in West live. This bias is partially the result of the kind of data psychoanalysis tends to rely on: clinical interviews that select for a relatively affluent group, people who have the time and financial resources to undertake psychoanalytic treatment. While it is still the case that men are rare among those who do the work of caring for the young and it seems likely that female mother-surrogates will also relate to girls as like them and boys as the opposite sex, we need to ask how a variety of gendered care-taking relationships shape the development of personality structure.

Finally, seeing gender as an individual attribute makes it seem natural, almost voluntary, downplaying the degree to which gender differences in beliefs and behavior can be outcomes of differences in power and access to resources. Standpoint epistemology prompted some feminist sociologists to ask how people understand themselves and their lives and that drew attention to the impact of situations on behavior. It is well known that people act differently than they

feel in some situations, and act differently from one situation to the next.

Attempting to understand what gender means from the standpoint of actual people also made it apparent that the kinds of situations people are placed in—the constraints they face and the resources they have—differs markedly depending on what class and race/ethnicity they are. Conceiving of people as conscious actors creatively and strategically responding to variable situational demands led these scholars to uncover the situational and enacted character of gender.

2. Gender as Something We Do

From a social constructionist perspective, gender is not an internalized personality structure as much as it is a social fiction we work to maintain through our everyday social practices. We use gender as a lens through which to perceive and evaluate one another. We do not see one another as generic individuals but as men and women, and we have gender-specific expectations for what people are and should be like. We hold one another accountable for acting in ways our culture says are appropriate for our gender (West and Zimmerman 1987).

Knowing that others have gendered expectations of us, we take that into account in deciding how we will act. We work to construct an appearance that will make us classifiable into one of two opposed sex categories: we make choices about what we can and cannot wear, how we cut our hair, and if and where we shave. We take actions to alter the shape of our bodies: we diet, girdle, pad, exercise, and even undergo surgery. We monitor how we conduct ourselves. We understand the appropriate range of gestures and postures for our gender: more expansive and resolute for men, more constrained and passive for women. Traditionally the burden on women has been much higher than for men: the range of attractive faces and bodies, the expectations for clothes and comportment, have been much narrower, requiring more careful self-monitoring and adjustment (Kessler and McKenna 1978).

Being held accountable for performing in gender-appropriate ways in a value system that privileges a certain kind of masculinity puts women in a double-bind. At the same time women are expected to do more work on their bodies, display, and comportment, they are devalued for spending excessive time in trivialities. At the same time women are expected to do the work of facilitating conversation by asking questions, seeking to find topics that men will find interesting, they are derided for talking too much.

The nature of gendered expectations and the resources for meeting them are shaped by class and race/ethnic relations. For example, in the face of centuries of racist barriers to Black men's employment in the US, Black women often have been breadwinners

and have been criticized as matriarchs; economically discriminated against and forced into domestic work, they have been trivialized as 'mammies' (Collins 2000). Asian men immigrating to the US in the nineteenth and early twentieth centuries were 'demasculinized,' denied the opportunity to have wives by restrictions on the immigration of Asian women and laws barring interracial marriage, and forced into traditionally feminine work in domestic service (Espiritu 1997). Feeding the family, a central expectation for women in many cultures, is a constant struggle financially and time-wise for poor women, but it is constructed as trivial work assigned to lower status others by affluent women (DeVault 1991). Motherhood occupies a position of virtue and protection among the economically and racially privileged and is defined as a social problem among poor women, especially members of racial minority groups, who lack access to good paying jobs or husbands with steady employment, and often must rely on state support to raise children. Gendered interactional practices are embedded in every social institution. In schools, for example, responding to children in gender-specific ways influences how, and how much we teach them (Sadker and Sadker 1994). We are more likely to help girls by giving them the answer and to help boys by giving them clues that support their discovering the answer independently. Because girls have been trained to be more cooperative and complacent while boys are expected to be more rowdy and outspoken, engaging boys' interest becomes a higher priority for teachers. The need to keep the boys interested facilitates the development of male-centered curricula and class experiences. Boys learn they are doers, should have high expectations for performance, and develop independent problem-solving skills; girls learn they are observers rather than actors, and have lower and narrower expectations of their own ability.

Classrooms are not the only place where gender is enacted in school. Thorne (1993) has analyzed the ways that elementary school children impose gender-specific expectations on one another on school playgrounds. By fourth or fifth grade, children are imposing gender segregation. For example, boys taunt boys who like to play with girls or who do not act 'manly' enough. Boys play in large groups, evading close adult supervision while developing physical and team-building skills. Girls form shifting pairs of 'best friends' and organize themselves into emotionally charged status hierarchies based on who is friends with whom. They are verbally intimate and much of the content of conversation is about romance and boys, about 'liking' and 'going with,' that is, who can win what boy's approval.

By middle school and high school, the expectation for feminine behavior makes high academic performance a threat to displaying appropriate femininity. Many girls who previously earned self worth through school performance learn that they must switch

attention to winning the recognition of an acceptable male through being sexually appealing. They must walk a narrow line, however, if they are too sexual, they are derogated as 'sluts.' Boys must demonstrate their masculinity through their ability to use force skillfully, through sports and/or technology, and through their conquest of girls. Boys who do not display some sexual power over girls have their own sexuality called into question. Again, performance resources and standards vary by class and race. Economically privileged boys may be academic achievers without undercutting their masculinity; the poorest boys may have to resort to fights to enact their masculinity. African-American girls' self-esteem does not drop as far as that of white and Latina girls (see *Education (Primary and Secondary Schools) and Gender*).

Gendered interactions permeate adult lives. We make many of our decisions about allocating resources and responsibilities in social groups and these groups use gender-specific expectations for determining who will exert influence on decision-making (Ridgeway 1993). We are much more willing to be influenced by men than women: in the absence of information, we will assume that men have competence but that women do not. Men's ability to exert influence seems independent of their interactional style or their apparent motivation. Whether and on what terms we are willing to be influenced by women depends on what gender we are. Men are more willing to be influenced by women who speak tentatively and express priorities on group interests. Thus, women interacting with men are forced to choose between having influence and being seen as competent. All-woman groups, on the other hand, are more willing to be influenced by women who speak assertively and appear to be self-interested, but women like group-oriented women more so women in female groups must choose between having influence and being liked (see *Small-group Interaction and Gender*).

Evaluation is particularly central to workplace experiences—evaluations determine hires, pay, promotions, and the distribution of opportunity—and evaluation is a thoroughly gendered process. Martin (1996) finds that managers tend to see men as having more ability and potential, thus important to groom and mentor. This assessment is shared by male workers who are more likely than women to see themselves as entitled to and thus seek out opportunities and special treatment. In evaluating performance, managers emphasize men's successes and downplay their failures while they tend to do the opposite for women. We see men as entitled to authority but find authority in women problematic, especially when women have authority over men. We are much more comfortable with openly criticizing female colleagues than male ones.

One concrete and pervasive consequence of our holding people accountable for gender-appropriate behavior is the gender gap in pay (see *Sex Differences*

in Pay). Standard job evaluation ratings systematically discount the skills and responsibilities involved in jobs primarily held by women. If those jobs involve taking care of others, they are paid even less, presumably because it is assumed that meeting human needs is somehow a natural extension of an inherent ability to nurture among women.

Knowing others hold us accountable for gender-appropriate behavior and holding ourselves accountable leads us to act in ways that may not seem to be in our individual interests. For example, moving up a career ladder often requires relocating for a promotion or a better job, but women are less willing than men to disrupt their families by changing locations for personal advancement. Also, even women who work outside the home and bring in a substantial portion of the household income will do well more than their share of household labor and feel that the arrangement is fair. Men who might want to be more involved in domestic life are reluctant to be evaluated as less serious about their work. Seeing gender as something we do exposes its malleability. If our acting in gendered ways is at least partly the outcome of gendered expectations and evaluations, we can expose those practices and make choices about their appropriateness. For example, feminist scholarship uncovering biases in job and performance ratings has facilitated the feminist political campaign for comparable worth to develop a more equitable system (England 1992). There are constraints on what we can do to change gender. A standpoint approach to methodology and situational understanding of gender as something we do have helped feminist sociologists to see that situations are not randomly and spontaneously constructed. There are some larger regularities that shape systematically the kinds of situations we find ourselves in. Over the 1980s and 1990s, feminist sociologists increasingly have been talking about gender as a social structure or institution.

3. Gender as a Form of Social Organization

The idea that gender is a social structure or form of social organization has not yet been developed fully. The basic picture seems to be this: gender is the outcome when a society divides labor by sex, assigns the work of meeting human needs to women, and devalues that work. While dividing labor does not lead necessarily to differences in power, this has been the pattern in what are usually thought of as the 'great civilizations,' those social formations that have dominated the world. As we divide labor, we have created a hierarchy of power and authority, largely by separating authority and power from the work of taking care of people, directly meeting their physical and emotional needs.

Historically in the West and in many other cultures, men have been assigned to different social positions

than have women. During the period of industrialization, this sexual division of labor was institutionalized in a division between public and private spheres. Work directed at generating profit and rewarded with wages and other important benefits became defined as a male activity. The work of feeding, clothing, nursing, and otherwise directly meeting people's daily needs for subsistence and emotional support was defined as private, unpaid domestic work and assigned to women.

The public/private distinction has always been more fantasy than fact. The work of taking care of people is not purely a private matter: it occurs in every domain of life (see *Care and Gender*). There are whole professions built around the work of care-taking: education, medicine, and social work. Many debates about social service spending, for example, spending for childcare, healthcare, elder care—are really debates about the degree to which we should take public responsibility for paying for care-taking or allocate it to unpaid domestic labor. In most jobs, some workers make coffee, remember birthdays, listen to troubles, bring treats, and organize social events. This, too, is care-taking work and it, too, is assigned usually to women and not recognized as paid work.

The notion that women had been confined to the private sphere is also inaccurate. Even in the nineteenth century, many women, particularly poor and immigrant women, worked for wages (see *Household Production*). Also, women have done the labor of creating and sustaining communities through volunteer work for churches, charities, and social clubs. The sexual division of paid labor has been resilient over time (Reskin 1988). Even though more and more women have been entering paid labor over the last half of the twentieth century so that now a great majority of women work for wages, we still have primarily men's jobs and primarily women's jobs—there are few jobs where the proportion of women workers is even close to the proportion of men. When women have entered professions previously dominated by men, those professions frequently re-stratify themselves into gender hierarchies (see *Sex Segregation at Work*).

What seems to be a constant in the sexual division of labor is that directly meeting people's needs, especially basic bodily needs, is devalued and assigned to women, and, in some cases, to low-status men (Glenn 1992). The work of care-taking is unpaid or underpaid, unrecognized, or assumed to be instinctive. One indicator of privilege in a gendered form of social organization is the degree to which one can distance oneself from the 'dirty work' of care-taking. All women are held responsible for domestic work, but not all women end up doing it. At the turn of the twenty-first century, most women work for wages and still do the 'second shift' of domestic work (see *Family and Gender*). Those who are in more privileged economic situations hire poorer women to do some or all of the domestic work, either in their homes or

through the modern, commodified domestic labor of the burgeoning service sector with its restaurants, cleaning services, and services that care for and entertain children. Thus, those who are most removed from care-taking work are economically well-off men, typically white men. Those who are the most likely to be involved in it are women, particularly poor women, disproportionately women of color. Increasingly, men and women in higher status jobs are opting out of parenting altogether.

The sexual division of labor is increasingly organized internationally (Mies 1986; see *Economic Globalization and Gender*). Women in countries of the South produce much of the food, clothing, and other commodities that women in the North put to work in their domestic labor. Male-dominated multinational corporations collaborate with male-dominated governments to maintain local policies that restrict the rights of laborers. The extremely low wages and bad working conditions that result from this collaboration enable the generation of high profits. The super-exploitation of third world workers, especially young women, undercuts the situation of working-class men and women in the West who see good jobs and secure futures disappear as more and more factories move offshore.

The sexual division of labor helps support men's political and economic power: their freedom from responsibility for domestic work has allowed them the time and energy for participating in the organizations and activities that underwrite their continued domination (Connell 1987). Men control industry, central state planning, and the means of institutionalized violence, the military and paramilitary institutions. Men dominate the institutions that produce official culture: science, the academy, the mass media. Even though women do the great majority of the work in the world, wealth is concentrated in male hands.

Their command over institutional resources gives some men a base from which to form alliances in solidarity with one another and against the interests of women (see *Male Dominance*). They have used this power to limit the public resources that go to the work of raising children and caring for the frail (see *Social Welfare Policies and Gender*). They allow wages in the workforce to be determined by 'the market,' thus reproducing the existing pattern of valuing men's work over women's. They have restricted women's ability to control their own fertility via birth control and abortion (see *Reproductive Rights in Developing Nations*; *Reproductive Rights in Affluent Nations*). They have raised obstacles against women's solidarity through sanctions against lesbianism (see *Lesbians: Social and Economic Situation*). This combination of practices pushes women into dependence, either on individual men or on the collective male-dominated state (see *Poverty and Gender in Affluent Nations*; *Poverty and Gender in Developing Nations*).

Gender as a form of social organization has until

recently involved two overlapping dichotomies. The social division between those who control and those who do the work of meeting human needs has until recently overlapped with a sexual dichotomizing of men and women. Perhaps what we are seeing in the West is the development of a reorganized gender order, one in which men and women are being further subdivided based on whether or not they have care-taking responsibilities.

4. Conclusion

Feminist sociologists have found that gender organizes our sense of self, is a set of expectations we encounter and must deal with in our daily interactions, and is a form of social organization shaping opportunities and constraints. These are all aspects of the same process. People's selves are the products of relationships and experiences shaped by where they are in a social order organized by gender, as well as race and class. That social order is the crystallization of myriads of daily interactions in which people evaluate and hold one another accountable for behaving in gendered ways. The nature of the expectations individuals confront and their ability to negotiate the outcomes of these interactions depend on the kinds of personal strengths, cultural advantages or disadvantages, and material resources they bring to each. Understanding how this multi-faceted process works, and how we might work to subvert it, requires looking at it from diverse perspectives, including variations in sex, race, class, and nation. The more we do, the more it seems that gender organizes us into many more than two categories.

Gender and Health Care

The healthcare system is a deeply gendered social institution, often affecting men and women in dramatically different ways. In the United States and many European countries, healthcare occupations are sex segregated: men constitute a majority of physicians, while women are concentrated in occupations that are less prestigious and poorly paid. Because women are more likely than men to seek medical treatment, they are the principal consumers of healthcare. However, research has demonstrated differences in the kinds of healthcare men and women receive, differences that often place women at a disadvantage. Together with inequalities of race, socioeconomic status, and age, gender shapes both the healthcare delivery system and the quality of healthcare men and women receive (see *Socioeconomic Status and Health; Minority Access to Health Services: United States*). Focusing on developments in the United States, this

article discusses men and women's encounters with the healthcare system, as both practitioners and recipients of healthcare.

1. Origins of Interest in Women and Healthcare

Interest in gender and healthcare developed from the engagement of the social sciences with the second wave of feminism that flourished in the 1970s. Feminists made medicine the centerpiece of their analysis, arguing that no institution so clearly epitomized women's subjugation. They developed a far-reaching critique of the healthcare system, which attacked: medicine, for its exclusion of women; the overuse and misuse of drugs, surgery, and technology; and physicians, for withholding information from their patients and trivializing women's concerns. Feminists asserted the right to be full and equal participants in medical decisions.

The women's health movement was particularly influential in the social sciences with, historians, anthropologists, and sociologists testing, applying, and extending feminist ideas. The result was a body of theory and research that reshaped how disciplines conceived of healthcare. In medical sociology, for example, theory and research on gender and healthcare has challenged fundamental assumptions of the medical model (Mishler 1981). Researchers have challenged the assumption that definitions of health and illness are unaffected by the social context by showing them to be culturally variable and historically contingent. Anthropologists, for example, have shown considerable cross-cultural variation in how menstruation and menopause are defined and treated (Lock 1993). Studies revealing gender showing that male and female patients presenting the same symptoms receive different diagnoses and treatments have challenged the assumption that medicine is scientifically neutral. Research on gender and health has been part of the move to create a social perspective on health, illness, and medicine.

2. Gender and the Medical Division of Labor

2.1 Gender and Healing: A Brief Historical Overview

Both men and women have been healers, although their roles have varied historically. By the end of the Middle Ages, the medical division of labor had assumed a form that was to continue in many European countries until the nineteenth century: a largely male stratum, consisting of guilds and dominated by university-trained physicians; and midwives and folk healers, usually women, who served the rest of the population (Ehrenreich and English 1978).

In nineteenth century America, multiple paradigms of healing existed in competition. The predominately male allopaths or 'regulars' served a wealthy clientele in Eastern cities. Regulars were known for treating disease with harsh remedies, such as purging and bleeding. Women were often rejected from regular medical schools and forced to attend women's colleges or proprietary colleges. Women (as well as some African-Americans) were also more likely to enter the schools of the sects that proliferated during that period. In contrast to regulars, sectarians avoided harsh remedies, and most served a rural or working-class clientele (Ehrenreich and English 1978).

At the beginning of the twentieth century, the leadership of the regulars, influenced by progressivism, began a campaign to make medical education more 'scientific,' culminating in the Flexner Report of 1910, a study of medical education commissioned by the Carnegie foundation. As a result of both licensing and the Flexner Report, medical education became university-based and grounded in laboratory science instruction. There were, however, additional consequences. Lacking the resources to build laboratories, proprietary colleges, including sectarian colleges, saw their enrollments dwindle. With the closure of the proprietary colleges, most women, African-Americans, and members of the working class, could no longer obtain a medical education. Medicine became a profession of a white, male elite. The process continued as many states outlawed midwives (Ehrenreich and English 1978) (see *Medical Profession, The*).

Excluded from medicine, many women chose the fledgling profession of nursing. In both the United States and England, the first professional nursing programs were established in the nineteenth-century after Florence Nightingale successfully commanded a contingent of nurses during the Crimean War. Some of Nightingale's views were to become a mixed blessing in the twentieth century. During the Crimean War, she ruled that no nurse could act without explicit orders from a doctor. Throughout the twentieth century, nursing has struggled to regain the autonomy from medicine that Nightingale had forfeited (Freidson 1970).

2.2 The Contemporary Medical Division of Labor

For most of the twentieth century, the gender composition of the American healthcare occupations has followed a single principle: the higher the prestige, power, and pay of the occupation, the smaller the proportion of women. Medicine, the most lucrative and prestigious occupation in the United States, remains a predominately male profession. Although the number of women physicians increased fivefold since 1970, in 1998 less than 23 percent of all physicians were women. Only three percent of all women physi-

cians—or less than one percent of all physicians—were African-American (Pasco et al. 2000–1).

Medicine also remains internally stratified by gender. Women generally are concentrated in the medical specialties having the lowest incomes, such as pediatrics, psychiatry, and family practice—specialties involving considerable direct patient contact. Conversely, the lowest proportions of women are found in the most lucrative specialties, radiology and surgery—specialties that involve medical procedures and require less patient contact. Moreover, the medical subspecialties are themselves internally stratified by gender. Very few women enter the most lucrative surgical subspecialties, such as orthopedic surgery. Within internal medicine, the proportion of women is lowest in cardiology and gastroenterology, subspecialties similar to surgery in their use of procedures and their salary structures (Pasco et al. 2000–1, Wassenaar and Thran 2001–2). The practice patterns of men and women physicians place women at a disadvantage. Women physicians are more likely than men to work in the least lucrative practice arrangements, that is, to be salaried employees (Wassenaar and Thran 2001–2). Less than five percent of women physicians enter administration, teaching, and research—sectors in which the leadership of the profession is found (Pasco et al. 2000–1).

Discrimination against women physicians extends to medicine's informal structure. Disturbing proportions of women physicians report experiencing sexual harassment (Olesen 1997). Women physicians are often excluded from sponsorship networks that channel medical students into prestigious specialties and enable younger physicians to establish practices (Lorber 1984).

Contrasting with medicine is a middle level consisting almost entirely of women, most of whom are white women (Olesen 1997). This level includes the allied health professions—registered nurses, pharmacists, dietitians, and therapists—as well as licensed medical technicians. These professions are also stratified according to race, with the largest percent of women of color found in the occupations with the lowest salaries.

Women allied health professionals and technicians usually advance more slowly and than men in those occupations. For example, the small number of men who have entered nursing have been promoted very quickly to administrative positions (Williams 1992). Women earn less than men who do the same work, and they also earn less than men in predominately male occupations who do different but comparable work. Pharmacy, the only predominately male allied health profession, is also the most lucrative. Pharmacists earn more than nurse supervisors even though researchers found the latter job to be more demanding (Achtenberg 1991) (see *Health Professionals, Allied*).

At the bottom of the occupational hierarchy are the health service occupations, consisting primarily of aides, orderlies, and attendants. Women represent

nearly 90 percent of this group, which also has the greatest proportion of black workers. As care of the chronically ill moved out of the hospital and into the home, the number of home health aides has increased. These jobs, typically performed by women of color and immigrants, are compensated at levels at or below the poverty line (Olesen 1997).

Women also perform most of the unpaid, informal caregiving for sick relatives in the home. Caregiving entails a number of strains, including: loss of social relationships outside the family; interference with work roles; and the strain of performing multiple caregiving roles simultaneously (Olesen 1997). Perhaps the greatest strain arises from the assumption that responsibility for providing care rests exclusively with women (see *Caregiver Burden*)

3. Gender and Medical Encounters

Although the number of female physicians increased dramatically, the most typical medical interview is likely to involve a male physician and a female patient. This pattern raises the question of whether the gender of either physician or patient affects the physician-patient relationship. *Are Male and Female Patients Treated Differently?* Differential treatment can assume two forms. First, physicians can interact differently with female patients by adopting a more controlling communication style or by giving them less information. Second, physicians may give a different diagnosis or recommend a different treatment to male and female patients with similar medical problems.

Some of the first studies to identify the structure of the medical interview were conducted in obstetrical and gynecological clinics. These studies found that physicians: persuaded patients to use or forego specific treatments by presenting information selectively; made recommendations that reflected cultural assumptions about gender (e.g., that only married women should have children); and gave poor women fewer choices than educated, middle-class patients (Fisher and Todd 1986).

These studies show that assumptions about gender affect the content of the medical encounter but do not demonstrate that male and female patients are treated differently. Studies comparing physicians' communication with male and female patients present contradictory findings. On the one hand, physicians spend more time with female patients and give them more explanations, possibly because women present more symptoms and ask more questions (Elderkin-Thompson and Waitzkin 1999). On the other hand, communication between male doctors and female patients is likely to be viewed as problematic: physicians report liking male patients better, and women are more likely to report that physicians talked down to them and trivialized their concerns (Elderkin-Thompson and Waitzkin 1999).

The second question, whether gender influences medical decision making, has been studied extensively. Research undertaken in the 1970s and 1980s tested the hypothesis that primary-care physicians share the commonsense stereotype of women as more emotional than men and are more likely to interpret the women's physical complaints as psychogenic. Consequently, physicians may overlook a physical disease or incorrectly diagnose a psychological disorder. Studies of routine decisions of internists and family practitioners provide strong support for the hypothesis that physicians stereotype female patients as more emotional, and weaker, more equivocal support for the hypothesis that stereotypes result in unequal treatment (Weiss and Lonnquist 1997).

In the late 1980s and 1990s, research on gender bias focused on specialists' decisions, particularly those involving 'high technology medicine.' Even after adjusting for confounding variables, many studies have found male and female patients with heart disease to be treated differently at one or more of the following decision points: women are less likely than men to receive prompt attention in the emergency room; less likely to be hospitalized; less likely to receive noninvasive diagnostic studies, such as treadmill tests, less likely to be treated with thrombolytics ('clot busters'), and less likely to receive invasive diagnostic procedures, such as catheterization. Women, particularly black women, are less likely to undergo angioplasty or undergo coronary bypass surgery. When they do receive angioplasty or surgery, they are referred later in the course of their disease—a pattern that may contribute to women's higher surgical mortality (Beery 1995). Recently, women have also been found to be less likely than men to receive kidney transplants (Elderkin-Thompson and Waitzkin 1999).

These findings should be interpreted cautiously for two reasons. First, a substantial number of studies has failed to find evidence of gender differences in one or more of the treatments of heart disease that have been mentioned. Secondly, because these studies use information extracted from written documents, they do not reveal the actual decision-making process culminating in differential treatment. Several explanations of these findings regarding heart disease have been proposed (Beery 1995). (a) Perceived risk of procedures. Physicians may be reluctant to perform angioplasty and cardiac bypass surgery on women because they view them as more risky for women. In fact, women who undergo bypass surgery are older, have higher comorbidity, and are at a later stage in their disease. However, this pattern may also reflect physicians' reluctance to diagnose and treat women with heart disease at earlier stages. (b) Beliefs about heart disease. The misconception that heart disease is a 'man's disease' may prevent both physicians and women from recognizing the symptoms of heart disease. (c) Different symptoms. Whereas men experience chest pain, women are more likely to have

shortness of breath or epigastric pain, more subtle symptoms that might be not be correctly identified. (d) Cultural assumptions about gender. This explanation receives empirical support from a study of chest pain evaluation in an emergency room, which found men more likely to receive emergency cardiology consults, nitroglycerin, aspirin, and thrombolytic agents but women more likely to receive anti-anxiety drugs (Lehmann et al. 1996). This finding suggests that physicians may fail to diagnose heart disease in female patients because of a belief that their symptoms are psychosomatic. (e) Presentation style. Some writers suggest that women's greater tendency to introduce contextual information into the medical interview may cause their complaints to be discounted or interpreted as psychosomatic (Elderkin-Thompson and Waitzkin 1999).

3.1 Do Male and Female Physicians Differ?

Many studies have examined whether male and female physicians differ in attitudes and values, choice of medical treatment, or interactive styles. This research presents a mixed picture. On the one hand, male and female family practitioners do not differ in their evaluations of common medical problems (West 1993). On the other hand, women physicians are more likely than their male colleagues to order preventive screening; to use a more collaborative mode of interaction; to engage in discussion of psychosocial issues; to deal with emotions; and to create opportunities for their patients to participate in the medical exchange (Roter and Hall 1998). When giving instructions to patients, male physicians are more likely to use the imperative, whereas women are more likely to use requests rather than commands, thereby creating more symmetry in the doctor-patient relationship (West 1993). In most cases, then, the physician's gender is more likely to affect the *style* of communication than to affect the *content* of medical decisions.

Although women first-year medical students show greater commitment to the interpersonal dimension of healthcare, by the time they have completed medical training, women are no more patient-oriented than their male colleagues. Sex role socialization, then, is only one of many forces that shape physicians' attitudes and behavior. Its effects diminish as men and women undergo a similar training and encounter pressures arising from similar work environments (Weiss and Lonnquist 1997, Olesen 1997).

These considerations suggest that increasing the number of women in medicine is a necessary, but ultimately insufficient condition for creating a humane healthcare system responsive to the diverse needs of both men and women. It is necessary because of what women contribute to the medical encounter. It is insufficient, however, because of the absence of women

of color and because very few women physicians enter teaching, research, and administration. What is needed are women who occupy positions of leadership within medicine and are able to reshape the medical curriculum, revise the textbooks, and influence funding priorities.

4. Gender and the Social Construction of Health and Illness

Research on gender and health has demonstrated that conceptions of health and illness are historically contingent, culture-bound, and ineluctably tied to the social context out of which they arise. These changing conceptions have affected the ways women's medical problems have been treated.

In the nineteenth century, for example, Victorians viewed women's psychological complaints as diseases of the uterus or ovaries caused by deviation from their social roles. Their treatments ranged from 'rest cures' to sexual surgery to remove the uterus or ovaries (Ehrenreich and English 1978). Ostensibly scientific ideas were used to make claims about women's proper place.

Although these ideas no longer hold sway, twentieth-century conceptions of illness, like those in the nineteenth, continue to be socially created. In the twentieth century, social and cultural forces have led to the increasing medicalization of women's lives—a process that proved consequential for women's healthcare.

4.1 Medicalization

A persistent trend in Europe and America is the extension of the medical model to an increasing number of deviant behaviors and natural processes. Women, particularly middle-class women, have been deeply affected by the tendency to treat the reproductive phases in the female life course—childbirth, menstruation, and menopause—as illnesses (Riessman 1983).

Since the 1800s, childbirth in the United States has been transformed from a natural event, taking place at home and assisted by midwives into a medical event managed by obstetricians. By the middle of the twentieth century, childbirth in America had been medicalized to an extent unparalleled elsewhere in the world. Women were subjected to myriad medical procedures, such as epidural anesthesia, forceps, and fetal monitors. However, US infant mortality rates continue to surpass those of other European countries in which medicalization has been less extensive (Riessman 1983).

Medicalization is also behind the controversial definition of premenstrual syndrome (PMS) as a

psychiatric disorder. Despite the lack of consensus as to how the condition should be defined and despite the lack of evidence that women's moods vary according to their menstrual cycles, PMS was included in the revised third edition of the American Psychiatric Association's *Diagnostic and Statistical Manual* and has even been proposed as a criminal defense (see Tavris 1992). Some doctors have treated women diagnosed with PMS with hormones. The medicalization of PMS can be a double-edged sword. On the one hand, women may be relieved to learn that they suffer from a real illness. On the other hand, the medicalization of PMS in the criminal law may revive the nineteenth-century view that women's mental lives are controlled by their reproductive systems.

There is reason to believe that the origins of PMS are cultural rather than hormonal. Since 1931, descriptions of this condition have varied considerably. In periods in which women were expected to work, the effects of PMS were depicted as mild. During periods in which women were expected to leave the labor market, the effects of PMS were described as debilitating. Further, although middle-class women interviewed in one study viewed themselves as suffering from PMS, working-class women did not believe in its existence.

In Europe and the United States, menopause, once viewed as a natural process has been defined as a disease requiring medical treatment. Inequalities of age and gender combine to create a highly negative view of menopause in medical texts, which depict menopause 'hormonal failure' having far-reaching consequences for the heart, the skin, and the skeleton and requiring treatment with hormone replacement therapy (Lock 1993).

These views of menopause are deeply culture-bound. In Japan, views of the aging woman are shaped by concerns with population aging, cultural views of the women's roles rooted in ancient Japanese society, and the preoccupation with work. In Japan, menopause has not been medicalized although aging women are nevertheless stigmatized as unemployed caretakers. Since women are viewed as 'natural' caretakers, government officials have suggested they should become full-time caregivers of both aging parents and aging in-laws. It is these issues, rather than their hormones, that concern Japanese women (Lock 1993).

4.2 Medicalization and Medical Technology

Medicalization is often accompanied by the growth of medical technologies. In fact, medicalization is encouraged by the drug companies, who have a stake in promulgating the ideas that pregnancy, PMS, and menopause are diseases requiring treatment.

Early studies of estrogen replacement therapy, DES, and the Dalkon shield focused on their rapid diffusion into medical practice before their consequences were

known and the drug companies' delay in recalling these technologies even after their risks had become apparent. (see Riessman 1983). This pattern, however, has occurred with other medical technologies unrelated to women's health.

More recent research has focused on the social consequences of new reproductive technologies, such as genetic screening, *in vitro* fertilization, and fetal surgery healthcare. Some new reproductive technologies have diminished women's control in decision making, while augmenting the power of professionals, social movements or the state. For example, the use of implantable contraceptives by the poor or by women in developing nations raises the spectre of a powerful group or society controlling the fertility of the less powerful (see Ruzek et al. 1997). New diagnostic technologies diminish the importance of women's experience of their bodies and force them to depend on experts to interpret the new technologies. With the development of ultrasound, for example, women became less reliant on their own experience of fetal movements and more reliant upon experts to help them 'see' the fetus in an otherwise obscure sonogram (Duden 1993).

Some commentators fear the potential of some new medical technologies to devalue the mother while increasing the social value of the fetus. For example, the new specialty of fetal surgery results in the creation of an unborn patient—the fetus—while the mother becomes peripheral to the treatment process (Casper 1998). This trend has culminated in the fetal rights movement, in which African-American mothers accused of using drugs have been prosecuted for allegedly endangering fetal health or even forced to undergo Caesarian sections. In these cases, women lose control of reproduction, which has been taken over by the state.

Most critics of new medical technologies do not simply assume that all medical technologies are intrinsically harmful to women. Rather, most take the more nuanced view that the consequences of any technology depend largely on the social context in which it is deployed.

4.3 Demedicalization of Reproduction

In the United States, broadly-based social movements have attempted more recently to demedicalize childbirth. In the 1960s, some middle-class parents sought alternatives to the medical model, even to the extent of bypassing the hospital altogether and turning to lay midwives. At the same time, the women's health movement challenged professional dominance even to the extent of usurping what had been previously considered professional prerogatives (Ruzek et al. 1997).

As a result of these social movements, alternatives to labor and delivery have developed, including home

births using lay midwives or nurse midwives and delivery by nurse-midwives in free-standing birth centers (Rothman 1983, Riessman 1997). These alternatives encourage mothers and families to become actively involved in the birth process, avoid technological interventions, and rely on hospitals only when complications arise.

While organized medicine has opposed home births and attempted to regulate freestanding birth centers, hospitals have accommodated the demands of many middle-class parents for a less medicalized childbirth by creating alternative birth centers in hospitals and by offering Lamaze classes. These changes, however, do not fundamentally challenge the technological and interventionist model of conventional medicine.

Despite opposition, home births and freestanding birth centers have continued through the end of the twentieth century. However, these social movements have appealed exclusively to a small, educated, middle-class clientele—a limitation that will be discussed in the next section.

5. *Intersecting Inequalities*

In the 1980s and 1990s, research on gender and health moved away from an exclusive focus on gender and toward understanding how gender intersects with race, class, and other forms of inequality. Academic feminist influenced by postmodernism criticized treating gender as a unitary category and eliding differences among women. As scholars and activists struggled to understand why the women's health movement had appealed only to white, middle-class women, it became apparent that many women had perspectives and interests that diverged from those of white, middle-class women. For example, disability activists oppose prenatal testing and the selective abortion of 'defective' fetuses—policies that, in their view, symbolically devalue the disabled. Nonwhite women and women of low socioeconomic status, lacking access to basic healthcare, seek to the very high-technology medicine that white, middle-class women reject. Women of color, for whom forced sterilization campaigns in the 1970s are a recent memory, seek protection from the enforced use of the very technologies white women view as a social good. Because medical technologies may benefit some women to the detriment of others, it is misleading to extrapolate from the experiences of one group of women and generalize about women as a whole (Ruzek et al. 1997) (see *Minority Access to Health Services: United States; Socioeconomic Status and Health Care*).

The focus on differences among women has opened avenues of inquiry. One line of research examines how the divergent worldviews of middle and working-class women result in different perspectives on abortion or reproduction (Luker 1984). Another line of research explores the role of race, class, and gender in shaping

healthcare policies. For example, the early birth control movement emphasized the potential of contraception to enhance reproductive freedom of all women. As control of the movement shifted to physicians and eugenicists, its focus shifted to population control, directed toward controlling the fertility of those deemed 'unfit' (Gordon 1983). Future research should also examine the differential impact of healthcare policies on different groups of women.

The mandate to study differences among women consumers of healthcare has yielded a richer and more complex picture of diverse women, whose perspectives and interests sometimes collide and sometimes coincide. Once these differences have been identified, it may be possible to draw more meaningful generalizations about the kind of healthcare that serves diverse women.

R. R. Anspach

Gender and Language: Cultural Concerns

Research on gender and sex in sociolinguistics and discourse analysis started systematically in the early 1970s, probably as a result of women's liberation movements. Investigators examined two domains of language behavior in particular: speech behavior of men and women on the phonological level, and interactions (conversational styles) between women and men in discourse (for overviews and the history of the field see Wodak and Benke 1996, Holmes 1996,

Wodak 1997, Kotthoff and Wodak 1997, Wilkinson and Kitzinger 1995, Crawford 1995, Hall and Buchholtz 1995).

1. Setting Out the Problems

Studies of gender-specific language behavior are often contradictory and depend on the authors' implicit assumptions about sex and gender, methodology, and samples used, etc. For example, some studies suggest that women use more standard language than men because they try to adapt to social norms (Trudgill 1974). On the other hand, other large-scale surveys have shown that young women tend to speak dialect and nonstandard language as well (Wodak and Dressler 1978), due to specific situations like family conversations and peer group talk.

The socialization of infants is often regarded as primarily the duty and work of mothers; mothers use 'motherese,' a very specific discourse adapted to the needs of infants (see Wodak and Rindler-Schjerve 1985); as a result of caretaking, children acquire the regional dialects and vernacular which their mothers use at home. Other investigations illustrated that professional women are under more pressure than their male colleagues; therefore they adopt high standard sociolects or even hypercorrect features (see Labov 1966, Moosmueller 1997). However, hypercorrectness is also clearly related to social class: Working-class and lower-middle-class men also tend to speak hypercorrectly in certain organizational contexts (Leodolter 1975). Very detailed case studies of code switching, moreover, have shown that the use of either standard or nonstandard styles as well as minority and majority languages depends highly on the context of the utterances as well as on social class (Gal 1989). Nonstandard lects can also be the manifestation of certain political opinions and attitudes as in the case of Ebonics (see Baugh 1999).

The same variation of correlations is true for studies on conversational styles: In some cultures, men clearly interrupt women more frequently and dominate topic choice, but in other cultures this need not be the case (see Shieffelin 1990). As a result, women's language has been said to reflect their conservatism, prestige consciousness, upward mobility, insecurity, deference, nurturance, emotional expressivity, connectedness, sensitivity to others, solidarity, and men's language is heard as evincing their toughness, lack of affect, competitiveness, independence, competence, hierarchy, control (Eckert and McConnell-Ginet 1992, p. 90).

Many empirical studies have thus neglected the context of language behavior and have often analyzed gender by merely looking at the speakers' biological sex (see the arguments in Nichols 1983, Cameron and Coates 1990, Henley and Kramarae 1991). By focusing

only on the biological sex, the whole group of women is contrasted to the whole group of men without taking differences in these holistic categories into account (see below).

Such a dichotomization clearly does not make sense when looking at many studies which have shown significant differences that occur with women or with men due to culture, social class, ethnicity, etc. (Wodak and Schulz 1986, Kotthoff and Wodak 1997). Some of the research has isolated the variable of sex/gender from other sociological or situational factors and has made hasty generalizations about genderlects (Chambers 1992). A context-sensitive approach, however, which regards gender as a social construct leads to more fruitful results (see Harres 1996, Wetschanow 1995). Moreover, gender is related to and overlaps with the sociocultural and ethnic background of the interlocutors, with their age, their level of education, their socioeconomic status, their emotions, and the specific power-dynamics of the discourse investigated.

The focus nowadays lies on the discursive construction of identities in interaction where gender is but one part of this attempt (Wodak et al. 1999). Thus, research on gender should take the whole interaction and context into account; of course, the biological sex will always be part of a categorization but other categories might prove more valid in a specific research which makes it possible to operationalize gender roles (the inclusion of professional roles and organizational roles with gender is of utmost importance as well as culture and ethnicity; the socialization of women who come from Islamic cultures is so different than the background of Western European women that intercultural problems clearly arise in interactions, see Martin-Rojo 2000, Wodak 2000a, Essed 1992, 1997). All these results suggest that gender has an enormous impact in many very relevant situations, like schools, hospitals, courtrooms, etc., but only in combination with other variables. However, it is not possible and is fruitless to try to decide which variable has more impact generally. Only very detailed qualitative studies can provide insight into such complex theoretical questions.

2. Feminist Linguistics

Analogous to the term 'racism,' the word 'sexism' was invented in the 1960s. It refers to discrimination within a social system on the basis of sexual membership. With the concept of 'sexism,' women defined themselves for the first time as a social group and as a suppressed minority expressing basic political interests of being judged and valued in equal terms as men. Of course, the history of women's fight for equal rights is much older (see Saurer 2000) but the political movements in the 1960s, together with innovations like the invention of the contraceptive pill and birth control on

a larger scale started a qualitative new time for women's emancipation. As such, they sought to reveal the mechanisms of suppression, making others aware of and fighting these devices. Social groups often define themselves by means of their common language, which plays an important role in identity creation and, for subcultures, serves as a means of differentiating themselves from the outside world. This specific identity manifests itself in certain conversational styles, manifestations of emotions, etc. (see Coates 1997, Buchholtz et al. 1999).

According to Hellinger (1990), feminist linguistics (FL) is distinguished from all other disciplines by the following three aspects, which similarly analyze the relationship between language and gender:

(a) FL places female and male linguistic behavior and the linguistic phenomena connected with the designations of women and men at the center of its considerations.

(b) FL interprets person-related asymmetries in the field of language systems and language use as expressions of the linguistic discrimination of women (sexism) and links these directly to the plane of social discrimination. Traditional studies usually make do with descriptive results. Clearly, languages differ in their linguistic realizations of such inequality. In German or Polish, for example, suffixes and certain prefixes manifest gender. Kargl et al. (1997) have submitted a whole register of possibilities of equal treatment of women and men in many everyday genres in communication, starting with names and labels up to whole reports in newspapers, as well as conversations. These attempts are valid in written as well as oral speech and have led to huge debates in the media (see Pusch 1984); in German, specifically, the use of capital 'I' in written texts was at the center of such political discussions (i.e., '*LehrerInnen*' vs. '*Lehrer*' and '*Lehrerinnen*' or '*Lehrer/jinnen*').

(c) FL does not accept phenomena as given, but seeks alternatives in keeping with the principle of the linguistic equal treatment of women and men. It pursues explicitly political goals by criticizing ruling linguistic norms and understanding the linguistic change it advocates as part of an overall change in society (Hellinger 1990, p. 12).

3. Sociolinguistic Studies of Sex/Gender

In the 1970s, 'sex' was established within sociolinguistic research as a social variable next to the already existing variables of social stratum, age, nationality, ethnic affiliation, religion, class, and region. In correlative-quantitative sociolinguistic investigations on the prestige and stigma variants of languages (see Kotthoff 1992) the sex variable became a factor which significantly affected the use of language. The best-known representatives of this quantitative-correlative approach in sociolinguistics,

with its focus on urban groups of persons, are William Labov, Peter Trudgill, and Lesley Milroy. The working methods within this sociolinguistic approach diverge considerably from one another in certain aspects (unlike Trudgill and Labov, Milroy works with network analyses) but in one respect they are identical: their methodology. All of them operate quantitatively, that is, linguistic variables are defined that are realized in different forms in different varieties. Then, the different variants are correlated with sociological parameters.

Several other studies have taken different approaches and have used new and other methodologies. In particular, a lot of criticism related to the implicit chauvinistic ideologies in these first studies and also to the undifferentiated analysis of the two sexes which totally neglected the range of variation in each of the genders under observation. In a study of the language of mothers and daughters in Vienna, for example (Wodak 1984, Wodak and Schultz 1986), it could be shown that, apart from these sociological parameters, other variables, such as psychological ones, are also responsible for the variation concerning each gender. This study stressed in particular the variation that was found among the women and girls investigated, one that relativized the factor of 'sex.' It could be shown that mothers with a positive relationship to their daughters spoke differently than mothers with a conflicting relationship. The same is true for the daughters (30 mother-daughter pairs were interviewed and tested). These results illustrate that emotions and relationships as well as educational styles and the content/discontent of mothers are more important than social class in an isolated way. Moreover, this study proves that the differences in one category of sex can be statistically significant due to all these parameters.

Such results and tendencies are of utmost importance for the whole debate on gender and sex as well as social class. First, it could be shown that significant differences exist in one category (either women or men). Second, many assumptions about the differences between working-class and middle-class socialization could be contradicted—educational styles do not vary so much by social class but more by the self-assessment of mothers and their attitudes to their own life and achievements. Third, it could be shown that no significant differences appear between mothers who work at home and mothers who have professional lives outside of their homes. Therefore, many claims that children need mothers who only stay at home are wrong; the satisfaction of women with their own lives is the most important factor that affects their relationship with others, in their families or outside of their homes. Fourth, generalizations about the use of vernacular and dialect could also be contradicted: Even daughters from upper-class families used Viennese dialect to distinguish themselves from the phonological styles of their mothers and to be able to

manifest their autonomy. This study illustrates the necessity of a very complex and interdisciplinary approach to gender research.

Another approach of considerable importance in recent sociolinguistics is the concept of 'communities of practice' (Eckert and McConnell-Ginet 1992, p. 92ff). Communities of practice are defined as 'An aggregate of people who come together around mutual engagement in some common endeavor. Ways of doing things, ways of talking, beliefs, values, and power relations—in short, practice—emerge in the course of their joint activity around that endeavor' (Eckert and McConnell-Ginet 1992, p. 95).

This approach relates to the proposals of context sensitivity made above: While researching gender, the emotions, attitudes, values, intergroup and intragroup relationships have to be accounted for as well. Specifically, Eckert and McConnell-Ginet studied peer groups of girls and boys and could illustrate why big differences on a phonological and conversational level occur between two groups due to all the above-mentioned factors. Eckert and McConnell-Ginet argue very convincingly and provide many examples to support their view that survey studies are too general and their level of abstractness too great because all the important sociological and psychological parameters cannot be integrated. Moreover, and this criticism applies to survey studies in general about other topics as well (e.g., research on anti-Semitism and racism, Wodak et al. 1990), surveys usually manifest self-assessments of the interviewees. A bias due to education must be considered as well: Better educated interviewees usually know what kind of answers are expected from them. They answer accordingly even though this might not be their opinion at all. This bias is very important in all studies related to stereotypes and prejudice research. Therefore, such quantitative studies must be complemented with qualitative case studies using authentic data tape-recorded in everyday interactions as well as ethnographic observations (see Titscher et al. 2000).

4. Sexism and the Language System

Feminists conceive language as 'a symbolical reflection of androcentric structures' (Günthner and Kotthoff 1991, p. 7), as one of the means of patriarchal society to discriminate, disregard, and incapacitate women. In their view, the language system already reflects the patriarchal structure of Western societies. Such an assumption manifests a basic consideration of sociolinguistics, namely that language and social norms are connected and that language manifests and also constructs social practices (Fairclough and Wodak 1997). If this claim is accepted (and such theories stem from Wittgenstein's 1967 concept of 'language games'), then the manifestation of women's domination must also be manifest in language.

The assumption that an individual language system has lexical elements and morphological and grammatical rules that are already sexist is based on the premise that 'due to their long history as public decision-makers, men not only determine the economic, political and social orientation of social life, but also influence the functioning and the semantic contents of each individual language' (Postl 1991, p. 89).

Once the language system has become the object of investigation for feminist linguists, it is interesting to note how the linguistic structure of an individual language is connected to the structure of society, how the structure of the language is conditioned by the structure of society, and vice versa. Unlike studies investigating divergent gender linguistic behavior, studies on the sexist use of language focus on the possibilities of reference to both genders or their practice that exist in an individual language. According to Pusch (1984, p. 7), the objects of 'feminist system linguistics' are 'patriarchalisms in diverse language systems.'

5. *The Analysis of Conversation and Discourse*

Unlike the above-mentioned research field, FL—which examines the use of language—concerns itself with gender differences in conversation and discourse (oral as well as written). Differences are investigated in the following fields of language use: voice, pronunciation, intonation, choice of words, argumentation, lexicon, syntax, interactional and conversational behavior, as well as visual features and modes and nonverbal communication. The gender-induced differences in the use of language are not treated simply as divergent variants standing side by side. Due to a patriarchally organized society, the interpretation of the differences ascertained is of major social and political significance.

The interpretation of the diverse linguistic indicators (like turn taking, indirectness, interruptions, and overlaps) varies according to the specific gender theory and ideology, which underlie the studies. (Due to the fact that there are no comparable standardized studies across cultures and social classes as well as contexts and ethnicities, no generalizations about any universal gender or sex-based differences in conversational styles are possible.) Probably the two best-known theories about the gender-induced use of language are those of 'difference' and 'dominance' (see Cameron 1997, Kendall and Tannen 1997).

Whereas investigations following the 'deficit model' have interpreted the use of such indicators as manifestations of 'powerless language of women,' research in the paradigm of the 'difference model' views the linguistic behavior of men and women as originating in opposed modes of socialization and equal in their meaning and impact. Hedging, tag questions, or indirectness can be viewed 'negatively' or 'positively,'

either as signs of female insecurity or as supporting conversational work, depending on the context of the discourse and the theoretical approach adopted. This controversy led to many polemical debates which in the end shows the invalidity of such dichotomous distinctions. Thus, nowadays, other research questions have become more important, viewing gender as constructed due to context.

6. *Recent Theoretical Approaches in the Feminist Study of Discourse*

6.1 *The Construction of the 'Sexes'*

In Judith Butler's arguments against the tenability of the categories of 'woman' and 'sex,' she refers to postmodernist theories. In the manner of Foucault she ascribes normative power to the idea of gender identity and the attempt to describe it. By the mere act of defining a gender identity many bodies, practices, and discourses are excluded or devalued, whereas the constructed and hence upright character of this gender identity is simultaneously concealed.

Thus, in such feminist theories (Butler 1990), the idea of two sexes is criticized as being a construction, a prediscursive factor taking the place of reality. Following this interpretation, 'sex' cannot be separated into a biologically inherent aspect and a socially acquired one. The category of 'sex' itself, in Butler's view, is a purely cultural product of discourse. Such an opinion, of course, relates well to Foucauldian theories of discourse; 'sex,' therefore, cannot be viewed as a 'universal, suprahistorical and extrasocial entity'; it is understood to be an 'integral component of every form of life' (Butler 1990, p. 23); such a view relates well to the assumptions of context sensitivity discussed above. On the other hand, 'sex,' of course, possesses a material basis: In many relevant contexts in our societies, women and men are still evaluated, judged, promoted, or paid according to their biological sex alone. These facts are not accounted for in Butler's approach. More recently, some authors have differentiated Butler's dogmatic position: It is a question of revealing 'the reproduction mechanisms, networks and institutional compulsions that ensure that constructions become persistent and resistant and appear timeless, immovable and identical with themselves' (Hirschauer 1992, p. 333). It is a matter of exposing the arbitrary construction of this binary opposition and hence also its mutability, and not of criticising the binarily organized perception as unreal.

6.2 *Doing Gender*

Unlike a research approach that accepts sexual differences as an aggregation of qualities and deals with the qualitative behavioral tendencies of women and men,

ethnomethodologically oriented studies produced a new focus of research: 'doing gender.' Such an approach complements traditional theories which viewed gender as an aggregation of static attributes and are concerned with investigating and displaying the peculiarities of women and interpreting them as 'gender-specific' or 'gender-typical' attributes so as to reveal the asymmetry of the difference between the sexes, to criticize it and to make it politically visible. The use of a bundle of characteristics and attributes to define gender complicates or renders impossible an interactional approach since attributes are 'entities' and not processes. This concept entails that definitions of gender cannot change, transform, and are not influenced by, spontaneous interactions. A further problem raised by the concept of gender as a concept of attributes is the possibility of individualization; that is, the individual who has been seen to possess or not to possess certain attributes becomes the centre of focus, and the level of the social system is neglected.

Unlike this noninteractive approach, 'doing gender' regards membership of a sex not as a pool of attributes 'possessed' by a person, but as something a person 'does.' In this sense, membership of a gender constitutes a performative act and not a fact. Gender is continually realized in interactional form. Gender is created not only in the everyday activities that characterize 'doing gender,' but also in the asymmetry of the relationship between the sexes, the dominance of the 'male' and its normativeness. Patriarchal inequality is produced and reproduced in every interaction. This concept of 'doing gender' stresses the creative potential and the embedding of gender-typical behavior in a social context.

Female Members of the European Parliament, for example, have created very different ways of positioning themselves in interactions with male colleagues in the European Commission or in the European Parliament itself. Interviews with female MEPs (Wodak 2000a) illustrate that they are very conscious of their gender roles and that they tend to construct very different ways of self-presentation in interactions: in particular, one MEP stated the following, in talking about her first experience as a rapporteur.

when I—entered the parliament— *Orientation* (lines 1–3)
on my first report it was about Leonardo
I don't know if you know:
((laughing)) well—I said 'I'm going to speak to the commissioner'
and—I—I knew—he only speaks very bad French
and my er my French was very bad as well.
so I said 'I want to have interpretation'
So—I went to the commissioner *Complicating Actions* (lines 4–14)
with a very good int/int/interpreter
and I/I/I/I talked more than an hour with him.
because we talked the same about it
and at the end he said—
'well: I have here the advice of my: civil servants but I—agree with you:

and this and this and this all goes through—'
so you have to be: —er—
I don't know/h/ow do we call it in English in /
in the Netherlands we say [brutal]
so you have to: ((laughing)) be polite *Evaluation* (lines 16–20)
but you have to—you:/you mustn't be/
you mustn't *sit* behind your -/your desk—
because that doesn't help. ((laughing))
but then then you have the worse system
that I tried several times *Coda* (22–31)
then you have the Council. ...

In this example, which has been marked for basic narrative structure according to Labov and Waletzky's (1967) model, we see that this MEP's story is objectively about having a successful meeting with a Commissioner while acting as rapporteur on a report about Leonardo—an EU youth and education related program established in 1995 to provide financial support for professional development and job training. In lines 4–6, the complicating actions, she shows how she went to the commissioner with an interpreter, and because she and the commissioner had the same understanding of the issues involved, he was willing to support her, despite contrary advice by his 'civil servants' on the matters involved. The main point of the story, or evaluation, from the MEP's perspective, is to show that as an MEP, to get things done, you must be active and assertive, 'not sit behind your desk.' Thus, in this narrative, she positions herself as an MEP who is proactive and who will do what it takes, including arguing directly with Commissioners, to see that her voice is heard. She also orients to being a rapporteur (line 2), which carries some responsibility in a committee, and to being from the Netherlands (line 17), although this last identity is evoked only to characterize her style of work ('brutal' in Dutch, or 'assertive'). (For further details of the analysis see Wodak 2000a). This narrative also manifests the complexity of the European Parliament, the interwovenness of languages, cultures, positions, political affiliations, and gender roles, as well as professional experiences.

Another of the interviewees is oriented to a particularly wide range of identities (left, woman, Swedish, mother, political outsider, etc.) during her interview. Most striking is the way in which she repeatedly positions herself as being an 'atypical MEP.' Here we see one such occasion.

I figure here the most common—ah civil—job—for an MEP
is er to be a lawyer.
me myself *I'm far from that*
the job I had doesn't even *exist* outside *Scandinavia*.
so: it's a sort of a social teacher—so
so I'm/I'm very in/an/a very special bird in this er:
Interviewer mhm mhm so now you don't feel like you—fit
into sort of a *typical* MEP er
ME *no. no. no: I'm not. I'm left I'm a woman I'm Swedish*
and I'm also everything—/everything's wrong (laughs)
