In this example, the MEP contrasts herself with what she considers to be a typical profile for an MEP (lawyer by profession), emphasizing the degree to which she feels different (I'm far from that ... I'm a very special bird ... everything's wrong'). She also points out many of the identities that she associates with and that she perceives as marking her as different (social teacher, left, female, Swedish). This MEP is very much concerned with her self-presentation as being different, different than other female MEPs and also male MEPs. Moreover, she explains her success as a female MEP by being exotic and narrates different strategies which she applies in 'doing politics and gender.'

Even such short examples illustrate the diversity and complexity of gender roles and make clear why an interdisciplinary, qualitative, and context-sensitive approach is necessary to access the whole domain of 'gender and language.' To be able to make more general observations, however, much more cross-cultural comparable research is urgently needed.

Gender and Physical Health

The health experiences of women and men differ, primarily reflecting gender differences in the cultural and socioeconomic circumstances of women's and men's lives. Gender is an important dimension of social life which intersects with others, especially social class and age. In this article gender differences in mortality and morbidity are examined, together with explanations. The divergent structural and role positions of women and men lead to gender differences in

the nature of inequalities in health, which vary over time and among societies.

1. The Distinction Between Sex and Gender

Expressed simply, sex refers to the biological differences between men and women, and gender refers to cultural differences relating to appropriate behavior of men and women. Gender roles are socially constructed and therefore change over time and across societies. The cultural and religious mores of a society influence the roles, attitudes, and behavior of men and women. Gender ideology prescribes and circumscribes the social behavior of men and women, and of different age or ethnic groups. Social myths and stereotypes about appropriate or supposedly 'natural' behavior for women and men impact on their health and well-being, for example, relating to body image and weight control (Lorber 1997).

1.1 Masculinity and Femininity

Over recent years the simple dichotomy of biological sex has been questioned, as has the cultural gender dichotomy of male/female. The distinction between masculinity and femininity is increasingly recognized as a continuous dimension, with each individual having both masculine and feminine attributes in varying degrees. Masculinity and femininity are inherently relational concepts, arising from gender relations in particular socio-historical contexts.

In Western societies, masculinity has traditionally been identified with physical courage, stoicism, hardness, endurance, aggressiveness, and taking risks. However, notions of masculinity vary with class and ethnicity, across the life course, over time, and among societies (Watson 2000). Structural factors and power relations among men in society may influence forms of masculinity which themselves have health consequences.

The 'risk' taking behavior of men is a key concern within health promotion and public health, but here masculinity is often seen as a unitary construct. Sabo and Gordon (1995) characterize masculinity as intrinsically damaging to men's health, in terms of predisposition to drinking, smoking, drug abuse, risky sports, and so on. However, this sees maleness as problematic, fixed, and immutable (Watson 2000), and fails to examine diversity among men.

In many cultures, illness is seen as a sign of weakness, closely allied to contemporary constructions of femininity, and thereby more easily accepted by women. In particular, chronic illnesses which undermine independence and self-control may threaten masculine self-identity. Masculinity and femininity may therefore influence the way symptoms are evaluated, willingness to consult healthcare providers

and to take medical remedies. This may help explain men's lower use of available health services.

2. Women's and Men's Health

2.1 Women's Health

In the 1970s and early 1980s, the primary focus of interest within medical sociology was women's health rather than gender and health. Biological differences were emphasized, linked to women's distinctive reproductive system, with social research on the specialized services for childbirth, contraception, abortion, and infertility (Doyal 1995) (see *Gender and Reproductive Health; Women's Health*).

Many women in developed countries expect pregnancy and birth to be a normal event, but their experience of maternity care is often a medicalized search for pathology. Medicalization in other areas of women's lives has received less attention from sociologists. There are rising rates of hysterectomy, while the menopause provides a new opportunity for medical intervention in mid-life, especially through the promotion of hormone replacement therapy (HRT).

The impact of gender roles on reproductive health needs to be considered. For example, women's capacity to control their fertility through contraception and abortion is influenced by partners, family members, governments, religious, and other social institutions. It is also important to examine the effects on women's reproductive health of poverty, class, race and ethnicity, and sexual orientation.

2.2 Women and the Male 'Standard' Patient

The focus on women and reproductive health has led to a lack of attention to women as patients within mainstream areas of health. The biomedical or scientific model assumes that disease is a deviation from 'normal' biological functioning. However, what is regarded as normal depends on who is being compared to whom. Men are treated as the 'norm' and women compared to a standard 'male' patient (Lorber 1997). Medical norms and research have primarily been based on white, male, middle class, working age bodies. This approach also disadvantages men, since they are seen as the normal, the 'control,' to which women are compared. This inhibits exploring diversity among men's health and recognizing that maleness itself is a cultural and social phenomenon.

Epidemiological research and clinical trials often exclude women or fail to include them in sufficient numbers, for example, in research on coronary heart disease (CHD) and AIDs (Sharp 1994, Doyal 1995). This lack of medical research on women means that less is known about the effects of drug or surgical treatment regimes on them.

Differences in men's and women's reported illness rates may result from diagnostic behavior and treatment by physicians, as well as gender differences in the process of seeking care—'illness behavior.' Reported gender differences in CHD may partly reflect doctors' behavior. US women are less likely than men to be diagnosed as having heart disease or to undergo coronary angiography or bypass surgery (McKinlay 1996). Thus, rates of recorded illness may differ from the 'true' prevalence in systematic and gender-related ways.

The image of CHD as predominantly affecting men is prevalent in the media, medical advertising, and among the medical profession. There is less publicity and discussion about the risk of CHD for women than men. Yet CHD is the most common cause of death for women. Similarly, there is high public concern with female-specific cancers, such as breast cancer and cervical cancer, and less publicity and research attention on other cancers such as stomach and lung cancer among women (see *Gender and Cancer; Gender and Cardiovascular Health; Gender and Health Care*).

2.3 The Emergence of Men's Health

A marked imbalance exists between the extensive literature on women's health and the paucity of research on men's health. Men's ill-health has remained a largely neglected area, with a lack of studies examining lay ideas about health and illness among men (Watson 2000), and men are often cast as a homogeneous group (Cameron and Bernardes 1998). While some conditions, such as CHD and lung cancer, have been highlighted, other areas, such as prostate problems or mental health, have been given little priority until recently.

Empirical work on ill-health conditions specific to men reveals a variety of problems stemming from the social invisibility of men's illness. In research on prostate problems, Cameron and Bernardes (1998) found that men regarded health as women's responsibility, knew little about men's health, and tended not to talk about any prostatic health problems they had experienced. Prostate problems appeared to represent a threat to the men's sense of masculine self.

In all societies, whether symptoms are perceived as illness by individuals is influenced by cultural values, gender roles, and family interactions. Health professionals also play a key role in defining presented symptoms as 'sickness,' sanctioning entry into the 'sick role,' and making decisions about treatment, all of which may be influenced by gendered norms and assumptions (see *Men's Health; Body Image and Gender*).

2.4 Gender Analysis of Health

A gender analysis of health sees both women's and men's health within the wider context of social and

economic relations between women and men. It recognizes the impact of gender inequalities in power and economic resources on both men's and women's health.

Many women perform the 'double shift' of housework, childcare, and paid labor, so it is important to assess how combining paid and unpaid work affects their health and varies with socioeconomic circumstances (Doyal 1995). Men's health may benefit from the unpaid labor of their wife in providing domestic services and health care; there is substantial evidence that married men have better health and health-related behavior than never married or previously married men.

Women provide the majority of care for elderly, frail, or disabled relatives (Arber and Ginn 1991). Caregiving places a major burden on carers, with consequences for their physical and mental health. The role of unpaid carers in the community is becoming increasingly significant within Western health care provision, as hospital stays become shorter, shifting the costs of care onto family members. The policy of promoting community care and de-institutionalization therefore has a gendered effect with a greater impact on women, who form the majority of carers.

Many women experience rape and domestic violence, which have adverse physical and mental health consequences, but the extent and nature of that violence varies among and within societies (Koblinsky et al. 1993, Doyal 1995). Violence is more common where men's masculinity is defined in terms of dominance, and women are relatively powerless economically and socially. Another form of culturally-sanctioned violence in some societies is female circumcision, which results in deaths, as well as pain, chronic urinary problems, and higher levels of maternal and child mortality.

3. Gender Differences in Mortality

In nearly all countries women outlive men. Four broad patterns of sex differences in mortality can be identified, each related to gender roles.

3.1 Women Outlive Men by 5–7 Years

This pattern is found in most Western countries. For example, in the UK in 1995, expectation of life for women was 79.4 years and for men 74.1, a 5.3 year difference; in the US, it was 78.9 for women and 72.5 for men, a 6.4 year difference; in Sweden, women outlive men by 5 years (expectation of life of 81.5 and 76.5, respectively), and in Japan by 6.6 years (83.6 and 77 years, respectively) (UN 1999).

The 'norm' of women having a 5–7 year longer life expectancy than men is the product of women's biological advantage and men's greater mortality from occupational hazards and risky behaviors such as

smoking, drinking, dangerous sports, fast driving, and violence. As women in Western countries have entered the workforce in larger numbers over the last 30 years and the male excess in smoking is now very small, there has been a reduction in the gender disparity of mortality (Hemstrom 1999). This trend is expected to continue as the lifestyles of women and men converge and women undertake more risky health behaviors.

3.2 Women Outlive Men by 2–4 Years

This pattern is exemplified by European countries in the mid-nineteenth century, and is currently typical of many developing societies in Africa and Asia. For example, in Kenya the expectation of life for women is 61.4 and men is 57.5 (a 3.9 year difference), and in China is 52.9 for women and 50.1 for men (UN 1999). This modest female mortality advantage is typical of transitional societies, where the previously high maternal mortality rate is falling, but where women occupy a disadvantageous structural position with adverse effects on their health. As countries move towards greater economic development and more education for women, the sex gap in mortality tends to increase.

3.3 No Gender Difference or Men Outlive Women

In some developing countries, there is little gender difference or men outlive women. In Bangladesh men outlive women, with an expectation of life of 58.6 for men and 58.2 for women. In Pakistan and India the sexes have almost equal life expectancy (in Pakistan, 59.0 for men and 59.2 for women, and in India, 59 for men and 59.7 for women) (UN 1999). This pattern occurs in countries where women's social status is very low. Women are more likely to have poor nutrition, have less access to healthcare, are subject to frequent births, and have high maternal mortality (Doyal 1995).

3.4 Women Outlive Men by Eight or More Years

This pattern is exemplified by countries in the former Soviet Union and among blacks in the US, partly reflecting a deterioration in men's life expectancy since 1980. In Russia, expectation of life is only 58.3 for men and 71.7 for women (a 13-year difference); the corresponding figures for Latvia are 63.9 and 75.6 (UN 1999). In some Eastern European countries and the former Soviet Union, mortality rates have risen for men over the past 20 years, but fallen or remained stable for women, showing how men and women can be affected differently by social and economic changes (Hemstrom 1999). There have been greater threats to the economic and psychosocial well-being of men in these societies, many of whom have lost a secure 'bread-winning' role. The fall in life expectancy of US

black men relates to socioeconomic disadvantage, unemployment, alienation, drug abuse, and violence (Lorber 1997).

4. Explaining Gender Differences

A range of types of explanations have been put forward to account for gender differences in mortality and in health. However, there can be no simple interpretation, since women have health advantages in some aspects while men are advantaged in others.

(a) *Biological differences* associated with genetic factors, including hormonal differences, tend to advantage women. However, the range of gender differences in mortality identified in Sect. 3 clearly demonstrates the importance of factors other than biology.

(b) *Psychosocial differences* between men and women may be related to socially-created differences in personality, coping behaviors, and self-efficacy, which influence the experience and reporting of symptoms. These include gender role orientations, associated with masculinity and femininity, discussed in Sects. 1.1 and 2.3. Emslie et al. (1999) show that high 'femininity' scores are associated with poorer reported health.

(c) *Risk behaviors.* Epidemiologists are particularly concerned with gender differences in health promoting and health damaging behaviors. In most societies, men have higher levels of smoking and drinking, including more 'binge drinking.' However, in Western countries women have a better diet and participate more in preventive health measures such as screening. The growing trend for women to engage in smoking, drinking, and more risky behaviors has been termed the 'female emancipation hypothesis' (Hemstrom 1999).

(d) *Occupational and work-related factors.* Health hazards are associated with both paid work and unpaid domestic work. Working class men have traditionally been employed in more dangerous occupations with greater industrial health hazards. Much of women's paid work is repetitive in nature and lacks autonomy, which may create stress and repetitive strain injuries (Doyal 1995). In addition, unpaid domestic or family work may involve hard physical labor, such as in developing countries carrying water long distances and heavy agricultural production.

(e) *Social roles and relationships* differ between women and men and may impact on health. Women in Western countries often have better social networks than men, and can more easily rely on contact with close friends and relatives in times of crisis and stress. Marriage may provide a major source of social support, but in a different way for men and women and across societies. In terms of social support, marriage seems to be good for men but less so for women. Men tend to rely more on their wife for social support and a confiding relationship, with divorced

and widowed men reporting particularly poor self-assessed and psychosocial health.

(f) *Power and resources within the home.* Patriarchal control within the family and domestic settings may lead to exploitation of women and violence against them. Women's lack of power and influence in the home and lack of access to valued resources (of food, opportunities for leisure, income) may have adverse health consequences.

(g) *Social structural differences within society.* Women in most societies are more likely than men to be poor, have less education and live in disadvantaged material circumstances, all of which are likely to be implicated in gender differences in health.

(h) *Health service related factors.* Women may have less access to health services in developing countries, but in Western countries women generally make greater use than men, both because of using health care associated with reproduction and contraception, and the gendered meanings of illness discussed in Sect. 1.1. There may also be gender differences in diagnosis and treatment, see Sect. 2.2.

5. Gender Differences in Morbidity

It has become accepted wisdom that 'women are sicker, but men die quicker' (Lahelma et al. 1999). The higher morbidity rate but lower death rate of women was characterized by Nathanson (1975) as a 'contradiction' which required explanation. Other authors in the 1970s and 1980s repeatedly demonstrated that females had higher rates of illness than males. A number of the explanations put forward related to gender-appropriate behavior, for example, that women tend to over-report morbidity more frequently than men.

There have been recent changes; in the 1990s in European countries, relatively modest gender differences in overall measures of health and well-being were found, which are less important than the previous orthodoxy suggested (Macintyre et al. 1996, Lahelma et al. 1999). Macintyre et al. (1996) examined different measures of health using various datasets and found no female excess morbidity on many health measures.

However, major gender differences in mental health remain substantial. Women are more likely to report a range of neurotic disorders, for example, anxiety and depressive disorders, although when men's higher rates of alcohol and drug dependence are included, there is a much smaller gender difference in the prevalence of psychiatric disorders. Moreover, older women are more likely than older men to suffer from physical conditions which are nonfatal but result in chronic and disabling illnesses (Lahelma et al. 1999, Annandale and Hunt 2000). In Britain, nearly twice as many women as men over 65 suffer from functional impairments sufficient to require help on a daily basis to remain living in the community (Arber and Ginn 1991). A key concern is the extent of gender difference

in 'healthy life expectancy,' that is, the period of life without disability or chronic ill-health. Because of women's higher level of disability, the gender difference in 'healthy life expectancy' is smaller than in life expectancy.

6. *Structural Inequalities in Health Among Women and Men*

In the late 1970s and 1980s, many researchers began to focus on differences in health *among* women. Early work examined to what extent additional roles, such as the parental role and paid employment, had beneficial or adverse consequences for women's health (Arber 1991). While a growing body of research, particularly in Britain, studied inequalities in men's health.

More recently, researchers have stressed the importance of examining women *both* in terms of their structural position within society and their family roles. This approach examines how socioeconomic circumstances, together with marital and parental roles, influence the health of women and men. The key structural variables influencing health are occupational class, employment status, and educational qualifications. The effect of women's family roles on health depends on the material resources of her household (Arber 1991, 1997).

Changes in family structure since the 1970s, particularly the growth in lone parenthood and cohabitation, are relevant to gender differences in health inequalities. The previous orthodoxy that married women have poorer health than single women no longer holds in Britain (Annandale and Hunt 2000), possibly reflecting changes in the meaning of marriage in the late twentieth century and the opening of career opportunities for married women which previously only existed for single women. Lone mothers report the poorest health, largely due to living in disadvantaged material circumstances.

A gender analysis of health requires consideration of differences in the structural position of women and men within societies, in terms of power, occupational status, income, and lone parenthood. It is therefore essential to examine the extent to which gender differences in health may be explained by women's social, income, and political disadvantages.

7. *Gender and Health Across the Life Course*

During the twentieth century there have been radical changes in actual and expected gender roles, as well as in norms about age-related behavior. Gender roles and responsibilities are socially constructed in ways which vary across the life course. Thus, gender differences in health are likely to reflect gender socialization as to behavior at different stages of the life course. Thus the nature of inequalities in health for

men and women may vary for different age groups (Annandale and Hunt 2000).

The health and other characteristics of women and men are influenced by their prior life course. This is vividly seen in later life, since the financial well-being of older adults is intimately tied to their previous role in the labor market and private pension acquisition. A life course approach emphasizes the linkage between phases of the life course, rather than seeing each phase in isolation.

Research often neglects gender differences in health in childhood and later life, while the dominant concern is working age adults. During the working ages, family structure has a greater effect on women's than men's health. Married men and women report the best health, irrespective of whether they have children, but lone mothers report the poorest health. Class continues to be a major factor determining the health of working age British men and women. However, other structural variables are likely to become increasingly salient in the twenty-first century. Whether or not a person is in paid employment has become a key marker of health status, while educational qualifications increasingly differentiate health, especially among women.

In later life, previous occupational class is the key determinant of health for older British men and women (Arber and Cooper 1999). The similarity in the pattern of class inequalities in health for older women and men is surprising given that the majority of the current generation of older women have spent less than half their adult life in paid employment.

The nature of health inequalities between women and men is likely to differ over time and across societies, reflecting gender roles and relationships historically and cross-nationally. Taking a life course approach provides added insights into the mechanisms underlying the creation and perpetuation of gender inequalities in health.

Gender and Place

'Gender and place' as an interdisciplinary field of study emerged during the 1970s. It attempts to identify ways in which gender stereotypes and spatial arrangements reinforce each other. Over its brief history, the field has become increasingly differentiated with respect to definitions of both place and gender. Spaces that acquire meaning through use or history are 'places' consisting of cities, neighborhoods, buildings, and even the human body. 'Gender' extends beyond the dichotomy of masculine and feminine to encompass gays and lesbians in a continuum of identities.

1. Introduction

'Gender and place' is a nuanced term for 'sex and space.' Both phrases refer to the ways in which gender or sex-role stereotypes are built into, and reinforced by, spatial arrangements. Take the adage that 'woman's place is in the home.' When ideology dictates

that women should occupy only the domestic sphere, they seldom learn skills that would prepare them to enter public spaces like colleges and the workplace. Conversely, men who spend their days in corporate boardrooms rarely are expected to excel at housework and childcare. Feminine and masculine activities both shape, and are shaped by, built environments. Homes, for example, are still more likely to evoke feminine connotations than offices and factories regardless of the number of women in the labor force.

Social scientists use 'gender' to represent socially constructed masculine and feminine characteristics, while 'sex' refers to the biologically determined categories of male and female. One's sex is determined at conception, but one's gender identity develops over the life course and can fluctuate across a wide continuum of masculine and feminine characteristics. Girls who work on the family car in the garage and boys who cook meals in the kitchen are exhibiting gender characteristics incongruent with those expected of their sex; they are also occupying spaces inconsistent with gender expectations.

Place is to space as gender is to sex. Actual spaces can be designated with commonly understood boundaries, but 'places' transcend simple attempts at measurement. Places are spaces imbued with significance, just as gender adds meaning to sex. The space of a neighborhood park may be a place to play for children, a place to sleep for the homeless, and a place to walk the dog for apartment dwellers. The park can be all of these places simultaneously or sequentially. Like gender, place is socially and subjectively created from objective elements. The park may occupy a *space* the size of a city block, but it functions as a *place* for fun, shelter, or exercise depending on one's construction of its purposes.

Space and place are quite different concepts. Space is abstract and limitless, while place is bounded and refers to a setting infused with identity and memory. Another way to think of space is as a location or site of activity. 'Location' is objective, as when real estate agents identify a house by its distance from an elementary school. Place is subjective. One neighborhood close to a school might be described as a 'good place to raise children,' while another neighborhood, equally close, fails to receive the same endorsement. Such different assessments could result from the type of housing or size of yards, but they all affect the 'feel' of the place. In short, space and location are analyzed and measured; place is experienced.

The analysis of gender and place is interdisciplinary in that the field seeks to combine the spatial orientation of geographers, architects, and urban planners with the social focus of anthropologists, sociologists, and historians to understand the ways space and gender mutually reinforce one another. A brief review of the literature reveals that its focus has grown steadily more differentiated. Places range from the geographic

scale of the city or neighborhood to the human scale of the body. Gender identities include masculine, feminine, gay, lesbian, and an ambiguous 'third gender' of queer that recognizes gender identity as variable both historically and individually over the life course (Herdt 1996, Ingram et al. 1997, Smith and Windes 1999).

2. Origins of the Field

One of the first social scientists to address the social construction of space was Goffman (1959), who used the theater analogy of 'front-stage' and 'back-stage' behavior to describe the spatial nature of formal and informal activities. Harvey (1973), a geographer, proposed that urban spaces and social relations are so intricately linked that a new language should be invented to capture the simultaneous occurrence of spatial form and social processes. Harvey's emphasis on the city (and the fact that the majority of American life occurs in metropolitan areas) may have directed subsequent investigations of gender and place toward its current urban focus.

Contemporary intellectual interest in the issues surrounding gendered aspects of space arose during the 1970s. When feminist political activism was at its height, women were, quite literally, entering spaces previously open only to men. Colleges, factories, and offices became increasingly integrated by sex as women's place expanded beyond the home. Young women attending, and teaching at, universities during that era were among those who challenged the boundaries of traditional scholarship. The literal and symbolic collision of place and gender soon became a conscious subject of study.

It is not surprising, then, that the first publications on gender and place were edited volumes generated from academic conferences about sex and space. Four of the most important volumes appeared almost simultaneously. *New Space for Women*, edited by Wekerle et al. (1980) emerged after the 1976 United Nations Conference on Human Settlements met in Vancouver. The editors organized a session addressing the role of women in the design and planning of urban settlements because they recognized that women's problems with housing, transportation, urban planning, and lack of access to environmental decisions transcended categories of developed and developing nations. The next year, British anthropologist Ardener published *Women and Space: Ground Rules and Social Maps* (1981) as part of a series based on lectures sponsored by the Oxford University Women's Studies Committee. *Women and Space* included ethnographies of sex differences in the use of domestic and public spaces in the Andes, Greece, Iran, Russia, Nigeria, and South Africa.

In the United States, the Lincoln Institute of Land Policy sponsored a conference that resulted in the publication of *Building for Women* (Heath 1981) edited

by sociologist Keller. It dealt with housing, community, and open space from a variety of academic disciplines; one of the chapters summarized the US Department of Housing and Urban Development's Women and Mortgage Credit Project to facilitate women's ability to buy their own homes (Shalala and McGeorge 1981). HUD played a role in producing the fourth volume on women and space when it awarded a research grant to *SIGNS: Journal of Women in Culture* to commission essays for a special issue titled *Women and the American City*. The editor of *SIGNS*, Catherine Stimpson, subsequently published the volume (with Elsa Dixler, Martha Nelson, and Kathryn Yatrakis) through University of Chicago Press in 1981. Contributors constituted the pantheon of researchers on women and space: Galen Cranz, Dolores Hayden, Jacqueline Leavitt, Susan Saegert, and Gerda Wekerle.

Donna Shalala, Secretary of Health and Human Services during President Clinton's administration, worked behind the scenes to support research on gender and place. Shalala was at HUD when the Mortgage Credit Project began and when *SIGNS* received funding for its special issue. As president of Hunter College, Shalala co-chaired the Ford Foundation-Hunter College Women and Housing Seminar with urban planning professor Eugenie Ladner Birch. Members of the seminar investigated the housing needs of single mothers, the elderly, and working women from the standpoint of design and affordability. The fruits of that pedagogical venture resulted in *The Unsheltered Woman: Women and Housing in the 1980s*, edited by Eugenie Ladner Birch (Center for Urban Policy Research 1985), one of the first books to alert urban planners to the gendered nature of the housing market.

Milroy and Andrews strengthened the tradition of edited volumes with *Life Spaces: Gender, Household, Employment* (1988), a volume written entirely by Canadians about Canada. Milroy and Andrews introduced American audiences to geographer Suzanne Mackenzie, a founder of the field of feminist geography in the 1970s. Mackenzie, in turn, linked Canadian and American authors to British geographers Jo Foord, Sophie Bowlby, and Linda McDowell. *Life Spaces* departed from the model of previous edited volumes in one important respect: Wekerle's chapter on women's housing cooperatives included floor plans and photographs. Wekerle was one of the few social scientists to illustrate spatial concepts on the written page. During the first wave of scholarship, only Hayden and Birch (an architect and an urban planner, respectively) provided images of their topics. Today it seems obvious that books about space should include drawings and photographs, yet at the time authors rarely incorporated them.

Among pioneering scholars of gender and place, Dolores Hayden deserves special mention because she approaches the topic from an architectural rather than

a social science perspective. Hayden's *The Grand Domestic Revolution: A History of Feminist Designs for American Homes, Neighborhoods, and Cities* (1981) unearthed the work of nineteenth century 'material feminists' who established collective solutions to household labor and demanded pay for their work. Her next book, *Redesigning the American Dream: The Future of Housing, Work, and Family Life* (1984), addressed the disparity between the massive housing stock constructed after World War II and changing household demographics. It opened debate among architects and planners about appropriate designs for new American families. Franck and Ahrentzen's (1991) edited volume on collective, single parent, and single-room occupancy housing was a direct response to Hayden's challenge.

3. *The Place Pyramid: Boroughs, Buildings, and Bodies*

The first stage of research on gender and place addressed sex and space, as the titles of books published in the early 1980s suggest. They all included the word 'woman' and reference to an actual space such as the house or the city. Research focused on women as active participants in, and shapers of, the built environment traditionally considered men's domain. For example, Cranz (1981) chronicled women as users and suppliers of urban park services. This is what some feminist scholars call the 'add women and stir' phase; it restored women's presence for the historical record. This stage also focused on a fairly large *geographic scale*: that of cities and neighborhoods. For alliterative purposes that will become clear, I call this the *borough* stage.

During the late 1980s and early 1990s, focus expanded from the geographic scale of boroughs to include the *architectural scale* of buildings. Urban and neighborhood analyses were not abandoned. Rather, they were seen as the larger context in which the design of buildings reinforced stereotypical gender associations. Weisman (1992), an architect, for example, analyzed the sexual symbolism associated with specific buildings—skyscrapers, department stores, public housing—and advocated the redesign of large swaths of urban architecture to take women's needs and preferences into account. Betsky (1995) produced an architectural critique of the gap between the masculine characteristics of the exterior built environment and the feminine traits of its interiors.

A significant British book illustrating the place pyramid was Moore's *Space, Text, and Gender: An Anthropological Study of the Marakwet of Kenya* (1986). Moore drew on the theories of Foucault (1972) to analyze household space as a 'cultural text' representing gender relations in Marakwet society. The study placed the Marakwet in their geographic context with a map of Kenya and a diagram of their Sibou

village, and in their building context with photographs of their dwellings. Moore's work progressed from a base of great geographical expanse to the smaller scale of the building. *Space, Text, and Gender* marked another important milestone. It was one of the first full-length ethnographies devoted to the topic of gender and place. Although edited volumes would still fill a niche, the field acquired stronger intellectual credentials with the publication of books posing theoretical arguments.

The author's own work sought to extend that tradition. Heavily influenced by previous research and theory, *Gendered Spaces* (Spain 1992) was a cross-cultural and historical study proposing that women's status is lower in societies in which men and women are separated spatially in homes, schools, and workplaces. An architectural perspective on gender and place also appeared in 1992 with *Sexuality and Space* edited by Colomina (1992). Chapters by Colomina, Lynn Spigel, and Mark Wigley dealt with the home, while one by Elizabeth Grosz examined the relationship between the body and the city. Drawing from Foucault's (1977, 1979) emphasis on bodily pleasure and pain, Grosz introduced a concept developed later by Sennett in *Flesh and Stone: The Body and the City in Western Civilization*. Sennett's (1994, p. 370) thesis, that 'urban spaces take form largely from the ways people experience their own bodies,' set the stage for subsequent emphasis on the 'body as place.'

Nowhere has the constriction of the definition of place—from the large city to the small body—been more evident than in geography. Initially, geographers worked on topics like the sexual division of space in cities and homes (McDowell 1983) and the public/private locations of production and reproduction (Mackenzie and Rose 1983, Massey 1984). More recently, however, geographers have adapted Foucault's (1977) perspective on the body as text. They write articles on *The Body and Geography* (Longhurst 1995) and on the male torso as landscape (Nash 1996). Urban spaces that were once the focus of geographic analysis have become the stages on which bodies display different degrees of fear of violence (Koskela 1997, Mehta and Bondi 1999). McDowell (1999) legitimized this move toward the body by including it among the themes currently qualifying as feminist geography (along with place, home, community, city, nation-state, public space, and travel).

4. *Current Theory and Research: The Expansion of Gender*

As the concept of place has been expanded to include a larger range of sizes, so too has the definition of gender been stretched beyond its original association with the dichotomy of biologically determined sex. This enlargement inevitably introduced homosexuality into descriptions of the relationships between

(heterosexual) men, women, and space. For example, the original four edited volumes reviewed in this essay contained not a single chapter on homosexual gender identities. In contrast, the current literature contains numerous references to gays, lesbians, queers, bisexuals, and transsexual and transgendered persons (those born one sex who identify themselves as the other sex through anatomical (transsexual) or behavioral (transgendered) modifications). Gender now reflects a continuum of identities.

Castells's mapping of San Francisco's gay male culture was one of the first explorations into the relationship between homosexual subculture and space. Castells proposed that spatial concentration is fundamental to the development of gay identity. He argued that gay men are more likely to establish urban neighborhoods than lesbian women because men's tendency toward dominance extends to territorial aspirations, while lesbians' emphasis on relationships transcends space, making lesbians 'placeless' and more politically radical (Castells 1983, p. 140, Castells and Murphy 1982; see Forsyth (1997) for a challenge to this interpretation).

Researchers have analyzed how gays and lesbians have shaped residential, commercial, and public spaces. Gay men, and to some extent lesbian women, have played significant roles in the revitalization of American urban neighborhoods (Forsyth 1997, Lauria and Knopp 1985). Commercial areas catering to gays and lesbians, such as San Francisco's Market Street and Chicago's Halsted Street, display highly visible rainbow flags to attract clientele and, increasingly, tourists. Gay and lesbian community centers, bookstores, and health clinics have become staples in many cities; gay and lesbian parades and festivals temporarily transform city streets (Forsyth 2000). Pressure is mounting to nominate prominent gay and lesbian sites as historic landmarks, such as the New York City gay bar (the Stonewall Inn) where a police raid sparked a riot (Dubrow 1998). Such places have become easier to identify as gay and lesbian histories with a spatial focus have emerged. Chauncey (1994), for example, has identified how gay men appropriated public and private spaces to provide settings for the expression of gay culture in New York City between 1890 and 1940, while Kennedy and Davis (1993) have mapped the landscape of lesbian meeting places in Buffalo, NY between the 1930s and 1960s.

What does the future hold for the study of gender and place? It will definitely involve cyberspace, as the literature already suggests (Boyer 1999, Light 1995). As the matrix of cyberspace supplements the grid of the city, women may experience the environment differently from men. Possibilities for gender ambiguities abound on the Internet in 'chat rooms' that allow more anonymity than face-to-face interactions. The digital landscape has the potential to change women's status if it changes the way knowledge is disseminated. The gendered spaces that once limited

women's access to knowledge, and thus power, may dissolve.

A fitting end for this article is reference to a feminist critique of historic preservation titled *Susan B. Anthony Slept Here: A Guide to American Women's Landmarks* by Sherr and Kazickas (1994). Everyone knows that George Washington slept (and owned slaves) at his Mt. Vernon plantation, but few people know where Susan B. Anthony, leader of the movement for women's right to vote, worked or slept. The ironic title captures the trend in the literature toward greater gender and place ambiguity. The first wave of scholarship would have highlighted the gendered nature of the town where Susan B. Anthony lived. The second wave would have analyzed the home she slept in, while the third wave would ask with whom, if anyone, she was sleeping. If Susan B. Anthony were alive today, the fourth wave might explore whether it matters if her body occupies a particular physical space at all.

Gender and Reproductive Health

With the world's population increasing at an alarming rate, reproductive health has become the focus of growing attention in recent years. While reproductive concerns and activities also influence men's health, both scientific studies and health policies primarily focus on the female gender. Because women become pregnant and can bear children, the risks of reproduction present a greater threat to their health.

1. Definition of Reproductive Health

Although research has long examined how human reproduction affects overall health, the concept of 'reproductive health' is relatively new. In many in-

dustrialized countries, a clinical view continues to dominate, with reproductive health seen as a specialty of obstetrics and gynecology. Characteristic of this clinical view is its focus on negative outcomes and the separation of services dealing with reproductive issues (Graham 1998). Recent years, however, have seen the rise of a more comprehensive concept of reproductive health, formulated in 1994 at the International Conference on Population and Development (ICPD) in Cairo as follows: 'Reproductive health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity, in all matters relating to the reproductive system and to its functions and processes. Reproductive health therefore implies that people are able to have a satisfying and safe sex life and that they have the capability to reproduce and the freedom to decide if, when and how often to do so' (Program of Action 1995, p. 202).

As this definition makes clear, sexual health is considered as a central feature of reproductive health. In line with this very broad definition, the scientific literature discusses a large range of reproductive concerns, with a preponderance of reproductive problems and risks (Graham 1998). The most well-known health risks associated with reproduction are sexually transmitted diseases (STDs), including HIV/AIDS, maternal mortality, unsafe abortion, adolescent pregnancy, and infertility. Over the last several years, the comprehensive ICPD definition of reproductive health has come to include additional aspects such as female genital mutilation and violence against women.

2. Major Reproductive Health Risks

Reproductive health risks or health crises are the source of high morbidity and mortality rates worldwide. Most are avoidable. The prevalence of reproductive risks or 'outcomes' varies enormously among populations throughout the world. The greatest differences in negative outcomes exist between developed and developing countries. At the same time, the clear improvement in the reproductive health of women in developed countries is a relatively recent achievement and can be traced back primarily to key medical advances (introduction of antiseptics, discovery of sulfonamide, modern obstetrics), as well as changes in gender roles. The significant reproductive risks women in Europe and the United States continued to face even until the turn of this century are described by Shorter in *A History of Women's Bodies* (1982).

The following section will outline the spread of some major reproductive health crises. Although not all concerns (such as infertility) can be presented in detail, attention will be given to the gravest dangers in terms of individual and public health (see Miller and Rosenfield 1996). Despite decreasing fertility rates in many parts of the world, it has not been possible to reduce *maternal mortality*. According to WHO statistics, every year 585,000 women die as a result of

pregnancy complications. More than 98 percent of these deaths occur in the developing world (Spicehandler 1997). In 1991, WHO calculated the incidence of maternal death for a woman in North America at 1:4,000, while her counterpart in West Africa faced a risk of 1:18. Both high overall fertility rates and the high rate of adolescent pregnancies in less developed countries contribute to the high incidence of maternal mortality. Compared with women aged 20–24, the risk of maternal death for women between the ages of 10 and 14 is five times greater, and between the ages of 15 and 19 twice as high (Miller and Rosenfield 1996).

According to WHO estimates, about every one in four pregnancies is intentionally terminated. Of an estimated 45 million abortions performed each year, almost half (ca. 20 million) are performed under unsafe and septic conditions. Most of these risky abortions, in turn, occur in developing countries. Illegal and unsafe abortions are responsible for another spectrum of morbidity (for example, cervical trauma, pelvic peritonitis, jaundice, chronic pelvic pain); if worst comes to worst, these cases end fatally (an estimated 50,000–100,000 deaths each year). Here one of the most important determinants for mortality risk is the illegality of the abortion (Miller and Rosenfield 1996). But also the high rate of legal pregnancy termination, for example in Central and Eastern European countries (until the end of the 1990s, abortion was the most common form of birth control), is problematic and has serious consequences for women's reproductive health. Short-term and longer-term repercussions of repeated abortions or abortions performed under unfavorable conditions in Eastern Europe include higher incidences of anemia, infertility, and premature delivery (Bruyniks 1994).

The prevalence of STDs has serious consequences for the health of women and their unborn children. The WHO estimates that more than 330 million cases of treatable STDs (such as chlamydia infection, gonorrhea, syphilis) occur each year, the vast majority in the developing world, particularly in sub-Saharan Africa (Drennan 1998). There are two reasons why STDs in general are understood as more serious for women than for men (Drennan 1998, Miller and Rosenfield 1996, Program of Action 1995): (a) during vaginal intercourse, the likelihood of infection from man to woman is higher than from woman to man, and (b) STDs in women are often not diagnosed and treated until the disease is in a later (and thus more serious) stage because in women the symptoms are often less conspicuous in their early stages (see Sexually transmitted diseases).

Among STDs, HIV and AIDS are particularly threatening; at the end of 2000, the HIV virus had infected almost 36.1 million people worldwide, about 18.3 million men and 16.4 million women as well as about 1.4 million children (UNAIDS/WHO 2000); the majority of these cases involve people in deve-

loping countries. In some parts of the world, the AIDS epidemic has already dramatically shortened the average life expectancy (Drennan 1998). While HIV and AIDS initially presented more of a threat to men than to women, there are now countries, including the United States and several sub-Saharan African nations, in which HIV is spreading faster among women than among men.

3. Determinants of Reproductive Risk Behavior

A range of factors influences reproductive health. Particularly important is the quality of medical care during pregnancy and birth. The main reason for the high reproductive morbidity and mortality rates in developing countries is found in inadequate health-care structures. Inadequate contraceptive behavior (or the lack thereof) is also responsible for a variety of risks to reproductive health (in particular unintended pregnancy and STDs); for this reason, special attention is paid to risky sexual behavior in connection with reproductive health (see *Sexual Risk Behaviors*).

Contraceptive behavior is influenced by a variety of internal and external factors, summarized in a model designed by Bruyniks (1994). Here knowledge of effective contraception and attitudes toward various methods of contraception are postulated as essential determinants of contraceptive behavior. Knowledge and attitudes are influenced by internal factors (age, intelligence, moral values) and external factors (access, social environment). It is precisely in less developed countries that access to contraceptive services is frequently blocked by financial, geographic, legal, or other barriers. Psychosocial acceptance or rejection of certain contraceptive methods in the social environment also plays a decisive role (Miller and Rosenfield 1996). Another issue is whether knowledge and positive attitudes toward effective contraception are in fact reflected in reproductive behavior, and depends on such personality variables as assertiveness or self-efficacy (Schwarzer and Fuchs 1995), as well as external barriers such as financial dependence (Wyatt 1994) or physical violence.

The social status of women is an essential factor in determining their contraceptive behavior. Social status influences not only the knowledge of efficient contraceptive methods and attitudes toward contraception, but also the possibilities for women to prevail in decisions for (or against) sexual activity and contraception, if need be against their male partner's wishes. Social status is a multidimensional concept; in terms of reproductive health, the educational level of women is the central and most frequently studied dimension. Also relevant are aspects such as political participation, employment and earnings, economic autonomy, as well as the reproductive rights of women (Kawachi et al. 1999). Williamson and Boehmer (1997) analyzed different status variables as predictors of

female life expectancy in 97 less developed countries. They found a positive correlation between the status of women and female life expectancy. Again, aspects of women's status apart from their educational level were important for determining female life expectancy. Of these other dimensions of women's status, reproductive autonomy had a particularly strong effect. This reproductive autonomy is operationalized via contraceptive prevalence as an indicator of women's control over their reproductive behavior.

The influence of social status on the (reproductive) health of women can also be found in developed countries. One recent analysis examined how the morbidity and mortality of women in 50 American states is related to different indicators of social status (Kawachi et al. 1999). Higher political participation was associated not only with lower overall female mortality but also with lower rates of death from different causes, including death due to reproductive risks such as cervical cancer or infant mortality. This analysis also examined an index for 'reproductive rights' ('reflecting reproductive well-being and autonomy') in connection with indicators of health. The index was operationalized in eight legal and political indicators reflecting the reproductive well-being and reproductive autonomy of women (for example, access to abortion services without a waiting period, public funding of infertility treatments, existence of a maternity stay law, whether gay or lesbian couples can adopt, etc.). For this indicator, however, no relationship to mortality was established, although a minor correlation to self-reported illness was found ('self-reported days of activity limitations').

Along with social status, *gender roles* have an important influence on reproductive decision-making and behavior. Gender roles refer to 'normative expectations about the division of labor between the sexes and to gender-related rules about social interactions that exist within a particular cultural-historical context' (Spence et al. 1985, p. 150). Traditional gender roles, which assign women the subordinate and dependent role in the partnership, are regarded as a particular risk for reproductive health. As Drennan (1998) shows in a detailed overview, in many developing countries men are the primary decision-makers about sexual activity, fertility, and contraceptive use. It is assumed that women who are not permitted to reject sexual intercourse or to decide about contraception have little means to influence their reproductive health. Cultural norms about femininity or masculinity might also harbor reproductive risks. In many Latin American or Caribbean countries, for example, promiscuous behavior among men is regarded as proof of their masculinity (Drennan 1998). The risky sexual behavior of their (marriage) partners frequently endangers women by increasing such risks as STD transmission. In many countries, recently married women continue to face strong pressure to 'prove' their fertility; contraception is rarely practiced,

and even adolescent or very young women become pregnant with the well-known attendant risks to the health of mother and child. In India, for example, 40 percent of all women between the ages of 15 and 19 are already married, and of these only 7 percent use contraceptives (Jejeebhoy 1998).

Gender inequality is expressed in various ways, including fewer educational opportunities for women, violence against women, female genital mutilation, and economic inequities (Miller and Rosenfield 1996). Some examples of gender inequality are concentrated on less developed countries, while others, such as violence against women and economic inequalities, are also found in developed countries. Gender roles are not independent of women's social status: improvements in social status, especially better education, generally go hand in hand with changes in traditional gender roles.

4. Promoting Reproductive Health

The ICPD Program of Action contains wide-ranging recommendations and calls for improving the reproductive health of women, especially in developing countries. What is innovative about this program in comparison to earlier approaches is that efforts to achieve this goal do not rely solely on isolated measures such as better access to contraceptive services. Rather, the program serves as a reminder that the essential requisite to bettering reproductive health is a fundamental improvement in the social status and rights of girls and women. The ICPD Program of Action lists the following points:

(a) Access to appropriate health care services: prenatal and postnatal care, obstetrics and emergency obstetrics care, treatment of STDs, abortion by qualified medical practitioners.

(b) Availability of contraceptive services: access to safe, effective, affordable, and acceptable methods of family planning.

(c) Sex education, including education for the adolescent population.

(d) Strengthening the legal, economic, and social position of girls and women.

The recommended measures of the ICPD conference continued to direct the greatest share of attention to women as the major agents of change. In the meantime, focus has shifted to include the male partner since the critical behavior unit is the sexually active couple (Becker and Robinson 1998). Overviews of research in this area (for example Becker 1996) show that reproductive health interventions (especially family planning) targeted at couples are more effective than those targeted at one or the other sex. The pair approach to reproductive health does, however, presume a certain level of equality between man and woman. In countries where very patriarchal structures continue to predominate, it is sometimes necessary to

provide initial separate services and consultations to men and women. In their report on an intervention program in Bangladesh, for example, Becker and Robinson relate how the male villagers first had to be convinced to 'allow' their wives to use contraceptive devices (Becker and Robinson 1998).

Improving the couple's communication is an essential way to increase men's participation and to promote reproductive health (Drennan 1998). In many less developed countries, only a minority of spouses talk about issues like sexuality and family planning. Demographic and Health Surveys in Nigeria, Senegal, and Pakistan conducted in the 1990s, for example, report that only one-quarter of men currently married had discussed family planning with their wives. The percentages in Cameroon (31 percent) and Ghana (37 percent) were not much higher. Drennan (1998) discusses social and cultural factors that obstruct couple communication. It is taboo in many societies to talk about sexuality. In addition, the inferior status of women often found in traditional societies continues to aggravate communication.

Many recent approaches to promoting reproductive health and preventing unintended pregnancies and STDs/HIV share a perceptible shift from models of behavioral change centered on the individual to attempts to include the partner and to consider the social network. This development can be traced back to the increasing awareness that sexual/reproductive behavior is strongly determined by social norms (Bond et al. 1999).

Gender and School Learning: Mathematics and Science

Scholarship related to gender, mathematics, and science has been extensive since the early 1970s and has accounted for a sizeable percentage of the published research in the fields of mathematics and science education. In response to concerns about the small numbers of females in upper level mathematics and science courses, the research started with the documentation of gender differences in participation and achievement, moved to the identification of related variables, and more recently has included the use of feminist and cognitive science research paradigms. A brief synthesis of the literature will set the stage for a consideration of the latest research in the field.

1. Documenting Gender Differences

1.1 Differences in Learning

It is impossible to draw firm conclusions about anything as global as overall gender differences in

mathematics and science learning. Data have been reported about a variety of populations, and measured in a variety of ways in diverse situations. The magnitude of gender differences reported varies depending on the content and/or form of the particular instrument used to assess learning. When open-ended forms of assessment are used, females tend to get higher marks while males tend to be more successful on multiple choice tests where time is a factor. For example, in Australia, gender differences in favor of males have often been reported on a multiple choice test of physics. But when the Australian state of Victoria changed the secondary school physics assessment to include extended response items and social context questions, females outperformed males (Hildebrand 1995). Females outperform males when course grades given by teachers are used as an indicator of learning (Kimball 1989).

The type of content measured also has an influence on gender differences reported. Females appear to perform as well as males do on overall measures of mathematical knowledge, but males have consistently outperformed girls on measures of complex problem solving (Hyde et al. 1990). In the Third International Mathematics and Science Study (TIMSS) study (Beaton et al. 1996), middle school females and males scored approximately the same on their test of mathematics achievement, but females scored significantly lower on the test of scientific achievement. In science, girls tend to do as well as boys in biology but far less well in physics and chemistry.

The diversity of the population being measured affects the findings. Some have suggested that gender differences are more prevalent in white populations, citing examples of populations where females outperform males at all levels. While there tended to be gender differences in favor of males in most of the participating countries of the TIMSS at the secondary level, the size of gender differences varied tremendously from country to country. It should be noted that for this portion of the study only European and American countries, predominantly composed of white citizens, participated.

To increase the complexity, the magnitude of gender differences over time may have changed. In the United States, there was some evidence of pervasive gender differences in favor of males in the 1970s (Fennema and Sherman 1977). By the 1990s, Kahle and Meece (1994) suggest that there was some evidence that gender differences in overall mathematics achievement had declined in the USA while in science they had increased. To summarize, in general males and females perform differently on measures of achievement in mathematics and science. But, while males tend to score higher on more complex measures of mathematics and science achievement, it is impossible to generalize about overall gender differences in mathematics and science learning across type of test, content, and population.

1.2 Differences in Participation

The data about gender differences in participation in mathematics and science is clearer than that regarding student learning. Females constitute diminishing proportions of the students in mathematics and science classes when these subjects become elective. In all of the countries participating in the TIMSS, with the exception of the Czech Republic and Austria, fewer females reported taking physics and advanced mathematics in secondary school than did males. The problem becomes more severe in postsecondary institutions where females constitute a small percentage of majors in engineering, physics, chemistry, and computer sciences. The differences are even more accentuated in adult life where women are dramatically underrepresented in the professional fields of engineering and information technology.

1.3 Gender Differences and Attitudes

Many studies have investigated several well-defined attitudes as they relate to mathematics and science as well as the relationship of these attitudes to learning and participation in mathematics/science. When compared to males, females have consistently reported lower levels of self-confidence in doing mathematics and science, as well as lower levels of perceived usefulness of mathematics and science. Results also have indicated consistently that males tend to report that mathematics is a male domain more than females have, while both males and females consider science to be a male domain. To illustrate this perception, students around the world typically depict a male when asked to draw a scientist. Girls tend to attribute their success to hard work rather than ability. They view their failures as evidence of their lack of ability in contrast to boys who attribute their success to high ability and their failures to bad luck or lack of effort. While a great deal of research has documented these differences in attitude and attributional style, little has been done to demonstrate if and how this affects the learning of mathematics and science (Leder 1992).

2. Understanding the Development of Gender Differences: Studies of Classroom Environments and Teachers

Although females and males sit in the same classrooms, they have different experiences in those classrooms. Researchers have observed that teachers, almost without exception, spend less time with girls than with boys. This finding has been replicated around the world in a variety of studies in both mathematics and science classrooms. Researchers have gone beyond just looking for the number of interactions with girls and boys and have studied the

types of teacher/pupil interactions. They have reported that teachers tend to ask females more routine questions for which they only have a short time to reply, while males are asked more complex questions and are given more time and encouragement to respond. Males tend to dominate the use of laboratory equipment in science classrooms and to take control of cooperative groups (Leder 1992, Kahle and Meece 1994).

While the classroom experiences of boys and girls differ, researchers have not been successful at measuring the correlation of these differences with learning. One classroom variable that has accounted for gender differences involves competition. Girls appear to learn more when classrooms emphasize cooperative activities and boys appear to learn more when classrooms emphasize competitive activities. Concern about the disparate experiences of boys and girls in coeducational settings has led some to advocate single-sex classrooms for mathematics and science. There is no evidence to indicate that girls' achievement in mathematics is significantly improved by being placed in single-sex classrooms (Leder and Forgasz 1998).

The attitudes and beliefs of teachers about their male and female students have also been studied. Teachers appear to be more aware of their male students than their female students. Teachers attribute the success of their male students to ability and the success of their female students to hard work, and hold many of the same perceptions as their students by viewing mathematics and science as masculine subjects. Based on the findings of the research on differences in attitude and classroom experiences, many educational intervention programs have been developed and implemented in various levels of schooling. While these have resulted in local change, the persistence of gender differences indicates that new perspectives on research in the field are needed to affect wide scale change.

3. Scholarship in the 1990s

During the 1990s, many changes have affected scholarship in the field. Feminist perspectives have become prominent. The field of cognitive science has matured, and mathematics and science pedagogy is changing. The impact of each of these developments will be explored in this section.

3.1 Feminist Perspectives

Many feminist scholars are critical of past research and have argued convincingly that there is a flaw in the assumption that before equity in education can be achieved, females must change. For example, many have interpreted past research to indicate that since

females lack confidence in their ability, the way to decrease gender differences in mathematics is to help females develop increased confidence, assuming females are dysfunctional because they lack confidence. Feminist scholars have suggested diverse but complementary interpretations of how females in mathematics and science education can be viewed. One feminist view critiques the subject matter, pointing out that females have not been engaged in the construction of mathematics and science. These subject matters must be redefined so that they are not alienating to females (Burton 1994, Harding 1991). It follows from this, that mathematics and science must become viewed as constructed by humans rather than as fixed and objective.

Another view suggests that instruction that has been predominately organized around a male perspective should be reorganized to include a female perspective. Several specific reorganizations have been suggested. One such reorganization has been to have single-sex classrooms where females will not be competing with males, and in which instructional activities which capitalize on 'women's ways of knowing' will be used (Rossi-Becker 1995). Another reorganization includes examination of the ways in which mathematics and science contribute to reproducing social inequality and the marginalization of females. Socially relevant problems form the basis of the curriculum providing females with the knowledge of the use of mathematics and science in political arenas (Mayberry 1998).

Recently feminist scholars have recognized that gender issues affect males as well as females. Males feel pressure from their peers to misbehave in class and find that high academic achievers are treated as social outcasts. These masculine stereotypes interfere with males' learning in all subject areas and have become the focus of a great deal of concern. (See Epstein et al. 1998.)

3.2 Perspectives from Cognitive Science

Cognitive science is a rich, complex field that defies definition. At its simplest, it has to do with the study of covert mental activities and the construction of models of mental functioning. Within mathematics and science education, cognitive science research has focused on the study of the mental strategies that are done as an individual solves problems or develops understanding of phenomena. Most work has been done with students in a specifically defined domain such as addition/subtraction or physics. Paths of the development of understanding within these domains have been identified that reflect development in many diverse cultures. However, there has been little work related to gender because it has been assumed that these paths were universal to all humans. Recently this assumption has been called into question in mathematics.

Until a few years ago, it was assumed that although children's solution strategies for addition and subtraction matured at different rates, the developmental paths for girls and boys were similar. However a recent longitudinal study called this assumption into question (Fennema et al. 1998). Results indicated that as children moved from first grade to third grade, girls tended to use immature strategies (counting and modeling) longer while boys tended to use more abstract invented strategies earlier. A significant number of girls skipped the use of these abstract strategies almost entirely, moving to standard computational algorithms before understanding of the concepts underlying the procedures had developed.

In spite of the speed with which they learned to perform the routine procedures, this developmental sequence appeared to interfere with the girls' work on difficult problems, and by third grade, boys were better able to solve more difficult problems than the girls. The researchers suggested that the girls were failing to develop their understanding in mathematics and this might presage the gender differences that are found in complex problem solving at about adolescence. These studies have alerted researchers that gender differences in mathematics may emerge at an earlier age than previously shown. This focus on how students think about problems shows promise for uncovering one of the sources of gender differences on solving complex problems. The study does not offer any evidence about why these differences developed. However, the reporting of the study was accompanied by interpretative comments by researchers with different scholarly backgrounds. They hypothesized that the differences were due to differential learning environments that existed in the classrooms.

3.3 Changes in the Teaching of Mathematics and Science

Educational scholars have been encouraging school-teachers to change the focus of their instruction to conceptual understanding rather than memorization of facts, rules, and procedures. Class discussion has become an integral part of this new form of instruction, where children have opportunities to share their problem-solving strategies and scientific observations. The curriculum includes ill-defined problems and complicated tasks which can be approached in a variety of ways.

Many educators believed that there would be fewer gender differences in classrooms with an emphasis on understanding. An examination of the research that has been done in nontraditional classrooms focusing on gender shows that this has not always been the case. It seems that when there is an emphasis on understanding, girls' performance improves but often the boys' performance improves as well, failing to ameliorate differences. New curricula do not always appeal

to girls any more than old curricula. When girls actively engage with science equipment doing experiments their performance tends to improve, but girls are often denied this opportunity by their male peers. It seems that to insure gender equity is achieved in these nontraditional classrooms, teachers must pay particular attention to insuring full participation of all children.

4. Conclusion

Few dispute that gender differences in participation in mathematics and science careers have existed for a long time and still exist. However, there is debate about the size and importance of the differences found in learning. Some believe that gender differences in mathematics and science learning indicate a pervasive educational inequity that demand major interventions in the educational system. Others believe the differences are inconsequential, and that attending to these small differences might exacerbate the problem by contributing to an erroneous perception that mathematics and science are male domains. Still others argue that mathematics and science tend to be privileged subject matters and are accorded more respect than they deserve because of their masculine/abstract qualities. They assert that society (and scholars in the area) should not be concerned about gender differences in mathematics and science but instead should celebrate interests that are more typically feminine. But, a majority of scholars in this field (including the authors of this article) believe that the gender differences found in school learning are both important and significant. They contribute to limiting the choices available to females as they progress through school, into adult life and careers. As long as this is the case gender differences are worthy of study so that equity in mathematics and science education can be achieved.

Gender and Technology

Since the 1980s an exciting new field of study has emerged, concerned to develop a gender perspective on technology. Feminists have identified men's monopoly of technology as an important source of their power; and women's lack of technological skills as an important element in their dependence on men. There has been a tension between the view that most new technologies are oppressive and controlling of women, and the obverse view that technology would liberate women from drudgery. A key issue here is whether the problem lies in men's domination of technology, or

whether the technology is in some sense inherently patriarchal. This debate resonates with, but is more recent than, the gender questions articulated in relation to science (Harding 1986).

1. Definition of Technology is Gendered

The definition of technology is cast very much in terms of male activities. Technology tends to be thought about in terms of industrial machinery and cars, for example, ignoring other technologies that affect most aspects of everyday life. The history of technology still represents the prototype inventor as male. As a result, women's contributions have by and large been left out of technological history. So, as in the history of science, an initial task of feminists has been to uncover and recover the contribution of women technologists who have been hidden from history. There is now evidence that during the industrial era, women invented or contributed to the invention of such crucial machines as the cotton gin, the sewing machine, the small electric motor, the McCormick reaper, and the Jacquard loom (Stanley 1995).

A greater emphasis on women's activities suggests immediately that women, and in particular black women, were amongst the first technologists. After all, women were the main gatherers, processors, and storers of plant food from earliest human times. It was therefore logical that they should be the ones to have invented the tools and methods involved in this work, such as the digging stick, the carrying sling, the reaping knife and sickle, pestles, and pounders. If it were not for the male orientation of most technological research, the significance of these inventions would be acknowledged. By diminishing the significance of 'women's sphere' technologies, the cultural stereotype of technology as an activity appropriate for men is reproduced.

2. Technological Change and the Sexual Division of Labor

A major concern of feminists has been the impact of technological change on women's lives, particularly in the context of paid work. The introduction of computer-based technologies into offices is a prime site of this research, mainly because the majority of clerical and secretarial workers almost everywhere are women. This research examines the effects of technological change on women's employment opportunities, their experience of work, and their skills (Hartmann et al. 1986, 1987). The exploitation of Third World women as a source of cheap labor for the manufacture of computer components has also been scrutinized (Mitter and Rowbotham 1995).

Much of this research has been influenced by a theoretical perspective, mainly Marxist in orientation, which identifies class conflict as a major factor affecting the technologies of production (Braverman 1975). In order to control the labor force and maximize profitability, capitalism continuously applies new technology designed to fragment and deskill labor, so that labor becomes cheaper and subject to greater control. Rather than technical inventions developing inexorably, machinery is understood to be the result of capitalist social relations. Building on this analysis, feminists questioned the notion that control over the labor process operates independently of the gender of the workers who are being controlled (Cockburn 1983). They pointed out that the division of labor characterizing paid jobs is a sexual hierarchy, and that its gendered nature is not incidental. Both employers as employers, and men as men, have an interest in creating and sustaining occupational sex segregation. Gender is shown time and time again to be an important factor in shaping the organization of work that results from technological change.

From this historical perspective, women's exclusion from technology may be seen as a consequence of the male domination of skilled trades that developed during the Industrial Revolution. Male craft workers actively resisted the entry of women to areas of technological work to protect their own conditions. This rigid gender division of labor within the factory meant that the machinery was designed with men in mind, either by the capitalist inventor or by skilled craftsmen. Industrial technology from its origins thus reflects male power, as well as capitalist domination. The continuing underrepresentation of women in engineering, and indeed all scientific and technical institutions, is a legacy of this history.

In the domestic sphere, by contrast, women are the main users of technology. Considerable optimism has attached to the view that technology may provide the solution to the drudgery of housework. Women's unpaid work in the home, servicing men, children, and other dependants, has for a long time been seen by feminists as a key to women's subordination. Since the 1980s, with the recognition of housework as work, research on domestic technology has grown rapidly, especially among historians (Cowan 1983).

Such research has challenged the main orientation within the sociology of technology towards paid, productive labor in the public domain. Issues that have been central here are the relationship between domestic technologies and time spent on household labor; whether technology has affected the degree of gender specialization of housework; and gender bias in the use of new technologies. Dominating the debates is the knowledge that the amount of time women spend on household tasks has not decreased with 'mechanization of the home.'

This is the central theme of Cowan's (1983) study on the failure of the 'industrial revolution in the home' to

ease or eliminate household tasks. She points to the contradictions inherent in attempts to mechanize the home and standardize domestic production. Such attempts have foundered on the nature of housework—privatized, decentralized, and labor-intensive. The result is a completely 'irrational' use of technology and labor within the home because of the dominance of single-family residences and the private ownership of correspondingly small-scale amenities. Domestic technologies clearly reflect the sexual division of domestic activities and the social organization of the family.

3. *Technology Based on Women's Values?*

By the late 1980s, attention was tending to shift away from the focus on women and technology. Instead it began to examine the very processes by which technology is developed and used, and those by which gender is constituted. In other words, feminists were exploring the gendered character of technology itself. This approach has taken two broad directions: that which is influenced by radical feminism, and that which is more in tune with the social studies of technology.

According to the former view, Western technology itself embodies patriarchal values and its project is the domination and control of women and nature (Merchant 1980, Mies and Shiva 1993). This approach has been particularly influential in relation to the technologies of human biological reproduction. It is fueled by the perception that the processes of pregnancy and childbirth are directed and controlled by ever more sophisticated and intrusive technologies. Strong opposition to the development of the new reproductive technologies has been voiced by radical feminists, who see these technologies as a form of patriarchal exploitation of women's bodies (Corea et al. 1985). Central to this analysis is a concept of reproduction as a natural process, inherent in women alone, and a theory of technology as intrinsically patriarchal.

In a similar vein, ecofeminists have analyzed military technology and the ecological effects of other modern technologies as products of a violent patriarchal culture. Technology, like science, is seen as an instrument of male domination of women and nature. Just as many feminists have argued for a science based on women's values (see *Standpoint Theory, in Science*), so too there has been a call for a technology based on women's values. From this perspective, a new feminist technology would be based on a nonexploitative relationship between nature and humanity, and would embrace feminine intuition and subjectivity.

The representation of women as inherently nurturing and pacifist has been subjected to a variety of critiques (see *Feminist Epistemology*). The idea of a technology based on women's values has thus lost

much of its salience. Ecofeminism relies on an idealized femininity and overlooks the role of culture and history in shaping women's needs and priorities in different contexts. It also negates the benefits of modernization in favor of a mythical unchanging tradition.

4. Gender Relations Shape Technology

Current theory and research on gender and technology emphasize the specific characteristics of each technology and the differing positions of women in relation to them. While maintaining that male interests have structured profoundly the form of technologies that have become available, neither men nor the technologies are treated as a homogeneous group.

This approach explores the effects of gender relations on invention and innovation, the design and development processes of technologies, as a counter to the previous stress on the impact of technology on women. It developed in response to the social studies of technology (see *Technological Determinism*; *Actor Network Theory*; *Technology, Social Construction of*). Feminists have demonstrated that the almost complete exclusion of women from the technological community has had a profound influence on the design and technical content of artifacts (Wajcman 1991). Indeed, technological systems implicitly place men's experiences and men's investments at the center, without acknowledging their specificity. The corollary is the simultaneous denial of other realities, such as women's. This gender analysis of technology does not view technology as a patriarchal conspiracy. Rather, it shows how preferences for different technologies are shaped by a set of social arrangements that reflect men's power and resources in the wider society.

As few women actually design technology, we must look elsewhere for their imprint on it. The increasing recognition of the pivotal role of users in technological development has therefore been important for feminist technology studies. Although technologies are designed with specific purposes in mind, the originators of a technology cannot predict or control completely its final use. In practice, the user or consumer of an artifact interacts with it, and can challenge and renegotiate its meanings and uses. By widening the research lens from a focus on innovation to include the processes of manufacturing, marketing, and consumption, women immediately come into view as active participants in the making of technology.

A good illustration is provided by the diffusion of the telephone (Martin 1991). There was a generation-long mismatch between how customers used the telephone and how its inventors envisaged it being used. The telephone was designed by telegraph men who intended that it would be used in the same way as its parent technology, the telegraph, as a business tool.

Women's use of the telephone for sociability instead eventually persuaded a reluctant telephone industry to conceive of its networks as a residential service for personal conversation. There are numerous other examples of women's capacity to subvert the intended purposes of technology and turn it to their collective advantage.

Indeed, largely as a result of actor network theory (see *Actor Network Theory*), technology is conceptualized as a fluid, relational process and the symbolic meanings attaching to it as being negotiated and reinvented continually. Contemporary feminist theory likewise stresses that gender is constructed in social interaction. Early studies of gender and technology tended to theorize gender as a fixed and unitary phenomenon, existing prior to and independently of technology, and then becoming embedded within it. Rather than construing technology and gender relations as separate spheres influencing each other, it is now understood that technologies and gender relations are mutually constitutive.

5. Technology as Culture

During the 1990s there was an explosion of feminist writing on technology, much of it being carried out at some conceptual distance from the sociology of science and technology which developed during the same period. This writing is informed explicitly by a combination of cultural studies, anthropology, and postmodern philosophy. Reflecting the postmodern emphasis on discourse, technology is conceptualized as an object of consumption, as a text, and as a communication medium. The central concern is with how technology as culture is implicated in the construction of subjective gender identities.

The most influential feminist commentator writing in this vein is Haraway (1997), who argues that we should embrace the positive potential of technoscience. Sharply critical of those who reject technology, she prefers to be a 'cyborg'—a hybrid of organism and machine parts—rather than an ecofeminist 'goddess' (see *Cyborg*). Genetic engineering, reproductive technology, and the advent of virtual reality are all seen as affecting fundamentally the basic categories of 'self' and 'gender.' Haraway and her ilk positively revel in the very difficulty of predicting what technology's effects will be, and warn against any purist rejection of the 'unnatural,' hybrid entities produced by biotechnology.

Most of the recent literature is about biomedical technologies and information technologies. The increasing preoccupation in sociological theory with the body and sexuality has been paralleled by research on biomedical technologies—technologies for the body. There are numerous studies of childbirth and contraception, in-vitro fertilization, cosmetic surgery and

genetic engineering. Since the late 1980s, feminists have begun to argue that there is now no such thing as a natural, physiological body. One consequence of this work is that the conventional distinction between sex (natural) and gender (social) has been contested and deconstructed thoroughly. Technologies, like science, are now seen as contributing to the stabilization of meanings of the body. With the rise of modern science, bodies have become objects that can be transformed with an increasing number of tools and techniques. Modern bodies are made and remade through science and technology; they too are technological artifacts. Life itself (human, plant, and animal) has been biomedicalized (Clarke 1988).

These studies illustrate the connection between the gendered discourses of the biomedical sciences and the institutionalization of medical techniques applied to women's bodies. They remind us that the conceptualization of male and female bodies as being essentially different, rather than similar, is a modern one, dating only from the eighteenth century. Women were defined in terms of sex and reproduction, and this was reflected in the establishment of gynecology as a separate branch of medicine. With the emergence of sex endocrinology in the 1920s and 1930s, the essence of femininity came to be located in hormones (Oudshoorn 1994). The development of a contraceptive pill for women, rather than for men, is the product not of biological necessity but of twentieth-century biomedical practices.

In the same way as biomedical technologies are seen as transforming the relations between the self, the body, and machines, so too are information and communication technologies. There is a profusion of studies on the Internet, cyberspace, and virtual reality. Many authors celebrate the myriad ways in which modern technology is challenging traditional notions of gender identity and creating new meanings and new entities (Turkle 1995). They argue that gender swapping, or virtual cross-dressing, on the Internet encourages people to reflect on the social construction of gender, to acquire a sense of gender as a continuum. The idea that virtual people or selves can exist in cyberspace, with no necessary link to a physical body, is sure to be taken up in future research.

New communication technologies have certainly opened up novel possibilities for sociality in cyberspace. Excitement has been generated about the capacity they offer to create new feminist communities, and the new tools they offer for global information exchange and political organizing. The significance of this technological revolution for power relations between men and women is still very much an open question.

As a result of the sociological and feminist research carried out in the last decades of the twentieth century, there is now a much more complex understanding of gender, of technology, and of the symbiotic relationship between them. Increasingly, it is accepted that

masculinity, femininity, and technology are not fixed, unitary categories but that they contain multiple possibilities and are constructed in relation to each other. At the same time, there has been a rejection of the technophobia evident in earlier feminist writing in favor of a popular cyberfeminism that embraces new technology as a source of empowerment for women. Albeit reflecting diverse perspectives, the study of gender and technology is firmly established as an integral part of science and technology studies.

Gender and the Law

In law, there are two different kinds of gender-related rules: those with gender-specific reference, and those with gender-specific meaning despite gender-neutral wording. These norms and their application in practice reinforce the social construction of gender. The norms depend, of course, on the historic and socio-political context in which they originated, and are subject to change. The development and extension of the equality principle as a human right has made gender inequality in law less and less justifiable, and gender discrimination has been reduced at least in the law on the books. Yet it was left to feminist theorizing to discover gender as a structural principle of modern legal orders in the Western world. This article deals with the questions why gender is used in legal norms, and how and why gender is constructed by the law.

1. Gender and Genealogy

All recorded legal orders contain at least some norms referring to the sex or gender of legal subjects, namely in the context of procreation where both women and men are unavoidably involved. Not everyone produces children, but everyone has a biological mother and a biological father, whether they are known or not. Yet the link between a child and its parents is established not only by biology, but also by law. In law, motherhood is in most cases linked to the mere fact of giving birth. The question of fatherhood is less easily settled, because the biological father is necessary for conception, but not for childbearing and giving birth. Therefore any sociopolitical order to which the paternal line is important has rules for establishing fatherhood legally.

The establishment of a genealogy is not necessarily a purpose in itself. However, in class societies and their respective political orders, two questions are of high importance: Who belongs to the ruling class? And who receives the property and other titles if an owner dies intestate? To avoid having to answer these questions by a legally binding act of will in every single case, a genealogy bestowing birth rights simplifies matters. Rules about linking the newborn to its elders then usually include rules about the distinction between rulers and subjects, locals and strangers, free persons and those who are not.

2. Marriage Law and Regulation of Sexuality

The legal mechanism of establishing fatherhood may be an act of will like recognition or adoption, but the most widespread mechanism is through marriage: all children born during an existing marriage are automatically considered to be their mother's husband's

children, regardless of whether this corresponds to the biological facts. Marrying then, is an anticipating legal act, but it has preconditions. Many rules exist that regulate the question of who may marry whom, or whether he or she may marry at all. And the implications of marriage make marriage a complex legal institution which regulates such issues as the rights and/or duties of the spouses (see *Family Law*). All these rules vary widely over time and space because marriage intersects with religion (see *Hindu Law*; *Islam and Gender*; *Jewish Law*; *Judaism and Gender*), class, race (see *Race and Gender Intersections*) and state interests in population control (encouraging or discouraging procreation). Moreover, many a marriage law treats men and women differently.

Therefore, marriage law is not only the central regulatory site for the establishment of a patrilinear genealogy, but also for the construction of gender. At the end of the Middle Ages, the only type of marriage acknowledged in Europe was, due to the influence of the Catholic Church, the monogamous and principally dissoluble marriage, and it was the only accepted way to procreate, i.e., to produce legitimate heirs. Whereas previously so-called bastards were accepted by noble families when the father was an aristocrat, now children born out of wedlock were always considered 'illegitimate' and were left with their mother's status. This was safeguarded by a criminal law penalizing all forms of sexual conduct save conjugal intercourse (see *Crime and Gender*; *Sexuality and Gender*; *Sexual Orientation and the Law*). Of course, actual behavior differs from legal norms, but nevertheless the impact of such laws worked in two directions: one was the state intervention in the sexuality of its subjects, the other was the gendered discrimination of those who did not comply. When an unmarried woman became pregnant, she could less easily evade prosecution than the man, whose begetting was harder to prove. At the same time, the gendered dependency for procreation was reversed: if a child was born out of wedlock, it was no longer the man who depended on the woman to confirm his fatherhood, but now the woman depended on the man to pass on the status of legitimacy to her children.

3. The Masculinization of Citizenship

The marriage laws had their importance for the reproduction of the medieval classes, and for the construction of gender, but gender itself did not yet function as a predominant structural principle for inclusion in the ruling classes (see *Class and Law*). The rulers in medieval Europe were mostly, but not exclusively, men. The laws of the aristocracy (see *Aristocracy/Nobility/Gentry, History of*) usually provided for heredity in the male line, but not all of them excluded women from ruling if there was no legitimate male heir. The rural population came under the

jurisdiction of the respective land owners, whereas the cities generally did not belong to the nobility, but were self-governed by their free citizens. Free citizens were persons who were listed as such, which usually required them to swear a civic oath and to pay civic taxes. Women, whether married or not, were also eligible for full citizenship in medieval European cities (Appelt 1999). This started to change when the feudal orders of the Middle Ages and absolutism were called into question.

Generally, the American and French revolutions are seen as the beginning of the formation of the civil state in the Western world, where estates and classes are abolished. These revolutions had been influenced by the writings of political philosophers of the seventeenth and eighteenth centuries, who had conceptualized a Natural Law in opposition to the Catholic order of the Middle Ages. The Natural Law conceives all human beings as God's creatures and thus became the basis for the equality principle (see *Natural Law*). However, when this concept was made the foundation of the modern state, only men who were free owners were judged capable of being equal citizens; slaves, serfs, Jews and women were, in the beginning, explicitly excluded from the citizenry. The contradiction between the equality of all human beings in Natural Law and the exclusivity of the class of citizens was circumvented by means of the legal mechanism of qualification for legal personality (see *Legal Personality*) which required, according to the same political philosophers, an equal footing in contracting, of which neither slaves and servants nor women were capable. (The exclusion of Jews followed another mechanism linked to the emerging concept of nation.)

It is well known that French women had a major part in the revolution of 1789. Female suffrage was even discussed, but was explicitly denied in 1793. The medieval concept of citizenship was gradually converted into a concept of gendered citizenship which contained also a new concept of gender and the family. Citizens were perceived as males, equals in the public sphere, participating in public affairs by exercising their right to vote and to be elected, and as heads of family in the private sphere. Women were perceived as inherently unequal to men, their 'natural' tasks being to please the men, marry, and care for the 'legitimate' children (Rousseau 1762). As wives they were subordinated to their husbands either by 'nature' directly (Rousseau 1762), or through the marriage contract by which the woman subordinated herself (Kant 1797). The exclusion of women from politics was followed by an exclusion of women from the market during the nineteenth century, the phase of the consolidation of Western nation-states. When finally Jews, slaves, and other nonowners had been enfranchised, women belonging to these groups of the population stayed excluded like the mothers, wives, and daughters of the 'old' citizens. The marital status was the only status that was left after the abolition of statuses connected

with the estates, classes, and birth. However, it had a legal meaning only for women, leaving them in some sort of inferior class, with the result that the social and state order was run exclusively along the line of gender.

4. *The Gendered Structure of Modern Laws*

The conception of the citizen as a member of the new ruling class was mirrored not only in the constitutions describing the political person who participates in ruling, but also in the civil laws describing the civil person who participates in the market. Therefore it is no accident that the nineteenth century was, in the Civil Law world (see *Legal Systems, Classification of*), also the period of 'great codifications' (see *Civil Law*). These included norms on the legal personality, on property, contract, tort, and on marriage, family, and succession. Hegel (1821) presents a concise normative foundation for the (bourgeois) civil perception of the relation between the individual, the family, society, and the state.

Marriage and family were made the ideals for both men and women, but with diametrical consequences for their legal capacity. Marriage meant for women that they fell back to the status of minor children even in countries where relief from paternal custody was granted to women of age. Wives lost their property (if they had any) to their husbands (like in England), or their right to dispose of it (like in German states). They gained in turn a claim against their husbands for maintenance, but were obliged to have sexual intercourse whenever their husbands wanted it, as can be seen from the longstanding exemption of marital rape from prosecution. The women's obligation to conceive and give birth to children was reinforced by the abortion laws. Child custody was legally given to the husband, and remained there even after divorce, if a divorce was legally attainable at all. Unmarried and widowed women were likewise judged incapable of exercising child custody, and a male custodian was appointed. (For the status of 'illegitimate' children which hardly changed between the sixteenth century and the end of the twentieth, see *Children and the Law*).

Married women were made economically dependent on their husbands not only by losing their right to dispose of the property they had brought into the marriage, but also because they needed their husband's consent for taking up paid work. However, unmarried women were not free to choose their occupation either, because of the complete exclusion of women from office holding, and an increasing exclusion from crafts and trade; they were dependent on maintenance granted by kin or the community, or on earning a living by working in agriculture, households, or the newly emerging factories—all of which was poorly paid.

This nineteenth-century segregation of the labor market along the line of gender, partly induced and

partly reinforced by legal norms, still exists at the beginning of the twenty-first century. The resulting gender inequality is extended when and where the entitlement to social security is subject to previous paid work. For further treatment of these issues, see *Sex Segregation at Work*; *Sex Differences in Pay*; *Sexual Harassment: Legal Perspectives*; *Social Welfare Policies and Gender*.

Taken all together, the laws of the nineteenth century can be characterized as founding and substantiating civil patriarchy.

5. Law as a Means to Fight Gender Inequality

That women were deprived of equal rights has been under criticism from the beginning of the modern constitutional nation-state, starting with the *déclaration des droits de la femme et de la citoyenne* ('declaration of the woman and citizeness') by de Gouges (1791) and the *Vindication of the Rights of Women* by Wollstonecraft (1792). The women's movements that emerged in all Western states around the middle of the nineteenth century called for political participation and civil rights, especially women's suffrage and liberation of the marital subordination of married women (see *Feminist Movements*). It has been a long uphill road to achieve most of these goals in the Western world, at least in black-letter law. The tool that was and is being used in this fight is the invocation of equal rights. So the law, in spite of its function as a means to secure heterosexual male supremacy, could also be used to fight gender inequality (see *Law as an Instrument of Social Change*).

In 1948, the United Nations included gender equality in their Universal Declaration of Human Rights, and many national constitutions followed suit (see *Civil Liberties and Human Rights*; *Civil Rights*; *Fundamental Rights and Constitutional Guarantees*). Since then, it has been much harder to legitimize discrimination against women. In most countries, at least in the Western world, much has been achieved in the name of equality and equal rights to fight women's subordination (and where not, it is still on the agenda); suffrage (see *Women's Suffrage*); access to education and professions; the right to dispose of marital property; the right of married women to work; child custody for unmarried and divorced women (see *Lone Mothers in Affluent Nations*; *Lone Mothers in Nations of the South*); access to social security; reproductive rights (see *Reproductive Rights in Affluent Nations*). Affirmative action laws in the United States (see *Affirmative Action: Comparative Policies and Controversies*) and equal opportunities legislation and adjudication in the European Union (see Hervey and O'Keeffe 1996) have their share in the promotion of gender equality. Women now have, in many countries, access to all kinds of professions and jobs, including the formerly typically male military service.

Gender inequality in law was not only related to the different treatment of men and women, but also to sexuality. In the traditional patriarchal concept of the civil state, heterosexuality was the only accepted form of sexuality until, during the last third of the twentieth century, the gay and lesbian movements in the Western world began to invoke the equality principle on their own behalf (see *Gay/Lesbian Movements*; *Sexual Orientation and the Law*). The decriminalization of homosexuality is still an ongoing process, but sexual orientation is gradually being acknowledged as a human right—e.g., in article 21 of the Charter of Fundamental Rights of the European Union (declared at the Nice European Council on December 7, 2000).

Another demand made by the gay and lesbian movements in the name of equality is directed towards access to marriage. The reason is that many rights and entitlements (e.g., in tax laws, inheritance laws, immigration laws) are restricted to married couples or spouses. Barring homosexuals from marriage according to marriage law means denying them access to these rights and entitlements. This demand has been taken up by the legislators in a number of European countries (first in Denmark in 1989) and some US States, yet without extending the term 'marriage' to such relationships, using a phrase like 'registered partnership' instead (see ILGA-Europe 1998). Only the Dutch laws allow for a 'real' same-sex marriage as of April 1, 2001.

Nevertheless the effect of the laws is often limited (see, e.g., *Affirmative Action: Empirical Work on its Effectiveness*), and in no case guaranteed over time. Therefore the struggle against gendered law is still going on, both in countries with no or little achievement and in countries with comparatively high achievement.

6. Resistance to Gender Equality

The fight for women's equal rights has always met with considerable resistance. The resistance has three reasons.

The first is that the exclusion of women from the public sphere, including business and the market, and the ideology of marriage and family as the 'natural' profession of women led to a Catch-22 situation: women were subordinated to their husbands if they married, and ridiculed as spinsters if they stayed unmarried, with limited access to the better-paid positions in the labor market. And, most importantly, women had, at the beginning of the twentieth century, no access whatsoever to the lawmaking process—be it parliament and government, or the judiciary—because they were excluded from higher education and the professions irrespective of their marital status (see *Education (Higher) and Gender*; *Legal Education*). Although universities and law schools hesitantly began to open their doors for women from the 1860s

onwards, it was only in the 1970s and 1980s that women's share in the legal professions went beyond tokenism.

The second reason is that modern Western law is conceptualized in terms of individual rights. This is the case also for marriage and family law, although a married couple necessarily consists of two persons. The underlying image of a male head of household and breadwinner, and a female housewife and mother, proved resistant to the mere extension of rights to women—such as suffrage, and access to education and office. It was only in the last third of the twentieth century, and after the emergence of new feminist movements, that the laws were gradually adapted to the image of equal partners, even if the gendered division of tasks, namely breadwinning and family-caring, still resonates.

The third reason is that the patriarchal image of marriage and family, and a corresponding image of professions acceptable for women, had infected all other areas of law. However, the gendered character of modern law went unrecognized by mainstream legal theory until feminist lawyers and political scientists (mostly women, although the recognition of the gendered character of the law is not restricted to females) began to scrutinize the contradictions between equality as a human right, the laws reflecting the civil patriarchy, and women's lived experiences. They uncovered 'The Hidden Gender of Law' (Graycar and Morgan 1990), i.e., many contradictory and/or gender-biased traits of the law (see, e.g., Smart 1984, MacKinnon 1987, Stang Dahl 1987, Patemann 1988, Moller Okin 1989, Young 1990, Fineman 1995, Levit 1998; for further treatment see *Feminist Legal Theory*; *Feminist Theory*).

7. Towards the End of Gender as a Legal Category? An Outlook

One aspect of gender as a legal category still remains to be dealt with: the gender dichotomy which is not only taken up, but also created by law. This has been proven for ancient Roman law (see Thomas 1992). Hermaphrodites were even explicitly dealt with by the colified Prussian law of 1794. What is called 'the third sex' vanished, however, from the Western laws in the nineteenth and twentieth centuries when the registration of nationals and residents became increasingly regulated, and the registers attributed either the male or female sex. This official sex dimorphism made the attributed sex seem essential, and also gender became a category with seemingly two mutually exclusive expressions, fitting perfectly the gendered state and law which assigned rights and duties in a gender-specific way.

Sex was usually assigned for life until medical treatment and surgery made it possible to change the originally assigned sex/gender, and a change of sex

was finally legally acknowledged (see *Transsexuality, Transvestism, and Transgender*). Yet the permission for a change of sex does not mean that the cultural dimorphism of sex and gender has been overcome. The same medical treatment is used to uphold this dimorphism in the case of hermaphrodites (intersexed, intersexuals) who, in Western countries, already as infants are treated for becoming unambiguous females or males (see Kessler 1998). It seems hardly questionable that the legally secured sex dimorphism and gender dichotomy has contributed to this branch of surgery. Up till 2000, only the Constitutional Court of Columbia (SU-337/97 of May 12, 1999, and T-551/99 of August 2, 1999) recognized the problem of genital surgery imposed on infants as a legal problem conflicting with the personal integrity and dignity of those concerned.

Altogether sex, and consequently gender, as a legal category is, at the beginning of the twenty-first century, called into question from four different, but partly related, angles:

(a) separation of 'legitimate' procreation from marriage;

(b) separation of marriage (or a functional equivalent) from heterosexuality;

(c) extension of political, civil, and economic rights to all individuals, irrespective of their sex, sexuality, and gender; and

(d) the (re)discovery that nature offers a greater variability than the Western dimorphic conception of sex and gender of the nineteenth and twentieth centuries.

Under such conditions, it would be superfluous to register sex/gender or refer to sex/gender in any legal provision. Legal regulation could refer to a given situation instead of generalized males or females. Even in the context of procreation (to come back to the starting point), the distinction along the sex/gender line seems disposable when motherhood and fatherhood are replaced by parenthood. The function of law for linking a newborn to someone responsible will remain, but the factual situation to which legal parenthood is knitted could be actual care instead of biological generation (which has become problematic in the light of the recent reproductive technologies; see Knibiehler 1987). Parenthood could then be assigned to one, two, or even more persons, whether the biological parents be among them or not. Likewise, laws protecting motherhood, which have a long tradition in Europe, could be linked to the actual occurrence, and, where only aimed at female reproductive capacity, be extended to everyone.

However, as long as a gendered structure can still be found in the laws, complete disregard of gender might be counterproductive to those who still have unequal access to power and the exercise of rights because the demand for equal rights, the tried and tested tool to fight discrimination by law, requires the reference to differences.

Gender, Class, Race, and Ethnicity, Social Construction of

1. Introduction

The categories gender, class, race, and ethnicity, widely used in the social sciences, history, and literature, have long been treated as distinct categories, which supposedly describe real differences among groups of people. In this article this assumption is debated and various theories about the usefulness and the interaction and interrelationship of these categories are examined.

2. Background

Since the 1970s under the impact of postmodernism, deconstruction, feminist scholarship, and challenges to it by women of color, fundamental categories of

knowledge and systems of explanation have been disputed, problematized and, in some cases overthrown. Rigidly defined categories that had long been accepted as based on 'natural,' self-evident differences, and as being disparate from one another, were now subject to critique and redefinition. This process of re-evaluation took place over several decades and in many different fields. It will be discussed here category by category, although there was considerable overlap and crossover from one category to the other. Each of the categories represents some noticeable distinction from an imaginary norm. Each also is a powerful mental construct, which can be positively or negatively evaluated, according to who it is that does the defining.

3. Challenging the Categories

3.1 Race

The term 'race' first appeared in the sixteenth century; only in the nineteenth century did it become biologized on the basis of evolutionary thought. The 'races of mankind' were classified and hierarchically ordered by Europeans, with whites inevitably at the top of the ranking order. Modern science, however, gives no support to essentialist racial theories. There is no such thing as 'black blood' or 'pure blood' and the only distinctions of blood—bloodtypes—have nothing to do with race (see *Race: History of the Concept*). Biological race is, in fact, a scientifically nonexistent category. Of course, the physical characteristics (such as skin and hair color) that we associate with race are determined biologically. But which physical characteristics are seen to define race, and where lines are drawn between groups, as well as how groups are treated differently, is determined socially. For example, we note differences in eye coloring and attach no value judgments to them, but when it comes to differences in hair and skin coloring, all the contradictory and often negative value judgements accruing to race come into play.

Challenges to a naturalized concept of biological race began early in the twentieth century and found expression in the thought of African-American intellectuals. W. E. B. DuBois early in his life regarded race as a sociohistorical term, but still accepted the idea of 'a common blood.' In 1911 he wrote: 'It is not legitimate to argue from differences in physical characteristics to differences in mental characteristics' (DuBois 1911 but by 1940 he concluded: 'race is the fact that a Negro in Georgia has to ride in the Jim Crow car' DuBois 1940 p. 153.). In short, 'race' is nothing else but 'racism.'

The unscientific nature of the category race was recognized legally by the Supreme Court when it ruled miscegenation laws unconstitutional in 1967 (*Loving vs. Virginia*). Contemporary scholars, both black and

white, agree with historian Barbara Fields: '... the view that race is a biological fact, a physical attribute of individuals, is no longer tenable. Race ... is a purely ideological notion' (Fields 1982, p. 144; Henry Louis Gates and Kwame Anthony Appiah have expressed similar views). Many authors have searched for words which might more adequately describe the content of this complex concept, such as institutionalized racism, experiential racism, resistance formation. Literary critic Hazel Carby asked academics to stop using the term, but rather to speak of 'racial formations.' In Germany, in the aftermath of the Holocaust the term race is rarely used in academic discourse and has been replaced by the term 'ethnicity.'

However, race as a factor describing and determining people's life chances continues to exist. It is manifested in three forms: (a) as an ordering concept for dominance and discrimination, which has become institutionalized; (b) as a historic experience, a force shaping the lives and consciousness of the designated group; and (c) as a distinguishing marker for the group, transformed into a mark of pride, resistance, and a tool for liberation.

By exposing the category race as a social construct and showing its connection to power and to the unequal distribution of resources in society, scholars opened the way to a critique of the other categories. They also showed that the ability to define and categorize had developed into a powerful tool for social control. Considered from the point of view of philosophy, false universalizing (the situation where one category, such as men, is defined as the norm and a category seen as opposite, women, is defined as 'the Other' or the deviant) was found objectionable, and seen as a basic conceptual error. False universalizing was also implicated in explanatory systems pertaining to race, to sexuality, to ethnicity (Minnich 1990).

3.2 Sex/Gender

Simone de Beauvoir's *The Second Sex*, which appeared in the USA in 1953, explained woman's subordinate status in society as the result of her being defined as man's 'Other.' The author argued that 'one is not born, one is created a woman.' This insight led feminist scholars to new definitions, whereby Sex (the biological given) was contrasted with Gender (the socially constructed behavior, and the roles deemed appropriate to each of the sexes). She argued convincingly that the definition of woman as man's 'Other' had led to the systematic disadvantaging of women in all aspects of society, law, and culture. Gender would later be developed as a tool of analysis in many fields (Scott 1988; see *Gender and Feminist Studies*).

Comparisons between the way 'Negroes' and women were characterized, stereotyped, and discriminated against appeared in the sociological literature of the 1950s and became central to the arguments

of modern feminists (Hacker 1951). The dichotomy male–female was paralleled to white–black and other binary contrasts, like heterosexual–homosexual. Feminists criticized the binary system of thought and began to concern themselves with the parallel structures of ideas, prejudices, and social customs by which African–Americans and women were conceptualized as ‘deviants’ from a white, male norm. This led to other questions. How did the categories by which people were defined as deviants affect their lives? Definitions are mental constructions; discrimination in access to education, to resources, to political power is tangible and real. How did this work? Were the categories, gender, class, race, and ethnicity linked in some way and if so, how? Were they part of one or several systems? In the 1970s and 1980s the feminist debate postulated the existence of separate systems. Rubin (1975) described a single sex/gender system that linked economic oppression with gender. Marxist-feminists tried to fit a feminist analysis into Marxist categories, adding new dimensions and structures (Rowbotham 1973, Mitchell 1974, Davis 1981). O’Brien described a capitalist system of production and class oppression, which operated in conjunction with a separate system of reproduction and sex oppression. The Canadian sociologist Dorothy Smith defined gender and race in relational terms. She argued that relations of power manifest themselves in multiple, fluid structures of domination (Smith 1987).

3.3 Differences Reconsidered and Universals Challenged

In the early 1980s the concept of ‘sisterhood’ came under sharp attack by women of color, by post-colonialists and various ethnic groups. The emphasis of the debate now shifted to differences among women. Where previously race, class, and ethnicity had simply been treated as aspects of women’s identity, which might render their situation different from one another, these differences were now seen as so great that no valid generalizations about ‘women’ were possible. African–American women historians challenged the notion of a homogeneous womanhood and argued for the integral connection of race, gender, and class in the thought and lived experience of black women (see, e.g., Fields 1982, Higginbotham 1992). Patricia Collins argued that the experiences of African–American women were so unique as to qualify them singularly to interpret their past from an ‘Afro-centric standpoint’ (Collins 1989). ‘Standpoint theory’ originally developed by Nancy Hartsock, has also been used in discussions of ethnicity, class, and identity (Hartsock 1983). While it is helpful in drawing attention to the faults of false universalization, it not only affirmed but seemed to increase belief in the fixity of the assigned categories.

3.4 Binary Sexual Categories

The binary distinction between heterosexuals and homosexuals mirrors the power relations in other dichotomized categories. In her incisive essay Rich (1980) showed how the marginalization of gays and lesbians derived from their being defined as ‘deviant’ and essentially different from the heterosexual ‘norm.’ She traced the intellectual constructs, the legal constraints, and the everyday cultural practices that undergird the resulting system of discrimination against yet another minority group. The pattern of construction and ‘othering’ is remarkably similar to that in the other categories. In recent decades gay history and theory has flourished and led to the formation of another new field, Lesbian and Gay Studies (an introduction to the growing literature can be found in Abelow et al. 1993).

4. Class

Class is a term that sorts people according to their relation to resources and power. The term is a social construct, but it is based on actual economic differences between people. There is a large literature illustrating the way race and gender affect a person’s class position. Studies of a gendered labor market, of racial and gender discrimination in educational opportunities and in access to jobs, the continuing wage differential between men and women, and the income gap between black and white citizens argue for the significance of sex and race in defining class. Various ethnicities have, at different times, been subject to similar economic discrimination. Many labor historians now argue that the concept ‘class’ is gendered and racialized inherently (Moody and Kessler-Harris 1989). Class privileges and disadvantages vary by sex and race. For example, in nineteenth-century America the definition of male middle-class status required a man to be the sole family breadwinner. A ‘white lady’ by definition was someone sharply differentiated from lower-class women, from women defined as ‘not respectable,’ and from all nonwhite women. Another argument for the gendered nature of class is that it has been maintained historically by homogamy (the practice of marriage among persons of the same class) and by gendered inheritance laws that specified that sons were privileged over daughters in inheriting property. Both practices have given men a long-range economic advantage over women, by giving sons land and daughters dowries, when land was the most valuable property to have. Similarly, in modern times, gendered inheritance has given sons more family investment in higher education than daughters, when such education guaranteed upward mobility (Lerner 1997, pp. 146–98). There is a large literature concerning the nature of women’s unpaid housework and child rearing services and its effect on class. Despite considerable analytic

differences, there is agreement that their responsibility for unpaid housework generally has debased the wages of working women and their opportunities for economic advancement (Hartman 1981, Kessler-Harris 1990, Boydston 1990).

5. *Ethnicity*

This is an affiliation of people sorted by cultural and historical characteristics. These categories are obviously imprecise and arbitrary and inadequately deal with people of mixed ethnic origin. The ethnic designations in the US census have come under constant attack by people who consider themselves of 'mixed' ethnicity or race and by others who object to the definition of categories such as 'Hispanic' (Root 1996, Anzaldúa 1987, Zack 1993).

Some scholars have developed the view that ethnicity is a modern, constructed identity which is reinvented in each generation and reinforced by a variety of cultural means in the interest of nationalisms (Sollers 1989). An outgrowth of the debates on ethnicity and on race was the creation of a new racial designation and a new field of study, the creation of Whiteness. If race cannot be proven on a biological basis, neither can whiteness. White people are defined as the norm against the 'Otherness' of people of color. Whiteness bestows privileges on whites that are withheld from 'Others.' One of these privileges is that it is whites who do the defining of the social categories and who can remain unconscious of their own racial construction (Minnich 1990, Roediger 1991, Frankenberg 1993). The racialization of whiteness was used to argue both against racism and against affirmative action, by the claim that whites should be considered a group of ethnics who were disadvantaged and oppressed by race-specific legislation.

6. *The Relationship of the Categories to Each Other; The System as a Whole*

The relationship of the categories under discussion has often been described in geometric terms as 'intersection' (race and sex intersect to form class); it has been visualized as forces (sex acts upon class creating gendered class) or as a relationship approximating that of a mathematical curve. More and more, these ideas deriving from mechanical thought have given way to more holistic concepts, such as interacting, interpenetrating. The key to such an approach is to challenge the very existence of separate categories and identities and the recognition that people do not define themselves by a single identity, but by a number of identities which are interactive and mutually constitutive (Memmi 1968, Lorde 1984).

Postcolonial studies have illuminated this process and argued for its wider applicability. Stoler has shown

how colonial powers, in Indonesia, Indochina, and India, constructed a concept of the 'colonizer' vs. 'the colonized' in which race did not serve as the main marker of difference. Rules of conduct and custom enforced strict segregation between the two groups, reinforced by the myth that white women needed protection from assault by colonized males. Rules against miscegenation, abandonment of 'mixed race' children by their fathers, and strictures against white single women together with the encouragement of marriage among whites, encouraged the domesticity of white women and upheld colonial rule (Stoler 1992). Mohanty described 'the ideological construction and consolidation of white masculinity as normative and the corresponding racialization and sexualization of colonized people' in the case of Africa. Other studies have strengthened this argument (Mohanty 1991).

The connections between the categories appear ever more dense and complex. There has slowly developed agreement among many scholars that the terms must be treated not as separate entities, but as interrelated. Bunch (1990) argued that various forms of oppressive systems interact. Hooks (1989) stated that: 'Sexism, racism and class exploitation constitute interlocking systems of domination.' Sacks (1989) saw 'Class, race and gender oppression as part of a unitary system.' Morgen (1990) explained 'that these social relations so interpenetrate that they are better understood as constituting...one another.' Noticing the arbitrariness of the selection of groups that are targeted for definition as 'the Other,' a number of scholars have come to view the process of forming deviant outgroups by way of categorization as part of the system of ruling (e.g., Lorde 1984, Williams 1991, Minnich 1990, Lerner 1997). Gender, race, ethnicity, and class are processes through which hierarchical relations are created and maintained in such a way as to give some men and women power and privilege over others by their control of material resources, sexual and reproductive services, education, and knowledge. Such control is maintained by a complex weave of social relations among dependent groups which offers most groups some advantages over other groups, sufficient to keep each group within the dominance system.

The categories are not just interrelated, they are also mutually constitutive. Gender is constructed racially and through class and ethnicity. Race is constructed genderically. Thus, the gender ideal of 'womanhood' was long defined for white women as embodying purity and dependency on male protection, while women of color were seen as 'impure,' open to sexual access by white men, and economically self-supporting. The gender ideal turns out to be race-specific. By a similar mental contortion middle- and upper-class mothers are today urged to stay home with their preschool children, while mothers on welfare are forced to leave their infants to go to work. This ideal turns out to be class-specific. A similar case can be

made for all other social formations. A holistic redefinition of the social categories may lead to a more accurate description of society as a functioning organism.

7. Conclusion

Scholarship on diversity and multiculturalism has gone through a process which began with the traditional acceptance of rigid, separate categories into which groups of persons were divided according to noticeable or invented differences. Challenging the categories as neither natural nor separate, denaturalizing them, led to the insight that this ordering system was connected with power—the power by which difference is turned into dominance. Underlying the construction of categories of difference was a binary system of thought, which soon came under attack from many quarters. The search for alternate modes of thinking and for models more appropriate to diversity in democratic societies led to greater concern with inclusivity, and a new scholarly interest in the problems of borderlands, mixed identities, hybridity, and holistic models.

G. Lerner

Gender Differences in Personality and Social Behavior

Research on psychological gender differences began before the beginning of the twentieth century, as scientists tried to discern differences between women and men in intelligence, reaction time, and personality, using measures that seem bizarre by today's standards, such as handwriting analysis. Sophisticated research on gender differences in personality and social behavior has flourished since the 1970s, generating hundreds of empirical studies as well as a number of highly informative meta-analyses. A meta-analysis is a quantitative review of the existing studies on a particular question; the meta-analyst extracts statistics from the existing studies and averages the results across all studies. (When reporting effect sizes from meta-analyses here, I follow the convention that a positive effect size means that men scored higher on the measure in question and a negative effect size means that women scored higher. An effect size tells how far apart the two groups—in this case, men and women—are in their average scores, standardized by dividing by the standard deviation.)

1. Gender Differences in Personality

Definitions of the term 'personality' vary widely. In order to sharpen the focus of this review, I will consider personality as conceptualized in the Big Five model (McCrae and Costa 1987), which specifies five basic dimensions of personality: conscientiousness, extraversion, openness to experience, agreeableness, and neuroticism. Below I review research on gender differences in each of these dimensions. A meta-analysis of gender differences in personality (Feingold 1994) is particularly helpful in discerning the overall pattern of findings.

1.1 Conscientiousness

Feingold located seven norming studies measuring conscientiousness using standardized personality tests.

Of those, women scored higher on four, one found exactly no difference, and men scored higher on the remaining two. The unweighted mean effect size was $d = -.13$ (Feingold 1994). Therefore, the gender difference in conscientiousness appears quite inconsistently across studies and, if there is a gender difference in conscientiousness, it favors women but the difference is slight.

1.2 Extraversion

Most studies find no gender differences in extraversion as measured by the MMPI (Zonderman et al. 1993), or the Eysenck Personality Questionnaire (EPQ) (Martin and Kirkcaldy 1998).

In his meta-analysis, Feingold (1994) distinguished between two aspects of extraversion: gregariousness and assertiveness. Most test norming studies show women to be more gregarious, although the gender difference is small (unweighted mean $d = -.14$) and inconsistent across countries (Feingold 1994). Test norms show men scoring higher on assertiveness or dominance, ($d = .50$).

1.3 Openness to Experience

Openness to experience—flexibility and openness to new ideas—has been less studied. The mean effect size for gender differences was $d = .03$ (Feingold 1994), indicating no gender difference in openness to experience.

1.4 Agreeableness

Findings regarding gender differences in agreeableness are mixed. Feingold (1994) distinguished between two aspects of agreeableness: trust and tender-mindedness. Test norming data showed a consistent trend for women to score somewhat higher on trust ($d = -.25$) and for women to score considerably higher on tender-mindedness or nurturance ($d = -.97$). Higher scores for women on tender-mindedness or nurturance have been documented in Canada, Finland, Germany, Poland, and Russia, but not China (Feingold 1994).

1.5 Neuroticism

Neuroticism is the tendency to experience negative emotions such as sadness or anxiety, as well as mood swings (Costa and McCrae 1985). Those scoring high on neuroticism tend to worry or ruminate a great deal and are prone to having their feelings easily hurt. Women consistently display higher scores on neuroticism scales than men do. These differences are found on the MMPI Neuroticism scale (Zonderman et al. 1993), the Eysenck Personality Questionnaire (Martin and Kirkcaldy 1998), and the NEO (Costa

and McCrae 1985). The magnitude of the gender difference is generally around $d = -.25$ (Feingold 1994, Zonderman et al. 1993), that is, the difference is small. For comparison, the gender difference on the masculinity–femininity scale of the MMPI is approximately $d = 2.0$ (Zonderman et al. 1993).

The gender difference has been documented in a wide variety of countries including the USA, Singapore, and Bangladesh (Lynn and Martin 1997), and Northern Ireland (Martin and Kirkcaldy 1998).

The gender difference in neuroticism is a particular concern because of the association between neuroticism and depression and the well-established gender difference in depression (Roberts and Gotlib 1997). Watson and Clark (1984) have demonstrated that the personality trait labeled neuroticism is part of a broader cluster of traits including emotionality, trait anxiety, and ego strength; they label this broad personality construct ‘negative affectivity.’ Scales measuring traits in this cluster consistently show women scoring higher.

1.6 Self-esteem

Self-esteem, although not one of the Big Five dimensions, is an individual difference variable that has stimulated much research on gender differences. On the basis of his meta-analysis, Feingold (1994) concluded that males had slightly higher self-esteem than females, ($d = .16$).

Kling et al. (1999) conducted a more extensive meta-analysis of gender differences in self-esteem (for another meta-analysis with similar results, see Major 1999). Averaged over 216 effect sizes, ($d = .21$), indicating a small gender difference favoring males. Contrary to claims in the popular press that girls’ self-esteem plummets in early adolescence, creating a large gender difference, the largest gender difference appeared in the high school years and was small to moderate in magnitude, ($d = .33$). Results based on nationally representative data sets from the National Center for Education Statistics showed smaller gender differences in the high school years, with nearly all effect sizes less than .16. When the studies were analyzed according to the ethnicity of the sample, the results indicated that a small gender difference favoring males exists for Whites ($d = .20$) whereas there is no gender differences for Blacks ($d = -.04$).

In conclusion, the gender difference in self-esteem is small at most and, in the USA, is found in White samples but not in Black samples.

1.7 Summary

On the Big Five dimensions of personality, there appear to be no gender differences in openness to experience and only a slight gender difference favoring women in conscientiousness. Within the dimension of

extraversion, if one distinguishes between gregariousness and assertiveness or dominance, there is a small gender difference favoring women on the former and a moderate gender difference favoring men on the latter. For agreeableness, if one distinguishes between trust and tender-mindedness or nurturance, there is a small gender difference in the former and a large gender difference in the latter; in both cases, women score higher. A small gender difference in neuroticism, women scoring higher, appears consistently across studies and cross-nationally. Finally, the gender difference in self-esteem is small at most and, in the USA, is found in White samples but not in Black samples.

2. Gender Differences in Social Behavior

This section reviews research on gender differences in aggression, helping behavior and altruism, group behaviors, and communication and nonverbal behaviors.

2.1 Aggression

Two meta-analyses provide summaries of the existing data on gender differences in aggression. Hyde’s (1986) meta-analysis used a developmental approach in reviewing 143 studies. Averaged over all studies, the average effect size d was .50; that is, the magnitude of the gender difference was moderate. Naturalistic studies of aggression yielded larger gender differences ($d = .56$) than laboratory experimental studies ($d = .29$). Studies of physical aggression produced larger gender differences ($d = .60$) than studies of verbal aggression ($d = .43$). One should note, however, that both effect sizes are positive; that is, males were more aggressive for both physical and verbal aggression. Gender differences were larger for preschoolers ($d = .58$) than for studies of college students ($d = .27$).

Eagly and Steffen (1986) took a different approach in their meta-analysis, limiting their review to social psychological research on aggression in adults, mainly college students. They obtained a mean effect size of .29. The discrepancy between this overall effect size and the value of .50 reported by Hyde (1986) doubtless lies in the fact that Eagly and Steffen reviewed only studies of adults, among whom gender differences are smaller; for studies of college students, Hyde found an effect size of .27, nearly identical to the one obtained by Eagly and Steffen.

2.2 Helping Behavior and Altruism

Eagly and Crowley (1986) conducted a meta-analysis of studies of gender differences in helping behavior. They grounded their meta-analysis in social role theory and argued that it made no sense to examine an overall effect size for gender differences in helping

behavior. Instead, whether males help more or females help more depends on whether the situation calls for helping that is consistent with the male role or the female role. The results are therefore highly dependent on the situations in which social psychologists have measured helping. Men, for example, are more likely to help in situations in which they know they are being observed ($d = .74$) whereas there is no gender difference ($d = -0.02$) when participants believe they are not being observed. Heroism is part of the male role and heroism requires onlookers. Helping in the private context of long-term relationships is part of the female role, for example, a mother helping a child. This type of helping has been neglected in social psychological research.

Eisenberg and Fabes (1998) conducted a meta-analysis of studies of gender differences in children's prosocial behavior. The overall effect size was $d = -.18$, indicating a small gender difference favoring girls. Girls scored higher on all types of prosocial behavior, including instrumental help and comforting; the largest gender difference was for being kind or considerate, $d = -.42$.

2.3 Group Behaviors

2.3.1 Instrumental and expressive roles. Research in this area has been influenced heavily by the early research and theorizing of sociologist Talcott Parsons (1955), who argued that two roles develop in all small groups including the nuclear family, the instrumental role (task-oriented, getting things done), and the expressive role (providing emotional support to group members), and that women specialize in the expressive role and men in the instrumental role. Support for the notion of instrumental and expressive roles came from a study of 14 all-male groups (Bales and Slater 1955), although Parsons apparently did not see the inconsistency between that research and his arguments about gender-based specialization. A reanalysis of a classic study that is often cited as evidence for gender differences in instrumental and expressive behaviors found that, although men exhibited significantly more task-oriented behaviors than women did, 79 percent of men's behaviors were task-oriented and 63 percent of women's were; that is, for both women and men, the majority of behavior was instrumental (Aries 1996). Several decades later, then, it is clear that, although there is evidence of gender differences in instrumental and expressive behaviors in groups, gender similarities are perhaps as striking. In addition, many features of the task and the situation influence the results (Aries 1996).

2.3.2 Leadership. In mixed-sex groups, men are more likely than women to emerge as leaders, al-

though the magnitude of the difference is modest and the results are too complex to encompass in a single statement about gender differences. Eagly and Karau (1991) meta-analyzed studies of the emergence of leaders, most of which were laboratory studies done with college students. For task-oriented leadership, men emerged more frequently as leaders ($d = .41$). For general leadership measures, men also emerged as leaders more, ($d = .32$). Women, however, were more likely to emerge as leaders when social leadership was assessed, ($d = -.18$).

Research on leadership styles generally distinguishes between democratic and autocratic styles. Eagly and Johnson (1990) meta-analyzed research on gender differences in these styles. They found that women showed a more democratic style than men ($d = -.22$). To make matters more complex, the results were found in laboratory studies but not in field studies in actual organizations. The null findings in the real-world setting may have to do with the tendency for organizations to select leaders with particular styles.

2.4 Communication and Nonverbal Behavior

Two recent volumes have reviewed the existing research on gender differences in communication and nonverbal behavior (Aries 1996, Canary and Dindia 1998). Here I summarize the trends in findings for gender differences in language use, the content of conversations, the evaluation of speakers in relation to gender-stereotyped speech, interruptions, and nonverbal decoding.

2.4.1 Gender and language use. In 1973, Lakoff published an influential paper on gender differences in language use. In it, she argued that women use a number of speech forms—for example, tag questions, hedges, and polite forms—considerably more frequently than men, and that these forms reflect uncertainty and deference. Lakoff theorized, in turn, that this speech style represents women's adaptation to their lack of power in society. The style avoids conflict and appeases others precisely because it is not forceful. For example, 'That was a great game!' is a forceful statement, but when the tag questions is added, 'That was a great game, wasn't it?' it becomes considerably less forceful, according to Lakoff.

Lakoff's thesis contains two empirically testable hypotheses: (a) there are reliable gender differences in the use of tag questions, hedges, and polite forms, with women using more of all three; and (b) these forms have the function of signaling uncertainty and deference. I review the data for each hypothesis in turn.

In regard to tag questions, research findings are inconsistent. Some studies confirm Lakoff's belief that women use more tag questions than men (e.g.,

Carli 1990, Holmes 1984), some find that men use more tag questions (e.g., Cameron et al. 1988) some find no gender differences (Baumann 1976, cited in Aries 1996), and some find that the direction of the gender difference depends on the situation (Holmes 1984, Cameron et al. 1988, Kollock et al. 1985). In short, the evidence does not strongly support Lakoff's assertion about gender differences in the use of tag questions.

The second of Lakoff's hypotheses concerns the meaning and function of tag questions. Do they really signal uncertainty? Holmes's (1984) data indicate that tag questions can serve three functions: expression of uncertainty ('The plane is scheduled to depart at 9:35, isn't it?'), expressions of solidarity ('You're still limping a bit, aren't you?'), and politeness to soften an order or negative comment ('To get tenure, you'll have to improve your teaching, won't you?'). In her data, men actually used tags to express uncertainty more than women did, whereas women were more likely to use tags for the other two functions, which maintain and facilitate conversation. Therefore Lakoff's second hypothesis is not supported, but the data suggest that women's tag questions have different functions such as expressing solidarity and softening a difficult comment.

The pattern of findings for hedges is quite similar to that for tag questions (Aries 1996). A purported hedge such as 'I think' may be a hedge or a statement of confidence depending on several factors, including whether the emphasis is on 'think' or 'I.' For example, in the sentence 'Melbourne is the capital of New Zealand, I think,' the phrase serves as a hedge, indicating uncertainty. In contrast, 'I think Truman was the best president of the century,' with emphasis on 'I,' is a strong statement of confidence. Again, there is little support for Lakoff's assertions.

The theme that there are striking gender differences in language use was taken up again vigorously by Tannen in her books written for a popular audience, such as *You Just Don't Understand: Men and Women in Conversation* (1991). Tannen argued that men's and women's language use is so different that they essentially belong to different linguistic communities, and therefore that male-female communication is as difficult and error-prone as cross-cultural communication. Moreover, she argued that men and women use conversation for different purposes: men to express status and independence and women to establish connectedness and intimacy with the other person. She believes that these differences arise because boys and girls grow up in essentially different cultures because of the gender segregation of childhood play. Aries (1996), however, in a review of the research, found little evidence to support Tannen's propositions.

2.4.2 Self-disclosure. A large research literature exists on self-disclosure in conversations and, in par-

ticular, gender differences in self-disclosure. Dindia and Allen (1992) conducted a meta-analysis of these studies. Across 205 studies, women self-disclosed more, but the difference was small ($d = -.18$). Patterns of self-disclosure depend on the sex of the target. There is no gender difference in self-disclosure to a male target ($d = .00$), whereas the gender difference is more substantial for a female target ($d = -.35$). Patterns also depend on the relationship between the two people engaged in the conversation. The gender difference in self-disclosure is trivial when the conversation is between strangers ($d = -.07$) and is found mainly when the conversation is with a friend ($d = -.28$), a spouse ($d = -.22$), or a parent ($d = -.26$).

2.4.3 Evaluation of speakers. If college students are asked to prepare and deliver a speech and the speeches are transcribed so that they can be rated blind to the sex of the speaker, women's speeches tend to be rated higher on sociointellectual status and esthetic quality and men's speeches are rated higher on dynamism (e.g., Mulac and Lundell 1980). This has been termed the gender-linked language effect and has been found as early as fourth grade (Mulac et al. 1990).

A large body of research in social psychology has demonstrated that the stereotypes we hold influence the impression that we form of an individual. Research has shown repeatedly that people hold stereotypes about women's and men's speech (Aries 1996). For example, people expect men to interrupt more than women (Hawkins 1988). By sixth grade, children's stereotypes of male and female speech agree with adults' (Edelsky 1976).

The evidence indicates that gender stereotypes do influence raters' evaluations of men's and women's speech. In one study, participants listened to tape recordings of male and female speakers, who in fact used tag questions equally; participants perceived the women to have used more tag questions than the men (Newcombe and Arnkoff 1979). In short, people perceive women's and men's speech to confirm gender stereotypes even when the actual speech does not.

Are women and men evaluated differently, depending on whether they display male-stereotyped or female-stereotyped speech? Erickson et al. (1978) created two scripts, in the context of a courtroom trial setting; in one, the speaker used powerful or male-stereotyped speech and in the other, powerless or female-stereotyped speech. Raters were led to believe that the speaker was either male or female. The results indicated that, regardless of the speaker's sex, raters found those who used more powerful, male-stereotyped language to be more credible and more attractive. Research using such a paradigm has consistently found that, regardless of the sex of the speaker, powerless, female-stereotyped language is

viewed more negatively and powerful, male-stereotyped language more positively on most dimensions (Carli 1990).

2.4.4 Interruptions. Research in the 1970s found that, in mixed-sex conversations, men interrupted women considerably more than the reverse (Zimmerman and West 1975). This pattern was found both in natural conversations (Zimmerman and West 1975) and in controlled laboratory situations (West and Zimmerman 1983). These results stimulated much interest; they were widely interpreted as an indication of nonverbal dominance of females by males (Zimmerman and West 1975, Smith-Lovin and Brody 1989).

Recent reviews, however, have challenged both the existence of the gender difference and its interpretation (Aries 1996). First, a review of more recent research as well as a critical examination of the original studies indicates that there are no well-documented gender differences in interruptions. Second, understanding of interruptions has become more sophisticated and it is clear now that, although some interruptions are power-oriented (e.g., cutting off a speaker to change the topic), interruptions can serve many other functions, including expressing support, interest, or agreement.

2.4.5 Smiling. One nonverbal behavior that has consistently shown gender differences is smiling. In an early meta-analytic review, Hall (1984) found that females consistently smile more than males, ($r = .30$), which translates to $d = -.63$, a difference that is in the moderate-to-large range and is noticeably larger than most other gender differences reviewed here. More recent studies continue to document the same phenomenon (Hall 1998). The pattern, though, is more characteristic of White women than African-American women (Halberstadt and Saitta 1987).

Generally this difference is interpreted as indicating the extent to which smiling is a part of the female role. For example, in one study, participants were given a written description of a person, accompanied by a photograph of a man or woman who was smiling or not smiling (Deutsch et al. 1987). Women who were not smiling were given more negative evaluations; apparently people react negatively to this violation of the female role.

2.4.6 Nonverbal decoding. Nonverbal decoding (also termed nonverbal sensitivity) refers to a person's ability to read correctly the nonverbal behaviors or body language of another person. A gender difference favoring females has been documented over several decades. In an early meta-analysis, Rosen-

thal et al. (1979) located 133 samples that had been administered the Profile of Nonverbal Sensitivity (PONS, which bases scores on responses to short video clips); females scored higher than males in 80 percent of the samples ($d = -.41$), a moderate effect. Later meta-analyses based on a wider variety of measures obtained quite similar results; for example, Hall (1984) found $d = -.52$.

3. Future Directions

Research on gender differences in personality and social behavior must certainly move beyond questions of simple gender differences, to systematic analyses of situation $\times$ person and situation $\times$ gender interactions. Which situations call forth gender differences and which do not? How can these situational variations be drawn into a coherent pattern that is theoretically meaningful?

4. Summary

Over a wide range of personality and social variables, there is much evidence of gender similarities. For the Big Five personality dimensions, there is no gender difference in openness to experience ($d = .03$) and small differences in conscientiousness ($-.13$), extraversion or gregariousness ($-.14$), and neuroticism ($-.25$); there is, however, a large difference in one aspect of agreeableness, termed tendermindedness or nurturance ($-.97$). The gender difference in self-esteem is small ($.21$).

Likewise, there are many gender similarities in the realm of social behavior. The direction of the gender difference in helping behavior depends largely on the situation. In small groups, men and women are similar in their instrumental and expressive behaviors. The gender difference in democratic vs. autocratic leadership style is small ($-.22$ for democratic style). The research evidence does not support popular media claims about enormous gender differences in language use. The gender difference in self-disclosure is small ($-.18$). There are several exceptions to this pattern of gender similarities. Gender differences are moderately large for aggression ($.50$), smiling ($-.63$), and sensitivity to nonverbal cues ($-.52$).

Gender, Economics of

1. *Gender and the Economics of Gender*

The term 'gender' traditionally has referred, as has sex, to the biological differences between men and women. In the 1980s, however, increasingly it came to be used to refer instead to the distinctions which society has erected on this biological base. This article describes the relationship of this concept of gender to economics, focusing on economic analyses of gender differences in behavior and economic outcomes. This focus may be differentiated from feminist economics that is a critique of the discipline and practice of economics from a feminist perspective (see *Feminist Economics*).

2. *Economists' Increasing Interest in Gender Issues*

Historically, gender has not been perceived to be a central concept in economic analysis. However, as the force of current events has thrust gender-related issues to the fore, economists have responded. The outcome has been not only a better understanding of the nature and causes of gender differences, but also an enrichment of the discipline itself.

One reason for the historical neglect of gender issues by the economics discipline is that, traditionally, economists focused on market transactions and, traditionally, most married women were primarily engaged in nonmarket activities. As women have come to comprise a larger share of the paid labor force and as market work has loomed larger in the typical woman's life, interest in the determinants of gender differences in behavior and labor market outcomes has grown. At the same time, the growing interest of economists in analyzing nonmarket work and demographic outcomes such as marriage, divorce and fertility also played an important role in increasing economists' attention to gender-related issues.

While early economic analyses paid scant attention to gender issues, the nineteenth century campaign for women's rights and female suffrage did focus some attention on gender inequality. With few married women employed outside the home, observers like American feminist, Gilman (1898/1966) and Marxist, Engels (1884/1972) (see *Marxian Economic Thought*) focused on the gender division of labor itself, espousing the emancipating effects of women's participation in market work. Classical economist Mill (1869/78) eloquently argued for women's 'admissibility to all the functions and occupations hitherto retained as the monopoly of the stronger sex' and expressed the belief that women's 'disabilities elsewhere are only clung to in order to maintain their subordination in domestic life.' These views highlight the notion that understanding women's status involves

an understanding of both the market and family spheres and of the interrelationship between the two. This insight remains applicable to the current day.

3. *Time Allocation in the Family Context*

Prompted in part by their desire to understand the causes of the rising labor force participation of married women in the post-World War II period, economists extended the traditional theory of labor supply (see *Labor Supply*) to consider household production.

3.1 *The Traditional Theory of Labor Supply*

The traditional theory of labor supply was a simple extension of consumer theory. Individuals maximize their utility, which is derived from market goods and leisure, subject to budget and time constraints. The labor supply decision is determined by the opportunity wage (the wage rate the individual could earn in the labor market), nonlabor income (the amount of income available to them from other sources), and the individual's tastes or preferences for work vs. leisure.

3.2 *Household Production and the Allocation of Time*

While this theory is sufficient for many purposes, it has substantial limitations for understanding the determinants of the gender division of labor in the family and the factors influencing women's labor force participation. The key to addressing these issues is a fuller understanding and analysis of the household production process.

An early pioneer in analyzing household production was Reid (1934), but it was the work of Becker and Mincer in the 1960s that was particularly influential in bringing these issues into the mainstream. In analyzing married women's labor force participation in the US, Mincer (1962) pointed to the importance for them of the three-way decision among market work, non-market work, and leisure. He attributed the growth in married women's participation during the early post-war period to women's rising real wages which induced them to substitute market work for housework. This response was large enough to more than offset the negative income effect on their labor supply associated with the growth in their husbands' real wages.

Becker (1965) advanced this process further by proposing a general theory of the allocation of time. In this and other work (summarized in Becker 1981), he laid the foundations of the 'new home economics,' including economic analyses of time allocation, marriage, divorce, and fertility. Interestingly, while Mincer opened a window on household production by distinguishing nonmarket work from leisure, Becker was

able to provide a further advance by again eliminating the distinction. However, while in the traditional labor supply model all nonmarket time is spent in leisure, in Becker's model all nonmarket time is spent in household production. Becker assumes that households derive utility from 'commodities' that are produced by inputs of market goods and nonmarket time.

These ideas may be illustrated by considering the relationship between children and women's labor force participation. Young children may be viewed as a 'time-intensive' commodity. Traditionally, it has been the mother who was the primary care giver. And, while it is possible to substitute market goods and services (e.g., babysitters, day care centers) for home time in caring for children, these alternative production techniques tend to be costly and may be difficult to implement. Thus, at any point in time, the probability that a woman will participate in the labor force is expected to be inversely related to the number of small children present. Over time, the increase in women's participation rates has been associated with decreasing birthrates, as well as increases in the availability of alternative child care arrangements.

3.3 Trends in Labor Supply

Continuing in the tradition of Mincer (1962), the labor supply model has been used to explain the trends in female labor force participation. One criticism that has been made of this type of economic modeling is that it abstracts from historical and institutional factors. Goldin (1990), however, turns this feature of economic models to her advantage in an especially innovative application. She finds that a model applied to decennial US Census data for the 1890–1980 period overpredicts married women's labor force participation for 1930, 1940, and 1950. She presents this as evidence that the process of change in participation was retarded for married women by institutional barriers like marriage bars (i.e., prohibitions against employing married women that were particularly prevalent in teaching and clerical work) and the lack of availability of part-time employment.

As wage inequality rose in many advanced countries in the last quarter of the twentieth century, increasing attention focused on the contribution of this trend to the continued rise in the labor force participation of wives and the related question of the consequences of the increased employment of wives for family income inequality. On one hand, the income effect suggests that wives of low skilled men would be drawn into the labor force to compensate for the deteriorating labor market position of their husbands. On the other hand, the substitution effect implies that the increasing rewards to labor market skills which underlie the rise in wage inequality, would draw more skilled (e.g., more highly educated) women into the labor market. Since more highly educated individuals tend to marry

each other, a larger role for the income effect in explaining the trends would tend to reduce the correlation between wives' and husbands' earnings, while a larger role for the substitution effect would tend to increase the correlation.

Juhn and Murphy (1997) found for the US that employment gains were in fact largest for wives of middle and high wage men. Their findings strikingly mirror Mincer's (1962) for the immediate post-World War II period: own wage effects dominate cross-effects between husband and wife in accounting for changes in female employment. The correlation between husbands' and wives' earnings has risen in the US, both as a consequence of these participation trends and also due to a rise in the correlation between the earnings of spouses when both are employed. A similar rise has been reported for Britain, which also experienced a substantial increase in wage inequality during this time. However, while this increased correlation contributed to rising inequality in family income in both the US and Britain, the rise in family income inequality among married couples in both countries was principally due to rising inequality of husbands' earnings (Cancian and Reed 1998, Machin and Waldfogel 1994).

3.4 The Gender Division of Labor

In the discussion of the allocation of time above, it was simply assumed that women tend to bear the primary responsibility for childcare and housework. However, the gender division of labor in the family is also an issue that the new home economics addresses. According to Becker (1981), the division of labor will be dictated by comparative advantage. To the extent that women have a comparative advantage in household and men in market production, it will be efficient for women to specialize at least to some extent in the former while men specialize in the latter. In Becker's view, the increased output resulting from this arrangement maximizes family utility and constitutes one of the primary economic benefits to marriage. Thus, women's rising labor force participation is expected to reduce the gains from marriage, thereby contributing to the trend towards higher divorce and lower marriage rates.

As women have been increasingly working throughout the life cycle, more attention has focused on their ability to combine work and family responsibilities successfully. Since men tend not to face the same dilemmas as women, or not to face them to the same extent, this is a potential source of gender differences in wellbeing. Waldfogel (1998) details the prevalence of a 'family penalty' in many advanced countries, that is, lower earnings for women who are mothers, all else equal. This likely reflects the loss of their tie to the firm and associated firm-specific skills when they withdraw from the labor force upon the birth of a child.

Some evidence suggests that policy intervention could reduce the size of the family penalty. For example, Waldfogel (1998) reports evidence from analyses of microdata for the US, Britain, and Japan indicating that women who were covered by maternity leave were considerably more likely to return to their prior employer after childbirth. And women who return to their employer after a birth have higher subsequent wages. Consistent with these results, Ruhm (1998) finds, using aggregate data on 16 countries during the 1969–88 period, a positive, but not significant, effect of 1 percent on women's wages relative to men's of short leave entitlements (1–13 weeks), although longer leave entitlements (over 26 weeks) had a significantly negative effect of 3 percent. The negative effect of longer leaves could indicate that such leaves encourage women to extend their time away from the firm. It is also possible that the higher costs of long mandated leaves provide greater incentives to employers to discriminate against women in wages or job assignments.

A consideration of the difficulties women face in combining work and family raises the possibility of conflicts of interest between husband and wife which in turn makes defining 'family utility' problematic (Ferber and Birnbaum 1977). Such concerns have been addressed by the growing application of bargaining models to family decision-making, led by Manser and Brown (1980) and McElroy and Horney (1981). These models assume that the preferences of husbands and wives may diverge and that outcomes for each spouse can be modeled using game theory (see *Game Theory: Cooperative Games*; *Game Theory: Noncooperative Games*). In the most popular application of these models to the family, the cooperative bargaining model of marriage, the utility received by each spouse in the Nash bargaining solution is related positively to the utility of each partner at the 'threat point,' most commonly taken to be the utility that each would receive if the marriage irretrievably broke down. If it is assumed that, in the event of divorce, each partner maintains ownership of income received separately within marriage, a woman who works outside the home will have a higher utility at the threat point and hence a more favorable distribution within marriage. Studies reviewed by Lundberg and Pollak (1996) provide empirical support for this model in their finding that earned or unearned income received by the wife has a different effect on demand patterns than income received by the husband.

As women anticipate spending increasingly more of their adult lives in the labor market, their investments in market-oriented human capital may be expected to continue to grow and their comparative advantage in home work to decline. Moreover, as the quality of the opportunities open to women in the labor market continues to improve, the disadvantages of specialization in home work in the form of forgone earnings and possibilities for career advancement will

also rise. Thus, greater sharing of household responsibilities between men and women is likely to become increasingly prevalent.

4. Gender Differences in Labor Market Outcomes

Women earn less than men, on average, in all advanced economies, though the extent of the gender pay gap varies considerably across countries and has been declining in many of them in recent years (e.g., Blau and Kahn 1996). Economists' understanding of gender inequality in such economic outcomes has been accommodated principally through the development of new and interesting applications of existing theoretical approaches. Such theories must explain the considerable employment segregation of men and women—by occupation, industry, and firm—as well as gender pay differentials. Segregation of men and women by occupation, for which summary data are most readily available, has been found to be prevalent in all advanced economies, though it has been declining in recent decades in most OECD countries, including the US (e.g., Blau et al. 1998, Anker 1998).

As in the case of the analysis of women's roles in the family, the catalyst for the development of analyses of pay and occupation differences was provided by external events. Some moderate degree of interest in the pay issue was generated in England by the World War I experience when there was some substitution of women into traditionally male civilian jobs, although not nearly to the degree that would later occur during World War II. Questions of the appropriate pay for women under these circumstances arose and stimulated economic analyses of the gender pay differential. These included the work of Fawcett (1918) and Edgeworth (1922), both of whom assigned a prominent causal role to occupational segregation, thus providing the antecedents for Bergmann's (1974) overcrowding model (discussed below). The analysis of gender differentials in the labor market received further impetus in the early 1960s, this time in the US, with the development of the women's liberation movement and the passage of antidiscrimination legislation.

Two broad approaches to the issue have since evolved. First is the human capital explanation which lays primary emphasis on men's and women's own choices in explaining occupation and pay differences. Second are a variety of models of labor market discrimination (see *Discrimination, Economics of*) which share the common characteristic of placing the onus for unequal outcomes on differential treatment of equally (or potentially equally) qualified men and women in the labor market. More recently, some advances have been made by considering the gender pay gap and other demographic differentials in the context of the overall structure of wages (see *Wage Differentials and Structure*).

4.1 The Human Capital Explanation

The human capital explanation for gender differences in occupations and earnings, developed by Mincer and Polachek (1974) and others, provides an explanation for gender differences in market outcomes on the basis of the traditional division of labor by gender in the family. Anticipating shorter and more discontinuous work lives as a consequence of their family responsibilities, women have lower incentives to invest in market-oriented formal education and acquire less on-the-job training than men. Their resulting smaller human capital investments will lower their earnings relative to those of men. Working in a similar direction is Becker's (1985) model in which the longer hours women spend on housework lowers the effort they put into their market jobs compared to men, controlling for hours worked, and hence reduces their wages.

These considerations are also expected to produce gender differences in occupations as women choose occupations for which human capital investments are less important and in which the skill depreciation that occurs during time spent out of the labor force is minimized. Women especially will avoid jobs requiring large investments in firm-specific skills (i.e., skills which are unique to a particular enterprise), because the returns to such investments are reaped only as long as one remains with a particular employer. At the same time, employers are expected to be reluctant to hire women for such jobs because they bear some of the costs of firm-specific training (see the discussion of statistical discrimination below).

To the extent that gender differences in outcomes are not accounted for fully by productivity differences derived from these and other sources, models of labor market discrimination offer an explanation.

4.2 Models of Labor Market Discrimination

Theoretical work in this area was initiated by Becker's (1957) model of racial discrimination. Becker conceptualized discrimination as a taste and analyzed three cases, those in which the discriminatory tastes were held by employers, co-workers, and customers or clients. Under certain circumstances, such discrimination will cause a wage differential between men and women. So discriminatory employers will only hire women at a sufficient wage discount that compensates them for the disutility of employing women. Discriminatory male workers will demand a wage premium to work with women thus raising men's relative wages, and the reluctance of discriminatory customers or clients to buy goods or services provided by women will make women less productive in terms of revenue brought in, thus depressing women's relative wages.

Models based on tastes for discrimination are also consistent with employment segregation, but do not necessarily predict it will occur. If wages are flexible, it is altogether possible that discrimination will result in

lower pay for women, but produce little or no segregation. However, if discriminatory tastes against women in traditionally male pursuits are both strong and prevalent, women may tend to be excluded from these areas. If such segregation does occur, it may or may not be associated with gender pay differentials. In the presence of sufficient employment opportunities in the female sector, equally qualified women may earn no less than men.

The relationship between occupational segregation and earnings differentials is clarified in Bergmann's (1974) overcrowding model. If, for whatever reason (i.e., labor market discrimination or their own choices), potentially equally qualified men and women are segregated by occupation, the wages in male and female jobs will be determined separately by the supply and demand for labor in each sector. Workers in male jobs will enjoy a relative wage advantage if the supply of labor is more abundant relative to demand for female than for male occupations. Such 'crowding' of female occupations can also widen differentials between male and female jobs that would otherwise exist due to women's smaller human capital investments or employers' reluctance to invest in women's human capital.

One question that has been raised about the Becker model is how employer discrimination can persist in the long run in the face of competitive forces. The least discriminatory firms, which hire more lower-priced female labor, would have lower costs of production. In the long run, they should expand and drive the more discriminatory firms out of business. One answer, suggested initially by Becker himself, is that discrimination will be located in sectors of the economy that are not competitive (see *Market Structure and Performance*). While Becker emphasized monopolistic elements in the product market, a related approach targets monopsonistic power on the part of the employer in the labor market (e.g., Madden 1973).

In addition, models of statistical discrimination were later developed, in part to explain the persistence of discrimination in the long run in the face of competitive forces. Such models assume a world of uncertainty and imperfect information; thus differences between groups in the expected value of productivity or in the reliability with which productivity may be predicted are expected to result in differences in the treatment of members of each group. So, for example, employers may believe that women are more likely to quit their jobs than men with similar observed characteristics (education, experience, etc.) or they may believe that women's turnover can be less reliably predicted by their measured characteristics than men's. As a consequence, they may pay women less, exclude them from jobs requiring substantial firm-specific training, or deny them promotions.

It has been argued that such statistical discrimination, making decisions on the basis of the average characteristics of the group, is consistent with profit

maximization and can thus persist in the face of competitive forces. However, Aigner and Cain (1977) contend that such models are no more convincing in explaining the persistence of discrimination than models based on tastes for discrimination. To the extent that employers' views are accurate, the lower expected productivity of women will reduce their wages but women as a group will be paid their expected productivity. This does not constitute labor market discrimination as economists define it, that is, pay differences that are not accounted for by productivity differences. Presumably they would make a similar argument regarding hiring and promotion decisions. Moreover, they note that when employer beliefs regarding average differences are erroneous, discrimination clearly exists but in their view discrimination based on such misperceptions is even less likely to persist in the long run than discrimination based on tastes. Finally, though they acknowledge that less reliable predictions of a group's productivity combined with risk aversion by employers could produce a discriminatory differential, a perfectly elastic supply of risk neutral entrepreneurs could be expected to erode discriminatory differentials based on this factor.

However, such models may have greater usefulness in explaining the persistence of gender differentials in pay than Aigner and Cain's analysis suggest. Consider first the situation where employer perceptions are correct. In this case, the concept of statistical discrimination provides a plausible reason for the existence and persistence of pay and occupational differences between men and women with similar measured characteristics; this is in itself a useful contribution even if it does not shed light on the persistence of economic discrimination in the long run. But if the employer views are correct, is it appropriate to consider this a form of 'discrimination' in any sense? From a normative perspective, the answer may be yes, to the extent that basing employment decisions on a characteristic like sex—a characteristic that the individual cannot change—could be viewed as inequitable. Indeed, the practice of judging an individual on the basis of group characteristics rather than upon his or her own merits seems the very essence of stereotyping or discrimination. Such behavior is certainly not legal, for example, under the antidiscrimination laws and regulations.

Now consider the situation where employer perceptions are incorrect. If statistical discrimination is accompanied by feedback effects, this may be a more credible source of persistent discriminatory pay differences between men and women than Aigner and Cain suggest. For example, if employers incorrectly expect that women are more likely to quit their jobs, they may respond by giving women less firm-specific training or assigning them to dead end jobs. Faced with few incentives to remain on the job, women may respond by exhibiting exactly the higher turnover that employers expect.

This criticism of the Becker model—its inability to explain the persistence of discrimination against women in the long run—has proved to be a double-edged sword in that it has led some economists to doubt that labor market discrimination is responsible, in whole or part, for observed gender differences in labor market outcomes. Yet it is important to recognize that discrimination is an intrinsically complex process. From this perspective, it is not surprising that no easy solution has been found to the question of why discrimination may persist in the face of competitive forces. Similarly, the various models of discrimination, each emphasizing different motivations and different sources of this behavior, need not be viewed as alternatives. Rather, each may serve to illuminate different aspects of this complex reality. When it is further recognized that, as our discussion above suggests, discrimination can adversely affect women's human capital investments and labor force attachment by lowering the market rewards to this behavior (e.g., Weiss and Gronau 1981), it is clear that the potential impact of discrimination on women's labor market outcomes may be large indeed.

4.3 Evidence on Human Capital, Discrimination, and the Gender Pay Gap

The typical approach to analyzing the sources of the gender pay gap is to estimate wage regressions specifying the relationship between wages and productivity-related characteristics for men and women (see *Econometric Software*). The gender pay gap may then be decomposed statistically into two components: the first, due to gender differences in measured characteristics and the second, which is 'unexplained' and potentially due to discrimination.

Such studies provide considerable empirical support for both human capital differences and labor market discrimination in explaining the gender pay gap. For example, Blau and Kahn (1997) report that, in 1988, US women's wages were 72 percent of men's, on average. Adjusting for gender differences in human capital (i.e., education and experience) would raise the ratio to 81 percent, while additionally adjusting for gender differences in industry, occupation and unionism would further increase it to 88 percent. Thus, while measured characteristics are important, women still earn considerably less than similar men, even when all measured characteristics are taken into account.

One problem with studies of this type is that discrimination may be overestimated to the extent that unexplained pay differentials between men and women are due in whole or part to gender differences in unmeasured qualifications. On the other hand, to the extent that the regression models include controls for characteristics like industry or occupation that could themselves be due to discrimination, discrimination may be underestimated. Recent studies that take a

different approach to the question provide additional evidence of discrimination that addresses the former concern.

First, studies have applied traditional econometric techniques to especially homogeneous groups and employed extensive controls for qualifications, thus minimizing the effect of gender differences in unmeasured characteristics; and still found evidence of an unexplained pay difference between men and women (see, e.g., Wood et al. 1993) which focused on graduates of the University of Michigan Law School).

A second set of studies uses an experimental approach. Neumark (1996) analyzed the results of a hiring 'audit' in which male and female pseudo-job seekers were given similar résumés and sent to apply for waiter or waitress jobs at the same set of Philadelphia restaurants. The results provided statistically significant evidence of discrimination against women in high-priced restaurants where earnings of workers are generally higher than in the other establishments. A second study, Goldin and Rouse (2000), examined the impact of the adoption of 'blind' auditions by symphony orchestras in which a screen is used to conceal the identity of the candidate. Using data from actual auditions, it was found that the screen substantially increased the probability that a woman would advance out of preliminary rounds and be the winner in the final round.

Finally, there is some evidence that gender differentials in wages or employment are larger in less competitive industries. For example, Black and Strahan (1999) report that with the deregulation of the banking industry beginning in the mid-1970s, the gender gap in pay in banking declined. This is consistent with the expectation that discrimination will be more severe in firms that are shielded to some extent from competitive pressures and thus indirectly provides support for the view that discrimination is a factor influencing gender wage differentials.

4.4 The Role of Wage Structure

Both the human capital and discrimination explanations for the gender pay gap might be considered 'gender specific' in nature, that is, focused on gender differences in either qualifications or treatment. Analyses of gender differentials traditionally have tended to emphasize these types of gender-specific factors. Important work by Juhn et al. (1991) on trends in the race pay gap over time in the US, has highlighted an additional factor, overall wage structure, which is also relevant to analyzing the gender pay gap. Wage structure is the array of prices determined for labor market skills and the rewards to employment in particular sectors.

The human capital model suggests that men and women tend to have different levels of labor market

qualifications (especially work experience) and to be employed in different occupations and perhaps in different industries. Discrimination models, too, suggest that women may be segregated into different sectors of the labor market. This implies that the returns to skills and the size of premiums for employment in particular sectors potentially play an important role in determining the pay gap. All else equal, the larger the returns to skills and the larger the rents received by individuals in favored sectors, the larger will be the gender pay gap.

Blau and Kahn (1996) have applied this insight to understanding international differences in the gender pay gap in order to address a paradox. The relative qualifications of American women are high compared to women in other countries, and the US has had a longer and often stronger commitment to antidiscrimination laws than most economically advanced nations. Yet the US traditionally has been among the countries with the largest gender pay gaps. The resolution to this paradox lies in the decentralized system of wage setting in the US that has resulted in a highly dispersed wage distribution and high returns to labor market skills and employment in favored sectors. In contrast, the greater role of unions and government in the labor markets of other economically advanced nations has resulted in higher wage floors and more compressed wage distributions from which employed women, as a relatively low wage group, have benefited disproportionately.

This raises the question of how, given the rising wage inequality that has occurred in many of the advanced industrialized countries, women have nonetheless been able to narrow the wage gap with men in many cases. A detailed study of the US by Blau and Kahn (1997) suggests that women have been able to compensate for the adverse effects of rising inequality and higher rewards to skills by improving their relative qualifications, particularly their average work experience and their occupational distribution. In addition, the unexplained portion of the pay gap declined, reflecting either an upgrading of women's unmeasured labor market skills or a decline in discrimination against them, or both.

Similar studies of the UK (Dolton et al. 1996) and Sweden (Edin and Richardson 1999) also find that gender specific factors were principally responsible for declines in the gender gap in those countries over the 1970s, although during a subperiod in which considerable wage compression occurred in Sweden due to its 'solidarity' wage policy (1968–71), wage structure played a major role.

5. Conclusion

This review suggests that women's economic roles in the family and their labor market outcomes are closely related. This has undoubtedly played a role in the

persistence of gender differences in both spheres. However, increasing opportunities for women in the labor market may be expected to reduce gender differences in family roles, while such a diminution of adherence to the traditional division of labor in the family is likely to enhance women's position in the labor market further. Thus, just as a fuller understanding of the interrelationships between women's roles in the family and their status in the labor market helps us to understand the persistence of gender inequality in economic outcomes, it also enables us to appreciate how changes in either one of these spheres, or both, can induce a mutually reinforcing process of change. Recent reductions in the pay gap in many of the economically advanced countries may well signal the operation of such a process.

Gender, Feminism, and Sexuality in Archaeological Studies

An important new field within archaeology, often referred to as the archaeology of gender, archaeology and gender, or gender archaeology, combines a critical feminist study of gender, sex, and sexuality with a feminist analysis and examination of central concepts within archaeology, and the ways in which archaeological knowledge is produced, presented, and represented. Although there are many different kinds of feminism, it is taken here in its broadest sense, with its major goal being a critique of the determination of women's lives by nature/biology, reducing their multifaceted lives to an essentialist category 'woman.' Rather, gender, sex, and sexuality are not constrained by essentialist and narrowly defined categories, but are seen as being historically constituted and varied categories, changing over time. The aims of feminist archaeology are to both investigate and challenge the assumed content of, and relationships between, gender categories such as women and men, femininity and masculinity; and to study gender divisions and sexuality over time and in different social and cultural contexts in the past. Archaeology is a way of knowing and investigating the past that is based on a particular androcentric understanding of objectivity that is historically constituted Euro-American. Feminist archaeology, using feminist critiques of science, challenges this traditional construction of archaeological knowledge.

1. A Slow Start

Although tied to the goals of Second Wave feminism, which not only critiqued gender relations in contemporary society, but also began very specifically to investigate how assumptions about the 'naturalness' of sex and gender affected the production of knowledge, feminism was slow in coming to archaeology. In the mid-1970s the first feminist critiques of equity issues in archaeology started in Scandinavia, particularly Norway. This concern quickly expanded to critiques of analyses and presentations of women in the past, and resulted in the founding of the first, and as yet only, feminist archaeology journal, *KAN: Kvinner i Arkeologi i Norge* (KAN: Women in Archaeology in Norway) in 1985. The previous year, Margaret Conkey and Janet Spector's groundbreaking article critiquing androcentrism in archaeology and discussing the possibilities of studying gender in the past was pub-

lished in the United States. It was, however, at the beginning of the 1990s that the archaeology of gender and feminist critiques exploded on the archaeological scene.

During the course of the 1990s there were numerous publications on the archaeology of gender, particularly edited volumes of symposia and conference papers, as well as a few monographs. Few of these publications use the word 'feminist' in their titles, preferring various combinations of the words 'gender' and 'archaeology.' However, the majority are feminist in content and intention, and in their interpretations of the past.

Feminist archaeology in its beginnings was particularly an Anglo-American, Australian, and Scandinavian phenomenon, but expanded in the 1990s to other European countries, particularly Germany and Spain. The slow development of feminist archaeology in some countries can be explained partially by how archaeology is viewed within the different academic systems. Archaeology and anthropology in North America are closely linked, and feminist archaeology benefited from its close connection with feminist anthropology. In many European countries, however, archaeology is not a social science but a discipline in the humanities, and thus society and social relations were not in the forefront of many archaeological studies. At the same time archaeology is one of the few humanities that works with material culture, rather than texts, and has thus been relatively isolated from the intense feminist discussions within the humanities.

This basic disciplinary difference between the North American and the European archaeology of gender is probably one reason for the different perspectives these two archaeologies had initially. North American gender archaeology has been concerned more with social processes while European gender archaeology continued with traditional interests in cultural (now gender) identity and distinctions. However, as the archaeology of gender has developed and changed, this tendency is now minimized as not only anthropology but social theory, post-structuralism, post-processualism, and feminist theory have become important elements of archaeological thinking in all areas.

The feminist philosopher of science Alison Wylie (1991) has considered why it took so long for feminist critiques to reach archaeology and emphasizes the essentialist assumptions in archaeological theorizing tied to macroscale analyses. Since these essentialist assumptions were based on biological determinism it was vital in the beginning to make a distinction between sex, a biological construct, and gender, a social construct. Here one must note the difference between the English language separation of sex and gender, and the fact that many other languages have but one word for both. Recent work in feminist archaeology, both in English and non-English-speaking countries, resurrects sex and sexuality from the

merely biological, but while viewing sex/sexuality as a social construction associated with gender, this work does not neglect changing biological processes.

2. Back to Basics

Much feminist work in the 1980s and 1990s concentrated on gender rather than sex and sexuality. As with feminism in general, this was necessary in order to negate the importance of previous biological determinism and essentialism in placing women in a subordinate position in the past. Androcentric archaeology considered women essentially the lesser part of the male–female, masculine–feminine, man–woman dichotomies. Women were often reduced conceptually to their biological function of giving birth. This also placed women on the lesser side of a whole series of related hierarchical dichotomies, such as public–domestic, public–private, powerful–dominated, active–passive, etc., thus giving biological reasons for social differences and social formations. For example, the origins of the nuclear family were tied closely tied to stable binary sex and gender distinctions which were seen as beginning almost 4 million years ago. This pattern was established in the archaeological literature before feminist critiques turned this set of universal hierarchical dichotomies into a problem to be investigated rather than assumed.

However, the classic feminist concern with the universal subordination of women played a peripheral role in feminist studies of the past. It was obvious that women were given a subordinated role in archaeologists' textual and visual presentations, and feminists critiqued such androcentric and essentialist assumptions. Conkey and Spector (1984) noted that despite its professed objectivity and neutrality, archaeology was 'neither objective nor inclusive on the subject of gender.' This false notion of objectivity contributed to making women invisible. The gender paradigms implicitly treated women and men differently, consistently linked certain activities to each gender/sex, and made men central and active in all societies in the past, while women were passive and 'at home.'

Feminist interpretations of the same past critiqued the subordinate role given to women in archaeological texts, exhibits, and illustrations. Feminist archaeologists have worked from the premise that universal subordination was not necessarily the case in the past, that gender ideologies and women's roles varied and were given different statuses over time and space, again emphasizing that these concepts are something to be investigated rather than assumed. In the 1980s both feminist theoretical and empirical work assumed that gender categories were not necessarily exclusive and that women were an active part of culture and society in the past. Studies were concerned

with defining women's various roles, contributions, and activities. Task differentiation was developed as a framework and methodology by Janet Spector in order to study the various dimensions of women's and men's activities in past societies. Some form of this method is still often used in current analyses in the archaeology of gender, and is one of many contemporary efforts to put women back into our understanding of the past.

Following feminist critiques of science, feminist archaeologists examined critically the basic assumptions behind previous understandings of the past. The majority of articles on gender have as implicit but important goals the examination of what counts as data, what counts as interpretation of that data, and what is considered acceptable interpretation and theory in the male-dominated archaeological community. Thus they examine the selective processes which determine relevant data for interpretation, and how this over-determines interpretations and results in ignoring gendered processes and structures. Why are 'men's' artifacts simply assumed to be of primary interest? Why did important interpretational frameworks consider only men to be the prime movers of social and cultural change? In addition, they examine androcentric theoretical concepts which were previously, and often currently, considered to be the only reasonably legitimate and, indeed, the only 'natural' and 'rational,' theoretical frameworks. Engendering the past not only redefines and extends what is considered as data, interpretation and theory, but also challenges many taken-for-granted concepts and models.

3. Approaches to Gender and Sexuality

As with all feminist projects, the archaeology of gender is grounded in the analysis and understanding of women's lives. Women's lives are reflected in archaeological remains of the past, in the material culture (objects and structures) of past societies. Richly detailed empirical studies, which put women (and children) back in to our understanding of the past, abound. These are tied to differing theoretical views of gender as a structuring principle, and examine how material culture was used to express and construct gender roles, differences, ideologies and gendered identities in past societies. Foregrounding gender effects changes in traditional archaeological thinking and leads to an interest in social relations between genders and between gendered individuals of differing ages, classes, ethnicity, and race.

Engendered studies of Stone Age archaeology have gone further than a concern with ecology and technology by considering the wider perspective of social relations between individuals and groups which leads to a restructuring of traditional archaeological understandings, offering new insights into social relations,

ideologies, and sociocultural institutions. Margaret Conkey (1991) considers the wider contexts in which tools were made, used and reused at a Magdalenian site where several families lived ('aggregation sites'). By viewing tools not as single objects, but as objects representing a complex set of technological, productive, and engendered social relations, she is able to show the changing contexts of action and contexts for power in which people and objects were involved. Gender is always in process, and the sexual/gender division of labor is being changed and negotiated constantly. These changing contexts of action are associated with the renegotiation of power relations and structures. This type of analysis challenges traditional views of stable and exclusive gender categories and opens up possibilities for analyses of archaeological material that can reveal that there can be different models of gender in one society, that these models may change in relation to particular contexts and changes in the lives of individuals.

European archaeologists have made considerable use of burial material in discussions of the construction of gender. In her study of the Viking period Oseberg burial, a rich grave with the burial of two women in a ship, Elisabeth Arwill-Nordbladh (1998) uses M. Conkey's 'context of action,' here relating to textile production, farm economy, communication, and ritual performance. Artifacts in the grave were analyzed in order to see how gender could have been constructed through the various contexts of action of which these objects were a part. Gender construction is not seen as following a strict set of gender categories, but as a process that can be maintained, changed, negotiated, or resisted through practice or performative acts. In this manner gender is seen as a difference between, and as a difference within, gender categories, so that the complexity of gender dynamics comes to the forefront.

Marie Louise Stig Sørensen (1991), working with grave material from the North European Bronze Age, has done a series of studies on how objects are active in expressing gendered identity. She examines especially how gender is constructed through appearance by examining the composition and placement of grave goods in relation to the body (skeleton) and in relation to their wider sociocultural contexts of use and meaning. In this manner it is possible to analyze not only gender but also cross-cutting social categories such as age, ethnicity and status.

Concentration on gender leads to an initial neglect of sex and sexuality. However, as feminism and feminist theory developed and was increasingly concerned with difference, rather than solely with the binary distinctions of gender, and view sexuality and the body as both socially constructed and historically constituted, so too has feminist archaeology newly expanded its interest to these previously neglected areas. Sexuality as an expression of desire is not limited to the heterosexual body, but is examined in its variety of

expression, including homosexuality. Much of this work is on representations of the body in art, particularly in classical Mediterranean cultures, but also in studies of prehistoric rock art.

As can be seen from this short overview, there are two threads in feminist archaeology. One is the 'archaeology of gender,' while the other is 'gendered archaeology' (Roberts 1993), what I have referred to as feminist archaeology. The archaeology of gender, while often premised on a feminist perspective and concerned with putting women and children back into our understanding of the past, reiterates traditional archaeological concepts and principles of interpretation. A gendered archaeology is explicitly feminist and tied closely to feminist critiques of science in an effort to generate new engendered ways of thinking, doing, and presenting archaeology. A gendered archaeology/feminist archaeology does not simply add women's contribution to past societies, but is concerned with interrogating and reworking our unquestioned starting premises and taken-for-granted concepts.

4. Feminist Practice

Although often considered to be neutral and objective, archaeological practice is highly gendered, and often implicitly so. Feminist interests include archaeological practice, particularly fieldwork and analysis, workplace issues, pedagogy, cultural heritage management, including museums, new ways of writing and presenting archaeology, and concern for the local communities in which one works.

Joan Gero (1996) has examined how fieldwork, particularly excavations and artifact analysis, is gendered. Gero has shown that observation and documentation are not neutral, objective processes but always contain an element of interpretation. Her work on excavations in Argentina show that there are gender differences in documentation, and these are often combined with differences in class and age. In addition, the gender of the person who typically does particular kinds of archaeological work varies. In North America men often lead large fieldwork projects, while women analyze extant collections. In other countries these tendencies take other forms, as in Australia, where men dominate in the universities while women dominate the work of cultural heritage management.

The status of women and equity issues in the archaeological workplace are continuing major concerns of feminists. Although there were some prominent women archaeologists in the past, these had little status and recognition in the profession. There is still a chilly climate for women in archaeology which not only slows down the advancement of female archaeologists but also seems to be preventing the full acceptance of feminist archaeology.

While an important aspect of feminism in archaeology is a concern with the institutional structure and workplace dynamics which hinder women from participating fully in the discipline, feminist archaeologists are also concerned with archaeology's relationship to the communities within which they work. In Australia, Laurajane Smith (1995) has written about the dominance of women in work with cultural heritage, or cultural resource management. Feminists have been particularly open to the importance and meaning that local communities and aboriginal peoples place on their past.

Much standard archaeological methodology is used in feminist archaeology. It is, however, reworked, because feminists ask different questions of the data. Instead of an interest in macroprocesses and population groups, typical, for example, of the systems approach, they ask questions at a microlevel, and are concerned more with social relations and processes, ideologies, and symbolism. Thus methods are combined in alternative manners. For example, emphasis is placed on entire artifact assemblages, and site assemblages, rather than tightly-defined typological categories (where the 'important' and 'interesting' types are often tools presumed to have been used by men), and comparisons over and between large regions. Ambiguous objects, often considered to be merely 'noise' in strict typological terms, are included in analyses since they are one way of analyzing the variety of social relations found at a site. In addition, interest is not placed on type of artifacts alone, but on the relationship between different kinds of artifacts and the processes involved in their production and use. This in turn emphasizes the variety of social relations involved in these processes and de-emphasizes the need to attribute the production and use of tools to an individual or group of the same sex.

5. From Margin to Center

Women have been invisible in archaeological interpretations of the past, but recent work grounded in feminist critiques, principles and perspectives have not only made women visible but have also shown the diversity of their lives and relations to others. Gendered archaeology/feminist archaeology has developed and changed considerably during its short existence. Feminist archaeology is exceptionally dynamic, drawing on new theoretical insights from other feminist disciplines, and expanding the scope and direction of archaeological analyses of gendered relations and ideologies in the past.

In a review article, Conkey and Gero (1997) note the lack of explicit feminist theorizing and critique of basic archaeological concepts in much of gender archaeology. There is little archaeological theorizing on gender/sexuality and there is little use of feminist theory in the archaeology of gender. Detailed empirical analyses are, of course, a necessary complement

to theoretical work, but too much of the archaeology of gender continues within this arena. Feminist archaeology must move beyond this implicit essentialism. The lack of theory only marginalizes the archaeology of gender, not only in relation to mainstream archaeology but also in relation to other feminist disciplines. Future work must continue to include women in our construction of knowledge about the past, but it will also need to grapple with the fundamentals of archaeological interpretation and theorizing, and incorporate feminist theoretical insights on gender and sexuality. Feminist archaeology is dynamic and constantly expanding its areas of interest, and is well on its way to realizing its critical and reconstructive potential.

E. Englestad

Gender History

Gender is a category of social analysis which denotes the social and cultural, as opposed to natural or biological, relations of the sexes. When this term first gained currency among historians of women in the early 1980s, gender was defined as the social relations between the sexes. As gender became an increasingly important and visible site of scholarly research and debate across the disciplines, its meaning widened to include the symbolic system or signifier of relations of power in which men and women are positioned differently. The embrace of the concept gender as a system of languages, symbols, and social practices that defined sexual difference and created sexual inequality, signaled the departure of feminist social scientists from the unchanging and universal notions of biological sex (Haraway 1991). The connotation of the English word 'gender' is a culturally formed set of social relations, distinct from sex, which is usually understood as rooted in biological or bodily differences. The word gender, however, does not exist in some languages, while in others its meaning diverges significantly from the English usage. The German term *Geschlecht*, for example, encompasses both 'sex' and 'gender' and thus blurs the core distinctions of the English term. In French the term 'sex' or *sexuel* is more commonly used than *genre*, which can refer to either grammatical or literary genre or serve as a classifying category in natural history (Riot-Sarcey 1999). The use of gender as an analytical tool does not *per se* connote a primacy of gender relative to other forms of inequality, such as race, class, or ethnicity; rather it suggests the inextricable links between gender and other social identities and categories of difference.

1. From Women's History to Gender History

The historical study of women, which became a vital field of scholarly inquiry during the 1960s, first sought to recover the ways in which women participated in and were excluded from processes of social transformations and political change. The empirical investi-

gation of the private (familial, sexual) and public (political) inequality of women in past societies drove the first decade of feminist social science. From its inception, women's history had a dual character: its practitioners were historians, trained and employed in history faculties, but the arenas of debate that shaped their inquiry, paradigms and methodologies were most often housed in interdisciplinary programs, such as women's studies.

In this first phase of women's history studies, sex and class often figured as parallel forms of oppression: the female *sex* was viewed as a subordinate *class*, subjugated by a dominant *class* of men. In feminist scholarship the notion of *patriarchy* signaled a shifting understanding of sexual exploitation as the primary form of women's oppression (see, e.g., Rubin 1975, Eisenstein 1978). Taking patriarchy as a hierarchical sexual order, women's historians located its origins in 'the private family' and sought to examine the ways in which it was reproduced in social modes of production, divisions of labor, and property relations (Kelly 1976). The examination of the origins and practices of patriarchal structures and ideologies, and the recovery of the lost stories of female actors and women's agency, significantly expanded the scope of scholarship on women and family, women and labor, social policy and social movements, and elevated 'sex' to a keyword of social analysis. Yet in furnishing a more complete rendering of the contemporary and past societies, the pioneering work of women's history also revealed the limitations of the keyword 'sex.' Unitary analytical categories, such as those of 'woman'/'women' and 'man'/'men,' were based on fixed, rather than historically or socially variable, notions of biological sex, thus creating a cohesive history of the oppression of women that overlooked differences of race, class, ethnicity, and sexual preference. Further, the emphasis on the patriarchal oppression of women by men meant not only that women formed a homogeneous category, but also that they were most often studied in isolation from men, leading to a fragmented and partial understanding of the workings of sexual difference in society (Davis 1976).

As sex became a crucial category of social analysis in the 1970s, its impact on other keywords of social analysis, such as class or race, became a topic of intensive debate among social scientists. Labor historians and political theorists often attempted to fit women into prevalent notions of class, some by arguing that women formed a separate or parallel class of their own, others by examining the ways in which (female) gender presented an obstacle to the formation of cohesive classes. Still others circumvented the dilemma of 'sex and class' by ascribing to women the same class position, identity, and interests as those of their fathers, or husbands. Feminist historian Joan Gadol Kelly sought to transcend this theoretical impasse by formulating a 'doubled vision' of society,

one that emphasized the ways in which both men and women's identities of class were shaped by sex and class (Kelly 1979). In emphasizing the inextricable links between sex and class, women's history studies also indisputably widened the scope of the political to include family and household, bodies and sexualities—all once considered as belonging to the sphere of the 'private.'

Joan Kelly's formulation of this doubled vision of society marks the point at which the concept of gender came into currency as feminist scholarship turned its attention to the ways in which ideologies, norms, and symbolic systems shaped identities, social institutions, and social relations. The editors of the pioneering collection, *Sex and Class in Women's History* (Newton et al. 1983), for example, noted that they employed gender in order to understand the systematic ways in which sex differences cut through society and culture and conferred inequality upon women. This formulation makes it clear that even as 'gender' began to emerge from women's history studies in the early 1980s, 'women' and 'gender' continued to be used as virtually interchangeable terms and scholarship on women continued to provide a foundation for study of gender in most fields (e.g., Hausen and Wunder 1992).

The intellectual forces driving the shift from 'women' to 'gender' were multiple. Despite the achievements of nearly two decades of accumulated scholarship in women's history, the overarching narratives of progress, the chronological and conceptual framings of historical change, remained unshaken. While feminist historians had delivered powerful critiques of the public/private dualism, widening the scope of the political to include family and household, bodies and sexualities, and had successfully dissolved the sex/gender distinction as well, the binary pairings of home/factory, production/reproduction and production/consumption remained tenaciously in place. As feminist historians sought, empirically and theoretically, to overcome or dissolve these dualisms, they began to pose more fundamental challenges to established chronologies, categories and theories of social transformation (Kelly 1984).

The dissatisfaction with biological essentialism as an explanation of sexual inequality, for example, focused new attention on the power of language—of discourses—to construct these inequalities socially and to anchor them in social practices and institutions. The work of analytically distinguishing gender from sex also took place in a more public context, namely in the arenas of debate about 'identity politics' in the USA and Britain, in which once-cohesive ethnic, racial, national or sexual identities were increasingly understood as multiple, mutable, even contradictory. The context for a redefinition of gender became broader as race also came to be viewed as a social construction rather than a genotypic or phenotypic form of difference. At the same time, the unitary category 'woman' began to break down, as historians

of race, particularly in the USA, castigated feminists for the false homogenizing of women and patriarchal oppression. Emphasizing the inextricability of gender and racial identities, feminist scholars of race argued that this category could only be dissolved by bringing race more centrally into the analysis of power (Higginbotham 1992). Feminist scholars of Western empires approached the history of white women's feminism as implicated in imperial ideologies, institutions, and practices. They called upon historians of white women's oppression to confront the racist, nationalist, and imperialist legacies of Western feminism (Amos and Parmar 1984).

2. The Turn to Gender History

Although a shift from women to gender was already well underway by the mid-1980s, the publication of Joan Scott's essay *Gender: A Useful Category of Historical Analysis* (Scott 1986), marks the turning point at which the two terms became distinct in the field of history studies. In the Anglo-Saxon academy the turn to gender as a cultural, linguistic, or discursive construct took place within a broader paradigm shift known as 'the linguistic turn' in the social sciences. The linguistic turn, a catch-all phrase representing a new receptivity of social scientists towards post-structuralist literary criticism, linguistic theory, and philosophy, as well as cultural and symbolic anthropology, signaled a new view of language as constituting historical events and human consciousness rather than as simply reflecting social reality (Toews 1987, Canning 1994). Scott's article, together with her essay collection, *Gender and the Politics of History* (Scott 1988), made explicit the theoretical innovation of gender, summoning 'mainstream' historians to consider gender as an essential category of historical analysis and unleashing a torrent of controversy, not least in the fields of women's studies and women's history.

At the same time Denise Riley (1988) interrogated the category 'woman,' noting its inherent and historically founded instability and pointing toward feminism as precisely the site at which that instability was systematically contested, taken apart and reconstructed. In this sense the turn to gender dissolved some of the stalwart categories of women's history, including both 'woman'/'women' and feminism, with 'experience,' 'identity,' and 'agency,' soon to follow. Furthermore, the breakdown of the category 'woman' and the more explicit formulation of gender as *relational*, as a category and process by which femininity and masculinity are mutually constituted, spurred the opening of gender history towards a more serious study of masculinity.

In the USA and Britain, feminist scholars of race also intervened at this juncture with powerful critiques of the categories and practices of women's history.

Defining race as a 'metalanguage,' as the 'ultimate trope of difference,' African-American critics explicated the powerful effects of race on the construction and representation of gender, class, and sexuality. Understanding race as a 'double-voiced discourse' revealed the ways in which it shaped both the oppression and self-representation of minorities (Higginbotham 1992).

3. *Controversies and Debated in Gender History*

Gender gained an analytic status of its own first by severing the links between sex-gender and biology and then by freeing it from the remnants of Marxism that hinged the production of gender to changing economic structures (Scott 1986). This process necessitated not only the dismantling of familiar concepts, but also the exploration of new methodologies that would illuminate the workings of language and symbols and their dissemination throughout society and culture. Feminist historians also debated the implications of extending gender historical inquiry to masculinity and men. Some of the controversy about these questions took place as an integral part of the debates among social historians on the 'linguistic turn,' while others were more specifically framed by the previous practices and boundaries of women's history. Historians of women feared, for example, that studying gender as a cultural, discursive, or linguistic construction in which masculinity and femininity are relationally and mutually constituted, would render female actors and women's agency invisible and obscure male oppression of women, ultimately producing a gender-neutral historical discourse (Bock 1991). Others suspected that the study of masculinity, while discovering the ways in which ideals of manliness were imposed upon men, might shift attention away from men's participation in those institutions and practices that oppressed women.

3.1 *Gender and the Keywords of Social Analysis*

The turn to gender, like all theoretical and methodological innovations, was an uneven and protracted process, as different fields and national scholarly arenas manifested widely differing responses to this challenge. The extent to which methodologies, concepts, and theories were redefined to meet this challenge also varies across these divergent contexts. In some cases women's history was simply renamed 'gender history,' leading to a protracted phase of interchangeability of the two without significant changes in concepts or methodologies. In other national contexts where the work of recovering the absent female subjects began later, historical research on women continues to provide the foundation for a more explicitly theoretical engagement with gender. In still other settings, where the turn to gender history

coincided with the rediscovery of masculinity and men, gender history denotes a dual engagement with the histories of both masculinity and femininity.

While the study of women once sought to fit female subjects into existing categories of social analysis, the turn to gender prompted more fundamental critiques, expanded meanings, and redefinitions of the keywords of social analysis. The concept of 'class,' for example, was at the heart of debates about both gender and the linguistic turn, leading some feminist scholars to call for an emancipation from class as a 'privileged signifier of social relations and their political representations' (Alexander 1984), while others have analyzed both middle-class (Davidoff and Hall 1987) and working-class formation (Clark 1995) as processes of differentiation in which gender is always centrally implicated. Eschewing models of class formation that seek to link economic, social, cultural, and political levels or stages of development, others have analyzed class as political language, emphasizing the significance of gender in the process of assigning and contesting the contingent meanings of class (Scott 1988, Sewell 1990, Canning 1992).

Other social-scientific terms, like 'public sphere' (Fraser 1992, Ryan 1992), 'civil society' (Pateman 1988, Hull 1996), and more recently, 'citizenship' (Lister 1997) have also been the site of fruitful rethinking by scholars of gender. Similar to the location of class in socioeconomic structures, citizenship is embedded in legal and constitutional frameworks and theories of state and nation formation. Gender scholarship on citizenship has critiqued models of citizenship as a progressive process of acquisition of civil, political and social rights, as outlined, for example, in T. H. Marshall's classic, *Citizenship and Social Class* (1950). New considerations of the gender dimensions of this term have analyzed citizenship as a process, as a set of claims upon the state and public sphere rather than as a historically fixed outcome or legal status. The historical meanings of citizenship can thus be understood to encompass not only those who possess citizenship rights, but also those excluded from them.

3.2 *Gender, Sexuality, Body*

Other key terms in the vocabulary of interdisciplinary gender studies, which were redefined in the course of the paradigm shift from women to gender, are those of 'sexuality' and 'body.' In addition to critiquing and redefining keywords of social and historical analysis, such as class and citizenship, the turn to gender also generated new waves of scholarship on topics which had been submerged within the complex of women and sex and which came into their own once gender had been analytically distinguished from sexuality and body.

Influenced by the work of Michel Foucault, historians sought to analyze the historically specific

domains in which sexualities were produced, such as the systems of medical knowledge and state moral regulation that defined both normal and deviant sexuality in nineteenth-century Europe, dispersing these definitions throughout the institutions of state and social reform (Mort 1987). In this sense, it is possible to view sexuality as a more specific site of definition, intervention and experience than gender. A new emphasis on the importance of desire in the articulation of sexuality suggested that sexuality might be understood as a site of agency which was quite distinct from gender. Yet Judith Butler (1990) posited gender as lived, at least in part, through sexuality, as embodied and performed through the production and ascription of sexualities. In recent years, studies of homosexualities have raised new questions about the implications of transgressive sexualities for the study of gender, suggesting that they disrupt gender categories by breaking up the neat opposition of male/female, masculine/feminine and by unmasking 'the epistemic regime of presumptive heterosexuality' (Butler 1990, Puff 1998).

'Body,' the term in the vocabulary of gender that was most deeply embedded in biologism and essentialism, was inextricably linked to sex before the 'linguistic turn' began to disentangle these terms. During the first wave of women's studies, the body had been the foundation for unities and shared experiences of women. The 'discursivation' of the body, which took place in the course of the 'linguistic turn,' not only detached the body from unchanging notions of physical difference, but also examined bodies as sites of inscription—as instruments of changing cultural meanings. While the advent of the discursive body delivered the final blow to biological determinism, it also raised new questions about the particular embodiedness or bodily mediation of female experiences that remained central in feminist historical research (e.g., Duden 1991). In the debates of the early 1990s about the relationship between discourse and experience, for example, the body became a litmus test of this relationship (Butler 1993, Bynum 1995).

In the course of the 1990s, then, body history became a prolific offshoot of gender history. Both theoretical debate and empirical research in the field have shifted recent discussions towards exploration of the process of *embodiment*, which takes bodies as sites of mediation between constructions of the body and its materialized experiences (pain, birth, death, illness, dismemberment) and suggests new frameworks for examining the ways in which bodies are lived, experienced and acted upon by the subject and the social collectivity (Grosz 1994, Gatens 1996).

While the turn to the concept of gender spawned new waves of historical scholarship on sexualities and bodies, gender history later expanded the scope of its inquiry to two new fields of historical inquiry: the history of consumption and history of empires. The study of consumption in Western societies was in-

vigorated in part by the collapse of communism in Russia and Eastern Europe, which made clear the ways in which consumption, as well as production, structure capitalist societies. Although consumption has historically been identified with femininity, Davidoff and Hall's *Family Fortunes* (1987) argued convincingly that domesticity, the ideology of the British middle classes, was vested in complex and elaborate practices of consumption and display. With gender as a framing concept, the historical study of consumption has expanded in recent years to encompass analysis of a social and cultural formation—consumer society—through the lens of commodification, spectatorship, commercial exchange and welfare reforms, each of which can be analyzed in conjunction with the gender identities produced through these processes (DeGrazia and Furlough 1996). Throughout the 1990s gender and sexuality also had a central place in the history of empire and figured centrally in new understandings of nations, empires, and imperial social formation.

4. Current Issues and Future Directions

This brief survey of gender historical scholarship indicates that the concept of gender has successfully broadened and deepened the meanings of some of the keywords of historical analysis, forged new arenas of scholarly inquiry, and helped to refurbish epistemologies and methodologies of historical analysis. Gender history has moved from the periphery once occupied by the 'herstory' of early women's history to the center in some historical fields, while in others it remains distant from the problems that define the field. The historical narrative of the French Revolution has been significantly transformed by gender scholarship, which went far beyond analyzing the exclusion of women from revolutionary citizenship during Jacobin rule to revise broader understandings of the crisis of state (e.g., Lynn Hunt's notion of 'family romance'), the emergence of the body politic, civil society, and notions of citizenship. The history of labor and labor movements, began to diminish in the late 1980s after two decades of field-defining scholarship, only to be significantly revived and recast through the wave of gender and labor scholarship of the mid- to late 1980s (Frader and Rose 1996). The histories of slavery in the antebellum South, of colonialism, empires, and post-emancipation societies have been rewritten as scholars explore the ways in which gender inequalities underpinned racial and imperial dominance. Gender has become a vital part of new scholarship on the two world wars, including military history. Yet other fields, such as the histories of the Weimar Republic or the Third Reich, for example, remain immune to the impulses of gender, despite an impressive accumulation of research on both women and gender for both

periods. Few would dispute that contests over masculinities and femininities are a crucial part of the post-World War I crisis of 'bourgeois Europe.' Yet in the historiography of Weimar Germany gender is meaningful mainly in those realms remote from high politics—realms as diverse as popular culture and sexual reform organizations. Nor has gender figured in the dramas of state, democracy, or the fragile social body of the 1920s. Recent scholarship on the Third Reich offers abundant evidence that the Nazis pursued, relentlessly and violently, a gender project, which was at the heart of the racial state they envisioned and built. But this knowledge does not significantly inform interpretations of the collapse of the Weimar Republic or the Nazis' mobilization of German society and economy for war and genocide. This uneven reception of gender history in various fields will undoubtedly shape the dynamic of gender history in years to come.

The relationship of gender history to 'mainstream' history has been of growing concern to those who formulated its emergence from women's history in the early 1980s. Joan Kelly's three-pronged project of renovating categories, chronologies, and theories of social transformation explicitly aimed at rewriting historical metanarratives, as she sought to do in her own essays on the Renaissance. Given the accomplishments of feminist history in recasting categories of historical analysis, it is now important to assess the potential of gender history to reconstruct historical narratives and to produce new syntheses of historical events and processes (e.g., Hunt 1998). Several dilemmas remain regarding gender history and the historical metanarratives it set out to subvert: should, for example, the empirical and conceptual achievements of gender history be assimilated into existing metanarratives? Should they inspire the composition of new metanarratives or prompt the abandonment of metanarratives altogether? These questions can perhaps be resolved first by breaking these metanarratives into their composite parts and examining the singular moments of subversion and incorporation along the narrative thread. Either task—that of revising existing narratives or that of composing new ones—requires a certain kind of piecework in which historical changes are rearranged on time lines and brought into new relationship with one another.

Attention to the temporalities of gender history, and to how they fit or diverge from those of established metanarratives, has only recently become possible. The genealogy of gender might be traced back to the eighteenth century, when humanist notions of the individual were synonymous with masculinity. The embodiment and masculinization of the male citizen during the French Revolution also provided the stage upon which women staked their first claims for inclusion in the terms of both equality and difference. The extensive scholarship on women and gender in nineteenth-century Europe encompasses the history of a wide range of public feminisms and domestic

ideologies, the emergence of 'women' as social category, of 'women's labor' as a social question, and the dissemination of these ideologies and social categorizations, which redefined both femininity and masculinity, through the media of the emergent social and natural sciences. This suggests (a) that the history of nineteenth-century Europe could now be rewritten from the perspective of gender, and (b) that the temporality of gender history may not follow the political or social chronologies of existent metanarratives. A rethinking of twentieth-century history may uncover distinct temporalities of a different gender history, one in which gender norms and ideologies were ruptured at points of political and cultural crisis but not necessarily restored at moments of political reconstruction and stabilization. This trajectory of twentieth-century gender history may indeed help to explain its extraordinarily embodied violence. The work of aligning the temporalities of gender history with those inscribed in established historical metanarratives represents the first step towards a history that admits distinct temporalities and allows for dissonance within grand narratives.

Gender Identity Disorders

1. Definitions, Prevalence, and Sex Ratio

The gender identity disorders are defined as disorders in which an individual exhibits marked and persistent identification with the opposite sex and persistent discomfort (dysphoria) with their own sex or sense of inappropriateness in the gender role of that sex. These characteristics may be manifest in statements such as wishing to be the other sex, dressing as, and taking on the roles of the other sex, engaging preferentially in activities usually enjoyed by the other sex, and expressing dislike for the roles and activities of their own sex, as well as a dislike for their own genitalia and other physical characteristics of their own sex. In order to distinguish the gender identity disorders from more minor cross-gender interests or role-taking these characteristics must be persistent and marked and result in distress or impairment (*Diagnostic and Statistical Manual of Mental Disorders*, Fourth Edition, (*DSM-IV*), 1994; *International Classification of Diseases*, Tenth Edition, (*ICD-10*), 1992).

The word transsexual was used in the earlier literature, as was inversion, to refer to individuals with marked gender dysphoria, most of whom perceived sex reassignment as the solution to their psychological distress. It remains as a category in the *ICD-10* classification. Also in the older literature transvestite was used to designate persons who cross-dressed and may have included those who identified as the other sex as well as those in whom the cross-dressing was sexually arousing (now referred to as Transvestic Fetishism). Transgendered is a more recent term used to encompass a broad group of individuals with varying degrees of cross-gender behavior. It is not a diagnosis and is often the self-label assumed by individuals with cross-gender feelings and behaviors, particularly the more politically active. Gender role

refers to behaviors, roles, and attitudes that the specific culture defines as more appropriate to males or females. Sexual orientation refers to the sex of person to whom an individual is attracted, predominantly the opposite (heterosexual), or the same (homosexual) sex. Sexual identity connotes the adoption of an identity as a hetero- or homosexual person and involves more than the narrow notion of sexual orientation.

Gender identity disorders (GID) are relatively rare compared to other psychiatric disorders. Although there are no large scale epidemiological studies to provide true estimates recent studies suggest roughly 1:10,000 to 1:30,000. Sex ratios of adults with GID (largely based on referrals to clinics) have fluctuated with more males than females in earlier studies to a more equal ratio in many recent reports. Childhood GID is more prevalent in males, roughly 6 to 1. In adolescence the ratio is more equal (Cohen-Kettenis and Gooren 1999, provide a recent review.)

2. Historical Background

Awareness of individuals who identified strongly with the other sex has a long history. Some cultures even created a privileged role for such individuals. However, the scientific study of individuals with cross-gender identities really began in the late part of the nineteenth century. Initially many such individuals were thought to be intersex individuals, possessing the physical characteristics (both internal and external) of the other sex. It was not until the middle of the twentieth century that it became clear that most such individuals were physically normal but suffering from a psychological disorder.

The modern era of gender identity disorder began with the much publicized case of Christine Jorgensen, an American ex-soldier, who underwent sex-change surgery in Denmark in 1952, under the care of Christian Hamburger, an endocrinologist. Although demasculinizing surgery and hormonal replacement had been used earlier, typically for cases thought to be intersex, the Jorgensen case stirred the public imagination and encouraged other like-minded individuals to seek treatment for their distress (Meyerowitz 1998). Sex change surgery had been available in Europe since the early 1900s, the most prominent center being the Institute for Sexual Science in Berlin under the direction of Magnus Hirschfeld. In the USA physicians were less willing to perform such surgery, particularly on those considered to be physically normal and in some jurisdictions such body altering was considered illegal. Prior to the Jorgensen case, David Cauldwell, an American psychiatrist and editor of *Sexology*, had distinguished cases which he labeled '*psychopathia transexualis*' from intersex cases. Harry Benjamin, an endocrinologist, born and trained in Germany, had begun to advocate on behalf

of individuals wishing sex change. This combination of public and professional interest set the stage for the scientific study of persons with gender identity disorders.

In 1955 John Money working with the Hampsons published his first follow-up study of individuals born with ambiguous genitalia. His conclusions that sex of rearing overrides the child's anatomy in determining gender identity was the first empirical evidence that psychological factors may be etiologically important in GID. The 1960s saw the publication of several important books and papers as clinicians working with individuals with GID began to describe their experience. Harry Benjamin, who had been diligent in his effort to bring understanding to the plight of those whose cross-gender wishes were often demeaned or dismissed, published *The Transsexual Phenomenon* in 1966. In the same year the first gender clinic in North America was established at Johns Hopkins Hospital in Baltimore. Green and Money (1969) co-edited the book *Transsexualism and Sex Reassignment*, a standard text at that time. A year earlier, Stoller (1968), a psychoanalyst, had published *Sex and Gender*, in which he articulated a theory that cross-gender identification arises from a blissful symbiosis of a son with his mother. Although Stoller's theoretical position has more recently been dismissed it sparked interest in understanding the psychodynamic origins of GID and led to more systematic study in several of the newly developed clinics for children and adolescents.

The 1970s and 1980s saw a growth of interest in treatment of adults with GID. Clinics developed in major centers in North America and Europe. Standards of Care were developed under the auspices of the Harry Benjamin International Gender Dysphoria Association in 1985 and provided some uniformity to patient management. Clinics for children were developed as clinicians realized that GID had its origins in childhood and might be prevented with early intervention. Green (1974) carried out the first systematic study of effeminate boys, published in *Sexual Identity Conflict in Children and Adults*. He compared boys displaying significant cross-gender behavior by parent report, with an equal number of age-matched masculine boys. His study provided the first systematic description of boys with GID and their parents. Green (1987) published the follow-up of these two groups of boys. The majority of the effeminate boys had a homosexual orientation when assessed in late adolescence. Only one boy continued to have significant cross-gender wishes. These findings were in marked contrast to the findings on the masculine boys who were almost entirely heterosexual in orientation and displayed no evidence of gender dysphoria.

The study of individuals with GID soon became a subject of religious, moral, and political debate. Some investigators urged treatment of GID to prevent homosexuality. In the 1990s funders of GID programs

began to debate the logic of a medical and surgical intervention for what is primarily a psychological disorder. This debate was fueled by the results of the first follow-up study of the patients from the John Hopkins clinic which suggested that surgically re-assigned patients were no better off than were those who had not received surgery. Although this study was methodologically flawed, its results, together with economic pressures, led to the closure of many clinics in the USA and the removal of sex reassignment surgery as an insured service. Generally the situation in Europe, particularly in the Netherlands, remained more supportive for those with GID. In the late 1980s the gay and lesbian community began to question the pathologizing of cross-gender behavior in childhood, regarding it simply as an early manifestation of homosexuality. In the early 1990s many individuals with cross-gender identification began to organize politically, assuming the label transgendered, and arguing that society should recognize a third or intermediate position between the more traditional male and female genders.

3. *Emphases in Current Theory and Research*

3.1 *Classification and Phenomenology*

Early work focused on dividing individuals requesting sex reassignment into 'true' and 'secondary' transsexuals. This effort was abandoned as GID began to be conceptualized as being more dimensional than purely categorical. However, there was a recognition that there are two types of GID in males, one originating from early or childhood GID and being predominantly homosexual in sexual orientation, and the other, arising from Transvestic Fetishism, and being hetero- or bisexual in orientation. Individuals with the latter present most typically in their thirties in contrast to the former who present in adolescence or early adulthood. Although usually described as bi- or heterosexual, Blanchard (1991) has established that many of the latter group display what he calls autogynephilia, an erotic attraction towards oneself dressed as a female. Mature females with GID are essentially homosexual in their erotic attraction.

3.2 *Etiology*

As mentioned above, the first theorizing about etiology arose from the belief that individuals with GID are in some way intermediate in their biology between males and females. Because of the link between cross-gender identification and homosexuality and because of the relatively small numbers of individuals with GID this led to extensive investigation of the biological differences between heterosexual males and females

and between these two groups and their homosexual counterparts.

Although many of these studies have provided interesting leads very few differences have been substantiated in a way that would suggest strong evidence for a significant predictor of gender pathology or of homosexuality. Rather the findings to date suggest that temperamental or other vulnerability factors may create a biological predisposition towards gender pathology which when combined with the appropriate psychodynamic factors produce gender dysphoria and cross-gender identification.

3.3 *Biological Studies*

Genetic factors are assumed to play a role in GID although there have been no large-scale studies of heritability in GID. This assumption is based on the studies of heritability in homosexuality and its putative relationship with GID. In monozygotic twins there is a greater likelihood of both twins being homosexual as compared to dizygotic twins (Bailey et al. 2000). This relationship has been shown most strongly in males. Despite a concordance rate as high as 50 percent there appears to be a strong nonshared environmental component (due to factors unique to the experience of the individual). Similarly, molecular genetics studies of homosexuality in men suggest the possibility of a marker specific to sexual orientation on the distal portion of the long arm of the X chromosome (Hamer et al. 1993) although the only other independent study failed to replicate this finding.

The prenatal hormone theory has provided the most coherent framework for an examination of factors affecting sex-dimorphic behavior in both animals and humans. This theory, now well supported by studies in animals, posits that the prenatal hormonal milieu affects the development of brain structures and organizes or shapes various sex-dimorphic behaviors, such as activity level, mounting behavior, and responsiveness to sexual partners. In humans, Congenital Adrenal Hyperplasia (CAH), a disorder in which females are exposed to high levels of circulating androgen *in utero*, provides a convenient natural experiment which gives some support to the theory. Girls with CAH have been shown to be more physically active and tomboyish than their nonaffected sisters and to report more homosexual attraction and less heterosexual involvement in adulthood. They do not, however, report more wishes to be the other sex. This latter finding may be partially a result of the small sample sizes in all studies, too small to detect a disorder such as GID, which is relatively rare.

Another approach to testing the prenatal hormone theory has been to examine hormone responses to a dose of exogenously administered estrogen. In the female such an injection produces an initial fall and then a rise in luteinizing hormone. Males do not

display the rise seen in females. Homosexual men show a pattern intermediate between that of heterosexual men and women. These studies have not been replicated consistently and have been criticized in terms of not being interpretable, as the endocrine systems of homosexual men may be compromised by such things as HIV infection.

Prenatal maternal stress is another factor thought to possibly influence the development of homosexuality (and by extension GID) through affecting the prenatal hormonal milieu and brain development. Early studies in rats showed that stressing pregnant females can produce a demasculinizing and feminizing effect on their male offspring. Although attempts to test this out on humans have been equivocal, Bailey et al. (1991) found that maternal 'stress proneness' was correlated with boyhood effeminacy. As there is an emerging literature that suggests that maternal stress may correlate with vulnerability to psychiatric disorder in offspring by affecting stress reactivity, these findings may be relevant in terms of vulnerability to psychopathology, as opposed specifically to homosexuality or GID (Bradley 2000).

Efforts to define and compare the brain areas responsible for sexually dimorphic behavior have been a part of testing the prenatal hormone theory. Once more this work has been carried out on samples of homosexual individuals, largely male. Although brain structures in rats appear more clearly sex-dimorphic, agreement about the comparable brain structures in humans has been more complicated. Swaab and Fliers (1985) reported differences between males and females in the preoptic area of the anterior hypothalamus but in a subsequent study could not define differences in volume between heterosexual and homosexual men. They did, however, find a difference in the suprachiasmatic area of the hypothalamus between homosexual and heterosexual men, an area previously not related to sex-dimorphic behavior (Swaab and Hofman 1990). Another cell group identified as possibly homologous with the sexually dimorphic area in lower mammals is the interstitial nucleus of the anterior hypothalamus, subdivided into four sections, INAH 1-4 (Allen et al. 1989). These authors found differences in size between males and females in INAH 2 and 3. LeVay (1991) subsequently reported a smaller INAH 3 in homosexual men (comparable to that of heterosexual women) in comparison to heterosexual men. This study has recently been partially replicated by Byne et al. (in press). Zhou et al. (1995) reported that the bed nucleus of the stria terminalis was smaller in six male-to-female transsexuals than in control males and was comparable to that of females.

Another area of potential difference between homosexual and heterosexual individuals is cerebral laterality. This has been examined through assessment of handedness, cognitive testing, dermatoglyphic asymmetry, and related brain volumes. Some studies have

suggested that homosexual men and women have a higher likelihood of being left-handed than heterosexual men and that transsexuals (both male and female) display more left-handedness than the general population (Lalumière et al., 2000). A preliminary study on boys with GID from the Toronto clinic examining handedness suggests a higher incidence of left-handedness (Zucker et al. 2000). Neuropsychological studies using visual hemifield dot detection and dichotic listening tasks suggest differences between homosexual and heterosexual men with the performance of homosexual men being more similar to that of heterosexual women. Studies of transsexual subjects also suggested less lateralization but again these results are preliminary. Study of fingerprint patterns, dermatoglyphy, shows sex differences with women having more ridges on the left than right hand and homosexual men showing a similar left-ward asymmetry. The anterior commissure, a fiber tract connecting the two cerebral hemispheres, is larger in women than men and has been shown to be larger in homosexual than heterosexual men. Although interpretation of these findings should remain open they suggest that early brain development and with it handedness and other indices of laterality may be affected in individuals who later become homosexual and possibly in those who develop GID.

Temperamental variables, specifically activity level and involvement in rough-and-tumble play, have been shown to differ in boys and girls. Boys with GID display a lower activity level and less interest in rough-and-tumble play than control boys. In contrast, girls with GID are reported to have a higher activity level and to be more interested in rough-and-tumble play than control girls. Although these findings suggest differences between GID children and controls, it is highly unlikely that these differences are more than predispositions that add a dimension to their general vulnerability to GID. Physical attractiveness is another factor that may act as a predisposing factor but is unlikely to be more specific to GID. Boys with GID are rated by independent raters as more attractive, beautiful, cute, handsome, and pretty than control boys. Conversely, girls with GID are rated as less attractive than control girls. Although physical attractiveness may be a social construction these findings are consistent with parental reports of their GID sons being beautiful babies and may be related to greater facial symmetry, a component of attractiveness.

Particularly feminine homosexual men and boys with GID have a greater number of brothers than controls. Being born later in the birth order also occurs more frequently in homosexual men (regardless of extent of cross-gender behavior) than in heterosexual controls. These findings have been interpreted from both biological and psychological frameworks with no evidence to suggest that either explanation is more valid.

Lastly, birthweight appears to be lower in boys with GID than in controls. Again this may reflect a neurodevelopmental factor which is related to a general vulnerability to psychopathology as low birth weight has also been found as a vulnerability factor to psychotic disorders.

3.4 Psychosocial Factors

As indicated in Sect. 2 above, Money et al. (1955) reported on their follow-up of children born with ambiguous genitalia. They concluded that sex of assignment and rearing, particularly when that was begun unambiguously prior to 24 months of age, was able to override a child's anatomy. These early studies by Money et al. led to the belief that gender identity was developed during a sensitive period and became relatively fixed at an early age. Despite challenges, this position has not been significantly refuted. Questions were raised by the finding that individuals with 5-alpha-reductase deficiency, apparently raised as girls, for the most part begin to self-identify as males at puberty when their bodies begin to masculinize. This and other similar findings appear less to have refuted Money et al.'s findings than to have suggested that in some instances gender identity may be less fixed than had originally been proposed. This same malleability of gender identity appears to be relevant in the case of males with Transvestic Fetishism who although originally identified as male begin, over a number of years, to self-identify as female. Other anomalous situations include males with accidental ablation of the penis at a young age. One such case has been used to argue that biology overrides rearing while another suggests the opposite. Generally, however, individuals with GID are physically normal and so psychosocial factors appear to be particularly relevant.

Parents have been shown to respond differently to male and female children, generally encouraging same-sex behavior more than opposite-sex behavior. Parents of children with GID tend to be neutral about if not encouraging of their child's cross-gender behavior. Further they appear to be less encouraging of same-sex behavior. Despite Stoller's premise of a 'blissful symbiosis' between a boy with GID and his mother, Green (1974) found that both parents spent significantly less time with their son with GID than did parents of controls. Further, both mothers and fathers of children with GID have elevated levels of psychopathology, which would suggest impairments in their relationships with each other and with their children. Lastly, clinical observations suggest high levels of conflict between children with GID and their parents, which these sensitive children interpret as rejection.

Etiological factors are reviewed more thoroughly in Zucker and Bradley (1995) where a complete set of references is also available. Clinical formulations of

these etiological factors are available in Coates (1990) and Zucker and Bradley (1995).

4. Management

There are few formal studies assessing management of children or adults with GID. Current management of children with GID involves addressing the familial and child issues through different combinations of parent counseling, parent groups, and child psychotherapy.

Adolescents with GID may be referred for psychotherapy to rule out factors that if addressed might change the wish for sex reassignment and to ensure the stability of the cross-gender wish. Some clinics use hormonal treatment to reduce the development of secondary sex characteristics and reduce sex drive when such adolescents have been considered treatment eligible (Cohen-Kettenis and Gooren 1999). Psychological support is considered very important but often rejected by the adolescent.

Management of the adult with GID is somewhat similar to that of the adolescent but can proceed to surgical reassignment after the individual has demonstrated their capacity to surmount the hurdles of living as the other sex for a period of time (1–2 years). Once more, psychological support is considered critical but is not always welcomed by the individual with GID. Hormonal therapy (estrogens to male-to-females and androgens to female-to-males) are begun in some clinics at the beginning of the real-life test and in other clinics somewhat later. Sex reassignment surgery typically is not undertaken until sometime in early adulthood although those individuals with a history of Transvestic Fetishism may not have surgery until their thirties or forties.

5. Outcome

Children with GID can relinquish their desire to be the opposite sex. This appears to be facilitated when parents address some of the familial issues thought to contribute to the child's gender dysphoria. Children presenting at a later age (10–12) or whose families cannot address the contributing familial issues appear to do less well and continue to display significant gender dysphoria. Adults who undergo sex reassignment are generally satisfied although the capacity of surgery to produce well-functioning genitals, especially in the female-to-male, is quite limited.

6. Methodological Issues

Given the relative rarity of this condition sample sizes adequate to test hypotheses are only available in one or two clinics in the world. Evaluating treatment is similarly complicated by small sample sizes in any one

geographic location. Multisite studies are needed to address some of these issues.

7. Future Directions

Comparison of children with GID vs. contrast groups such as children with anxiety disorders are needed to address general (psychopathology) vs. specific (to GID) etiological factors. Evaluation studies of interventions in children, adolescents, and adults are needed.

Gender Ideology: Cross-cultural Aspects

Gender ideology is concerned with normative beliefs about the proper roles for and fundamental natures of women and men in human societies. The distinction between sex and gender is central to the concept of gender ideology. When a child is born, the biological differences between males and females, or their sex differences, are used as the basis for the assignment of gender and the cultural construction of gender identities. People are assigned a gender identity in all societies, but gender systems and the gender ideologies that are thought to help sustain them are culturally variable.

1. The Historical Context for Studies of Gender Ideology

The Women's Liberation Movement of the late 1960s and 1970s, which started in the United States and then spread to Europe and other parts of the world, was an important stimulus for cross-cultural research on gender ideologies, and the politics of the movement significantly influenced this research as it emerged in the early 1970s. The most general political position of the Women's Liberation Movement that shaped the study of gender ideologies was the view that women are not equal to men in American society. They do not have the same control over their own lives and the lives of others that men have. They are dominated by men in their family life, in the workplace, and in other social domains as well, particularly religion and politics. This domination, it was argued, is bolstered by patriarchal gender ideologies that provided justification for men's domination of women. The term 'patriarchal' was used to refer to ideologies that either

assumed or asserted that the correct social order was one in which men dominate women, have authority over them, and tell them what to do. The patriarchal ideology that received the greatest attention in the Women's Liberation Movement was the American view that women are biologically inferior to men—less intelligent, physically weaker, less aggressive, and more emotional—in ways ultimately explained by differences in their biological makeup. The political theorists of this social movement actively criticized this patriarchal ideology. They acknowledged that there were biological differences between women and men, but argued that these were exaggerated by cultural processes and were in themselves not sufficient to be a basis for men's political and social domination. Instead, differences in women's and men's socialization experiences explained cultural differences between women and men that were used to justify men's authority. Academic disciplines that had contributed to the development of biological patriarchal ideology, also came under attack from the women's movement. 'Science' in general was conceptualized as a form of ideology, that is as a framework promulgated by people in power to help them maintain their power, rather than as objective factual truth. There was evidence that scientists who had studied sex differences between humans had indeed been influenced by the patriarchal ideologies of European cultures. For example, nineteenth century physical anthropologists found that women's brains were smaller than men's and argued that this was the reason women were less intelligent. Yet by the early twentieth century, physical anthropologists were arguing that intelligence was a reflection of the size of an animal's brain in proportion to its body, and women and men did not differ in this proportional relationship.

Patriarchal gender ideology was also apparent in the way women were largely absent from scholarly representations of human activity in the social sciences and humanities of the 1960s. For example, in anthropological theory about early human societies, considerable attention had been given to the importance of men's collaborative hunting for human evolution. But women's gathering of plant foods, which provided the bulk of foodstuffs eaten by early humans, was almost completely ignored. Feminist theorists argued that both biological theories which denigrated women and representations of humans that rendered women invisible conveyed gender ideologies which were psychologically harmful to girls and young women. These scholarly visions of gender undermined young women's self-confidence, encouraging them to believe that they were incapable of much in life that they were in fact quite capable of, and providing perspectives that suggested male domination was indeed an appropriate state of affairs.

This vision of the role of gender ideology in US women's subordination was projected to the world as a whole in early feminist anthropological comparative

research on the topic. In the early 1970s, Rosaldo (1974) argued that the cross-cultural evidence on gender relations available at that time indicated that in all societies of the present and past men have had greater power and authority than women. In all societies, although both men and women have culturally legitimated authority in the domestic or household sphere, it is overwhelmingly men who have had culturally legitimated authority in public spheres, due to women's greater involvement in childcare. Rosaldo suggested that this arrangement was supported everywhere and reinforced by gender ideologies in which men were held to be superior to women by virtue of their greater involvement in culture and their lesser involvement in nature. Women were held to be more involved in nature than men because of their role in the natural process of giving birth to and caring for children. This argument was appealing in part because of its scope: it was a theory about women and men in all times and places. It was also appealing because it resonated with the views of feminists involved in the Women's Liberation Movement of that time.

In many ways, Rosaldo's position set the agenda for comparative research on gender ideology for the next several decades. Her position was challenged as well as embraced and the research it stimulated showed that there is far more diversity in gender ideologies than was initially envisioned. The rest of this discussion focuses on the nature of this diversity in gender ideologies. Consideration will first be given to how many gender categories there are in gender ideologies. Early work assumed two—woman and man—but this view has been questioned. Then the discussion will shift to the nature of cross-cultural similarities and differences in fundamental features of gender ideologies that are predominantly dualistic in organization. Finally, the extent to which patriarchal gender ideologies sustain male domination cross-culturally will be considered.

2. How Many Genders Are There?

One key source of cultural and historical variation in gender ideologies is the extent to which gender systems are thought of as fundamentally dualistic, or binary. Much contemporary Western scholarship assumes that binary gender systems are universal: sexual females become women and sexual males become men. However, research on sex and gender ideologies suggests that this is itself a culturally specific gender ideology. To begin with, binary biological sex is itself a cultural construct. Laqueur (1990) argues that until the nineteenth century, Europeans conceived of only one sex, that of male, with female as a lesser version of him. It was only in the late eighteenth century that a two-sex model of human biology began to emerge in which the differences between males and females were rhetorically elaborated. Today, although it is common to assume that all babies will be obviously biologically

male or female, sex is sometimes ambiguous. In such cases an infant will still be assigned to one category or the other and surgery may be performed to alter the body in a manner consistent with that assignment. Adults sometimes decide that they want to have the physical characteristics of the 'opposite' sex. To achieve this they engage in cultural activities that will either create this impression, as when women bind their breasts, or bring about sex changes as a physical reality through surgery and hormonal treatments.

There is no doubt that binary biological sex is partly a material reality. It is not something that we as humans have imagined completely. But it is also partly a cultural construct. Scholars agree that binary gender ideologies, as well as binary sex ideologies, are ideological constructs. They also agree that the gender ideologies articulated by people do not capture for any society the range of gender identities expressed in that society. But they disagree about how to conceptualize nonbinary models of gender. Some researchers assert the existence of societies in which there are three rather than two salient genders, where the third gender is most commonly a named category referring to a man who is womanly in dress, occupation, sexual preference, or some combination of these aspects of gender identity. For example, Europeans who first contacted North American Indian societies reported that many of them had a third gender category of men who dressed like women and carried out women's work roles, the name for which was sometimes glossed into English as 'manly hearted woman.' Other scholars argue that even in cultures with three or more named gender categories, gender as an ideological system is still and always about cultural transformations of a biological difference between males and females. In any case, gender dualism, or the idea of two genders, woman and man, is very strongly developed and salient in gender ideologies around the world and through time, and most scholars working on gender ideologies have focused on the nature, causes, and consequences of gender ideologies that posit woman and man as central categories.

3. Cross-cultural Similarities and Differences in Dualistic Gender Ideologies

Dualistic or two-category gender ideologies are concerned with how women and men are similar and different, with the emphasis on difference. The widespread presence of ideologies of difference indicates the importance of culture and ideology in creating women and men as unlike. Anthropologists have found that cross-culturally, people are concerned with similar aspects of human experience in their production of gender ideologies. People also engage in similar cognitive and symbolic processes as they talk about and otherwise represent women. At the same time, there are also differences from society to society

and within societies in the nature of dualistic gender ideologies, so that similarities and differences across cultures are intertwined.

There are at least four aspects of human experience that regularly enter into gender ideologies. These include work, appearance, sexuality, and reproduction. People constitute themselves and are socially constituted by others as women and men through their behavior in these areas and the meanings attached to those behaviors. At the same time, societies vary in the emphasis that is given to each of these four aspects and in the extent and kind of variation tolerated in behavior relative to canonical expectations about gender.

It is very common cross-culturally for women and men to be expected to do different kinds of work, and for girls and boys to be socialized into different kinds of labor. So, for example, in hunting and gathering societies, which no longer exist in isolation from other economic types of societies, it is common for women to be expected and trained to gather plants and for men to be expected and trained to hunt for game. Among European agriculturalists, large-scale cultivation has been associated strongly with men. Consequently, where women were largely responsible for cultivation in places that have been colonized by Europeans over the last 500 years, strong pressure was often exerted to get men to replace women in these activities as, for example, with the Seneca Indians in New York state.

After about the age of 3 years, girls and boys and women and men are also commonly expected to look different from each other in ways that are specific to individual cultures. They are expected to dress differently, to wear their hair differently, to differ in the presence and nature of body decor such as jewelry and tattoos, and to differ in patterns of nonverbal behavior such as gesture and facial expression.

Sexually, binary gender ideologies entail the expectation that men's sexual object choices will be women and women's sexual object choices will be men. But whether or not and how departure from these expectations leads to the view that a male is not a man or a female is not a woman varies greatly cross-culturally.

Finally, binary gender ideologies commonly entail expectations of women and men regarding the roles they will play in the reproduction of human communities, through giving birth to, taking care of, and socializing children. It is well documented that failure to meet cultural expectations in these areas can often have major consequences in the lives of the people involved. However, a worldwide decrease in emphasis on this aspect of gender identity may be ongoing as changes in global economic processes bring about changes in family size.

Cognitively and symbolically, it is common for these substantive areas of gender ideology to be elaborated around specific gender dyads (Mathews

1992). Typically these dyads are drawn from cross-gender relationships within the family, reflecting the fundamental centrality of the family for both the maintenance of and changes in gender ideologies. Some key nuclear family dyads that are frequently ideologically elaborated cross-culturally include wife–husband, sister–brother, mother–son, and father–daughter.

However, societies differ in which gender dyads get selected for ideological elaboration. For example, in many European societies, the husband–wife relationship is the primary relationship that is ideologically elaborated, and the mother–child relationship is also the focus of a great deal of cultural production. But in the South Pacific, in Polynesian cultures such as those of Samoa, Tonga, and Tokelau, it is the sister–brother relationship that is most celebrated and discussed, and the husband–wife relationship is simply not developed explicitly or represented to the same extent in public events. So, for example, stories and plays depict the kind of work the sister should do and the kind of work the brother should do, but not what husbands and wives do, though one may infer that the division of labor will be similar for them.

While a good deal of gender ideology develops around nuclear family dyads, it also receives expression in representations of culturally idealized individual men and women, who usually represent the good, but can also represent the bad. For example, in Mexico, there are three key female icons: the Virgin of Guadalupe, La Malinche, an Indian woman who betrayed her people by consorting with the Spanish conqueror, and La Llorona, a ghostly figure who wanders riverbanks weeping over the loss of her dead children and luring men to death by drowning (Limon 1986).

The use of simple cross-gendered dyads from the family and the use of individual icons to convey gender ideology are, then, common cross-cultural cognitive and symbolic strategies. An additional such strategy is to metaphorically project gendered family dyads and individual gendered prototypes outside the family onto other more encompassing levels of social organization. For example, George Washington is referred to as the father of his country. And entire nations may be gendered, often as women, as in the expression, ‘India is the mother of her people’ and the term ‘Mother Russia.’

The processes involved in cross-cultural similarities and differences in gender representation that have been described so far also provide resources for the production of intrasocietal as well as intersocietal similarities and differences in gender ideologies. Different segments of a society—e.g., classes, ethnic groups, or religious groups—may emphasize different aspects of gender identity in their gender ideologies. Diversity in gender ideologies within a society can consequently become the basis for criticism and conflict between groups over how women and men

should be expected to behave and should treat one another. This can lead to the imposition of the gender ideology of one group on another, and to changes over time in gender ideologies.

For all of these reasons it can be problematic to talk about ‘the’ gender ideology of a given society or culture. It is true that some ideas about gender may be ‘dominant’ in a given society, in that they are represented widely or represented by those in power. But diverse views on gender are held in all societies, if only by virtue of role differentiation within the family, so that what is expected of a sister is not what is expected of a wife or mother.

4. Gender Ideologies and Male Domination Over Women

The final important and controversial aspect of gender ideologies to be considered here is the extent to which they provide justification for men’s control of women and contribute to its perpetuation. Patriarchal gender ideologies are very widespread, but not all of them are alike. The political critique of the Women’s Liberation Movement concentrated on the American and European patriarchal ideology that gender differences are rooted in biologically based sex differences which render women inferior to men. But this was and is not the only patriarchal gender ideology in the United States or elsewhere. Biological differences between women and men are not always involved. Nor is women’s inferiority always asserted. Neither is necessary for a patriarchal gender ideology. What is necessary is that there be a cultural understanding that men should have power and authority over women that women should not have over themselves or men. Two important bases for patriarchal gender ideologies besides biology are tradition and religion.

Adhering to tradition means continuing to do something because it has been done in the past, often a highly valued past that itself defines who people are in the present. In religious ideologies, in contrast, patriarchal gender ideologies are often conceptualized as supernaturally ordained. This is true of gender ideology in the three world religions that originated in the Middle East and spread around the world: Judaism, Christianity, and Islam. In all these religions, gender roles and the greater authority of men is interpreted as the will of God.

Although patriarchal gender ideologies are very widespread, nonpatriarchal gender ideologies and gender ideologies that do not denigrate women but value them and represent them in positive ways are also very widespread. Quite often they co-exist with patriarchal gender ideologies. In Tonga, for example, gender ideologies reveal different attitudes toward and expectations for sisters and wives. Women are conceptualized as below their husbands, but above their brothers, so husbands can tell wives what to do and

sisters can tell brothers what to do, but brothers are not supposed to boss their sisters and wives are not supposed to boss their husbands. A good deal of comparative research on gender ideologies assumes or asserts a close relationship between the amount of power women have and the extent to which gender ideology portrays women positively in a given society. Both women's power and gender ideology about them are in turn affected by aspects of cultural systems other than the gender frameworks themselves. The idea that gender ideologies and power relations between women and men vary in ways shaped by other social forces is important. It raises the possibility that women's positions can be enhanced by human transformation of social systems through identification of processes in them that favor gender equality. Various aspects of social systems have been put forward as influencing gender ideologies and power relations. For example, many scholars have argued that women have more power and more positive images in societies where they make significant visible contribution to the economic well being of the groups they belong to. Others argue that although present day societies may all have patriarchal gender systems, this has not always been the case. Some argue that 'states' as a type of political system entail a concentration of power in men's hands that was not true of prestate political systems in the evolution of human societies. Others focus on European colonialism over the last several centuries as a cultural influence that has made many societies patriarchal which were not patriarchal before. However, these ideas have been criticized for romanticizing past societies whose gender ideologies and power relations may never be completely reliably retrieved. Since the 1990s, there have also been changes in the way the power of gender ideologies has come to be conceived. It is increasingly common for anthropologists and others to write of the 'gendering' of very large-scale social processes, particularly colonialism, the emergence of nation states, and international relationships. This work suggests that the ideological power of gender is located not so much in explicit representations of gender in myths and rituals as in a more implicit, pervasive, and diffuse semiotic gendering of all of social life. Still, the most important contribution to date from the study of gender ideologies has been the documentation of considerable cross-cultural diversity in gender ideologies that describe and explain how and why women and men are different from each other. The documentation of this diversity in itself undermines and deconstructs essentialist views that differences between women and men are natural, supernaturally ordained, or fixed for all time in any society.

Gender-related Development

Being born a girl or boy sets a wide range of forces in motion. These forces go beyond the genetic, hormonal, and genital differences inherent in one's sex. Parents provide many opportunities for learning about what it means to be a boy or girl. Teachers and peers reinforce and encourage gender-typed behaviors in children. Children also become active participants in learning about gender. Gender development is a term that

encompasses all the many gendered aspects of children's development. To understand children's gender development, the entire range of social, cognitive, and biological influences must be considered.

1. Overview of Gender Development

In recent years, gender has come to be viewed as a multidimensional construct that covers many domains including biological sex, activities and interests, personal-social attributes, gender-based social relationships, gender-based styles and symbols (such as gestures, style of dress), and gender-related values (see Ruble and Martin 1998, Huston 1983). Each domain can be examined in terms of an individual's concepts, self-perceptions, preferences, and behaviors. In the past, there was an implicit assumption that a person who was gender typed in one domain also was gender typed in other domains. The multidimensional view of gender has been useful in questioning this assumption and replacing it with the challenge to researchers that interrelations among domains need to be assessed. Also, this view has the advantage of making clear the distinctions among the different domains.

Certain aspects of gender development have been investigated more than others, including gender roles, self-perceptions of gender, gender identity, and gender-related behaviors. Gender roles have been a popular topic of study, within both psychology and sociology. Gender role is a broad term referring to the behaviors, attitudes, and traits that are associated with being male or female. Many studies have been done to identify the roles that men and women fulfill in western cultures as well as in other countries and in our history. Gender stereotypes, which are culturally defined expectations about the sexes in terms of personality, appearance, occupations, abilities, and interests, have been a very central subject for social psychologists. Also, psychologists have been involved in studying self-perceptions of gender, especially individual's perceptions of masculinity and femininity. Gender identity, the sense of oneself as being a male or female, has been studied by clinical and developmental psychologists, whereas a typical gender identity has been investigated largely by medical researchers. Gender-related behaviors and characteristics have been the subject of numerous studies, including how children develop skills and social behaviors such as their relationship preferences.

2. Age Trends in Gender Development

2.1 Gender Identity

Gender identity is the sense of oneself as a male or female. Gender identity involves more than the anatomical—it involves the inner knowledge and outer expression of one's sex. The dominant view has been

that gender identity resides within the individual, although more recent views challenge this assumption by arguing that gender identity is created in the context of interactions, societal structures, and cultural expectations (Deaux and LaFrance 1998). Research on gender identity has also focused on the consequences of developing gender identity that is consistent with or different from one's genetic sex.

The predominant view has been that for typical children, the process of developing a sense of oneself as a girl or boy undergoes three stages. First, at about the age of 2–3 years, children learn to label themselves and others by sex. Second, 3–4-year-old children come to understand the stability of gender over time. Third, by the age of 4–5 years, children recognize that one's sex is a constant aspect of oneself that is not variable over situations (Slaby and Frey 1975). As children's sense of gender identity develops, they often show increased attention to people of the same sex, and are motivated to be like members of their own sex (Kohlberg 1966).

A very small group of children, about 2–5 percent of the population, develop a sense of gender identity that does not match their biological gender. These children, labeled as having gender identity disorder, express discomfort with their own sex, wish to be the other sex, and engage in behavior typical of the other sex (Zucker and Bradley 1995). The development of gender identity disorder may be related to biological factors, such as hormones and temperament, in addition to environmental factors, such as parental encouragement of cross-gender play.

An even smaller group of children are born with ambiguous genitalia or genitalia that do not match their genetic sex. These children may be assigned a sex that differs from their genetic endowment or may not be assigned a sex until later. Gender assignment, and also gender identity, become very complicated issues for these children. Although early research suggested that children who were assigned sex at an early age would develop according to their assignment regardless of their biological sex, more recent research has challenged this view. In some reports, both biological and social factors play a role in developing gender identity, whereas in others, only biological sex or only gender assignment is central in developing gender identity. Controversy continues over how to best support these children in developing their gender identities (see Ruble and Martin 1998).

2.2 Gender Differences in Interests, Behaviors, and Well-being

As early as 2 years of age, children begin to show sex-differentiated activities and interests (Ruble and Martin 1998). In the preschool years, children's preferences for stereotypic play become even more apparent. Girls and boys prefer different toys and prefer to play in different areas. The tendency to play with stereotypic

toys increases during early childhood. Both girls and boys show preferences for stereotypic activities, although boys seem to avoid other-sex activities more than girls.

Sex differences in activities persist into middle childhood and adolescence although the similarities in behavior are more striking than differences. Boys are more involved in sports, outdoor chores, and leisure activities; girls are more involved in indoor chores, shopping, and socializing. Through adolescence, girls spend increasing amounts of time in interpersonal activities, personal care, and household chores and less time in sports whereas boys' interest in sports remains stable or may increase.

Males are more active than females with the differences being more pronounced in older than in younger children. Girls and boys differ in many motor tasks, with boys outperforming girls in throwing and girls outperforming boys in tasks involving flexibility and fine-motor skills. These differences increase with age, possibly owing to differential participation of girls and boys in sports after puberty, although biological factors may also play a role in differences (see Ruble and Martin 1998).

Moderate and consistent sex differences are found in the area of physical aggression, with boys showing more aggression than girls. The exception to this is relational aggression—using behaviors to damage friendships—which girls engage in more than boys. Sex differences in aggression are larger in children than in adults, although men commit many more violent crimes than women.

The sexes differ to only a small degree in prosocial behavior and differences vary depending on the kind of behavior being assessed. Generally, girls help other people more than boys (Eisenberg and Fabes 1998). Females also are more accurate in decoding emotions from visual cues and they are more expressive and responsive than males.

Many varied indicators of well-being suggest that boys experience higher levels of well-being than girls. Beginning in adolescence, females are more likely to be clinically depressed or have depressive symptoms than males. Although the differences are small, boys report higher levels of self-esteem than girls and several studies suggest that girls experience a drop in self-esteem after the age of 9 years as compared with no change for boys. Girls have many more appearance and weight concerns than boys and these concerns increase during adolescence (see Ruble and Martin 1998). Girls' concern with their appearance may relate to their self-esteem and to eating disorders and disturbances.

2.3 Gendered Social Relationships

One of the most pervasive and consistent differences between the sexes is their choice of play partners (Maccoby 1990). Girls and boys are often found

playing with members of their own sex. The phenomenon of sex segregation appears to be virtually universal across cultures. Sex segregation varies in differing situations, however. Children's tendency to interact with same-sex children is common in situations in which children have choices about playmates, such as in school, and in unstructured situations, and is less common when fewer choices are available, such as playing in their neighborhoods, or when children are in structured situations in which they need to cooperate.

Sex segregation begins very early in life. Girls tend to segregate before boys, usually starting between 2 and 3 years of age. Boys who are more socially disruptive and girls who are more socially sensitive segregate earlier than other children (Moller and Serbin 1996). Sex segregation increases as children grow older. Sex segregation continues until middle adolescence when children begin to form heterosexual dating couples. Children's friendship patterns mimic their play partners in that most often, children's friends are of the same sex as themselves.

The kinds of play typical of girls' groups and boys' groups are different. Boys tend to play more actively, encompass more space, and they often play outdoors. Girls tend to play indoors, more quietly, and use less space. Girls are more likely to encourage cooperation and interaction among play partners; boys are more often interested in issues of dominance and competition. From their experiences with same-sex partners, girls and boys learn different methods of interacting with others and may be considered to be socialized in 'different cultures' (Maccoby 1990).

The origins of sex segregation are unclear. One contributing factor to sex segregation is similar interests. Children tend to play with same-sex children regardless of activity, so similarity in interests is not the only explanation for sex segregation. Compatibility in play styles is also important. Children show higher levels of social interaction when playing with their own sex, which suggests that same-sex play is more entertaining than other-sex play. Activity level may also be a factor. Boys tend to play actively and that may be compelling to other boys but not to girls. Finally, children's expectations about the sexes also likely contribute to sex segregation (Ruble and Martin 1998).

The developmental course of social relationships in later adolescence and adulthood, especially the development of sexual orientation, has been difficult to chart. Although both sexes show very strong propensities to select other-sex romantic partners, about 5 percent of the population selects same-sex partners. The origins and developmental pathways of sexual orientation have been hotly debated. The central issues appear to be the extent to which sexual orientation is influenced by biological factors, such as genes, hormones, and brain structures, or by social factors, such as one's upbringing.

2.4 Gender Differences in Cognitive Skills

Many studies have been conducted to examine whether the sexes differ in cognitive abilities. In many areas, no sex differences are found, e.g., in overall intelligence or in analytic reasoning (Halpern 1992). When the sexes differ in a cognitive ability, the differences tend to be fairly small and hence are unlikely to account for differences in career choices or trajectories. Nonetheless, the topic of sex differences in cognitive abilities remains controversial.

Most of the research on sex differences in cognitive abilities has focused on three areas—mathematical, spatial, and verbal abilities. In the domain of mathematical abilities, the patterns of similarities and differences vary depending on many factors including the particular skill being assessed, the age and skill level of the sample, and assessment procedures. Differences tend to be larger and favor males when studies are conducted on the most mathematically skilled children and when using certain standardized tests, such as the SAT. Also, sex differences vary for different skills, with girls receiving higher grades than boys in mathematics courses, and a small difference in favor of girls for computational skills in elementary school. Males show better performance in problem-solving tasks beginning in junior high or high school. Some evidence suggests that sex differences in mathematical abilities are lessening over time.

The sexes differ in some aspects of spatial abilities but the size of the difference depends on the particular ability being assessed and the age of the participants. Few differences are found between young girls and boys. Most sex differences begin to appear in adolescence and differences increase with age. A moderate-size difference favoring adolescent and adult males is found in tasks involving mental rotation, which involves the rapid manipulation of three-dimensional objects. A moderate to small difference favoring males occurs in tasks involving recognition of the horizontal or vertical. A small difference (or no difference) is found when assessing performance on spatial visualization tasks, which involves finding hidden spatial figures (Halpern 1992).

Very small sex differences are found in verbal tasks, with females outperforming males. The differences are found most often in the areas of spelling and language and tend to be stable across age. Verbal differences may be lessening over time although not all researchers concur with this conclusion.

In a large-scale assessment of adolescents' academic abilities, researchers have found that males outperformed females in tests of science, mathematics, social studies, and vocational aptitude (mechanical reasoning and electronics), whereas females outperformed males in reading comprehension, perceptual speed, associative memory, and writing (see Ruble and Martin 1998).

2.5 Gender Stereotypes

Gender stereotypes are the beliefs that people have about the characteristics of males and females. The content of stereotypes varies over cultures and over time. These expectations are often related to the roles that the sexes fulfill in the culture.

Children learn some aspects of stereotypes at a very young age. By the age of $2\frac{1}{2}$ –3-years, children show evidence of having some rudimentary knowledge of the activities and objects associated with each sex. Children's gender stereotypes of activities and occupations develop quickly during the preschool years, reaching a very high level by kindergarten. During the elementary school years, gender stereotypes broaden to include sports, school subjects, and personality traits. With age, children become increasingly knowledgeable about gender stereotypes and yet the rigidity of their stereotypes declines as they increasingly recognize the cultural relativity of these norms (Huston 1983). Some evidence suggests that boys hold more rigid gender stereotypes than girls and are held to more rigid ideals than girls. In adolescence, flexibility in stereotypes fluctuates in response to two opposing forces—increasing cognitive flexibility tends to increase adolescents' flexibility in applying stereotypes whereas increasing pressure to conform to stereotypes in preparation for sexual roles and adult status increases adherence to stereotypes (Ruble and Martin 1998).

Children use gender stereotypes to make inferences about others at a young age. When making judgments of other people, children and adults will apply their gender stereotypic expectations to them. Even more than adults, children will rely on a person's sex to make judgments and they are less likely to consider other relevant information about the person than adults are (see Ruble and Martin 1998).

3. Theories of Gender Development

3.1 Psychoanalytic Theory

The earliest and most influential theory of gender development was proposed by Sigmund Freud in the 1930s. Freud contended that boys and girls acquire gender identity by learning to negotiate desires for the opposite sex parent and by eventually identifying with the same-sex parent. Although little empirical support has been found for his theoretical framework, his ideas have been very influential in encouraging research on gender development. Over the years, additions and amendments have been made to Freud's original psychoanalytic theory. Many of these changes take into consideration the role of societal influences and include a feminist perspective.

3.2 Social Learning Theory

Social learning theorists (Bandura 1977, Mischel 1966) propose that gender development is accounted for by social factors. Girls and boys learn different roles through the effect of direct reinforcement, differential socialization, and imitation of models.

Direct reinforcement, which refers to the reaction children receive in response to their behavior, leads to children learning to discriminate between the behaviors typical of boys and girls. Children learn that there are different consequences for engaging in behaviors depending upon whether one is a girl or a boy. Behaviors considered to be stereotypic for their sex are more likely to be rewarded. Children perform activities that are consistent with their reinforcement histories (Mischel 1966).

Children also experience differential socialization of girls into feminine roles and boys into masculine roles as they are exposed to distinct environments in which gender differences are encouraged by socializing agents, such as parents, teachers, peers, and media. Parents fill boys' rooms with educational, interactive toys that promote exploration, whereas they fill girls' rooms with toys that promote nurturance and domesticity, such as doll houses and tea sets. Teachers respond differently to boys and girls: boys are more often called on to answer questions when their hands are raised than girls. Differential treatment by social agents provides boys and girls with separate sets of rules, expectations, and opportunities which, in turn, encourages traditional gender development.

Children also learn gender roles through observing others. Social learning theorists contend that individuals learn and reproduce the actions and responses of the models they encounter in their families, schools, and neighborhoods, and in books, television, and films. Gender-typed behavior develops as girls imitate the behavior of females and boys imitate the behavior of males. Children's imitation also is affected by their relationships with the model, in addition to the amount of power they perceive the model to possess (Mischel 1966, Bussey and Bandura 1984). Witnessing people's reactions to others as they display a behavior transmits information about the appropriateness of the behavior (Mischel 1966).

3.3 Cognitive Social Learning Theory

In the late 1970s and 1980s, social learning theory was adapted to emphasize the cognitive aspects involved in learning from the social environment (Bandura 1986). In 'cognitive social learning theory,' emphasis was placed on the processes involved in creating expectancies of other's behaviors and how these expectancies guide one's own actions. Specifically, it was proposed that observational learning required four processes: paying attention, being motivated to enact the behavior, having the ability to reproduce the action, and

having the ability to remember the behavior (Bandura 1986).

Social learning approaches have encouraged an expanded view of the forces that influence gender development. This theory has motivated researchers to include a more diverse view of the child's social environment. In addition, it has led to closer scrutiny of the social settings provided for children and the gender-laden messages these settings contain.

3.4 Cognitive Developmental Theory

According to Kohlberg's cognitive developmental theory, children's cognitive organization of the world around them is the basis for their gender development (Kohlberg 1966). Kohlberg proposed that between the ages of 2 and 7 years, children make cognitive judgments about their gender identity (whether they are a boy or a girl) and then come to understand that gender is constant over time and situation. This understanding about gender becomes the foundation for further gender development. A child's recognition of being a male or female determines the value they place on masculine and feminine traits, initiates a child's desire to be similar to same-sex children, facilitates the development of gender stereotypes, and encourages children to hold positive views of their own sex (Kohlberg 1966).

A debate has ensued over whether Kohlberg's theory requires the acquisition of gender constancy as a necessary antecedent to learning stereotypes and attending to same-sex models (Ruble and Martin 1998). Empirical studies suggest that children have only a basic knowledge about gender before the onset of the gender-typing process, and that stereotyping can begin once children are able to label the sexes correctly. Gender constancy may help consolidate gender development, rather than initiating it (Ruble and Martin 1998). Cognitive developmental theory emphasizes the child's active role in gender development. Kohlberg's theory has been enormously influential in shaping the way researchers think about gender development.

3.5 Gender Schema Theory

Gender schema theory is a cognitively based theory that uses an information processing approach to explain how gender development occurs. The basis of this model is the cognitive representation called a schema. A schema is an organizing structure that helps simplify and categorize new information.

There are two types of gender-related schemas (Martin and Halverson 1981). The first is a general 'superordinate' schema that helps children categorize objects, characteristics, and traits into basic male and female categories. The second is a more narrow version of schema, called the 'own-sex' schema, that children

use to identify and learn in-depth information consistent with their own sex. These two schema types allow children to process information about events, objects, attitudes, behaviors, and roles and, in turn, categorize these aspects in terms of masculine or feminine, or as similar or different from the child (Martin and Halverson 1981).

Gender schema theorists (Bem 1981, Martin and Halverson 1981) proposed that gender schemas are developed and applied by children at an early age. In addition, it was proposed that the presence and use of gender schemas can explain the ways in which children and adults attend to, acquire, and remember information; how they behave; and the kinds of attitudes they develop (Martin and Halverson 1981). Gender schemas affect which kinds of information are noticed, encoded, and remembered, with information inconsistent with the existing schema being overlooked and consistent information being processed (Signorella et al. 1997). Research also shows that gender schemas can guide children's preferences, toy choices, and play partner choices.

Because schemas are used to interpret and categorize information, however, they can result in the drawing of incorrect inferences. Distortion of information has also been found to be a consequence of gender schematic processing. Altering information that does not fit into a currently held schema or placing neutral information into a gender schema leads to remembering information in a gender-consistent manner, which may not match with how it exists in reality. These processes illustrate how gender schemas can be easily maintained and how resistant they are to change.

Gender schema theory emphasizes the child as an active processor of information and that the gender schemas that guide thinking also influence children's behavior. The major strength of gender schema theory is in the understanding it provides about the maintenance and power of gender beliefs.

3.6 *Biological Approaches*

Much of the research using a biological approach has focused on understanding differences between the sexes. These approaches often consider, for instance, the influence of hormones and brain structure and function on sex differences.

Sex differentiation begins with the presence of an X or Y sex chromosome in the twenty-third pair of chromosomes. These sex chromosomes carry the genetic information that determines the development of fetal sex organs. The amount of a specific androgen, called testosterone, which is present in both male and female fetuses, determines further development of sex organs. Increased levels of this hormone lead to the formation of the penis and scrotum in males. Female sexual organ development continues in the absence of

increased testosterone levels. Variations in the levels of hormones in these critical periods of development can lead to the formation of sex organs opposite to what would be expected from the sex chromosomes.

Hormones also influence the development of the central nervous system and the brain (Hoyenga and Hoyenga 1993). Hormones are most likely to affect brain development and behavior during two stages of life: during prenatal development and during puberty. Exposure to abnormal levels of hormones (due to genetic disorders or hormonal treatment during pregnancy) allows researchers to study the link between levels of hormones present during developmental processes and behaviors exhibited by individuals postnatally (Hoyenga and Hoyenga 1993). Studies of hormones, their effect on brain development, and the link to behavior suggest that they have an influence on gender development, although it is difficult to disentangle biological effects of hormones from social factors.

The structure and function of the brain have also been studied to compare the similarities and differences in males and females. One area of brain structure that has been studied is brain lateralization, or how much one hemisphere of the brain is responsible for carrying out specific functions. Some studies have shown that women are less lateralized in that they use both hemispheres simultaneously more often than men. It has been hypothesized that differences between men and women in a variety of abilities and behaviors could be due to a gender difference in lateralization. The findings of such studies show mixed support.

Another section of the brain that has been studied as a possible source of gender differences is the corpus callosum (CC). The CC is a group of fibers that connects the right and left hemispheres of the brain and is thought to be related to more intricate processes of thought, including language. Because the links between the structure, function, and size of the CC are not certain, research on differences in brain structure remains difficult to interpret. However, studies have shown that women have a larger CC than do men, and that enlargement of certain parts of the CC is linked to increased language skills.

Controversy surrounds the study of biological information on gender differences, especially concerning the extent of influence of biological and social factors. Most researchers of gender development accept an interactionist position, assuming that both nature and nurture are working together to produce human behavior. Furthermore, neither nature nor nurture should be viewed as steadfast or unmalleable (Hoyenga and Hoyenga 1993).

3.7 *Evolutionary Perspectives*

The evolutionary perspective draws on Darwinian principles of evolution and natural selection to explain

how gender differences evolve. Individuals who are fertile, live long enough to reproduce, and are able to raise their offspring will successfully pass on their characteristics to the next generation. Therefore characteristics of individuals who were successful in passing on their genes are more highly represented in future generations. According to the evolutionary viewpoint, gender differences arise because men and women play different reproductive roles (Trivers 1972).

Gender differences are hypothesized to develop because of differing parental investment levels. Evolutionary theorists contend that, because women are responsible for carrying the child during pregnancy and for producing food for the infant, their levels of parental investment are higher than men's. In contrast, men's reproductive role is limited to producing and investing their sperm. Thus, sexual selection differs for men and women. Because of a woman's increased investment level, she is more selective in her mates and searches for someone with access to resources. In contrast, men look for a woman who will care for the child, so that the child will eventually be fit to reproduce and pass on the family genes. However, because men never know if the child is actually carrying their genes, they are focused on mating more often and with shorter-term investments. Individuals who are most successful at their reproductive role are more likely to have their genes perpetuated, leading to a further divergence in men's and women's behaviors.

Evolutionary theoretical viewpoints have stirred much controversy, and empirical support for the theory's components is mixed. Critiques include the lack of ability to test the theory directly and the heavy dependence on animal studies.

4. Future Directions

The field of gender development moves quickly, making the prediction of future trends difficult. Nonetheless, some topics have garnered attention because they are important issues that have yet to be addressed. First, questions about the relation of mental health and domains of gender are worthy of additional research efforts. Why does the self-esteem of preadolescent girls drop more than that of boys? Second, research that focuses more attention on affective issues is needed to provide answers to questions about the role of self-regulation in gender development. Little is known about the affective and cognitive components that are involved in how people construct a view of their own gender and how others interpret gender identity. Third, many issues about how children are raised and about the contributions that parents, peers, and teachers can and do make to gender development are worthy of future research efforts. Finally, additional studies using multidimensional aspects of gender are important for understanding the complexities of gender development.

For instance, multidimensional studies are necessary to understand how a traditional vs. nontraditional view of one's gender identity relates to a variety of outcomes such as internal psychological states, relationships, and achievement in school and careers. The picture of gender development continues to emerge but is far from complete.

Gender Role Stress and Health

1. The Term 'Gender Role'

The term gender role is used in sociology and psychology to refer to the prescribed behaviors, attitudes and characteristics associated with one's gender status as a female or a male. Attributes associated with gender are the result of learning in accordance with cultural standards or prescriptions.

Gender-role socialization refers to the processes through which individuals acquire attributes appropriate to males and females. Examination of gender roles indicates differences in the content of roles seen as appropriate for men and women. Men are socialized more often than women to be active and to ignore their feelings of weakness. Men are expected to be more independent, autonomous, and strong. It is more acceptable for women to express a wide range of emotions, to pay attention to their moods, and to seek out others for help. While men may be encouraged to be independent, women are taught to be more interdependent. The term interdependence refers to the ability to express interpersonal needs, particularly in emotional relationships, and to relate meaningfully to others in relationships (Greenglass 1982).

2. The Term 'Stress'

Stress is often used to refer to the perception that the demands of the environment exceed the resources of the person, resulting in a threat to well-being. These may emanate from work, family, and daily hassles, as well as significant life events, and include time pressures, conflicts, and frustration in meeting one's goals (see *Stress and Coping Theories*).

2.1 Stress and Health

The way individuals cope with their stress is important for mental health. To the extent that individuals have resources to handle their pressures, they are less likely

to suffer deleterious effects of stress. However, when individuals have difficulties in managing demands and stressors, they experience strain. Strain is a consequence of insufficient personal resources to meet demands. To the extent that individuals experience strain, they are more likely to experience deterioration in their physical and/or mental health. Some of the psychological effects of uncontrollable stress are depression, anxiety, panic attacks, hostility, and anger. High levels of stress may also result in physical symptoms including insomnia, headaches, muscular aches and pains, digestion disturbance, and difficulty in carrying out day-to-day activities (see *Stress and Health Research*).

2.2 Stress and the Feminine Gender Role

Research indicates that women are exposed to more stressful life events than are men and, as a result, have higher rates of psychological distress. Women experience depression, anxiety, and mood disorders more than men. Women may appear to be more distressed as a result of the kind of outcome measures typically used in this research. These studies tend to employ self-report measures of symptomatology. Some argue that women appear more distressed because they are more likely than men to report symptoms of all kinds. Gender-role factors contribute to the degree to which individuals report symptoms and seek help. Traditional masculine and feminine gender roles differ in the amount of vulnerability and permissibility in seeking help from others. Traditionally, men are seen as strong and invulnerable, thus restraining men from showing symptoms of mental illness or seeking help. The traditional feminine gender role allows and even encourages vulnerability to problems, thus resulting in greater reporting of symptomatology in women. It is assumed generally that if an individual is coping reasonably well, she/he is free from anxiety and depression. This conceptualization of effective coping leads to a bias in research findings given that women, more than men, often express distress (Greenglass and Noguchi 1996).

Notwithstanding women's greater 'openness' regarding their psychological symptomatology, research indicates many reasons for women's greater distress. Reproductive life events including menstruation, pregnancy, childbirth, and menopause are stressful life events for women. Within the employment sphere, women tend to be concentrated in low-paying 'female' occupational spheres, including education, healthcare, clerical, domestic, and service industries. Women have fewer promotional opportunities, make less money, and often do not have access to membership of the 'old boys' network,' all of which restricts their advancement in the employment sphere. Women professionals and managers are subject to negative stereotyped attitudes that portray women as doing a poor job

fitting into the masculine work world. Sex discrimination and harassment are ubiquitous in the workplace. Such attitudes not only harm women's salary and promotion prospects, they are also detrimental to their mental health. Women in the labor force also perform most of the domestic work, and on average spend more hours in housework and childcare than men. Employed married women manifest higher rates of distress than employed married men. Employed married women with young children experience higher rates of psychological distress than their female childless counterparts or comparable men. Given the demands on women when combining employment and familial roles, many women experience inter-role conflict and/or role overload (Barnett and Marshall 1991, Baruch et al. 1987).

Women's roles are inherently stressful in that they obligate them to respond to others, including the very young as well as the elderly. Informal care for elderly parents and relatives generally is provided primarily by women. These demands are a significant source of stress, thus playing an important role in women's mental health. Elements of the feminine gender role endanger women's mental health, since provision of care for their families and friends is often emotionally and physically draining, particularly given the relative lack of men's participation in work at home.

2.3 Stress and the Masculine Gender Role

Men have been diagnosed more than women with antisocial personality disorders in which there is a pervasive pattern of disregard for others' rights. Men are also diagnosed more as having schizoid personality disorders, characterized by detachment from social relationships and a restricted range of expression of emotions in interpersonal settings. These diagnoses may be seen as exaggerations of the traditional masculine gender role that stresses independence, separation, strength, and invulnerability (Greenglass 1982).

Research in the area of stress and burnout shows that men experience higher levels of depersonalization than women. Burnout at work commonly is measured using a scale (the Maslach Burnout Inventory) (Maslach and Jackson 1986) which yields three subscales: emotional exhaustion, depersonalization, and lack of personal accomplishment. Depersonalization refers to an attitude characterized by being impersonal, callous, and distant from others (Maslach and Jackson 1986). In this context, depersonalization may be regarded as a reflection of men's repressed emotionality and an ineffective coping form which allows men to continue their work with people yet remain untouched by the others' suffering.

The strict prohibition against emotional expressiveness in men (except perhaps anger) is one of the most powerful cognitive masculine mandates influencing men and their behavior. Male inexpressiveness

is the result of gender role socialization that begins early in childhood. Men are taught that emotional expressiveness is a feminine trait and they learn to distance themselves from femininity. Masculine socialization contributes to and encourages aggressive behavior in men. Men are more involved than women in violent crime, including armed robbery, spouse and child abuse, and rape. While aggression in sports and the military is approved and rewarded socially, the social program associated with masculinity also includes competitiveness and aggression that are socially sanctioned as masculine coping styles.

While women more often express distress in internalized and depressive symptomatology (Chesney and Ozer 1995), men often cope with their feelings differently, since they are more likely to externalize their feelings such as becoming physically aggressive or by distracting themselves from their feelings by engaging in a variety of activities. The violence committed by men against women in its many forms is in part an outcome of a patriarchal society which is dominated by men who see themselves as controlling women in many different contexts. Research suggests that power, sexual control, and aggression are amplified in men in a patriarchal society. The mental health costs of male violence justify re-examination of the prescriptions of the masculine gender role (Greenglass and Noguchi 1996).

Masculine prohibitions and difficulties with emotional expressiveness make it difficult for men to maintain mutually supportive relationships. When under stress, men seem to be less flexible in their coping than women, since they have difficulty expressing positive feelings.

3. Stress, Coping, and Gender Roles

Research shows that the ways people cope with stress differ according to their gender role. Some argue that men are more problem-focused in their coping, and women are more emotion-focused (Folkman et al. 1986). For example, men have been reported to engage more in coping that alters a stressful situation. Some assert that men more often possess psychological attributes, i.e., self-esteem and mastery, which influence their coping. However, gender differences in mastery or self-efficacy are likely to be linked to differences in social experiences rather than to gender *per se*. A consistently unresponsive or negative environment has been found to affect a person's sense of self-efficacy, which in turn leads to anxiety and depression. Studies of gender differences in psychological characteristics have pointed out that models of stress and coping were developed primarily on men without consideration of women's roles and experiences, and may not encompass other aspects of coping including relationship-focused coping techniques.

In research on coping, findings indicate that when education, occupation, and/or position are controlled for, few gender differences are found in coping strategies (Greenglass et al. 1990). The type of coping an individual employs when dealing with stress is often related to the status, resources, and power associated with one's position. Many more women than men hold lower level jobs with less scope for the use of problem-solving and direct action strategies. Women are also more likely to experience high levels of demands, with low control over demands in the workplace (Greenglass 1985).

In coping research, the focus tends to be on individual behavior as the unit of analysis, and often, autonomous, agentic, and independent behavior is seen as synonymous with effective coping. But research shows that coping is highly specific to both the individual and the context. The social milieu in which a particular stressor is experienced should be incorporated into research paradigms that inquire into the relationship between gender and coping. Women may behave in a more passive way in groups with men, where stereotyped roles and social norms may be more strictly enforced. Women may appear different when acting alone or in a group of women.

3.1 Gender, Social Support, and Mental Health

There is a close relationship between positive health outcomes and social support. Close relationships can help a person cope with psychological distress. In such relationships people can disclose and discuss problems, share concerns, and receive advice keyed to their psychological needs. These relationships can also provide useful information, practical advice and morale boosting, all of which can assist individuals in dealing with their stressors (Cohen and Syme 1985). Both men and women benefit from supportive social interactions, especially intimate ones (see *Social Support and Health*).

Women are more emotionally involved in others' lives and serve a nurturing role for a wider network of people. In general, women give and receive more social support than men. Women have more close friends, and emphasize intimacy and disclosure in their friendships. Women's friendships are more involving and emotionally supportive. Social relationships with women are more health promoting than those with men. Wives are better providers of both instrumental and emotional support than husbands. Men tend to benefit from relationships with women; women generally benefit from relationships with their friends of the same sex (Belle 1982).

Research shows that the connection between social support and coping is stronger in women. Women employ more coping forms involving interpersonal relationships. Other research findings suggest that women use support from others through talking with

one another. Women are able to make more effective use of their support networks, since they talk more as a way of coping with stress.

E. R. Greenglass

Genealogy in Anthropology

1. The Concept of Genealogy

Genealogy owes its position in modern cultural and social anthropology to the genealogical method, which will be the main focus of this account, giving it an inevitable bias toward British social anthropology. The English term genealogy has three components: it refers to the descent of a person, family, or group from an ancestor or older forms; to a written or graphic account of those relationships; and to the study of

family pedigrees. English genealogy is closely associated with pedigree. Pedigree refers to the record of an ancestral line or lineage; the origin or history of something; a distinguished ancestry; and the recorded purity of breeding of an individual or strain. The overlap between genealogy and pedigree has been significant for the way genealogy has been incorporated by anthropology, especially in the study of kinship.

Anthropologists distinguished pedigree, as a vernacular account of ancestrally defined relationships, from genealogy as a systematic or scientific account of those relationships. The distinction rests upon the genealogical method, whereby the blood and marriage connections recognized by the people being studied could be systematically recorded. The genealogical framework obtained in this way provided the basis for the comparative study of terminological systems of address and reference, which were also sometimes called systems of relationship; for tracing marriage regulations (prescriptions and proscriptions); and for discerning the rules of descent and inheritance. Genealogies, or parts of them, collected in this way were (and are) often presented in graphic form to illustrate how persons or groups are related to one another. Genealogical information was the bedrock of comparative studies of kinship, descent, and marriage that were characteristic of structural-functionalist analyses of social organization during the first half of the twentieth century. Genealogy was also the basis for terminological and semantic studies of kinship, and used by alliance theorists. The use of genealogy to map the kinship system was even more pervasive, however, becoming a routine part of anthropological practice during the second half of the twentieth century.

2. The Intellectual Context of Genealogy in Anthropology

The genealogical method, developed by W. H. R. Rivers during the Torres Strait Expedition of 1898, was formalized in an article published in 1910 and became an important entry in the 1912 *Notes and Queries in Anthropology* and subsequent editions. The nineteenth century intellectual context of this addition to the anthropological instrumentarium lay in a rich combination of biblical, philological, heraldic, and evolutionary ideas. Darwinian theories concerning the origin of species and the descent of man had recourse both to linguistic and graphic genealogical imagery. The familiarity of biblical and historical family trees made genealogy a perfect vehicle for translating new ideas about the relationships between all forms of life, and the slow transformation (or evolution) of these forms through the immense abysses of geological time that opened up through the discovery of prehistoric sites and remains during the nineteenth century. Graphic phylogenies, such as those drawn by Hae-

ckel (1874), expressed these evolutionary connections in the form of a tree.

Genealogies are central to the creation story in Genesis, which was a source of inspiration for late eighteenth and early nineteenth century philologists and ethnologists who sought to explain the relationship between the languages (and hence peoples) of the world in genealogical terms. Still earlier, culturally diverse objects brought from the new world to Europe from the sixteenth century onward, were accommodated by cabinets of curiosity within the category pagan, which already housed the classical world and barbarian Europe. Discussions about the origins of Incas and Aztecs, for example, revolved around their identity with lost tribes of Israel, and their being remotely descended from Noah (Shelton 1994).

Philological, biblical and Darwinian genealogical ideas influenced L. H. Morgan, author of *Systems of Consanguinity and Affinity of the Human Family* (1871), in his kinship and beaver research among the Objibwa around Marquette, which took place against a background of wilderness receding from American farms (Feeley-Harnik 1999). This was rather different from Darwin's invocation of genealogical imagery in his theory of evolution, which was filtered through the ideas of British animal breeders for whom keeping records was an important means of exercising control over procreation. The fact that the British aristocracy could trace their genealogies, just as they could trace the pedigrees of their favorite animals, such as thoroughbred horses, helped to distinguish them, in terms of descent and breeding, from middle- and working-class Britons.

Rivers borrowed and translated the English aristocratic notion of pedigree into the genealogical method. It became a means of organizing fieldwork and written ethnography, despite being later overshadowed by the long-term fieldwork practices of participant observation. The incorporation of pedigree into anthropological methodology for assimilating knowledge about others is a fascinating maneuver by a middle-class intellectual in the context of turn of the twentieth century Cambridge, which was still very much dominated by a few great families. Borrowing pedigree was simultaneously an assertion about being above this sort of hereditary class system, and yet harnessing the power of its connotations in the form of intellectual capital in the comparative study of mankind.

Genealogical thinking informed arrangements of material culture before the advent of public ethnographic museums, and continued to be influential after these collections had been systematized according to geographical provenance, or as evolutionary typologies. Museum collections played a significant role in the rise of disciplinary knowledge, including anthropology, during the nineteenth century. Rivers' early twentieth century reformulation of the genealogical method scaled down the vast abysses of nineteenth century ethnological time to the more modest tem-

poral requirements of the emerging ethnographic present. In this respect, he made a major contribution to modern ethnographic field techniques by developing an explicitly scientific method for collecting immaterial cultural data, and imbuing it with a distinctive material form.

3. *The Genealogical Method of Social Anthropological Inquiry*

Rivers' genealogical method moved from the concrete level of personal names to the abstract system of relationships. That abstract system was accessed through the terminological categories used by Ego to address and to refer to the persons named as relatives. Rivers explains the steps by which he collected a pedigree (he used the terms genealogy and pedigree interchangeably). First the descendants of the informant's 'real' (as opposed to classificatory) parents were listed, including previous or other marriages, and children listed in order of age, together with their marriages and offspring. The mother and father's respective pedigrees would be collected according to the same procedure. Rivers claimed that the most extensive pedigrees could be collected using only five terms of relationship: 'father', 'mother', 'child', 'husband', and 'wife.'

The fact that Rivers treated some categories—'brother', 'sister', 'cousin', 'uncle', and 'aunt'—as problematic, gave the entire method a lineal bias. Later commentators have argued that lineal relationships were seen as less ambiguous than either collateral or affinal ones (Barnard and Good 1984). Information concerning social condition, residence, totemic, and other group affiliation, along with other relevant facts, were to be recorded for each person on the pedigree as far as possible. An extraordinarily wide range of topics could be studied by collecting information in this way. Kinship was about the social recognition of certain genealogical relationships; and genealogy was assumed to be about biology.

Despite Malinowski's (1930) critique of the over-abstractness of kinship studies and his emphasis on the importance of long-term participant observation, the genealogical method proved to have remarkable staying power as a technique for structuring this kind of fieldwork.

4. *From Corporate Descent Groups to Critique*

One of the main uses of genealogies for Rivers and for subsequent (especially, but by no means exclusively, British) anthropologists lay in studying social organisation. This concern was sometimes connected with colonial administration, seeking to identify and use indigenous social structure for governmental purposes. Interest in descent, in studying ancestral

connections reckoned through the female (matrilineal), or male (patrilineal), or both (bilateral) lines, gradually emerged as a dominant theoretical concern by the 1940s. The juridico-political importance of unilineal descent, especially in the African societies to which anthropologists turned their attention after an earlier interest in the Pacific, led Fortes to distinguish between domestic (internal) and political (external) social domains.

Fortes' (1945) 'Paradigm of the Lineage System' diagram is a particularly striking use of a genealogical-style diagram to represent the all-male lineage structure. Despite Leach's (1961) critique of the paradigm, and his insistence on the ideological rather than empirical nature of corporate lineage groups, he himself made extensive use of genealogical evidence to back up his argument. The continuing recourse to genealogy, despite the eclipse of kinship from center stage after the 1960s, helped to maintain a notion of biology as something separate (like nature) from society, until almost the end of the twentieth century. It is therefore remarkable that Barnes (1967) refers to the collection of genealogies as part of the ethnographer's stock-in-trade, and genealogical diagrams as part of the 'minimum obligation' for making fieldwork intelligible. He did, however, recommend recording the way informant's talked about their kin before embarking on formal questioning.

The ethnologists of France, who set out to study kinship at home in the same way that their colleagues did abroad, developed the technique of talking family, as a complement to genealogy, much more explicitly than their Anglo-Saxonic counterparts. Firth and his colleagues' 1960s study of middle-class kinship in north London collected and made use of genealogies only to discover that these were often part of oral knowledge—as in peasant societies. Schneider, too, constituted genealogies in his studies of American kinship (Schneider 1968), although he engaged in more open-ended questioning.

Bourdieu called for a social history of the genealogical tool, with particular attention to the functions that have produced and reproduced the need for such an instrument (Bourdieu 1977). Schneider (1984) was to criticize 'the doctrine of the genealogical unity of mankind', arguing that all comparative studies of kinship are rooted in our own beliefs about biology, and the enormous value attributed to human sexual reproduction in (what he variously called) Western/European/American cultures. Schneider's critique proved to be the catalyst for a number of new directions taken in the study of kinship. Strathern developed the argument that nature no longer serves to ground the understanding of society, which means that interventions such as the new reproductive technologies are an integral part of both English kinship and wider (political) society. Bouquet (1993) analyzed the cultural specificity of the genealogical method, arguing that it was infused by English notions of

pedigree so specific that it bears little resemblance to the Portuguese notions of relatedness, which were used to problematize English middle-class kinship. Although the genealogical diagram, with its more ramifying cultural-historical roots, simplified and facilitated the divulgation of genealogy in anthropology, it did not cancel the complexities and contradictions of genealogical ideas even within Europe (Bouquet 1996). Franklin (1997) has elucidated the effects of new reproductive technologies on the meaning of genealogy, understood as life's progression and as a way of making knowledge, among prospective parents in northern England. She coined the notion of post-modern genealogy to capture the way technology has come to stand in for and improve upon the natural process of procreation, despite all its attendant uncertainties.

5. The Future of Genealogy

Critical reappraisal of the assumptions implicit to genealogy in anthropology is likely to play a significant role in future studies of kinship. Genealogical thinking is certainly not universal, which renders problematic the anthropological attempt to use genealogy as a standard. Yet anthropologists have already been struck by the growth of popular genealogy in different parts of the world, and through the Internet (Segalen and Michelat 1991), both of which are subjects deserving further empirical study. Indigenous peoples' uses of historically collected genealogies in establishing land claims, constitute another highly significant development: for example, among Torres Strait and Australian Aboriginal communities. The impact of new technologies on genealogy, and new uses to which genealogies collected in the past by anthropologists may be put in the future, are but two examples suggesting that despite recent critical work, genealogy has by no means had its day in anthropology.

Generalizability Theory

1. Overview

Generalizability theory (G theory) provides a framework for conceptualizing, investigating, and designing reliable observations. It was originally introduced by Cronbach and colleagues (1963, 1972) in response to limitations of the popular true-score-model of classical reliability theory (Spearman 1904, 1910). Classical reliability theory centers around the notion that each observation or test score has a single true score, belongs to one family of parallel observations, and yields a single reliability coefficient (Nunnally and Bernstein 1994). While this model may be reasonable for carefully equated parallel forms of tests, it is overly restrictive and often unrealistic in situations where, for instance, raters differ in the central tendency and variance, observations depend on the context in which they occur, and constructs are patently heterogeneous. Several writers argued in the 1950s and 1960s that the same observation could conceivably belong to more than one set of parallel tests and, thus, have more than one reliability coefficient (Cronbach et al. 1963, Guttman 1953, Tryon 1957). The fact that the internal consistency reliability estimate of a multidimensional measure tends to be low even when test–retest and alternate forms reliability estimates are high illustrates

the contradictions and limitations of the classical reliability model.

It was Cronbach's vision to reinterpret classical reliability theory as a theory regarding the adequacy with which one can generalize from a sample of observations to the universe of observations that was randomly sampled. G theory acknowledges that the reliability of an observation depends on the universe about which the investigator wants to draw inferences. Because a particular measure may, conceivably, be generalized to many different universes, a measure may vary in how reliably it permits inferences about these universes and, therefore, be associated with different reliability coefficients. G theory explicitly requires investigators to specify a universe of conditions over which they wish to generalize. The extent to which different conditions are associated with different observations has implications for designing dependable observations.

G theory not only reinterprets classical reliability theory, but also shows how the traditional distinction between reliability and validity can be overcome to design dependable observations. Traditionally, construct validity is concerned with drawing inferences about a latent construct based on observable measures, whereas reliability is concerned with drawing inferences about a true score from observations across parallel measures. In G theory, a universe, its facets, and the conditions for admissible observations are defined through careful construct explication, the traditional domain of validity theory. G theory defines observations as dependable if they permit accurate inferences about the latent construct (i.e., the universe of admissible observations) they are meant to represent. In so doing, G theory blurs the traditional distinction between reliability and validity. The use of the terms 'dependability' and 'generalizability' instead of 'reliability' reflects the interest in unifying reliability and validity. How to go about designing and investigating dependable measures is the subject of G theory.

2. Key Concepts

2.1 The Decision Maker

Measurements are designed with applications in mind, and their quality has to be examined in the context of their application. This context is symbolized by the 'decision maker' who is interested in measuring a particular construct in a particular population of persons, under a particular universe of conditions, and with particular types of decisions in mind.

2.2 Types of Decisions

The types of decisions for which a measurement instrument is to be used must be known before an

instrument that yields dependable observations can be designed. Two major types of decisions have to be distinguished. The first concerns decisions that rely on the relative ranking of individuals. Accepting the three top-scoring applicants for a position is an example of a decision that relies on the relative interpretation of scores. Measurements that emphasize the interpretation of the relative differences between scores are the domain of classical test theory with its traditional focus on interindividual differences.

The second major type of decision is based on the interpretation of the absolute level of scores. Mastery tests in education provide an example of a decision based on the absolute interpretation of a score. Similarly, pre-established admissions standards for college (e.g., minimum SAT score) or pass/fail standards on job selection tests rely on the interpretation of absolute score levels.

2.3 The Universe of Admissible Observations

A measurement consists of a sample from the universe of admissible observations. What defines a universe for a particular measurement is based on what the decision maker is willing to treat as interchangeable for the purposes of making a decision. Thus, a universe may consist of interchangeable three-letter syllables, symptoms of depression, or interviewers if the decision maker is willing to treat as interchangeable three-letter syllables, depressive symptoms, and interviewers. Or, a universe may consist of interchangeable time points for urine collection, survey questions about voting behavior, or situations for observing altruistic behaviors if the decision maker considers those aspects of measurement to be interchangeable.

2.4 Estimating a Person's Universe Score

Given a particular universe of admissible observations, a person's universe score ($\hat{\mu}_p$) can be defined as the average score based on all admissible observations (X_{pi}) of the universe of interest. The purpose of a measurement is to accurately estimate this universe score ($\hat{\mu}_p$) based on a sample of observations.

The degree to which a measurement is generalizable depends on how accurately the measurement permits us to estimate the universe score. The accuracy of an observation is captured in the variance associated with the different presumably interchangeable observations. The extent to which different items or different observers or different measurement occasions yield different observations determines how dependable a single specific observation is. In other words, if different items, observers, etc., yield similar observations, a single measurement may allow accurate inferences about the universe of observations. If different items, observers, occasions, etc., yield dis-

similar observations, inferences about the underlying universe based on a single observation may be questionable.

2.5 The Universe and its Facets

Universes can be simple or complex, homogenous or heterogeneous, and small or large depending on the construct of interest and the decision maker's interest in investigating different aspects or facets of generalizability. The terms 'facets' and 'conditions' are analogous to 'factors' and 'levels' in the literature on experimental design. A universe of observations is said to consist of one facet if the generalizability of observations regarding one source of variation in the universe, say arithmetic questions of varying difficulty, is at stake. For instance, a particular arithmetic test includes a sample of items, covering different addition, subtraction, multiplication, and division problems of one- and two-digit numbers. The decision maker is interested in general arithmetic achievement, and is indifferent to the particular questions on the test. In the one-facet design, one is interested in estimating the universe score of each person based on the sample of items included in the test. A universe is said to have two (or more) facets if the generalizability of observations regarding two (or more) sources of variation in the universe, say items and occasions, is at stake. For instance, to the extent that arithmetic achievement depends on the difficulty of the items and the test occasions (e.g., beginning or end of school year), the generalizability of a particular measure taken early in the school year on a sample of difficult items may be compromised.

2.6 Generalizability Studies

Generalizability studies (G studies) are conducted to investigate the relationship between an observed score and a universe score. They are designed to provide information regarding the sources of variability (i.e., facets of the universe) that influence the generalizability of observations. Because the dependability of a measure rests on its purpose (and thus the universe of admissible observations it is meant to represent), different G studies may be needed depending on the proposed application of the measure. Alternatively, a single G study has to anticipate the multiple uses of a measurement to provide as much information as possible about potentially important sources of variation.

In the above example, arithmetic items varying in difficulty is an obvious choice of a facet to be examined in a G study. In addition, decision makers may be interested in whether measures taken at different occasions, based on, for example, different response formats or different presentation modes yield different

observations. To examine these issues, a universe has to be defined more broadly to include items of different difficulty, response formats, presentation modes, and taken at different occasions. Having defined such a multifaceted universe, a G study has to be designed to investigate the contributions of these facets and their interactions to the overall variance in observations.

2.7 Decision Studies

G studies are designed to assess the dependability of a particular measurement technique. In contrast, decision studies (D studies) are designed to gather data based on which decisions about individuals are made. D studies rely on the evidence generated by G studies to design dependable measures for a particular decision and a particular set of facets about which a decision maker would like to generalize. The goal is to design a measure that samples sufficient numbers of instances from different facets of a universe of observations to yield a sufficiently dependable estimate of the universe score which the measure is meant to represent.

3. Illustrative Generalizability Design

3.1 Generalizability Design

For illustration, the statistical models and analyses for a one-facet G study will be presented. This most simple G design requires making observations (X_{pi}) on individual subjects ($1, 2, \dots, p, \dots, n_p$) under different conditions of a facet ($1, 2, \dots, i, \dots, n_i$), where subjects and conditions represent random samples from their respective universes. In a one-facet design, the universe of admissible observations consists of observations that differ with respect to one characteristic, such as item difficulty. The generalizability question is: How dependable are observations made under different conditions to draw inferences about the universe consisting of all conditions?

3.2 The Statistical Model

A one-factorial ANOVA model can be used to describe how the observed score of person p under condition i can be partitioned into a grand mean (μ), an effect for each person (π_p), an effect for each item (α_i), and a residual (ε_{pi}).

$$X_{pi} = \mu + \pi_p + \alpha_i + \varepsilon_{pi} \quad (1)$$

In Eqn. (1), the grand mean (μ) is a constant value for all persons, positioning the score for all persons on the particular scale of measurement. The person effect (π_p) describes the difference between a person's universe score and the grand mean ($\mu_p - \mu$), indicating inter-

individual differences in universe scores. The item effect (α_i) indicates the difference between an item's difficulty and the average item difficulty ($\mu_i - \mu$), reflecting the variability associated with the facet of error being investigated. The residual combines the influence of the person-by-item interaction, systematic sources of error other than items, and random events.

According to this model, specific observations X_{pi} vary due to differences between persons (i.e., person effects), differences between items (i.e., item effect), and other unaccounted for sources (i.e., residual). Accordingly (see Eqn. (2)), the variance of a set of observed scores (σ_{Xpi}^2) can be partitioned into components due to persons (σ_p^2), items (σ_i^2), and the residual (σ_e^2). The residual combines two sources of variance that cannot be distinguished from each other in this model. They are the person-by-item interaction (i.e., items vary in difficulty between persons; persons vary in their ranking on different items) and chance fluctuations in scores.

$$\sigma_{Xpi}^2 = \sigma_p^2 + \sigma_i^2 + \sigma_{pi,e}^2 \quad (2)$$

3.3 G study: Estimation of Variance Components

To estimate these variance components, a G study has to be conducted in which data are collected on a representative sample of persons and items. Variance estimates can be derived from the mean squares (MS) reported as part of the standard ANOVA printout of statistical analysis programs (see Eqns. (3)–(5)), in which persons are identified as between-subjects factor and items as within-subjects factor.

$$\hat{\sigma}_{pi,e}^2 = MS_{\text{residual}} \quad (3)$$

$$\hat{\sigma}_p^2 = (MS_p - MS_{\text{residual}})/n_i \quad (4)$$

$$\hat{\sigma}_i^2 = (MS_i - MS_{\text{residual}})/n_p \quad (5)$$

3.4 A Numerical Example

Table 1 presents the ANOVA summary table from a G study in which 1,140 persons rated the frequency with which they experienced 20 depressive symptoms. The table presents the numerical estimates and the percentage of total variance accounted for by persons, items, and the residual.

3.5 Interpretation of Variance Components

Variance components reveal information about how different sources of variability affect the response to a

Table 1

ANOVA mean squares (MS) and estimates of variance components for a one-facet G study

Source of variation	MS	Numerical estimate	Percentage of total variance
Persons (p)	1.5005	$\hat{\sigma}_p^2 = 0.0596$	15
Items (i)	26.4947	$\hat{\sigma}_i^2 = 0.0230$	6
Residual (pi, ϵ)	0.3089	$\hat{\sigma}_{pi,e}^2 = 0.3089$	79
Total	0.3902	$\hat{\sigma}_{Xpi}^2 = 0.3915$	100

single item. For instance, the variance component associated with items in the above example is 0.0230, accounting for 6 percent of the total variance. This variance component indicates how much the mean of any one randomly selected item is expected to vary from the mean of all items in the universe. Clearly, the magnitude of a variance component depends on how the items were scored (e.g., 1, 2, 3, 4 or 10, 20, 30, 40). In this example, items were scored 1, 2, 3, 4, where 1 indicates the absence of depressive symptoms and 4 indicates the symptoms were present all of the time. The average item mean (i.e., estimate of the mean of all items in the universe, $\hat{\mu}_i$) was 1.38 indicating that most respondents reported the absence of depressive symptoms. Taking the square-root of the variance component $\sqrt{0.023}$ yields 0.1517, indicating that we would expect approximately 95 percent of item means to fall between ± 0.2972 of the overall mean (i.e., $CI_{95\%} = [1.08; 1.68]$). Given that the possible range of item scores is 1 to 4, the expected range indicates that the item means in the universe of admissible items will mostly vary between 1 and 2. The variance component for persons is 0.0596, or approximately 15 percent of the total variance. This variance component estimates the universe score variance, that is, the between-person variability in the average item scores across all the admissible items of the universe. Based on the variance component, the standard deviation is 0.2441, indicating that 95 percent of universe scores are expected to fall between ± 0.4885 of the grand mean (1.0, 1.86).

Similar to the reliability coefficient in classical measurement theory, G theory yields a coefficient of generalizability (ρ^2) based on a particular G design. It is defined as the ratio of universe- and observed-score variances. In this example, the G coefficient for a single item is $\hat{\rho}^2 = \hat{\sigma}_p^2 / \hat{\sigma}_{Xpi}^2 = 0.1522$. Similarly, intra-class correlation coefficients can be determined. For one item it is $\alpha_{(1)} = (MS_p - MS_{\text{res}}) / (MS_p + (n_i - 1)MS_{\text{res}}) = 0.1617$, and for the set of 20 items it is $\alpha_{(20)} = (MS_p - MS_{\text{res}}) / MS_p = 0.7941$. The latter is also known as the Cronbach α coefficient or KR20 formula.

By far the largest variance component is due to the residual (i.e., 0.3089), accounting for approximately 79 percent of the total variance. This suggests that there are important sources of variance not accounted

for by differences between persons or differences in item difficulties (i.e., item means). Because the residual consists of the item-by-person interaction, this variance component reflects the fact that subjects indicate somewhat different levels of depressive symptoms depending on which item they are responding to. Based on the variance component, the standard deviation is 1.0893, indicating that the response to a specific item is expected to fall within ± 1.09 of a person's universe score in 95 percent of observations.

In summary, the results show that responses to a single item are mostly influenced by measurement error. Information about inter-individual differences make up only 15 percent of the total variance, and information about differences in test items make up only 6 percent of the total variance in item responses. Clearly, a single test item is of little use in estimating a person's universe score. Consequently, decision studies must sample many items to achieve more dependable estimates. Exactly how many items is the subject of D studies.

3.6 D study: Designing Generalizable Observations for Decisions

To conduct a D study, the relevant universe of observations and its facets must have been investigated in the G study. The type of decisions to be made must be known and the accuracy necessary to make the decisions specified. With this information at hand, the number of items from each facet of the universe can be determined such that dependable inferences can be drawn about the entire universe of observations at stake.

For instance, the decision maker in the previous example may want to design a measure that yields a 95 percent margin of error of ± 0.25 for the estimate of a person's universe score. That is, the decision maker wants to be 95 percent confident that a person's universe score is within ± 0.25 of the observed score. Based on this 95 percent margin of error (i.e., $0.25 = 1.96 * \sigma_{\text{error}}$), the error variance of the universe score can be determined: $\sigma_{\text{error}}^2 = (0.25/1.96)^2 = 0.0163$.

For decisions based on the relative ranking of scores, the required number of items is:

$$n'_i = \frac{\sigma_{\text{pl,e}}^2}{\sigma_{\text{error|relative}}^2} \quad (6)$$

For decision based on the absolute ranking of scores, the required number of items is:

$$n'_i = \frac{\sigma_i^2 + \sigma_{\text{pl,e}}^2}{\sigma_{\text{error|absolute}}^2} \quad (7)$$

Thus, for relative decisions, we need to sample $n'_i = 0.3089/0.0163 = 18.95$ or 19 items. And, for absolute

decisions, we need to sample $n'_i = (0.0230 + 0.3089)/0.0163 = 20.36$ or 21 items. In this example, very little variance is contributed by differences between items in their difficulties (i.e., σ_i^2), indicating that, regardless of which items are sampled, similar absolute scores will be obtained. Consequently, only two additional items have to be sampled to yield equally dependable estimates of universe scores for relative and absolute decisions.

4. Extensions

The principles presented here for a simple generalizability scenario can be extended to more complex designs consisting of two or more factors, which may be random or fixed, and which may be crossed or nested. The interested reader is referred to the works by Cronbach et al. (1972) and Shavelson and Webb (1991). G theory can also be applied to the analysis of score profiles, composites, and difference scores. Furthermore, extensions have been developed to estimate variance components via maximum likelihood, Bayesian, and covariance structure methods, and for studying the dependability of any facet of observation. The interested reader is referred to the work by Marcoulides (1996, 1999), Shavelson et al. (1989), Wittmann (1988), and Webb et al. (1983).

G. E. Matt

Generalization: Conceptions in the Social Sciences

All social scientists use observed particulars to draw conclusions about abstract entities. In measurement theory, the argument that ‘IQ is what an IQ test measures’ is discredited, and informed debates take place to interpret what the observed scores mean in general language. Some qualitative researchers are also reluctant to generalize beyond observables, but their language is replete with summarizing statements and they invite readers to construct theoretical meanings beyond the descriptions offered. In laboratory research, scientists often study local student samples, not to construct theories about them or about students in general, but to make inferences about humans. Some laboratory researchers use animals to substitute for humans, and their case for cross-species generalization has to depend on arguments—e.g., that cats and humans share the anatomical and physiological attributes central for understanding whatever aspect of vision is under study. This entry describes and evaluates many of the procedures for generalization that social scientists actually use.

Cronbach (1982) has perhaps the most comprehensive framework for understanding generalization. We use his theory, though slightly modifying it. He claims that social scientists typically draw conclusions about four not completely independent entities—human populations, physical settings, causes, and observables (including effects and moderators of cause–effect relationships). Time, understood as historical period, might also be added. Cronbach further contends that scientists work with samples, instances,

cases, exemplars, or particulars (terms he uses almost interchangeably), and that these represent study-specific populations, categories, entities, universes, classes, constructs, or categories (terms he also uses interchangeably). A major task of all scientists is to identify the class a given set of lower-order instances represents.

Cronbach also understands generalization in terms of inferences about classes that the sampling specifics manifestly do not represent. Such knowledge transfer is particularly salient, for instance, when animals are studied as proxies for humans or when laboratories substitute for other social settings. But transfer is also involved when research on American senior citizens, say, is used to extrapolate to Americans in mid-life or to seniors in Western Europe; or when findings about factories are extrapolated to schools on grounds that both are complex organizations. Extrapolation also pertains to causes and effects, as when studies of healthcare subsidies are applied to housing subsidies, or when a finding about a subsidy’s effect on hospital utilization is applied to effects on mental health. Cronbach believes that methods are needed both for justifying inferences from particulars to generals (as from samples to populations or from measures to constructs) and for justifying extrapolations beyond the categories studied.

His schema also includes subcategories—e.g., the racial groups within some human population or the components constituting a construct-like stress. Researchers routinely partition data both to test a relationship’s stability across the subcategories examined and to identify the conditions under which it varies. The more heterogeneous the subpopulations are over which a relationship holds, the greater its generality is usually assumed to be. In addition, the more specifically identified are the boundary conditionals limiting a relationship, the better its generality is understood. Campbell’s external validity (Campbell 1957) also emphasizes generalization across entities, but without restricting it to subtypes. For him, a relationship found among Austrians should be examined not just by partitioning Austrians into regional or generational subgroups, but also by examining the same relationship across other nations. Findings that dependably replicate across very different circumstances are the foundation of all general science.

Using the Cronbach framework, we structure this exposition into four parts: (a) methods based on formal sampling theory, as they are and are not used for generalizing to clearly designated universes of people, settings, times, causes, and effects; (b) purposive sampling methods, especially as they are used in validating constructs; (c) methods for assessing the range of circumstances over which a causal connection holds; and (d) methods for extrapolating knowledge to entities with different characteristics from those on which the knowledge was originally established.

This phrasing acknowledges that many social scientists use universe (and population) differently from construct, though the later Cronbach tends to use them almost interchangeably. In statistics, populations are ostensive; their elements are real and can be pointed to. But constructs are hypothetical and more obviously theory dependent. Moreover, the formal methods statisticians prefer when sampling elements from a population cannot be used with constructs, because the necessary enumeration and sampling of elements cannot be readily achieved with measures of abstract constructs. This is why Cook and Campbell (1979) used external validity to refer to people and settings and construct validity to refer to instances of more hypothetical causes and effects. However, the distinction is partly arbitrary. Constructs have constitutive elements theoretically specified as their components, and instances of any one construct vary in which components they incorporate. Moreover, human populations are not totally ostensive *per se*. Despite official definitions, there is still room to disagree about what being an Australian means: what about someone with an Australian passport who has always lived abroad, or the illegal immigrant who has always lived in Australia without a passport? There is room for legitimate debate about the definition of any human class and about whether certain individuals fit within that class. Also, whether human populations or abstract constructs are involved, the functional task is always the same: justifying inferences from particular cases to general categories. Hence, we see no fundamental reason for treating populations and constructs differently, though we do respect social science terminology and often use the one to refer to people and settings and the other to cause and effect variables as well as causal moderators.

1. Formal Sampling Theory

The best way to represent a population is to enumerate its members before selecting a random sample from that population. When properly implemented, this guarantees that the sample will formally represent the population within known limits of sampling error. The sample and population distributions will match on all measured and unmeasured attributes. This makes random sampling the centerpiece of survey research, often complemented by other sampling details. To reduce costs, cases can be clustered within a geographic area before being randomly selected. To ensure that subpopulations are reliably represented, stratification can also occur before random selection. Formal sampling theory provides an impeccable justification for generalization to well-designated populations. And methods for implementing are now so improved that its use in describing human populations and some settings is almost routine.

The problem with random selection is its own limited generality. It rarely applies to causes and other abstract constructs (or to time). One cannot readily imagine enumerating all instances of a specific causal agent before selecting a random sample of these instances for study. In practice, causal agents are purposively chosen because of a presumed correspondence between substantive theory and operational instance(s). Likewise, it is rare for all possible measures of a construct to be enumerated before some are randomly chosen. The selection of measures to represent a construct is again purposive. Also, it is hardly practical to sample historical periods at random for generalizing, if not to eternity, then at least to some meaningful interval. Detailed measures are not always available from the past; and anyway, many theories predict temporal contingency rather than constancy. This last justifies the purposive selection of time periods for the unique light each throws on some causal process.

Even when selection is at random, unambiguous inference still depends on large samples that are not always readily forthcoming. How often can we randomly sample 50 or 100 time points for assessment? Or 50 or 100 institutions, unless the aim is to describe a particular class of institutions? What about manipulating causal agents within institutions? What proportion of those asked to participate will agree to do so? What types are these volunteer organizations likely to be—the most typical or the most proud?

Random sampling rarely applies to assessing the conditions under which cause and effect are related. We know of only six experiments where individuals or households were randomly selected before being randomly assigned to a treatment (see Shadish et al. 2001). However, survey researchers often use random sampling to test causal hypotheses, using item responses to identify variation in a possible causal agent and to provide outcome data. But this is widely acknowledged to generate inferior causal conclusions compared to experimenter-controlled intervention. So how can causal relationships be better generalized via the random selection that surveys afford if these relationships are more uncertain because a survey was used? Moreover, surveys do not routinely use random selection for other generalization-relevant features of the research. For instance, data are typically collected at one or a few time points only, and then in one type of setting (usually the home),

Random selection was not developed for extrapolation, generalizing beyond the sampling particulars. So, it is not surprising that it is not relevant to this function. Indeed, none of the extrapolation methods we later detail depends on random sampling. Other premises are involved, as they are for generalizing causal relationships and for selecting measures to represent constructs. Thanks to its logical and empirical warrant, random selection is *the* method of choice for generalizing to populations of persons

and sometimes settings. But it is rarely relevant to other tasks with which a comprehensive theory of generalization must struggle.

2. Purposive Selection and Construct Validity

Purposive samples are selected without randomization and require only that the selected cases have certain prespecified characteristics. If these characteristics coincide with those of a population, then a match is achieved between the details in the population description and the details achieved in the sampling particulars. Unfortunately, such proximal matching cannot guarantee that the cases and categories are matched on all unmeasured characteristics, let alone perfectly matched on the measured ones. Purposive selection is less well theoretically justified than random selection. By itself, it justifies claims about category membership but not category representativeness.

Yet purposive selection is used throughout the social sciences. Even passionate advocates of random sampling measure behavior by first describing the construct to be assessed and then ensuring that measures of it include all attributes in the theoretical description. Empirical patternmatching between constructs and measures is the basis for generalization in this case, and substantive theory provides the template for choosing how to measure (or manipulate). The correspondence between construct and operational representation is usually multidimensional, with the most important attributes being the prototypical ones that most clearly define the construct's uniqueness (Brunswick 1956).

Such pattern matching (also called proximal similarity) is not restricted to measurement contexts. When random selection is infeasible it also applies to selecting persons, settings, and times. Thus, experimenters might partition their data into gender subgroups. The resulting subsamples clearly correspond to the categories 'male' and 'female,' as inferred from body shape or valid self-reports. Selecting this way ensures a proximal similarity between the class 'female' and the sampled instances of that class. But do they represent their gender if all attend the University of Berlin? In such a case, the gender specifics and the construct match on some prototypical attributes; but the sample is much more internally homogeneous than the population with respect to age, intelligence, geography, and culture, among other factors. Belonging in a class does not entail formally representing that class. Proximal similarity is necessary but not sufficient for inferring the representativeness of sampled instances. Sophisticated construct validation requires more.

One auxiliary principle concerns 'the heterogeneity of irrelevancies' (Campbell 1988), ensuring that the sample is not homogeneous on attributes that are irrelevant to the inference being made—such as age,

intelligence, and nation in the case of female students in Berlin. To make these conceptual irrelevancies heterogeneous requires adding samples of women of different ages, social classes, and countries. In measurement contexts, heterogeneity requires multiple measures of each construct or varying multiple instances of a treatment, provided that each instance has unique irrelevancies and that no irrelevancy is shared by all instances. It also requires testing the degree of triangulation achieved across the sources of presumed irrelevancy.

Another way to deal with homogeneous irrelevancies requires focused comparison. If female students in Berlin are compared with their male counterparts, this holds constant irrelevancies like country, language, and city of testing, while also varying gender. But such internal comparisons are not always feasible; and groups may differ in other unmeasured irrelevancies that affect responding—e.g., if female students in Berlin have higher intelligence than males on the average, or if data collection there occurs in chemistry classes that attract different kinds of females than males. Whatever the construct being targeted—gender, intelligence, or being Australian—purposive sampling requires critically examining whether the instances selected are more homogeneous than their presumed population.

Construct validation also requires 'discriminant validity' (Campbell and Fiske 1959), demonstrating that a relationship obtained with constructs labeled one way is not due to another construct that is correlated but nonetheless conceptually unique constructs. Thus, the validity of an anxiety measure requires not only showing that its measured attributes behave as hypothesized but also that they, as a whole, behave differently from conceptually related concepts like depression. Likewise, testing a hypothesis about how new computer firms are unique requires sampling more than just this type of firm. Also needed are firms making new products in other sectors. Relationships that hold across sectors can be generalized to firms in general, including computer firms. However, only relationships limited to computer firms help define what is unique about computer firms.

All sophisticated construct validity is about testing unique predictions entailed by the substantive theory of a population. We always validate interpretations of categories rather than categories themselves, even with human populations (Cronbach 1989). Lawyers might pronounce that an Australian is anyone eligible for an Australian passport. But this definition is not adamant. It includes individuals with Australian parents who have never lived in the country; it excludes illegal immigrants who have lived there for decades; and what about persons eligible for a passport who deliberately choose not to claim one despite living in the country for decades? No specification of a construct or population is beyond reasonable criticism and so each preferred interpretation must be defended.

Usually, the interpretation can be formulated as hypotheses about some combination of components, antecedents, consequences, or correlates. Construct validation requires specifying and testing the nearest to unique of these hypotheses. Only then can we be truly confident about generalizing from purposive samples and measures to their target constructs rather than to some other entity correlated with them. However, constructing the arguments needed is more laborious and uncertainty-riddled than random sampling. Still, most social scientists sample purposively most of the time, though they vary greatly in how much auxiliary information they collect after a modicum of proximal similarity has been achieved.

3. Generalizing Causal Connections

Much effort goes into testing causal hypotheses—statements that variation in one construct leads to variation in another and that no alternative cause can account for their covariation. Generalizing causal statements depends on methods other than formal sampling theory, given that experiments with both random selection and random assignment are rare and surveys provide causal tests that are flawed when compared to experiments. So, how is generalization achieved when the object to be generalized is a causal claim?

One way is when a population has recently been described using measures that are also available on a purposive sample of persons or sites. Then, any causal relationships obtained at the sample level can be weighted to the population level, using the empirical relationship between sample and population for this purpose. But such weighting only approximates what the population effect size would have been if the sample had been randomly selected. Correct inference depends on the sample level effect sizes not being affected by unmeasured sample characteristics that are not fully captured by the shared, measured variables. Still, we can anticipate that weighting procedures will be used more often in the future as methods for social experiments and estimating missing data advance. After all, survey researchers now describe human populations from biased sample data using basically the same weighting technique.

Sometimes, substantive theory is specific enough to detail the conditions under which a causal relationship holds. Then, a program of research can test explicit hypotheses about specific sources of population, setting, or time variation in the strength or direction of the causal relationship. This involves deliberate attempts to falsify the hypothesis that a causal connection is general (Gadenne 1976). Rejecting the hypothesis entails identifying specific causal moderators; failure to reject implies that the hypothesis of a general cause–effect relationship remains viable. A less formal variant of this describes common practice in the laboratory sciences. A causal claim is made and

then independently replicated, often under conditions that approximate the original ones. Successful replication leads to concluding that the causal relationship is provisionally true—that is, true until future failures to replicate indicate the need to invoke causal moderator variables. In both approaches, special emphasis is on identifying moderators that reduce the causal relationship to zero or that change its sign, as opposed to those that merely vary its size without affecting its sign.

Purposive sampling is also used in other less formal generalization probes. In clinical trials, hospitals recruit patients with a given disease and then adhere to the study's intervention and data collection protocols. Hospitals are basically chosen for their willingness to comply and for their heterogeneity with respect to, say, region of the country, predominant ethnic group served, or type of hospital sponsorship. Statistical power is often only adequate for cross-site analysis, suggesting that the goal is not to identify site-level main and interaction effects, but to see if the causal estimate exceeds zero despite heterogeneity in the hospitals studied. If it does, the causal effect is held to be general. If it doesn't, several alternative claims are viable and need to be tested, especially the following: there is no effect; the causal sign varies by hospital type and obscures a main effect; or the methods used cannot detect an effect of the size expected. Only increasing the sample of sites allows direct tests of which hospital types are involved in site-level interactions. Even so, relying on a purposive sample of sites that are heterogeneous on many attributes except for volunteering is only logically defensible if researchers know from other sources that no confounds are associated with all the hospitals being volunteers for the clinical trial.

Exploratory analyses often involve measuring many constructs from among a large array of possible causal modifiers in order to probe which ones affect the strength of a causal relationship. Without *a priori* hypotheses about modifiers, the approach can be time-consuming and run afoul of error rate problems due to the many tests conducted and the small sample sizes for some values on the moderator. Nonetheless, subcategory breakdowns are often used within experiments to probe how robust a relationship is across persons, settings, times, and measures. This can prevent the overgeneralization that occurs when researchers conclude that a relationship found with the entire sample holds in each subgroup within the sample. The entire sample allows one to conclude that the effect is found despite the internal heterogeneity achieved. It does not imply there is independent replication within any of the individual subgroups. The story is essentially the same when partitioning data from a single survey. With adequate sample sizes per group, one can probe the robustness of a relationship across the subgroups sampled. But only those potential conditional variables directly sampled can be assessed.

The best tests of causal conditionals come from synthesizing multiple studies on a topic rather than from subgroup breakdowns within a single study (Cooper and Hedges 1994). Experiments and surveys relevant to the same causal hypothesis accumulate and can be used in meta-analysis, the best-known form of synthesis. Meta-analysis combines data across multiple studies asking the same question, taking advantage of the between-study variation in measures, manipulations, populations of people, settings, and times. The dependent variable is each study's standardized effect size(s) and these are manipulated (a) to generate an average effect size across all the studies and all the irrelevant sources of heterogeneity they contain, and (b) to identify the specific contingency factors responsible for variation in the effect sizes.

What logic buttresses meta-analysis? It is not random sampling since individual studies are selected for their relevance to the hypothesis and the hope is to achieve a census of all published and unpublished studies. However, the more relevant target population is all studies that could be conducted on the topic, not all those done on it. In meta-analytic practice, generalization depends on the sample of achieved studies including a wide range of human populations, setting types, historical periods, and operationalizations of the cause and effect. Each study is first coded to label its sampling particulars in terms of theoretical constructs and to examine the sources of irrelevancy with which the particulars are and are not collectively imbued. Thus in a hospital experiment, hospitals might be described as being university-based, public, or private, and as being large or small. Patients might be described in terms of diagnosis, age, and gender mix, etc. The treatment might be described in terms of its components, duration, and manner of delivery; and the outcome might be described in similar terms. Then researchers typically test whether the same causal relationship holds despite these sources of sampled irrelevancy.

Sample sizes permitting, researchers also test whether the relationship holds across individually identified sources of potential irrelevancy so as to generalize to hospitals in general, people diagnosed with cancer, or whatever the target inferences might be for a particular study. Important here are the number and especially the heterogeneity of the types examined. Of course, some sources of variation might have *a priori* substantive meaning, as when university hospitals are a special target. Then one has to do a discriminant validity test and show that the effect size for such hospitals is different from that for other hospitals. Otherwise, there is nothing unique about university hospitals. So, meta-analysis depends on the very tests for proximal similarity, heterogeneous irrelevancy, and discriminant validity that are so central in construct validation. In addition, to achieve such tests multiple replication is needed across studies that may each be individually very narrow in the range of

people, settings, times, and cause and effect operations it includes. Central is the heterogeneity across studies and the pattern of results achieved despite this sampled heterogeneity.

4. *Extrapolating to Nonsampled Entities*

Some social scientists probably think it silly to use samples for generalizing to populations that are not even proximally similar to the samples used. So, many animal researchers abjure all talk of generalizing to humans. But their language is often anthropomorphic, and their research is usually funded because others think it is relevant to humans. So, elaborate reasoning has evolved over time to justify generalizing from animals to humans.

In this regard, consider the use of cats in visual research (Blake 1988). The rationale for their use is in two parts. The first is entirely pragmatic and stresses the conveniences of working with cats (or *Drosophila* in genetics research), usually because of cost and ethics. The second is theoretical and is based both on cats sharing some anatomical and physiological features with humans and on behavioral research showing that cats and humans behave similarly when confronted with similar visual stimuli. However, the empirical work necessary for showing such correspondences has also revealed that cats are much less like humans in some physical ways—especially features related to night vision—and that some behaviors are not replicated across species when the same stimulus is presented. So, a contingency theory has evolved of the conditions under which cats are better or worse substitutes for humans.

But when asked, honest vision researchers will avow that convenience is the paramount rationale for using cats. Would they rather work with chimpanzees? Undoubtedly, since the chimps' visual system is much closer to humans' than the cats'. But the expense of maintaining chimps precludes using them. Would the researchers rather use humans than chimps? Undoubtedly, if ethical research procedures are possible—which they often are not. However, now that new imaging technologies are available that allow observing the human eye reacting to planned stimuli in great micro-detail and real time, many vision researchers are turning to work with humans rather than cats because the pragmatic obstacles to using humans now hardly apply. Thus within the community of vision researchers the preference for generalization to humans via within-species proximal similarity is clear. So, too, is the distaste for arguments that depend on the (only partial) proximal similarity between cat and human on some vision-related attributes given their obvious dissimilarity in others. A similar story could be told for conducting research in the laboratory rather than in the field. Convenience is paramount, and the reasons given for preferring the lab often

contain elements of rationalization. But even so, extrapolation across species and settings is surely superior when there is an empirically defensible contingency theory of the conditions under which the extrapolation is better and worse warranted.

How is extrapolation otherwise achieved? Causal explanation is often held to play a major role, explaining how or why two or more things are related (Mackie 1974). Once an explanatory process has been identified, the argument is that it can be reproduced in other settings, with other kinds of people, at future times, and with unique ways of instantiating the process. Indeed, this is the major public rationale for basic science. Once one knows why fire happens, one can replicate it with new kinds of materials (say, some newly invented polymers), in new settings (an uninhabited desert island), and with people who have never seen fire before (so long as they can understand the explanatory recipe). The problem with this view is that full explanation is hard to conceptualize and achieve. It is difficult enough to use data for discriminating among explanatory claims even at one level of explanation, let alone for simultaneously investigating factors at the biological, individual, and social levels. Even so, causal explanation is the holy grail of science, not just for its aesthetic parsimony, but also for the utilitarian causal generalization it promotes in the form of extrapolation.

Extrapolation is also achieved through careful induction. If patient education reduces the length of hospital stays and does so with patients suffering from 25 different diagnoses, then it is likely to do so with the 26th. Of course, the logical warrant for such induction is limited, and seems more reasonable the more numerous and heterogeneous are the patient types already examined. If all 25 were different forms of cancer diagnosis, or involved patients aged between 25 and 40, or were restricted to men, this limited heterogeneity would reduce our confidence in any inductive-empirical extrapolation. Meta-analysis is particularly important in this regard, especially when it permits replication across multiple different sources of irrelevancy. A relationship that has proven to be robust in whatever form it was operationalized is more likely to re-occur when other ways of operationalizing its components are attempted—more likely, but not certain. We see here the value traditionally assigned in science to discovering both general dependencies and the contingencies that describe when a given relationship does and does not hold.

The final context for extrapolation relates to formal modeling. When subgroups can be arrayed along a single continuum, the functional form of a causal relationship can then be described. Is it stable? Is there a linear increase or decrease? If a pattern clearly emerges, one might want to argue that the strength of the relationship can be inferred for unobserved subpopulations with values that fall within the continuum range. Simple interpolation is involved here, while the

strength of the relationship for values beyond the continuum is inferred by extrapolating from the observed function. But comfort with such extrapolation depends on how distant the nonobserved subpopulation values are from the sampled ones.

Model-based extrapolation is always tricky, but especially so when the models are more complex. Consider much of macroeconomics. Models of a given economic system are developed from theory and past findings, and changes in parameter values are introduced to see how the system reacts to this perturbation. This is basically an extrapolation exercise to discover what would happen if some details of the economic system were not as they actually are. Can we extrapolate from what we think we know, in order to learn what would happen under novel circumstances? The validity of any extrapolation depends on the model being correctly specified with respect to the variables included, the relationships postulated between them, and the strengths of these relationships. Be wrong about any of these assumptions and any conclusions about the effects of the novel perturbation will be biased to some unknown extent. The assumption that the model is complete and accurate is difficult to test, though crucial to the credibility of the results (Glymour et al. 1987). Still, the creation of valid multivariate models of causal interdependency is another major goal of science, and it is not difficult to see why. It promises the extrapolation of results beyond whatever circumstances were studied in the past.

5. Conclusion

In the behavioral and social sciences at the beginning of the twenty-first century, theory and practice are most developed when individuals or households are sampled to describe a human population. Here, best practice requires randomly sampling units from the population. Theory and practice are also well developed for generalizing from a measure to an abstract construct or from an experimental treatment to a more general causal agent. Here, best practice requires an explicit theory of construct validity that necessarily invokes proximal similarity, but preferably also the heterogeneity of irrelevancies, discriminant validity, and causal explanation. However, the purposive selection and theory-linked methods needed for construct validation are not as formally well supported as random selection is. Theory and practice are even less developed for generalizing to settings and historical time periods and for identifying the conditions under which a causal relationship holds. However, various deliberate sampling and replication strategies are relevant here, including meta-analysis. At their best, such strategies borrow much of the logic underpinning sophisticated construct validation. Least well developed are theory and practice for extrapolating results to nonstudied circumstances. But even here,

understanding causal explanatory processes can permit re-creation of the same causal forces in novel settings. Also, there are now decades of research and reflection about using animals to extrapolate to humans and about using the laboratory to extrapolate to other social settings. In addition, substantive modeling is sometimes used to examine what would happen to a system if one or more of its parameters were changed. Of all the methods examined, only random sampling provides an impeccable formal rationale for generalization. But its reach is, alas, limited. It is a great irony that the best formal method for generalization in the behavioral and social sciences can be used for only a small part of the generalization tasks that practicing social scientists routinely face. Given this, practicing social scientists and theorists of method reflecting on these practices have cobbled together more complex methods of generalization that depend more heavily on substantive theory, purposive sampling, heterogeneity of irrelevancies and demonstrated replication and the identification of causal contingencies.

Generation in Anthropology

In anthropology, the term generation has two primary meanings. In one of its senses, generation refers to a group of people who have lived through a time period together and have developed some kind of shared consciousness. Generation has been used even more commonly by anthropologists in its genealogical, kinship-related sense, to refer to the relationship between parents and their children, these children and their children, and so on. Using one or both of these senses of the term, anthropological interest in generation has focused on four primary topics, pertaining to the ways people across cultures organize and envision social relationships, identities, and the processes of human social-cultural life. This article will look at each approach in turn.

1. The Cultural Construction of Intergenerational Ties

Work on the cultural shaping of intergenerational ties focuses on generation in its genealogical sense as a descent relationship. Interest in intergenerational family relationships has existed since the beginnings of anthropology as a discipline, largely due to the analysis paid by anthropologists to kinship systems. Since about the 1970s, the majority of work on intergenerational ties has come out of the subfield of anthropology of aging, where one of the central research issues has surrounded the degree to which the elderly can expect to receive various forms of support from their younger relatives. Research on intergenerational ties, however, goes well beyond the (interesting and important) problem of how the elderly are cared for, to speak to broader conceptions about the nature of the family, the relationship between individuals, families and the state, and the social-moral order.

Lamb (2000) examines such problems through a focus on West Bengal, India. She finds that Bengalis perceive intergenerational family relations to entail long-term bonds of reciprocal indebtedness extending throughout life and even after death. Juniors provide care for their elderly parents, reconstruct relations with parents as ancestors after death, and ritually nourish these ancestors, as a means of repaying the tremendous 'debts' owed for producing and caring for them in infancy and childhood. What parents once

gave their children to produce and raise them—such as a body in birth, food, material goods, money, a home, forms of love, the cleaning of urine and excrement—children are expected to provide in return for their parents years later in old age and after death. (Children, for instance, construct new spirit-bodies for their parents as ancestors, parallel to the bodies parents create for their children in birth). Other anthropologists have found that relationships of lifetime intergenerational reciprocity, conceptualized and practiced in varying ways, are not uncommon cross-culturally (see, e.g., Cattell 1990).

The shaping of intergenerational ties can bear significance beyond the family as well, to implicate the social-moral-political conditions of a broader society and nation. Indian discourses, for instance, present close, multigenerational families as signifying a 'good' and 'Indian' society; whereas disintegrating generational ties—the break-up of joint families, uncared-for old people, independent daughters-in-law—are held to be paradigmatic signs of a widely degenerate 'modern,' postcolonial, and urbanizing era (Cohen 1998, Lamb 2000).

Some anthropologists argue that the shaping of intergenerational ties can be understood through scrutinizing surrounding cultural values. Simic (1983) suggests links between an American model of intergenerational relations and a broader cultural orientation toward self-fulfillment and individualism. Children in middle-class, Anglo-American households maintain their own rooms and possessions, and by about age 18 are expected to move out and live separately from their parents. Though parents often extend financial aid to their children after they have left home, Simic observes, 'it is almost always with the overt rationale of helping them get established as independent units, rather than creating a binding reciprocity of mutual dependence between the two generations.' In later life, this same ideology prevails: among the aged economic independence is a fundamental value; dependency is 'demeaning.'

In general, research has shown that in developing countries, intergenerational family relations tend to be closer and more mutually interdependent than in capitalist, industrial settings, although many important exceptions can be found (see Albert and Cattell 1994, Sokolovsky 1990). A wealth of careful, detailed, cross-cultural data on generational ties has been produced by anthropologists, revealing a profound variety in the ways intergenerational relationships are conceived, maintained, practiced, and given value.

2. Generation as an Element of Social Organization

Anthropologists have also examined the ways social and cultural groups employ some concept of generation to organize social relationships beyond the

family. Many cultures group people into generation-defined categories, taking some notion of genealogical succession within the family and extending it to think about broader social relations (Kertzer 1979). Examining generation in this sense, as a principle of social organization, has allowed especially social anthropologists and those concerned with social structure to address questions about the very ordering and continuity of societies (e.g., Baxter and Almagor 1978, Eisenstadt 1956, Fortes 1984).

In some societies, social generational ordering is highly formalized and elaborate. Rituals, variations in dress, forms of speech, permitted behaviors, specialized tasks, and places of residence may sharply distinguish persons of one generational group from another. The most highly institutionalized organizations of generations into social groupings, often referred to as generation-set systems, have been found among a number of East African groups (Baxter and Almagor 1978). In such groups, the generation model is extended so widely as to provide the basis for regulating social relationships in an entire society. Every male is a member of a named generation set, and the generation set a man is in is determined by the generation set his father is in.

The crucial rule in such generation-set systems is that successive genealogical generations of fathers and sons must be socially and politically separated. Some scholars suggest that this is a way of minimizing generational conflict and competition, for instance over wives, land, and political leadership, for members of different generation-sets generally cannot compete over the same resources and privileges. Generation-set systems have almost always been organized around males, and women may be tied to them peripherally as daughters, wives and mothers. Versions of such systems have also been found in Melanesia, among Australian aborigines, and among some Native American groups.

Even in societies where people are not organized into formal generation sets, some notion of generation as a principle of social organization is almost universally employed (see Kertzer 1979). For instance, the social roles or identities a person assumes may depend on whether he or she represents the junior or senior generation in a family. In many societies, a person's transition to social adulthood is linked to the birth of his or her children; and in India, the transition to a 'senior' stage in life and society comes about not so much through reaching a particular chronological age but through the marriage of one's children (Lamb 2000).

It is necessary to distinguish between generation and chronological age as principles of social organization and of cultural value. Most societies use some version of both in ordering social relations, but these categories are often confused or overlapping in social scientific analyses and among the people being studied (Kertzer 1979). Age, however, is distinct from gen-

eration: it has to do with the chronological passage of time, and rests on the formally isolated individual as the unit of reference whereas generation is family-generated. There are many situations in which relationships by generation conflict with relationships by age. For instance, among the Tallensi, no man, even if very advanced in age, can achieve jural autonomy until his father dies (Fortes 1984). In the US, social criticism may ensue if a man marries a woman 'young enough to be his daughter' (the woman as wife becomes the man's generation, but has the chronological age of his children's generation).

Several anthropologists have been intrigued by the fact that what is essentially an intrafamily principle of genealogical generations has been used so widely by human groups to think about social relations outside the family. People of diverse cultures, it seems, find families 'good to think with.'

3. Generational Identity as an Axis of Social Difference

A third way that anthropologists have approached the study of generation relates to what is probably the most common usage of the term in English: generation as a cohort of people who have lived through a time period together and share a sense of identification with others of their era. Sociologist Mannheim's classic essay, *The Problem of Generations* (1952), is often cited as the piece that popularized this sense of generational studies within the social sciences. To Mannheim, a generation is not simply a cohort—a group of people having a statistical factor, such as age or decade of birth, in common; a generation is made up of people who, born during the same time period, feel the impact of common historical events and cultural forces, and develop a shared consciousness or identity around these experiences. Anthropologists have expanded upon this sense of generation as a form of identity, using it to heed the multiple, competing perspectives, voices, and experiences that make up any culture. Along with gender, class, race, and ethnicity, generation can be a salient axis of social difference.

Newman's work (e.g., 1996) highlights such a sense of generation as an important theoretical concept for anthropology. In one study, she collected life-history data from divorced mothers in the US who had been pushed into downward mobility. The study did not begin as a generational story, yet she found that the life history texts bifurcated strongly by generation. Women who were born during the Depression were invested in different versions of American culture than those who were raised amidst the plenty of the 1950s and 1960s. 'It became clear,' Newman reflects, 'that the source of their views was a fairly tightly woven and self-conscious generational culture, or symbolic dialect,' which formed a grid through which their life circumstances were interpreted (1996).

Comaroff and Comaroff (1999) take a powerful look at generation as one of the dominant idioms through which youths in postcolonial South Africa frame their identities and place in the world. Widespread anxiety over the hardening materialities of life in an era of global capital translates frequently into bitter generational opposition. Many young black men blame their current incapacity to ensure a viable future for themselves on a perceived sinister, all-consuming aged elite, referred to as 'witches' or 'old ladies' (even when they are men). The Comaroffs cite one example of a group of youths pelting an old woman with sticks and stones. 'Why are you killing me, my grandchildren?' she wailed. Her assailants responded, 'Die, die you witch. We can't get work because of you!' The major lines of opposition in contemporary South Africa, the Comaroffs find, are not race or class, but generation, mediated by gender.

Such work reveals the potential salience of generation as a category of social experience and analysis. A society at any given moment may be perceived, by the people within it, and/or by the anthropologists studying it, as being crosscut by generations representing powerfully divergent values, beliefs, perspectives, and agendas.

4. Generation and Social Change

Finally, anthropologists have used generation as a means to explore social change, history, and time. Just as generation is one of the key images people around the world use to represent social change (for instance, by telling of how children are growing up in a world vastly different from that of their parents or grandparents), social theorists often think about processes of social or cultural change in generational terms. Mannheim speculated in the 1920s that cultural transformation comes about through the continuous emergence of new generations: as each generation comes into 'fresh contact' with its social and cultural heritage, it remodels what is found (1952). Anthropologist Fortes mused several decades later that such a generational model is an 'apt imagery by means of which to depict continuities and discontinuities in a community's social and cultural life over a stretch of time' (1984). It is within the framework of the succession of generations, Fortes explains, that all people acquire their cultural heritage. 'Mediated from earliest infancy by the natal family, the society readily takes on a generational form to the individual.' The concept of culture has always been defined by anthropologists as something that is 'transgenerational' at the same time that it is open to creative revision and change.

In the contemporary era of globalization and rapid social transformation, perceived 'gaps' between the lifeways of senior and junior generations may become, for many, ever more profound. Generation will be a

provocative place for anthropologists to look to apprehend the ways global processes of change take shape in particular places and lives.

5. *The Importance of Generation in Future Work*

Generation in anthropology has been a key topic in the study of aging, kinship and social organization, but it has otherwise remained rather undeveloped. That is, conceived as a form of subcultural identity, axis of social difference, or dimension of social change, generation has not taken center stage. The category of generation can be fruitfully exploded, however, to explore problems of current critical interest to the discipline—such as the ways processes of globalization play out in local lives, and diverse voices and identities make up particular cultural worlds.

Generations in History

Generations—cohorts of humans born about the same time and growing up through the same slice of society and history—have played a more important role in the human past than is generally acknowledged. During the nineteenth and twentieth centuries, younger generations in particular played colorful, sometimes crucial roles in history. As awareness of generational differences and conflicts has grown, furthermore, an evolving theory of social generations has developed to explain the phenomenon. The writings of such thinkers as Karl Mannheim, José Ortega y Gasset, and a host of more recent scholars have analyzed the impact of changing sociocultural influences and traumatic historical events in forging social generations which may then themselves become powerful forces for change in history.

1. Generations: The Term and the Concept

The term generation has been commonly used in a variety of senses, some of them marginal, others of central relevance to the generational historian's task. This opening section will suggest six quite different uses of the term generation and of the more precisely focused concept of the social generation in history.

Genealogical accounts of the history of individual families commonly refer to each new wave of siblings as a new genealogical generation. Useful as it may be, however, this tight focus on an individual family evidently lacks the scope of developed generational studies, which typically seek to survey an age-defined subdivision of society as a whole.

Family history more broadly conceived may probe relations between biological generations—parents and children—across a whole society. Even this broader approach, however, still suggests that generational

relations consist exclusively of relations between biological parents and children—another unnecessary limitation on the range of generational history.

Prosopography, offering a group portrait of coevals who occupy the same social niche as politicians, writers, or business leaders, for instance, does offer a form of generational history. Emphasizing similarities of backgrounds, beliefs, careers, and achievements as well as generational contemporaneity, such analyses clearly move beyond the family into the larger sphere of society as a whole.

Another form of generational analysis divides up historical time itself into generational periods of about 20 years, the time believed to elapse between the birth of one biological generation and the next. While this approach may uncover significant differences of generational perspective, it may also impose a series of generations of unconvincingly equal length upon the alternating longueurs and crisis periods of human history.

Perhaps the most useful form of generational analysis has been that which sees social or historical generations as birth cohorts, people born about the same time. This sort of generational analysis moves beyond the family and the single professional group and recognizes that different social generations may be of varying lengths and of greater or lesser significance, depending on social or historical circumstances. Above all, cohort analysis provides a solid foundation for generational studies in a given society at a specific moment in its history.

2. Age Groups in History

Age groups—groups of coevals—have been recognized in most societies and have been elaborately institutionalized in some. Like other subsets of society such as race, class, and gender, age groups have sometimes been both active forces in social conflict and creative agents of social change.

2.1 Age Groups in Human Societies

Anthropologists have detected age groups (age-grades or age-sets) among many pre-urban peoples. Progress from one age grade to the next may be celebrated by elaborate rites of passage, and membership in a particular age group often brings both duties and privileges. Young men will be expected to fight wars, young men and women may look forward to marriage, and older people of both sexes may serve as decision-making elders or perform important ceremonial functions.

But age groups are detectable in more complex urban societies also. Apprentices in guilds, students in schools, and even conscript armies may segregate many of the young from most of their elders. At the

other end of life, retirement homes and communities separate older age groups from the rest of society.

In most pre-urban societies, younger and older people apparently tend to accept the same traditions and taboos. In more complex societies, however, conflict between age groups seems to have become considerably more common.

2.2 Conflict Between Age Groups

There is evidence of generational conflict in earlier urban societies than ours. Aristotle saw differences between youth and age at the heart of the social wars that frequently rent the fabric of Greek city-states. Medieval observers were dismayed by the riotous behavior of guild apprentices or the town and gown violence of university students. Many of the leaders of the European Reformation were young preachers, and historians have noted that the founding fathers of the USA were actually young men.

The clearest and most numerous examples of generational conflict, however, have been detected over the last two centuries. Nineteenth-century European commentators noticed the youth of the barricade-building ideological revolutionaries who challenged authority in the 1820s, 1830s, and 1840s. Twentieth-century observers around the world recognized the youthfulness of the ideologically inspired guerrillas, urban-terrorist groups, and revolutionary cadres who played such a central role in the history of Russia, China, and the developing societies of Asia, Africa, and Latin America, as well as in the most developed nations, in the 1900s.

3. The Generational Idea in History

Theoretical understanding of the generational idea has evolved in tandem with this apparently increasing historical significance of generational conflict. Earlier insights into the significance of generations in human society were brief and suggestive. The nineteenth and particularly the twentieth century, however, have seen much more elaborate and sophisticated development of the concept.

3.1 Early Awareness of Generations in Society

Old Testament genealogies and Homeric poetry reveal clear concern with the succession of human generations. The traditional father of history, Herodotus, posited 33-year generations in his *History of the Persian War*, and the Arab world historian Ibn Khaldun proposed a basic theory of generations in his *Muqaddimah: An Introduction to History*.

Only in the nineteenth century, however, did social thinkers of the caliber of Auguste Comte, John Stuart

Mill, and Wilhelm Dilthey begin to develop a coherent and convincing theory of social generations. Julián Marías (1949), a leading historian of the generational idea, emphasizes their major contributions. Comte, he points out, clearly recognized the succession of generations as an important causal factor in social change. Mill was aware that the generational concept must be expanded beyond a familial or genealogical framework. Dilthey attempted to analyze the basic structure and significance of social generations.

3.2 Classic Formulations of the Theory of Social Generations

The first half of the twentieth century, particularly the period between the two world wars, saw classic formulations of the generational idea by the Spanish philosopher José Ortega y Gasset (1923, 1933) and the German sociologist Karl Mannheim (1928). Ortega's account of the phenomenon focuses on the internal development of the typical social generation through four 15-year stages: childhood, youth, initiation to positions of power, and domination of society. This stages-of-life perspective has influenced many generationists since.

Mannheim's analysis emphasizes the roots of generational differences in changing social and cultural circumstance. Arising in different social locations (e.g., middle or working class, rural or urban environment) and shaped by new trends in society at large, new social generations develop different points of view and patterns of behavior from those prevalent among their elders. Mannheim also analyzes the structure of the social generation, suggesting that a given birth cohort may be subdivided into a number of distinct generational units, subgroups who work up the common generational experience in very different, often ideologically definable ways.

3.3 Development and Validation of the Generational Idea

In the wake of the global pandemic of youth revolt of the 1960s and earlier 1970s, finally, sociologists, political scientists, and other social scientists researched the realities and refined the theory of generational development and interaction as never before. Such theoretical and empirical students of the generational phenomenon as Vern L. Bengtson, Richard G. Braungart, T. Allen Lambert, Robert S. Laufer, and Marvin Rintala elaborated a convincing model of the social generation in history. These scholars probed the sociopsychological roots of generational consciousness in immense detail. They documented the persistence of generational identity long after the strong orientation toward one's youthful peer group has faded. They collected masses of contemporary evidence of the existence of generational conflict and of its influence on social change.

4. The Theory of Social Generations

As the twenty-first century begins, then, one form or another of generational analysis is used routinely, not only by historians, political scientists, sociologists, anthropologists, and critics of literature and the arts, but by journalists, politicians, marketing experts, and many others. These diverse commentators explore age groups just as they do groups defined by gender, class, or ethnicity. The brief exposition of a developed, essentially Mannheimian view of the sociohistorical generation that follows will try to build on this broad awareness.

4.1 Social Circumstances Shape Social Generations

A social generation, then, consists of a birth cohort, a group of individuals born in similar circumstances during the same span of years, and thus shaped by common social and cultural influences. The critical period in the shaping of a generation comes in its earlier years, when its members are most malleable and open to the influence of their sociocultural environment.

During the childhood of a birth cohort, common family structures, child-rearing methods, and educational practices begin this socialization process. Thus a patriarchal family structure, a child-rearing philosophy of spare the rod and spoil the child, and an education built around rote memorization may tend to produce one sort of younger generation. A more egalitarian family structure, permissive child-rearing methods, and schools committed to developing the individual propensities of each child may produce a very different social generation.

During the adolescence and youth of a birth cohort, the larger society in which it develops may also exert powerful developmental influences. Hierarchical or egalitarian relations in society as a whole, traditionalist or cosmopolitan cultures, authoritarian or democratic politics, all have an impact on young people just emerging into the world beyond the family. Within the society as a whole, furthermore, the particular generational location within which youth matures will also have its influence. Young people raised in working-class ghettos will grow up with a very different view of the world from that of their coevals raised in middle-class suburbs, even if both these locations are within the same larger society. At every level, the books young people read, the films they see, the songs they hear and sing, shape the beliefs and values of a social generation in ways we are only beginning to understand.

4.2 Historical Traumas Define Rebellious Generations

The socialization process thus shapes the members of each new generation from their earliest years well into

their twenties. To these influences of home, school, and society at large, however, historical study of the generational phenomenon would add a special emphasis on the traumatic historical event in the shaping of a generation.

Popular accounts of specific social generations have tended to stress the impact of history on the young. Wars may have a much more profound impact on the lives and attitudes of the young men who fight them than on their elders. A major economic depression can be far more traumatic for young people discouraged by poverty from starting careers and families. Such historic events, furthermore, frequently challenge the view of the world the young have absorbed from other sources, producing confused, disillusioned, angry, or rebellious younger generations.

As Lewis Feuer pointed out, traumatic events may thus undermine the authority of both traditional institutions and of the older generation that imposes them (Feuer 1969). In this way the mores and morals of the young may change drastically as they shrug off the prescriptions of a de-authorized older generation. Where anti-establishment ideas and attitudes are already present in the culture, such historic traumas may transform hitherto isolated advocates of change into leaders of large-scale generational revolts. Any historic dissonance between widely held social ideas and changing social realities may produce generational disillusionment. A traumatic historical event may multiply this effect, shaking the foundations of society and calling its deepest principles into question in the minds of the young.

4.3 *Generations Shape the Course of History*

It is sometimes difficult to identify the historic victories or social transformations brought about by generational revolts. Youthful rebellions like the European political revolutions of 1848 or the very different American and Chinese cultural revolutions of the 1960s may fail to achieve many of their declared goals. Yet the new commitments and the youthful activism of social generations who march to a different drummer do often make a difference.

When young black Americans, for instance, took to the streets in the early 1960s, laws and attitudes changed. As a result, doors to social advancement opened, and the lives of at least middle-class black Americans were significantly altered. Similarly, the dominantly young people who rallied to the banners of leaders like Vaclav Havel in Eastern Europe in 1989 toppled political and economic institutions, radically transforming life in such nations as Poland, the Czech Republic, East Germany, and Hungary.

The openness of younger birth cohorts to new cultural influences may also have transforming social consequences. Around 2000, the spread of capitalism, computer technology, and even such specific ideas as freedom of thought and expression, or gender equality

began to change the lifestyles of the young, and through them their societies, in many parts of the world.

5. *Problems and Potential of Generational Analysis*

Major theoretical problems remain for the generational historian. There does, however, appear to be real potential for future development and application of the generational approach to history.

5.1 *Problems of Generational Theory*

Like any broad attempt to explain society and history, the theory of social generations has generated its share of challenging questions.

How long is a generation, for instance? Thirty-three years as Herodotus declared, 15 years with Ortega, or even three years, as some modern demographic studies might suggest? Historically, the length of a significant social generation seems to depend on the pace of change. The more rapidly things change, the more quickly enough changes accumulate in the shaping social matrix to produce a significantly different generational point of view.

But how important are social generations? People unsympathetic to the approach often ask this question, frequently having a rival theoretical framework to suggest, such as social class. However, generational theory makes room for class differences in the concept of generational location, which Mannheim saw as an expanded form of class identity. There would in fact seem to be room for analyses of the same population in terms of its component races, classes, genders, or social generations—all important bases for analysis, none more fundamental than the others.

Finally, are social generations historical realities at all? Some observers have noted that even when the streets are full of young demonstrators, most young people seem to share their parents' views. Certainly the socialization process does succeed more often than not, even in eras rent by generational discord. In history, however, numerical majorities are not necessary to produce significant consequences. When socialization fails with even a critical minority of the young, the resulting conflict of generations can produce historic changes in society.

5.2 *Historical Research on Generational Themes*

The uses to which generational analysis has been put during the twentieth century are manifold, and new topics well suited to interpretation in terms of generations emerge with every passing decade.

The generational approach has been widely utilized by historians and critics of art and literature. Students

of such increasingly important features of modern history as immigration have also found generational analysis invaluable. And there is a vast literature on younger generations mobilized in student or youth movements, countercultures, or revolutionary cadres.

During the late twentieth century, the generational approach was also applied to changing attitudes and patterns of activity in many non-Western lands. India's crisis of values has been explored in a number of such studies. Several Chinese student movements, as well as the massive Maoist Cultural Revolution, have been analyzed as revolts of younger generations. And more research is needed on the generational factor in the postwar colonial liberation movements and in the jolting changes that have accompanied urbanization, modernization, and globalization in the developing world since.

In developed societies with rapidly aging populations, finally, the other end of the spectrum of age groups would seem to demand historical study. With the progress of gerontology and our growing awareness of the persistence of generational memory as background, historians might profitably probe generational relations in past cultures in which older age groups have enjoyed both prestige and real power.

5.3 Related Concepts

Both the historic reality and the historiographical concept of the generation are ancient ones, yet we are often surprised when generational differences surface once again in history. Given the likelihood that such challenges will continue to occur, the theory of social generations would seem to merit both further development and more vigorous application to the study of society and history.

Generations: Political

'Political generations' can be defined as politically distinctive age groups delimited by their years of birth or some major event, such as their year of entry into the electorate. Rintala (1979, p. 8) defines a political generation as 'a group of human beings who have undergone the same basic historical experiences during their formative years.' According to Braungart and Braungart (1989, p. 283) 'a political generation is an age group in history that mobilizes to work for political change,' although an age group could work to maintain the status quo and still be a political generation.

1. Generation and Cohort

Birth, aging, and death gradually transform the composition of any society. New generations supplant the old, but transforming the population may or may not lead to social and political change. The young may resemble the old in their political attitudes and

behaviors and, even when young people do differ from their elders, they may come to resemble them when they themselves age.

But although each generation perpetuates society, it may also change it. If the young could be isolated from their elders, it would be easier to create a new social order, and thus Plato argued that philosophers could establish the ideal polity more quickly if they expelled all citizens above the age of 10 from the republic. At times a generation may be too corrupt to establish a new political order. The Book of Numbers relates that the generation freed from Egypt, which again and again showed its faithlessness, was condemned to have its carcasses consumed in the wilderness until a new generation, born in freedom, was reared to conquer Canaan.

Although the concept of generations has biblical and Greek roots, the social scientific study of generations began with Mannheim's essay, 'The Problem of Generations' [1928] (1952).

According to Mannheim (1952), the concept of generations is both biological and sociological. Generations are produced through 'the biological rhythm in human existence,' but 'individuals who belong to the same generation, who share the same year of birth, are endowed, to that extent, with a common location in the historical dimension of the social process' (p. 290).

Mannheim (1952) maintains that historical experiences are most likely to influence persons in their late adolescence and early adulthood, postulating that 'personal experimentation with life' usually begins at about age 17. Whether young people are actually influenced by historical events depends on social and historical conditions. For example, young adults living in different cultures may experience quite different events, and, even within a single society, some persons may be relatively isolated from the mainstream of social events and thus be unaffected by major historical movements. Nor do all historical periods produce conditions that influence young adults in distinctive ways. Mannheim (1952) argues that distinctive generations are more likely to form in periods of rapid social change. But his basic point is that there is no guarantee that socially or politically distinctive generations will emerge: 'Whether a new *generation style* emerges every year, every thirty, every hundred years, or whether it emerges rhythmically at all, depends entirely on the trigger action of the social and cultural process' (p. 310).

Following Mannheim's (1952) cautions, it is unwise to label a group of people a political generation unless one can establish that they are actually distinctive in their attitudes and behaviors. Therefore, social scientists need a term describing persons born during the same years, but making no other assumptions about their distinctiveness. The term 'cohort' is used for this purpose. This term derives from Roman military terminology, since the cohort was a unit within a

Roman legion, but the term now has a much broader usage. Scholars usually define a cohort as a group of people born during the same years, but there are many other factors that can define a cohort: the entry class of a school, persons married during the same period, or persons who vote for the first time in the same election. But the most basic experiences are usually birth and death, and the former is usually used to define a cohort.

There is no definitive answer to how many years a cohort should include. In the 1960s, and even into the early 1970s, survey researchers often used arbitrary age categories to code years of birth, often grouping respondents into 10-year age categories in order to save one column of usage on the IBM punch cards that were used to store data. Scholars who want to work with these early data sets must employ these arbitrary age categories. With computerized storing techniques, survey age is usually coded by year of birth, and one has great flexibility in analyzing survey results. For example, a major analysis by Converse (1976) divides respondents into three-year age categories, and throughout their study of the US electorate, Miller and Shanks (1996) generally divide their results into cohorts that are four years in width.

2. Life Cycle, Generational, and Period Effects

Whenever young adults differ from their elders there are usually two plausible interpretations for these differences. A life cycle interpretation maintains that these differences result mainly from the inexperience of the young, and postulates that the young will become more like their elders when they age. A generational interpretation maintains that these differences result from the differences between the formative experiences of young adults and those of their elders.

One of the most extensive controversies in political science research has been the well-documented finding that young US citizens tend to have weaker party loyalties than their elders. This finding was reported in *The American Voter*. Lacking longitudinal data, Campbell and his colleagues (1960) relied upon an indirect test comparing the partisan loyalties of persons of the same age who have held their partisan loyalties for different lengths of time. Even though their test was indirect, Campbell and his colleagues (1960) reached strong conclusions that favored a life cycle formulation. The weak party loyalties of young Americans, they argued, resulted from their youth and political inexperience. These conclusions were strengthened through a cross-national analysis, re-analyzing Almond and Verba's study of the USA, Britain, West Germany, Italy, and Mexico. As Converse (1969) showed, *The American Voter* formulation could explain a process through which partisan strength among the electorate is held in equilibrium.

Even though older voters with strong party ties are dying and being replaced continuously by younger voters with weak partisan loyalties, the dynamics that increase partisan strength with age could prevent the erosion of partisan strength among the electorate. If, as Campbell and his colleagues (1960) argued, party loyalties among the electorate contribute to political stability, the life cycle explanation, if valid, had major implications for the political system.

Although *The American Voter* explanation was unchallenged for a decade, in the early 1970s scholars began to question it, based upon the finding that partisan loyalties did not become stronger as cohorts were tracked across the life cycle. Converse and his supporters acknowledged that partisan loyalties after 1964 did not increase among cohorts as they aged, but maintained that this resulted from the political dislocations of the 1960s and 1970s. In other words, the failure of partisanship to increase with age was held to result from the events of the post-1964 period. By the late 1980s at least 20 articles had focused on this controversy (for a summary, see Abramson 1989) and several more appeared in the 1990s. But the space devoted to this controversy has declined as scholars have increasingly recognized the intractable difficulties of distinguishing among life cycle, generational, and period effects. Instead, scholarship has turned to studying the impact of generational replacement upon political attitudes and behavior.

3. The Impact of Generational Replacement

There is no debate that the population is gradually transformed as a result of generational replacement. (Some scholars use the term 'cohort succession.') Replacement can play a major role in transforming the political attitudes and behaviors among mass publics. For example, during the 1930s and 1940s, replacement helped make the Democrats the majority party in the USA, and during the postwar years replacement was a major force eroding US party loyalties. Replacement benefited the British Labour party during the 1960s, but it contributed to the erosion of British partisan loyalties between 1964 and 1987. Between 1969 and 1988, replacement contributed to the decline of the Labor Party Alignment in Israel. During the postwar years, replacement may have contributed to a more partisan electorate in West Germany. Replacement may also help transform political values. For example, replacement helped to increase political tolerance in the USA between the mid-1950s and the mid-1970s. (For the citations to the sources documenting these trends, see Abramson and Inglehart 1995.) Women who came of age in the USA after the enactment of the Nineteenth Amendment played a major role in increasing women's turnout (Firebaugh and Chen 1995).

The most extensive analysis of the impact of generational replacement upon value change among mass publics has been conducted by Inglehart and his

colleagues (Abramson and Inglehart 1995) who focus on changing levels of postmaterialism. Respondents who give high priority to postmaterialist values tend to emphasize freedom and quality of life concerns, whereas materialists emphasize economic and physical security. In all of the European societies they study, young adults are more likely to have postmaterialist values than their elders. During the two decades that Abramson and Inglehart (1995) studied, about two-fifths of the population of these societies had been replaced. As Europeans with higher levels of materialism were dying out of these societies, and as they were being replaced continuously by Europeans with postmaterialist values, population turnover had affected the overall distribution of values in these societies. Analysis of a combined sample of the European societies that can be studied between 1970 and 1992 suggests that about nine-tenths of the overall shift toward postmaterialism resulted from replacement.

4. Methodological Issues and Future Research

Future research on the impact of generational replacement will face methodological problems. As cohorts are tracked over time, the older cohorts die. Samples of the very old become small and nonrepresentative and, eventually, dwindle away. The standardization procedures used by Abramson and Inglehart (1995) need to assign some value to cohorts that can no longer be tracked, but imputing any such value is problematic. The best one can do is to present estimates using a variety of assumptions, some of which have been suggested by Firebaugh (1989).

Generations, Relations Between

The concept of intergenerational relations has different meanings that are not always sufficiently distinguished. One of its aspects is the relations between age groups demarcated by demographic criteria. To the extent that these relationships are regulated by the institutions of the welfare state, one speaks of a 'generational contract.' The concept of intergenerational relations also encompasses the personal relations between the members of different generations. As a major focus of theory building and empirical research, this latter aspect—intergenerational relations within the family—is the subject of this article, which also touches on intergenerational relations with friends and acquaintances. Because the modern (or now perhaps postmodern) family is usually compared with the traditional family, a brief historical review is included as well.

1. Historical Patterns of Intergenerational Relations

Historical research shows that the rise of the bourgeois family in the late eighteenth century implied a change in family relations. This change is described in terms of growth in emotional closeness, intimacy, or affective individualization (Stone 1990). Although the finding of increasing affective attachment between parents and young children has become accepted as a matter of course, historical research has been less successful at changing popular beliefs about intergenerational relations between adult children and their parents in traditional society.

Many people, including a number of sociologists and especially politicians, cling to the 'misbelief' (Laslett 1991, p. 111) that adult children in premodern times lived with their parents under the same roof. Actually, types of families in preindustrial European society were quite diverse. The stem family, in which the members of the younger generation continued to

live with their parents, was quite common in south and southeast Europe. Another type of family was the *zadruga*, an arrangement whereby the families of brothers lived together. By contrast, the nuclear family was (and still is) the main type in north and northwest Europe (Burguière and Lebrun 1997). In that part of Europe, the adult children did not provide housing, financial support, and care for their old parents, though the opposite claim has often been made. The relatively few persons who did survive into old age had to work as long as they could. If they were poor, frail, or sick, they received a very low level of support from the local community. People who owned property or land or who had a business decided themselves when one of their children should succeed them. Monthly contributions were regulated by contract, with the heir having to provide the parents with either money or natural products.

The nature of intergenerational relations changed at the end of the eighteenth and beginning of the nineteenth century. The new emotional quality of the early parent-child relationship became encoded in new norms that defined the conduct of a good mother. Similarly, normative ideas began to spread about obligations that adult children had toward their parents. Until the seventeenth century, there seems to have been no legal provisions that committed children to support their old parents (Grimm 1899). However, Prussian common law (*Allgemeines Preussisches Landrecht*) of 1794, the most advanced codification of its time, ruled that children had to care for their parents in case of need (Paragraph 63). It was only after life spans (longevity) increased and after the industrial economy put old people out of work that the number of three-generation households increased (Ehmer 1982).

2. Intergenerational Relations at the Turn of the Second Millennium: Parents and Their Adult Children

Contrary to the assumptions in sociological theories of modernization, premodern norms of solidarity do not seem to have been eroded by the dynamics of modernization. The norm that adult children owe their parents support and affection has been spread by modern middle-class society. Simultaneously, however, the idea has emerged that children have a right to make decisions about their own lives. Parent-child relationships have thus come to be characterized by two sometimes incompatible dimensions: attachment and the pursuit of independence.

Additional changes in intergenerational relationships have been due to demographic factors in the twentieth century. Secular decline in the birth rate, which has been particularly apparent since the 1960s, has reduced the number of siblings, uncles, aunts, cousins, nephews, nieces (a family's 'horizontal' di-

mension) but has increased the number of generations within the family (the 'vertical' dimension of a family). In the 1990s, for example, 81 percent of all children ranging from 10 through 14 years of age in Germany had a living grandfather or grandmother (Federal Ministry 1998).

Research on intergenerational relations in late phases of the family cycle began in the 1960s, when it became apparent that the rising number of old and frequently frail people was going to confront society with a problem. In response to the structural 'isolation of the conjugal unit' (Parsons 1943, p. 27), researchers have sought evidence that relationships between old parents and their adult children are characterized by solidarity (Litwak 1965). Rosenmayr and Köckeis (1965) summarized their research results with the words 'intimacy at a distance' (p. 204), a formulation that became known worldwide and that still seems to hold for the relations between old parents and their adult children, at least in Western industrialized countries. Numerous studies have meanwhile shown that parents and children provide each other instrumental, emotional, and financial support (Attias-Donfut 1995, Schütze and Lang 1996, Silverstein and Bengtson 1997). Because intergenerational financial transfer flows from the older to the younger generation, it seems plausible that some of the public transfers to the elderly are channeled back to the young through the family (Attias-Donfut 1995, Kohli 1999).

Although researchers have particularly addressed questions about the stress and feelings of gratification experienced by middle-aged children who become caregivers for their parents, care is primarily given by spouses. Often, adult children become the caregivers only if one of the parental spouses is not available. Daughters are more likely than sons to assume this responsibility, and the daughters experience much greater stress, social isolation, and disruption in their daily lives than sons do (Horowitz 1985). The number of studies on conflict and consensus in parent-child relationships, particularly on caregiving relationships, is probably due to political concerns about whether the family will continue to perform this function or whether it will fall to state institutions. The focus on sociopolitical issues has led to a relative neglect of theoretical questions, such as the transformation of the parent-child relationship during the late phases of the family cycle.

3. Theoretical Perspectives on Intergenerational Relations

Erikson (1959) occasionally referred to the developmental task of overcoming dependency stemming from the period of childhood. In a similar vein Blenkner (1965) developed the construct of filial maturity, arguing that a transformation occurs in the

late phases of the family cycle irrespective of the quality of the early parent-child relationship. When the children cannot help but realize that their old parents are becoming frail, they experience a filial crisis because they recognize that the parents are having to rely completely on themselves. In the subsequent phase of filial maturity, the children acquire a new perspective, conceiving of their parents as individuals with their own rights, needs, and limitations. With this new perspective, there emerges a sense of responsibility that did not exist before. The concept of filial maturity may well be a way in which to integrate autonomy and attachment, moral obligation and affection, distance and closeness.

Taking Blenkner's concept of filial maturity as a model, Nydegger (1991) developed the concept of parental maturity. Parental maturity means that parents cease interference in their children's lives. Mature parents successfully cope with the fact that some hopes they had had for their children have not been met. They recognize whatever differences there may be between their values and those of their children. Mature parents also have learned to accept help and do not claim a degree of independence that is no longer realistic. Unfortunately, neither the concept of filial maturity nor that of parental maturity has been empirically researched (for an exception, see Marcoen 1995).

Another theoretical framework for the analysis of late parent-child relationships can be derived from the view of generations offered by Mannheim ([1928] 1952). Mannheim held that the members of different generations (cohorts) are located at different places in the historical process and that they therefore differ in the way they experience and cope with historical events. Mannheim applied this concept to classifications of age groups in the population, though not to family lineage. It seems legitimate, however, to ask how location in the historical process affects relations and mutual perceptions in the family. In a cross-cultural comparison, for instance, Attias-Donfut (1998) found much less convergence between value orientations and much greater emotional distance between old and younger generations (age groups) in Germany than in France. The author suggested that this generation gap in Germany may be a consequence of the Nazi period. The findings are consistent with those from the literature on family therapy, in which it is shown that Germany's Nazi past weighs heavily on relationships within the family as well (Stierlin 1981, Rosenthal 1997).

4. Intergenerational Relations beyond the Family

In both sociological theory and popular understanding, it is assumed that people choose friends on the basis of similarity, for friends mostly have similar social status, converge in their lifestyles, and belong to

the same sex and age group (Merton and Lazarsfeld 1954, Rosow 1967; for more recent literature see Filipp and Mayer 1999). Homogeneity of age, however, is viewed positively in relations between children or adolescents but negatively (as an indicator of discrimination) in relations that old people have. In reality, it is questionable whether the low number of friendships between older and younger people is evidence of discrimination. After all, friendship is usually between members of the same age group.

All in all, it is primarily through the family that the members of two, three, or even four generations maintain personal relations. Within these relations cultural traditions and family-specific experiences and narratives are passed on. At the same time, however, new forms of dealing with each other are created as well. There is no evidence to support suspicions of cultural pessimists that this balance between continuity and change is going to collapse.

Generations, Sociology of

Generations constitute—just as the closely related categories of age, youth, adulthood and old age—seemingly universal categories in all human societies signifying the different stages of human life; the same is true of tensions between generations, as well as of concepts of the age group or set—in particular the youth group—as a special social category with its own distinct self-consciousness. But it is only in very specific civilizational and historical circumstances that these features come together. Only in special circumstances does historical change become articulated in terms of generational consciousness in general, and that of youth in particular.

It was Karl Mannheim—as well as J. Marias and J. Ortega y Gasset—who emphasized the apparent universality of generational consciousness or at least posed it as a major problem of research; but this tendency, at least as reported by them, was indeed very closely connected to rather specific civilizational traditions—the European ones—and to specific historical circumstances in the development of this civilization. Accordingly a central problem in the analysis of generations is under what conditions does historical change become articulated in terms of generational consciousness in general and that of youth in particular?

1. The Cultural Definitions of Age and of Youth

Generational consciousness is naturally connected with that of age and age differences, and therefore it might first of all be worthwhile to specify the general conditions under which specific age groups and generational tensions and consciousness develop in human societies.

Age differences in general and youth in particular constitute a universal phenomenon. They are first of all a biological phenomenon. Although the basic biological processes of maturation (within the limits set by such factors as relative longevity) are probably more or less similar in all human societies, the definition of age differences in general and of youth in particular is always cultural. Their cultural definition varies from society to society, at least in its details.

The cultural definitions of age and age differences contain several different yet complementary elements. First, these definitions often refer to the social division of labor in a society, to one of the criteria according to which people are assigned to various social positions and roles; for instance, in many societies certain roles—especially those of married men, full citizens, independent earners—are barred to young people, while others—such as certain military roles—are specifically allocated to them. Second, the cultural definition of age is one important constituent of a person's self-identity, his self-perception in terms of his own psychological needs and aspirations, his or her place in society, and the ultimate meaning of his life.

Within any such definition, the qualities of each age are evaluated according to their relation to some basic, primordial qualities, such as vigor, physical and sexual prowess, the ability to cope with material, social and supernatural environment, wisdom, experience, or divine inspiration. Different ages are seen in different societies as the embodiments of such qualities. These various qualities seem to unfold from one age to another, each age emphasizing some out of the whole panorama of such possible qualities.

The various qualities attributed to different ages are usually interconnected in many ways, constituting a series of sorts. The characteristics of any one 'age,'

therefore, cannot be fully understood except in relation to those of other ages. Only when taken together do these different 'ages' constitute the entire map of human possibilities and limitations as envisaged in different societies; and, as every individual usually must pass through them all, their complementariness and continuity (even if defined in discontinuous and contrasting terms) become strongly emphasized and articulated. The same holds true for the age definitions of the two sexes, although perhaps with a somewhat different meaning. Each age-span is often defined differently for either sex, and these definitions are usually related and complementary, as the 'sexual image' and identity always constitute basic elements of man's image in every society.

This close connection between different ages necessarily stresses the problem of transition from one point or stage in a person's life to another as a basic constituent of any cultural definition of an 'age.' The personal transition or temporal progress, or change, tends to become closely linked with the designation or perception of cosmic and societal time—with the rhythms of nature or history, the cycles of the seasons, the unfolding of some cosmic plan (whether cyclical, seasonal, or apocalyptic), or the destiny and development of society. The nature of this linkage often constitutes the focus round which an individual's personal identity becomes defined in cultural terms and through which personal experience, with its anguish, may be given some meaning in terms of cultural symbols and values.

2. Youth as a Liminal, Transitory Phase; Kernels of Generational Consciousness

The problems of age definition and the linkage of personal time and transition with cosmic time become very often accentuated in that age-span usually designated as youth—which constitute in most societies the most liminal of age definitions—the transition from childhood to full adult status, to full membership in the society. In this period the individual is no longer a child (especially from the physical and sexual point of view) and is ready to undertake many attributes of an adult and to fulfil adult roles. But he is not yet fully acknowledged as an adult, a full member of the society. Rather, he or she is being, as it were, 'prepared,' or is preparing himself for such adulthood.

This image of youth—the cultural definition of youth—contains all the crucial elements of any definition of age, usually in a specially articulated way, and often in confrontation with other age categories. Moreover, in this phase the problem of the linkage of the personal temporal transition with cosmic or societal time becomes extremely acute.

The fullest, the most articulate and definitive expression of these archetypal elements of youth and of their liminal potentials is best exemplified in the ritual

dramatization of the transition from adolescence to adulthood, such as the various *rites de passage* and ceremonies of initiation in primitive tribes and in ancient civilizations. In an even more diluted form, these elements may be found in the various spontaneous initiation ceremonies of the fraternities and youth groups in modern societies (Bettelheim 1954, Erikson 1963, pp. 54–93). Hence the youth period and its symbolism, and the liminal situations in which it becomes expressed, may become the focus both of continuity of the social order as well as of protest against it, and of its change.

The very emphasis on the transitory nature of this stage and on its essentially preparatory character, however, often create a somewhat paradoxical situation—namely an image of youth as the purest manifestation and repository of ultimate cultural and societal values of all the major human virtues and primordial qualities. Such an image may be reinforced by the identification of physical vigor in youth with a more general flowering of the cosmos or the society. It is this situation that contains the kernels of the development of strong generational consciousness especially around the image of youth, with strong potentialities of protest.

The social organization of any age and especially of the period of youth is constructed in all societies according to two major criteria. One is the extent to which age in general and youth in particular form a criterion for the allocation of roles in a society, whether in politics or in economic or cultural activity—aside from the family, of course, in which they always serve as such a criterion. The second is the extent to which within society there develop specific age groups, specific corporate organizations, composed of members of the same 'age,' such as youth movements or old men's clubs.

3. *The Social and Cultural Contexts of Different Patterns of Age and Generational Symbolism and Organization*

The importance of age as a criterion for allocating roles in a society is closely related to several major aspects of social organization and cultural orientation. The first aspect is the relative complexity of the division of labor. In general, the simpler the organization of the society, the more influential age will be as a criterion for allocating roles. Therefore, in parallel tribal or preliterate traditional societies, age and seniority constitute basic criteria for allocating social, economic, and political roles.

The second such aspect is that the major value orientations and symbols of a society, especially the extent to which they emphasize certain general qualities, or types of activity (such as physical vigor, the maintenance of cultural tradition, the achievement and maintenance of supernatural prowess) become

expressed and symbolized in specific age-spans. Thus for instance, in those societies in which military values and orientations prevail, young adulthood is emphasized as a very important—sometimes even as the most important—age, while those in which sedentary activities prevail emphasize older age. Similarly, within some traditional societies, where older people may serve as important 'storers' of collective memory, old age may be emphasized if it is seen as the most appropriate one for expressing major cultural values and symbols—for instance, the very upholding, symbolization, and perpetuation of a given cultural tradition.

The social and cultural conditions that determine the extent to which specific age groups and youth groups develop differ from the conditions that determine the extent to which age serves as a criterion for the allocation of roles. At the same time, the two kinds of conditions may be, in some situations or societies, closely related. Age groups in general and youth groups in particular tend to arise in those societies in which the family or kinship unit cannot ensure (it may even impede) the attainment of full social and political status on the part of its members. These conditions appear especially, although not uniquely, in societies in which family or kinship groups do not constitute the basic units of the social division of labor. Membership in the total society (citizenship) is not defined in terms of belonging to any such family, kinship group, or estate, nor is it mediated by such a group.

The emergence of distinct age and generational organization and consciousness, as Meyer Fortes has shown in one of his last papers, lies in the political realm, in the search and definition of citizenship beyond the family sphere and not through the family, while generational differences are mostly elaborated in the structure of the family and kinship unit.

4. *Age Organization and Generational Consciousness in Tribal, Archaic, and Historical Societies*

The type of social division of labor and of political and cultural symbolism that generates such conditions is found in varying degrees in different societies—primitive, historical, or modern. Such a division of labor has existed, for example, in several primitive tribes: in Africa, among the chiefless (segmentary) tribes of Nandi, Masai, or Kipigis; in the village communities of Yako and Ibo; in the more centralized kingdoms of the Zulu and Swazi; and among some of the Indian tribes of the Plains, as well as among some South American and Indian tribes. Such division of labor likewise existed to some extent in several historical societies (especially in city states such as Athens or Rome), although most great historical civilizations were characterized mainly by a more hierarchical and ascriptive system of the division of

labor, in which there were greater continuity and harmony between the family and kinship groups, and the broader institutional contexts.

The fullest development of this type of social division of labor is to be found in modern, especially industrial, societies in which inclusive membership is usually based on universal criteria. In these societies the family does not constitute a basic unit of division of labor, especially not in production and distribution, and even in the sphere of consumption its functions become more limited; occupations are not transmitted through heredity. Similarly, the family or kinship group does not constitute a basic unit of political or ritual activities. Moreover, the general scope of the activities of the family has been continuously diminishing, while various specialized agencies tend to take over its functions in the fields of education and recreation.

At the same time in most modern—as well as in some historical—societies, there developed a certain dissociation between organizations of groups based on age and the symbolic distinction between different age categories. It is such dissociation that constitutes the background for the potentialities for the crystallization of specific generational consciousness formed around the image of youth and in which there develops a strong articulation of the dialectics between, on the one hand, the ‘rebellious’ protest-oriented aspects of youth organization and generational consciousness, and, on the other hand, continuity-oriented aspects (Bettelheim 1954, Erikson 1963, pp. 54–93).

5. Generational and Youth Symbolism and Consciousness in Modern Societies

5.1 Generational Consciousness in Modern Society

The generational consciousness, about which Mannheim, Marias, and Ortega y Gasset and many other modern writers wrote, has developed against the background analyzed above. Such consciousness is indeed connected, in a rather paradoxical way, with the fact that in modern societies the development of specific youth organizations is linked with the weakening of the importance of age in general and youth in particular as definite criteria for the allocation of roles in society become weakened. Yet this very weakening of the importance of age, as a criterion of allocation of roles, has been connected with intensive development of youth groups and movements—and lately also, perhaps paradoxically, among ‘retired’ people. Indeed, it is very interesting to note that in some of the contemporary industrial societies there tends to develop a distinct organization based on age as well as generational consciousness that are again coming together at the other end of the life-span—in

old age—among the older people, that is, those who have retired from work.

It is because of these developments—some incipient phases of which can be also discerned in different archaic and historical societies, but which have not been studied adequately (Nash 1978)—that in modern societies there also arises the possibility of the development of very strong generational consciousness in general, and of the articulation of such consciousness in terms of youth in particular. It denotes the general development of the self-consciousness of generations, which develops in the public realm—whether the realm of politics or of culture—and it contains very strong potentialities of social, political, or cultural protest.

6. Historical Change, Revolutionary Orientations, Generational Consciousness in Modern Youth Movements

The development in modern societies of such a dissociation between generations, and the concomitant possibility of the development of a special type of a distinct generational consciousness, are due not only to the complex division of labor that characterizes these societies. They are also closely connected to the relatively quick tempo of historical change, and above all to the consciousness of such change. Such consciousness is often connected with changes rooted in the revolutionary orientations which constituted important components of the construction of modern civilization, cultural values, and orientations. These revolutionary orientations were most fully articulated by the major social movements that have developed as part and parcel of modern life, of the constructions of modern social and political order and of struggle around such construction. The possibility of the development of distinct generational consciousness has been enhanced in modern societies by the occurrence of rapid historical changes or ruptures, the consciousness of which is shared by members of the same age group or age cohort.

But while historical change is particularly rapid and the consciousness of such change very widespread in modern societies, it does not always give rise to fully articulated generational consciousness—although to some degree such consciousness is probably rather common in modern societies and is not necessarily confined to the symbolism and ideology of youth. It is only in rather special historical circumstances and situations—like wars, changes of regime, and the like, especially of events which entail strong ruptures—that such generational consciousness has become articulated in modern societies in terms of youth symbolism.

Among such situations in modern societies two are probably of special importance. One was developed at the end of the nineteenth and the beginning of the twentieth century, and found its fullest expression in

the free German youth movements, though it was also present in the less spectacular youth movements of Central Europe and to some extent in the youth culture of various more flexible youth groups that developed in most modern societies. In all these movements very strong attempts have been made to overcome the dislocation between personal transition and societal and cultural time. It was in them that dreams of a new life, a new society, freedom and spontaneity, a new humanity, and aspirations to social and cultural change found utterance. It was in these youth movements that the forging of youth's new social identity became closely connected with the development of new symbols of collective identity or new social-cultural symbols and meanings, which thus become foci of protest aimed at the reconstruction of society and culture.

While some of these orientations could be found in many of the youth groups that developed in most modern societies—be they in England or the United States—they developed most fully in situations where these groups became closely interconnected with major social movements oriented at the reconstruction of the centers and symbols of their respective societies. This was the case above all in the major nationalistic and revolutionary movements in Central and Eastern Europe, in Italy, Germany, Hungary, and Russia, or in the Zionist movement, where these orientations and student movements played a crucial role.

One of the major characteristics of many, probably most, of these movements was that in their ideology the symbolism of youth was very closely connected with that of the construction of new modern, especially national, collectivities that were being constructed at the period, and among the aims of these youth movements the reconstruction of such collectivities—national, social, or cultural—was central. These movements aimed at changing many aspects of the social and cultural life of their respective societies, to reconstruct the centers and premises of their respective societies in terms of some of the major revolutionary orientations of modernity. They depicted the present in a rather shabby light; they censured it for its materialism, exploitation, restrictive views, and lack of opportunity for self-fulfilment and creativity. At the same time they held out hope for the future—seemingly the not very far-off future—when both self-fulfilment and collective fulfilment could be achieved and the materialistic civilization of the adult world shaken off. They tried to appeal to youth to forge its own self-identity in terms of these new collective symbols, and this is why they have been so attractive to youth, for whom they provided a set of symbols, hopes, and aims to which to direct its activities.

The influence of such movements and orientations was very great, not only political and educational but also in many cultural arenas. In a way, education itself has tended to become a social movement. Many schools and universities, and many teachers, have

been among the most important bearers of collective values. The expansion of education itself is often seen as a means by which a new epoch might be ushered in.

7. *The Routinization of Revolutionary Movements; the Demystification of the World; and Youth and Student Rebellion of the 1960s*

The second historical situation in modern societies in which generational consciousness, couched in the symbolism of youth, became very prominent in the new social movements burgeoned in the late 1960s and early 1970s, and became most fully manifest in the various student rebellions and movements of the time.

The background to these new developments was a combination of the growing institutionalization of many of the collective values and symbols of the social, national, and youth movements discussed above, and the continuous expansion of education and changes in occupational structure. These developments had several important repercussions on the structuration of the life spans of youth.

The area of social life that the specific youth or student culture encompasses has tended to expand continuously. First, it has extended over a long period of life, reaching, through the impact of the extension of higher education, to what before was seen as early adulthood. Second, it tends more and more to include areas of work, leisure time activity, and many interpersonal relations. Third, the potential and actual autonomy of these groups, and the possibility their members have for direct access to work, marriage, and family life, to political rights, and to consumption, have greatly increased, while their dependence on adults has greatly decreased.

Paradoxically enough, the growing direct access of young people to various areas of life has given rise to a growing insecurity of status and self-identity and to a growing ambiguity of adult roles. This insecurity and ambiguity has been enhanced, first, by the prolongation of the time-span between biological and social maturity and by the extension of the number of years spent in 'preparatory' (educational) institutions, and, second, by the growing dissociation between the values of these institutions and the future—especially in terms of occupational and parental roles—of those participating in them. A third factor is that for a long period many 'young' people may as yet have no clear occupational roles or responsibilities and may be dependent on their parents or public institutions for their economic needs, while at the same time they constitute an important economic force as consumers and certainly exercise political rights. In turn this situation may become intensified or aggravated by the growing demographic preponderance of the 'young' in the whole population and by the increasing possibilities of ecological mobility.

All these developments gave rise to new types of generational and youth consciousness—a new combination between the symbolism of youth and collective symbolism. The older classical movements of protest and youth movements tended to assume that the framework and centers of the nation-state constituted the major cultural and social reference points of personal identity and of the charismatic orientations to some sociocultural orders, and that the major task before them was to facilitate the access of broader strata to these centers and full participation in them and possible changes in them. In contrast, the new movements of protest have been characterized by their scepticism towards these new modern centers and by lack of commitments to them—all of which denoted important aspects of what has been called by Weber the demystification of the world.

The foci of protest promulgated by these movements shifted from demands for greater participation in national political centers or from attempts to influence their socioeconomic politics to new directions. The most important of these directions were: first, attempts to 'disrobe' these centers of their charismatic legitimacy and perhaps of any legitimacy at all; second, continuous searches for new loci of meaningful participation beyond these centers and the concomitant attempts to create new centers which would be independent of the existing center; third, attempts to formulate the patterns of participation in their centers not so much in sociopolitical or economic terms but more through symbols of primordial or of direct social participation.

These developments have often been connected with the breakdown of consciousness of historical continuity and of the conception of the future in terms of such continuity. The image of the societal future has become flattened and has been deprived of its allure. No sharp ideological discontinuity has been conceived between present and future.

Through these developments, youth has been, as it were, robbed of the full experience of the dramatic transition from adolescence to adulthood and of the dramatization of the difference between present and future. Their own changing personal future has become dissociated from any changes in their societies or in cultural activities and values. As a result of all these processes, the possibility of linking personal transition to societal and cosmic time—which was so strongly emphasized in the youth movements and observable also to some extent even in the earlier, looser youth culture—has become greatly weakened.

One of the most important results of these developments has been the development of a new configuration of youth symbolism and generational consciousness—the major characteristic of which was the development of strong antinomian intellectual tendencies as a central component of such symbolism and consciousness.

It is not just the contents of these antinomian

tendencies that are new, but the convergence of these contents with the spread and location of these movements. Of special importance in this context is the fact that this type of protest was not confined only to small, closed intellectual groups but involved widespread circles of novices and aspirants to intellectual status. Given the expansion of the modern educational system and the parallel effects of the spread of mass-communication media, a very large part of the educated public have become aspirant to such status, and impinge on the centers of intellectual creativity and cultural transmission and become integral, even if transient, parts thereof.

This rather unique combination of intellectual antinomianism with youth rebellion gave rise to a new type of youth ideology that was connected to the reversal of the hitherto existing relation between the definition of different age-spans and the possibilities of social and cultural creativity. Unlike in the past—even the not-so-distant past—youth became more and more seen not only as a preparation for independent and creative participation in social and cultural life, but as the very embodiment of permissive, often unstructured creativity—to be faced later on with the constants of a relatively highly organized, constrictive, meritocratic, and bureaucratic environment. Thus youth now became, even more than before, the transmitters and symbols of a continuous antinomian confrontation between the pristine values it embodies and a demystified social reality, and the impact of this new type of generational consciousness has been of crucial importance in the crystallization of what has been designated as the postmodern trends in contemporary societies. While the intensity and the concrete manifestation of this consciousness will naturally change from one situation to another, the consciousness itself with the various antinomian tendencies analyzed above seems to have become more and more prevalent.

Generative Grammar

Generative grammar is the label of the most influential research program in linguistics and related fields in the second half of the twentieth century. Initiated by a short book, Chomsky's *Syntactic Structures* (1957), it became one of the driving forces among the disciplines jointly called the cognitive sciences. The term *generative grammar* refers to an explicit, formal characterization of the (largely implicit) knowledge determining the formal aspect of all kinds of language behavior. From the start the program had a strong mentalist orientation instance, documented, for, in a fundamental critique of Skinner's *Verbal Behavior* (1957) by Chomsky (1959), arguing that behaviorist

stimulus–response theories could in no way account for the complexities of ordinary language use. The 'Generative Enterprise,' as the program was called in 1982, went through a number of stages, each of which was accompanied by discussions of specific problems and consequences within the narrower domain of linguistics as well as the wider range of related fields such as ontogenetic development, psychology of language use, or biological evolution. Four stages of the Generative Enterprise can be marked off for expository purposes.

1. Transformational Structure and Levels of Description

The foundation of all further developments is to be found in the Chomsky's monograph *The Logical Structure of Linguistic Theory* (1975, henceforth LSLT), which was published only 20 years after the manuscript was completed. Starting from the notion of structural analysis as developed by Bloomfield and made precise by Harris (1951), LSLT introduces a radically new perspective on the nature of linguistic structure. On the one hand, LSLT takes up Harris's notion 'level of linguistic structure,' in terms of which the form of utterances, i.e., their phonetic and syntactic shape, is characterized. On the other hand, however, LSLT develops a notion of linguistic structure that differs fundamentally from the empiricist orientation of American structuralism. More specifically, Chomsky proposes a notion of grammar that provides a full and explicit account of the tacit knowledge a speaker/hearer has of the form of utterances of his or her language. Under this perspective, a grammar *G* is a theoretical construct, dealing with internal states of knowledge that relate only indirectly to overt behavior of the speaker. In other words, *G* is viewed as an empirical hypothesis about the mental structure underlying ordinary speech behavior. To make this notion precise, LSLT highlights the importance of intuitive judgments a speaker is able to make about properties of utterances, such as the grammatical well-formedness of the famous nonsense-sentence (1) as opposed to the ungrammaticalness of (2), or the rather different properties of (3) and (4), in spite of their superficial similarity:

- (1) colorless green ideas sleep furiously
- (2) furiously sleep ideas green colorless
- (3) this picture was painted by a real artist
- (4) this picture was painted by a new technique

Hence *G* of English has to account for the properties on which intuitions like these rely. The study of the general features of *G* can furthermore be assumed to reveal principles of the internal organization of mental states in general and of knowledge of language in particular. This is in fact the basic motivation underlying the research program of Generative Grammar.

More technically, LSLT gives the following account of the concepts needed for this program. First of all, a linguistic level **L** is defined as an algebraic structure of the following sort:

- (5) $\mathbf{L} = [L, R_1, \dots, R_m, \mu, \Phi, \varphi_1, \dots, \varphi_n]$, where
 L is the set of primes of **L**;
 R_1 to R_m are sets of relations in **L**,
 such as linear ordering, inclusion,
 identity;
 μ is a set of so-called **L**-markers,
 generated by the primes of **L**;
 Φ is a mapping that maps μ onto
 the set of grammatical utterances;
 φ_1 to φ_n are operations relating **L** to other
 levels.

Roughly speaking, an **L**-marker is the representation of the structure of an utterance on the level **L**. The particular levels assumed in LSLT include the phonetic level **Pt**, the phonemic level **Pm**, the morpheme level **M**, the word level **W**, the level of word classes **C**, the phrase structure level **P**, and the transformational level **T**. For **Pm**, the set μ consists of strings of phonemes, for **W**, the elements of μ are sequences of words, and for **P**, the set μ consists of phrase markers, roughly tree structures indicating the constituency of an utterance. The relation between the different levels defined by the operations φ_i depends on particular conditions of the various levels and is, as Chomsky argues, anything but trivial. The full structural representation of an utterance comprises the **L**-markers assigned to it at the various levels in question. The mapping Φ relating the levels of representation to the actual (or possible) grammatical utterances is correspondingly indirect and complex. The assumption in LSLT is that it may be sufficient to define Φ for phonetic representations, i.e., strings in **Pt**, provided that the relation to **Pt** is defined for all other levels. This accounts for the fact that the structure of an utterance cannot be arrived at by simple operations of segmentation and classification, as assumed in classical structuralism, but depends on highly indirect and complex relations.

Second, a grammar **G** is a system of operations or rules that generate the sentences of a language with their structural representations. Technically, **G** determines the set of **L**-markers for each level **L** and the operations by which they are related to the other levels. LSLT deals with the general form of phonological rules, defining the relation between the phonemic and phonetic level, and more extensively with phrase structure rules, generating **P**-markers, and with grammatical transformations. The role of transformations is a matter of central interest in LSLT (such that for quite a while the term 'transformational grammar' was taken as largely equivalent to 'generative grammar'), they are assumed to capture structural properties **P**-markers could not account for. For instance, the difference between (3) and (4), which are not distinct in terms of constituency, is explained by

different transformational derivations, informally indicated in (3') and (4'):

- (3') a real artist painted this picture = T_{Passive}
 $\Rightarrow$ this picture was painted by a real artist
 (4') someone painted this picture by a new
 technique = $T_{\text{Passive}} \Rightarrow$ this picture was
 painted by a new technique by someone
 = $T_{\text{Agent-deletion}} \Rightarrow$ this picture was
 painted by a new technique

An important point of the theory developed in LSLT is the assumption that grammars must systematically be evaluated. To this effect, a simplicity-metric is introduced by which a grammar is preferred if and only if it expresses more natural generalizations than its competitors. For example, a grammar that accounts systematically for the different properties of sentences like (3) and (4) is to be preferred over one that can only assign to them the same structure. This is the reason why a grammar with a transformational component comes out as simpler than one without it. One of the factors entering the evaluation is the principle of rule ordering, which recognizes the possibility that rules might have a different structural effect, if they operate in different ordering. As a simple case in point, in (4') the Agent-deletion can operate only after the Passive Transformation has applied. (The importance of rule ordering had already been observed in the Sanskrit grammar of Panini.)

The productivity of the proposed framework is demonstrated by an analysis of large sections of English with respect to phrase structure and transformations in LSLT and in a stimulating monograph on nominalization by Lees (1960). A seminal study of phonology is given in Halle (1959) for Russian and in Chomsky's unpublished master's thesis on the *Morphophonemics of Modern Hebrew*.

A feature that LSLT inherits from the notion of transformational analysis proposed by Harris (1957) is the notion that transformations not only relate individual sentences to their more elementary basis, as shown in (3') and (4'), but are also used to decompose complex sentences into their constituent parts made up. Thus (6c), for instance, is composed by embedding of (6a) into (6b), replacing the bracketed pronoun:

- (6) (a) this picture was painted by a new technique
 (b) the director suspected [it]
 (c) = $T_{\text{Embedding}} \Rightarrow$ the director suspected
 [this picture to be painted by a new
 technique]

This assumption requires a distinction between simple transformations like T_{Passive} and so-called generalized transformations like $T_{\text{Embedding}}$. Another distinction that must be made is that between optional and obligatory transformations. Passivization, for instance, is optional, while the fronting of relative and wh-pronouns is obligatory, as the ungrammaticality of (7b) shows:

- (7) (a) I know the man who you met last night
 (b) *I know the man you met who last night

The clarification of these and a wide range of other complexities concerning the level **T** is one of the driving forces in further developments of Generative Grammar.

Another, more general feature that the Generative Enterprise inherits from American Structuralism is the assumption that all grammatical structure, from the most concrete level **Pt** of phonetics to the most abstract level **T** of transformational structure, is a matter of linguistic form which must be embedded in a wider context of a theory of semiotics that accounts for sense, reference, and use of linguistic expressions. Although there have been several proposals to include a level of semantics into the framework of generative grammar, the main emphasis has been on the knowledge of linguistic form throughout.

2. The Standard Theory of Generative Grammar

Immediately after the publication of *Syntactic Structures* (actually lecture notes excerpted from LSLT), the theory it proposed attracted interest from various sides, including mathematical linguistics and psychology. An overview of the formal properties of grammatical rules, especially of phrase structure grammars, in Chomsky (1963) established what became known as the Chomsky hierarchy of formal grammars as a branch of subrecursive function theory. Miller and Chomsky (1963) gave a first outline of the role of Generative Grammar for the study of language comprehension and production. Furthermore, Katz and Fodor (1963) made a first proposal to extend the theory of grammar by a semantic component, using so-called projection rules to integrate compositionally the meaning of lexical items according to their syntactic relations.

The main development, however, was due to continuous efforts to constrain systematically and strengthen the theory, increasing its explanatory power by reducing the range of possible grammars compatible with a given set of data. Such a reduction reduces at once the task assigned to the evaluation metric. Efforts to this effect led to what was later called the 'Standard Theory' of Generative Grammar. Based on preparatory ideas discussed, *inter alia*, in Katz and Postal (1964), it is formulated in Chomsky's *Aspects of the Theory of Syntax* (1965). The core point is a reassessment of the nature of transformational structure. Instead of a separate level **T** of transformations, grammatical transformations are now construed as operations that define the relation between two levels of syntactic representation, both of which are characterized by P-markers. This modification is related to one of the most influential distinctions proposed in the Standard Theory, namely that between *deep* and *surface structure*. According to this view, each sentence is assigned a deep and a surface P-marker, with trans-

formations mapping the former on the latter. Thus except for the different choice of personal or wh-pronouns, (8)(a)–(d) are just different surface realizations of the same deep structure, where the bracketed Agent phrases might furthermore optionally be deleted by $T_{\text{Agent-deletion}}$, known from (4')

- (8) (a) John may expect her to meet him
 (b) she may be expected (by John) to meet him
 (c) who does John expect her to meet
 (d) who may be expected (by John) to be met (by her)

On this account, the semantic interpretation of linguistic expressions could apparently be determined on the basis of their deep structure, which would be an interesting step towards an integration of grammar into an account of meaning and reference. Another important point of the Standard Theory is a more systematic distinction between (a) the lexical system, i.e., the complex system of rules that introduce lexical items with their (idiosyncratic) phonetic, syntactic, and semantic properties, and (b) the grammatical rules that integrate the lexical information into the structure of complex linguistic expressions. Finally, the distinction between levels of representation on the one hand and components of grammar generating and inter-relating these representations is made more perspicuous than in LSLT. The syntactic levels that appeared to be crucial are deep- and surface-structure, while word- and morpheme-structure do not have an independent status. The components of grammatical rules are (a) the base component, including the lexical system and the phrase structure rules, (b) the transformational component, (c) the phonological component, and, possibly (d) the semantic component. Rules and representations are inter-related according to the schema in (9), with levels of representation italicized:

The base component and the transformations together constitute the syntactic component. The semantic component raises problems to be taken up below, while the organization of the phonological component, extensively discussed by Chomsky and Halle (1968), is assumed to have a fairly clear organization, parallel to that of the syntactic component in relevant respects. The underlying phonemic structure is defined by the phonological features of lexical items and their arrangement in surface structure:

- (10)
- | |
|--|
| <i>Phonemic Structure</i> |
| ↓ |
| Phonological Component: Phonological Rules |
| ↓ |
| <i>Phonetic Structure</i> |

While there are still optional and obligatory transformations, generalized transformations are dispensed with, the deep structure of complex sentences being generated already in the base component. A particularly elegant feature that emerges from this reorganization is the principle of cyclic operation of the rules, which is added to the earlier assumption that rules are ordered. Cyclic operation apparently captures a deep property of natural languages: the same sequence of operations applies to increasingly larger parts of an utterance, defining its syntactic properties, its phonetic patterns, and the compositional integration of its semantic structure.

An important general effect of the Standard Theory is the perspicuous account it allows for the traditional notion of linguistic universals, or Universal Grammar (UG), considered as the innate, biologically fixed structure underlying the species-specific language capacity. The range of possible rules and the architecture of their interaction, as schematized in (9) and (10), could now be construed as formal universals, the potential primitive elements entering the rules and representations as substantive universals. Under this perspective, the set of possible grammars *G* accessible as instantiations of UG determines the diversity of possible natural languages, including the range of variation delimiting processes of linguistic change. By the same token, UG provides the innate, formal basis and predisposition that makes language acquisition possible. These accompanying considerations of the Standard Theory led to a new, principled approach to problems of language acquisition, as well as linguistic change.

3. Towards the Principles and Parameters Theory

Shortly after the Standard Theory was formulated, empirical analyses as well as efforts to improve the structure of the theory created modifications of the model. Controversial proposals concerned the role of semantics as indicated in (10). Lakoff (1971) and others proposed a model, according to which semantic representations are the underlying structure of linguistic utterances, from which surface structures are step by step derived by means of transformations and lexical rules. The insights and difficulties related to these proposals created a counterproposal, called the Revised Standard Theory. Based on observations discussed in Jackendoff (1972) it became obvious that meaning is not unaffected by surface structure phenomena. For example (11) and (12) are based on the same deep structure, with passivization applying to (12) but not to (11); they do not in general have the same meaning:

(11) Three students in the class wrote only one paper

(12) Only one paper was written by three students in the class

(Due to what is called the scope of quantification, in (11) the restriction of having written one paper is ascribed to three students, while in (12) the restriction of being written by three students is ascribed to a single paper.) As phenomena of this sort are by no means marginal, the Revised Standard Theory recognized a more complex relation between syntax and semantics than that indicated in (9). Only certain aspects of meaning are determined by deep structure, while scope and certain other relations depend on surface structure, such that transformations—contrary to the Standard Theory—might now affect the semantic interpretation.

A technical way to handle these problems is the so-called Trace Theory proposed in Fiengo (1977). According to this proposal, a constituent that is moved by a transformation leaves behind a trace that is phonetically empty, but may play a role in semantics, as indicated in the following example, where e_i is the trace left in the initial position of the co-indexed pronoun:

(13) who_i do you want to talk to e_i

In many cases, the trace turns out to be similar to what logicians consider a variable bound by the operator contained in the moved constituent. In this sense, invisible elements of the surface structure account for its contribution to semantic interpretation. Other empty elements of the surface structure are 'invisible' pronouns, as in (14)(a) and (b), where the actor of the infinitive clause is controlled by (i.e., co-referential with) different constituents of the main clause:

(14) (a) John_i promised Mary [e_i to take the train]

(b) John recommended Mary [e_i to take the train]

The structural aspect that emerges from transformations, as for instance in (13), cannot be the Deep Structure of (9), but it also differs from Surface Structure, as it contains elements like traces and empty pronouns. This more abstract surface, called S-structure, is assumed to provide the information for phonetic as well as semantic interpretation. On this account, (9) might be replaced by the general schema (15), where LF, namely the Logical Form, represents all the information *G* contributes to the meaning of an expression, just as PF, that is the Phonetic Form, specifies the conditions *G* imposes on its pronunciation:

- (15)
- | |
|----------------|
| Deep Structure |
| |
| S-structure |
| / \ |
| PF LF |

The theory of traces and other 'empty' elements is not a purely technical modification, however. It is

rather part of a general orientation striving for systematic restrictions on the still much too complex possibilities to construct a grammar according to the Standard Theory. One of the reasons motivating this orientation has been called the logical problem of language acquisition. This problem consists of the requirement to specify the conditions under which an appropriate grammar can be identified on the basis of the restricted and partially defective evidence the learning child is normally exposed to. This problem cannot be approached seriously if UG is as unconstrained as it would be with all the complexities initially allowed for as transformations. On the other hand, it turned out that many of the formal complexities exploited, for instance, in operations like the standard passive transformation, can be reduced to more elementary operations if the application and interaction of these operations is subject to more systematic constraints.

Induced by the Trace theory, a number of systematic conditions have been explored which determine the conditions of empty elements of different sorts. These conditions allow transformations to be reduced ultimately to just one simple operation, called Move α , where α is any constituent. The systematic and by no means trivial conditions determining the possible choice of α , the domain and bounds of movement, the consequences of movement (such as leaving a trace), are all expressed by general principles needed on independent grounds. One of the conditions concerns relations lexical elements impose on their necessary or optional complements. This is called their Argument- or Theta-Structure. Another rather general condition entering these principles is a systematic reorganization of phrase structure rules in terms of the so-called X-bar Theory. This theory takes up an observation made already in Harris (1951) about the restricted options according to which constituents X and Y combine in order to form a complex constituent $\bar{X}$. In somewhat simplified terms, properties of $\bar{X}$ are determined by its head X, which furthermore selects Y as its complement or is modified by Y as a free adjunct.

These and a number of other developments led to a new version of the overall framework called the Principles-and-Parameters Theory, formulated in Chomsky's *Lectures on Government and Binding* (1981). The basic idea of this theory is to replace the notion of different types of highly complex rules, from which individual grammars are made up, by a system of universal principles that constrain the effect of rather basic operations like Move α and the options of X-bar theory. The principles in question determine the relation between the positions of a moved constituent, the domain of movement, the possible candidates for movement, and the conditions that require the operation. They constitute separate subsystems, called Government, Binding, Bounding, Control, Case, and Thematic Structure. The properties distinguishing different languages are no longer seen as consequences

of intricate systems of different and rather complex rules. It rather seems possible to account for the relevant phenomena by the interaction of these general principles. The obvious differences between different languages is assumed to be reducible to different values of a restricted set of parameters contained in these general principles. Thus the head X of a constituent $\bar{X}$ may be in initial or final position, an embedded clause may need an introductory element or not, etc. Most (or all) of these parameters seem to be related to classes of particular lexical items so that all language particular properties are basically related to lexical information. This leads to a rather different notion of how UG determines an individual grammar G: besides lexical items making up the language particular dictionary, grammars of different languages might differ only by their choice of parameter values, while the principles these parameters rely on are given by UG and hence identical for all languages. Under this perspective, language acquisition consists essentially of identifying the lexical system of a language, thereby fixing the particular values of the parameters contained in UG. Presupposing the schema of levels given in (15), the organization of a grammar G within the Principles-and-Parameters theory can be indicated roughly as follows:

- (16) (a) Lexical System, fixing the idiosyncratic phonetic, semantic, and syntactic properties of lexical items
- (b) X-bar syntax, Move α
- (c) Principles of Government, Binding, Bounding, Thematic Structure, Control, and Case-Assignment
- (d) PF-component
- (e) LF-component

Among the numerous stimulating consequences of this model is a new perspective on historical and typological variation: like language acquisition, linguistic change and typological differences are not only constrained by UG, but also closely related to choice of parameter values on the basis of universal principles.

4. *The Minimalist Program of Generative Grammar*

Research within this framework explored the principles listed in (15c) in more detail, keeping to the overall orientation of the Generative Enterprise, namely improving the explanatory power by constraining the theory as far as possible. This led in particular to the attempt to derive the principles in question from general conditions of cognitive organization plus the boundaries that are conceptually necessary to identify the domain of language. Minimal assumptions in this sense require linguistic expressions to compositionally relate patterns of the perceptual and articulatory system A-P to representations in the range of con-

ceptually and intentionally organized experience C-I. This requires the internal or I-language determined by G to provide at least the interfaces PF and LF, relating language to A-P and C-I, respectively, as indicated in (17):

$$(17) \text{ signal} \Leftrightarrow \text{A-P} \Leftrightarrow \text{PF} \leftrightarrow \text{LF} \Leftrightarrow \text{C-I} \Leftrightarrow \text{environment} \\ \text{G}$$

Thus G must determine pairs $\langle \pi, \lambda \rangle$, where π and λ are representations in PF and LF, respectively. One must assume furthermore, that each pair $\langle \pi, \lambda \rangle$ must be based on a selection N of elements of the lexical inventory of the language. The research strategy of the Minimalist Program proposed in Chomsky (1995) pursues the aim to derive the properties of UG as far as possible from these minimal assumptions together with the hypothesis that UG is subject to conditions of structural economy. This requires first the lexical items entering the selection N to contain all and only the idiosyncratic specifications by means of which N participates in determining the pair $\langle \pi, \lambda \rangle$. This includes, besides phonetic and semantic features interpreted in P-A and C-I, respectively, certain grammatical or formal features controlling the computation of $\langle \pi, \lambda \rangle$ from N . The minimal assumption to be made about this computation is an operation *Merge* which combines two expressions X and Y into a complex expression Z , made up from the features of X and Y , adding the formal features of the head to characterize the formal properties of Z . As a matter of fact, the operation *Merge* is the minimalist version of X-bar syntax, reviving, moreover, a reduced version of the generalized transformations combining two expressions of arbitrary complexity. With this background, it is an interesting, empirical fact about natural language that the derivation from N to $\langle \pi, \lambda \rangle$ cannot in general be restricted to the simplest possibility requiring only the operation of *Merge*, but needs the effect of what was called *Move α* in order to account for facts like *Who_i did he_j talk to e_j*. As a matter of fact, the operation can be simplified to *Move*, as it is some formal feature of the moving constituent α , which triggers the operation if and only if the feature cannot be eliminated otherwise. More technically, then, the computation of linguistic expressions proceeds as indicated by (18):

$$(18) N \Leftrightarrow \text{Merge, Move} \Leftrightarrow \text{PF, LF} \rangle \text{ Spell Out PF}$$

A wide range of facts in different languages have been shown to follow from appropriate lexical information together with minimal assumptions about *Merge*, *Move*, plus two sorts of general conditions regulating the economy in representation and derivation of expressions of I-language. What this leads to is indicated in (19):

- (19) (a) Conditions on lexical items i.e., sets of phonetic, semantic, and formal features
- (b) Operations of the computational system of language: *Merge*, *Move*
- (c) Economy Principles:
- (i) Representational: Full Interpretation FI

(ii) Derivational: Shortest derivation from N to $\langle \text{PF}, \text{LF} \rangle$ -pairs

The requirement of Full Interpretation presupposes that *Merge* and *Move* check and eliminate step by step the formal features, leaving only information that can appropriately be interpreted in terms of articulatory and conceptual conditions at the two interface levels. Derivational economy is a fairly abstract notion, the appropriate formulation of which is still under exploration. In any event, violation of these principles is now taken to be the source of ungrammaticalness: only optimal derivations allowing for complete interpretation yield well-formed expressions. The control of these conditions is a crucial effect of formal features, coming primarily with special lexical items called functional categories. These include grammatical words like Determiners, Auxiliaries, but also inflectional elements like Tense, Number, or Case.

From a more general perspective, the conditions in (9) are rather general, compared with the still rather special principles in the Principles-and-Parameters model (16), very much like these principles were a strong generalization compared with the rule systems of the Standard Theory in (9). The shift from (9) to (16) replaced rules of individual grammars by universal but still language-specific principles; the organization of UG indicated in (19) replaces these language-specific principles with even more general conditions of cognitive organization. Language specificity is now essentially a matter of formal features and their effect on *Merge* and *Move*, that is the operations that compositionally relate P-A to C-I, modules of cognitive organization which are largely independent of the language capacity.

From this point of view, the species-specific language capacity might consist essentially of the disposal of discrete infinity and in fact be related, as Chomsky (1982) speculates, to the computational capacity underlying arithmetic. The language capacity clearly recruits and enhances general cognitive and communicative capacities, but its evolution, which Pinker (1994) persuasively argues to be due to adaptive selection, might well be an independent step accompanying evolutionary changes in the architecture and size of the human brain.

5. General Perspectives

The intellectual force of generative grammar comes from the combination of two equally important factors. First, it provides a suggestive methodological and theoretical perspective for the study of language as part of the biological endowment of the human organism, supporting a central system of the overall cognitive capacity. Second, it shows how this perspective can be made precise, turned into an effective research program, and pursued with respect to a large domain of empirical facts not recognized before. It is

indeed the wide range of phenomena—from syllable structure and inflection to quantifier scope and syntactic embedding—as well as the diversity of languages—from English, German, and Chinese to Hebrew, Malayalam, and Walbiri—that gives the Generative Enterprise its unusual place in the field. The explicit formulation of the theory, its technical means, and its cognitive orientation are the reason for its strong impact on a wide range of subdisciplines from research in language comprehension and production, acquisition and aphasia to typology, historical linguistics, computer science, poetics, theory of music, and philosophy of language.

As can be seen from the above, various offshoots developed different, though related, ideas. These are, *inter alia*, Categorical Grammar, Dependency Grammar, Case Grammar, Lexical Functional Grammar (LFG), Generalized Phrase Structure Grammar (GPSG), Head-driven Phrase Structure Grammar (HPSG), Relational Grammar, to mention the more influential proposals. Another type of offspring is the Optimality Theory (OT), which develops certain ideas of the Minimalist Program in a different way, assuming that conditions on linguistic structure may be of different strength and can be violated.

A peculiar relationship must finally be noted between Generative Grammar and the various theories of semantics and pragmatics. Sticking to the initial notion that grammar can and must account for the form, but not properly for the complexities of interpretation and use of language, Chomsky did not extend his theory of language to the domain of semantics and pragmatics. It might be noted in this respect that he always considered Logical Form as a syntactic level, pertaining to the form rather than the interpretation of language. Therefore, Formal Semantics as developed by Montague (1974), Discourse Representation Theory as proposed by Kamp and Reyle (1993), Speech Act Theory as conceived by Searle (1969) and a fair number of related approaches to aspects of interpretation and use are compatible with and in part stimulated by Generative Grammar, but they have not been included into its proper domain. Even though this situation was occasionally met with disappointment, it could not in general reduce the attraction exerted by the Generative Enterprise.

M. Bierwisch

Generative Syntax

The term generative syntax refers to research on the syntax of natural languages within the general framework of generative grammar. As in generative grammar, the term 'generative' means explicit. Thus, generative syntax differs from much other research on syntax in its emphasis on precise and explicit specifica-

tion both of general theories and of specific analyses. Most work in generative syntax like most work in generative grammar has also been seen as an investigation of I-language (internalized language), the cognitive system underlying the ordinary use of language. Like generative grammar, generative syntax has its origins in Chomsky's *Syntactic Structures* (1957). It is often seen as the central component of generative grammar and it has always been the most prominent.

1. Origins

Syntax was very much a secondary concern for pre-Chomskian linguists and their ideas about syntax were largely unformalized. Chomsky's first concern was to make these ideas explicit and to investigate their adequacy. He argued that they were unsatisfactory in various ways and proposed a richer conception of grammar; known as transformational grammar (TG).

Most pre-Chomskian work on syntax implicitly assumed that words can be classified and that they combine together into phrases which can also be classified. In other words, it assumed that sentences have a constituent structure (or more than one if they are structurally ambiguous). Constituent structures are commonly represented by tree diagrams like (10):

This tells us what categories the words in the sentence belong to and what phrases the sentence contains. Chomsky pointed out that constituent structures could be characterized by phrase structure (PS) rules. A PS rule has the form in (2) and the interpretation in (3).
 $C_0 \rightarrow C_1 C_2 \dots C_n$ (2)
 A C_0 can consist of a C_1 , followed by a C_2 , followed by ... followed by a C_n (3)
 Chomsky argued that grammars consisting just of PS rules could not provide an illuminating account of various syntactic phenomena, and argued for a richer conception of syntactic structure in which some constituents are introduced into the structure somewhere other than their superficial position and then moved to their superficial position. For example, he argued that the subject of a passive sentence such as (4) originates in object position.

Kim was arrested (4)

This provides an explanation for the fact that 'arrested' is acceptable here without an object although it

normally requires one, as the ungrammaticality of (5) shows.

* The policeman has arrested. (5)

It also provides an explanation for the fact that 'Kim' is understood in the same way in (4) as in (6), i.e., as the person undergoing the action.

They have arrested Kim. (6)

Phenomena like these led Chomsky to propose that sentences have an underlying constituent structure characterized by PS rules and that the superficial constituent structure is derived from this by various transformational rules. Thus, for most versions of TG, the full syntactic structure of a sentence is a sequence of constituent structures. The underlying structure has been called deep structure or D-structure and the most superficial structure, surface or S-structure.

Since 1957 a variety of different theories have been developed within generative syntax and they have been applied to many different languages.

2. Data

Generative analyses make complex predictions about what is and what is not grammatical, i.e., in accord with the speaker's I-language. The most efficient way of investigating these predictions is through the judgments or intuitions of native speakers. Hence, generative syntax has always been based mainly on intuitions. Of course, intuitions have to be treated with caution. The fact that a speaker finds some sentence unacceptable does not necessarily mean that it is ungrammatical for her. A speaker might find (7) unacceptable because it is false, and might find (8) unacceptable because it is misleading. (It is natural initially to assume incorrectly that 'her' forms a constituent with 'contributions to the fund.')

Three fours are thirteen. (7)

Without her contributions to the fund would be quite inadequate. (8)

However, if a sentence is unacceptable and there is no other explanation for the unacceptability, it is reasonable to assume that it is ungrammatical.

None of this implies that other kinds of data, e.g., corpora of naturally occurring speech or writing, cannot be useful. In fact generative syntacticians have often used corpus data. Moreover, there is no alternative to corpus data if the speakers are dead. Hence, generative work on dead languages is inevitably based on a corpus supplemented by intelligent guesses about meanings. Corpus data has also played a central role in generative work on the early stages of first language acquisition.

The emphasis on intuitions has encouraged researchers to work on their own language. In the early years of generative syntax, most researchers were native speakers of English, and as a result English had more attention than any other language. However, as Newmeyer (1986, p. 40) emphasizes, generative syntax

was never limited to English. Moreover, languages other than English have been increasingly prominent since about 1980 as a result of the growing numbers of generative syntacticians who are native speakers of other languages. Work in generative syntax often focuses on a single language, but work that compares and contrasts a pair of related languages is also quite common, and some work deals with a broad range of languages.

3. Structures

As has been noted, most versions of TG assume that the full syntactic structure of a sentence is a sequence of constituent structures. Different versions of TG differ in how complex these constituent structures are. Typically, since the early 1980s, they have been much more complex than (1) as a result especially of the presence of various phonologically empty elements. These include traces, empty categories 'left behind' by movement processes. Thus, (4) will have a trace in object position left behind by movement of the NP 'Kim.' Empty elements also include empty functional categories. Functional categories include C (complementizer) and I (inflection), exemplified by 'that' and 'may' in (9), respectively.

I think that the cat may chase the dog. (9)

It is standardly assumed that a simple sentence contains empty members of these categories. Thus, instead of (1), one might have something like (10)

A variety of functional categories, which are commonly empty, have been assumed in recent TG work.

The assumption that the syntactic structure of a sentence is a sequence of constituent structures has been largely abandoned within the recent minimalist version of TG (Chomsky 1995, Radford 1997). Within this framework, movement processes apply within a constituent before it is combined with another constituent. In (11), for example, 'Kim' is moved to subject position in the subordinate clause before this clause is combined with the verb 'think.'

I think Kim was arrested. (11)

Hence, there is no level of structure after all processes of combination have applied and before any move-

ment processes apply. In other words, there is no level of D-structure.

Much work in generative syntax has argued for different sorts of structures. Standard constituent structures do not incorporate labels like subject and object. It is assumed within TG that these notions can be defined in structural terms. Assuming structures like (10), one might define subject as an NP that is an immediate constituent of IP and object as an NP that is an immediate constituent of VP. Proponents of Relational Grammar (RG) argued in the early 1970s that such functional notions should be primitives and that constituent structure trees should be replaced by relational networks like (12), where 1 and 2 stand for subject and object, respectively, and P stands for predicate:

In early work in RG, the structure of a sentence is a sequence of such relational networks and the order of constituents is only significant in the most superficial network. In more recent work, the structure of a sentence is a single complex network and order is determined by its most superficial properties. (For discussion, see Blake 1990.)

The idea that certain functional notions should be primitives is also a feature of Head driven Phrase Structure Grammar (HPSG) (see Pollard and Sag 1994). Here the structure of a sentence is a single quite simple constituent structure enriched with information about whether a constituent is a head (the constituent which determines the identity of the larger expression, a noun in a noun phrase, a verb in a verb phrase, etc.), a subject, a complement, etc. (Object is not a primitive in HPSG.) A somewhat different position is found in Lexical-Functional Grammar (LFG). Here the full structure of a sentence consists of a fairly conventional constituent structure and a functional structure, in which constituents are identified as subjects, objects, etc. Similarity structures provide a way of capturing the similarities between superficially rather different languages. For example, the following sentences from English, Welsh, and Turkish, which have rather different constituent structures because subject, verb, and object are ordered differently, could have essentially the same functional structure:

The cat saw the dog. (13)

Gwelodd y gath y ci (Welsh) (14)

saw the cat the dog

'The cat saw the dog.'

Kedi köpeğ-i gör-dü (Turkish) (15)

cat dog-ACC see-Past

'The cat saw the dog.'

See Bresnan (2001) for discussion.

An important question about the various forms of generative syntax is: what sorts of categories do they assume? Chomsky (1965, 1970) argued that various syntactic phenomena require the assumption that syntactic categories are complex entities made up of smaller elements normally known as features. This position has been generally accepted since then. However, different approaches differ in how complex their categories are. Categories are particularly complex within HPSG, where, as has been noted, the structure of a sentence is a single quite simple constituent structure. In contrast, they appear to be relatively simple within recent TG, which assumes much more complex structures.

4. Rules and Principles

Like any scientific research, work within generative syntax is concerned to capture whatever generalizations can be found in the data. A consequence of this is that broad general statements are preferred to statements of more limited scope.

In the 1960s and early 1970s TG assumed a variety of different PS and transformational rules. More recently, the various transformations have been replaced by a single rule known as Move Alpha or in recent work just Move. This is essentially a license to move anything anywhere. It interacts with various conditions on movement and the results of movement to allow just the right movement processes. Particularly important in recent work have been certain economy conditions, which prefer simpler to more complex derivations. In much the same way, the various PS rules have been replaced by a few general principles interacting with the categorial makeup of lexical items to give the observed variety of basic, pre-movement structures. In the minimalist version of TG, it is assumed that a single rule of Merge is operative here. A similar position is found in much work in HPSG, in which it is assumed that the variety of syntactic structures are the product of a small number of rules and principles interacting with the properties of lexical items.

Within TG, the move away from large numbers of PS and transformational rules has been associated with a denial that constructions as traditionally understood are of any theoretical significance. Thus, Chomsky remarks that '[t]he notion of construction, in the traditional sense, effectively disappears; it is perhaps useful for descriptive taxonomy but has no theoretical status' (1995, p. 25). However, since the late 1980s a number of syntacticians have argued that it is impossible to characterize the full range of syntactic structures with just broad general principles and individual lexical items, and that it is necessary to recognize constructions with certain properties of their own after all. For example, Sag (1997) argues that data

such as the following require the recognition of a relative clause construction with properties of its own which do not derive either from broad general principles or individual lexical items:

someone on whom I relied (16a)

someone who I relied on (16b)

someone on whom to rely (16c)

*someone who to rely on (16d)

(See Kay and Fillmore (1999) and Culicover and Jackendoff (1999) for similar arguments.)

Different approaches to syntax have taken different views about the nature of rules of syntax. Much work in TG and especially the minimalist framework has treated most rules as procedures for constructing well-formed structures. In contrast RG, HPSG, and LFG have interpreted rules as constraints to which well-formed structures must conform. Consequently these approaches are often described as constraint-based.

A further important issue is: how do grammatical constraints interact? The traditional view is that syntactic structures must conform to all relevant constraints. In contrast, proponents of what is known as Optimality Theory (OT) have argued that constraints are ranked and that a structure may violate a constraint if that is the only way to satisfy a higher ranked constraint. This view of constraints has been very influential within phonology but has also had some influence within syntax. It is combined with TG assumptions in e.g., Grimshaw (1997). Grimshaw argues, for example, that there is a constraint which rules out the movement of constituents. However, a higher ranked constraint requires movement of 'who' to sentence initial position from its underlying position as object of 'to' in the following:

Who did you talk to? (17)

The OT view of constraints has also been combined with LFG assumptions e.g. in Bresnan (2000).

5. Syntax and Other Components of Grammar

A central question for any theory of syntax is: how does the syntactic component of a grammar relate to other components? What is the relation between syntax on the one hand and semantics, morphology, phonology, and the lexicon on the other?

In the late 1960s and early 1970s, the relation between syntactic and semantic representations was a major topic of debate. Proponents of Generative Semantics argued that the deepest level of syntactic representation is a semantic representation. Proponents of Interpretive Semantics rejected this view and argued that semantic representation is derived by rules referring to both deep and surface structure. There are questions as to how different the two positions really were in the early stages of the debate. In the later stages they were clearly distinguished as generative semantics sought to bring more and more linguistic phenomena within the scope of grammar. Generative semantics collapsed in the mid 1970s, partly because of

a realization that some of the phenomena it had brought within the scope of grammar could be handled more satisfactorily within pragmatics. (See Newmeyer 1986, Chaps. 4 and 5 for discussion.) It is now generally accepted within generative syntax that syntactic and semantic representations are rather different, and that there is no one-to-one correspondence between them. The following examples are relevant here:

Have you seen a unicorn? (18a)

Never **have I** seen a unicorn. (18b)

Kim has seen a unicorn and so **has Lee**. (18c)

Had I seen a unicorn, I would have told you. (18d)

All these sentences exemplify what might be called the English auxiliary + subject construction. The key words are in bold. They show that this construction has a variety of different semantic interpretations. (18a) contains an interrogative, the kind of sentence that is normally used to ask a question. (18b) and (18c) contain declaratives, the type of sentence normally used to make a statement. Finally, (18d) contains a conditional clause. Here, instead of auxiliary + subject order, one might have 'if' and subject + auxiliary order.

Since the mid 1970s, most work in TG has assumed that semantic interpretation is based on a level of logical form (LF) derived from S structure by various movement processes. However, Jackendoff (1997) develops a detailed critique of this view. For HPSG, general principles provide a semantic representation for all expressions on the basis of the semantic representations of their constituents. For LFG, semantic interpretation is based on functional structure.

There are also important questions about the relation between syntax and morphology. At various times it has been proposed within TG that word stems may be combined with affixes in syntax. For example, it has sometimes been suggested that an English verb stem combines with the past tense suffix '-ed' through a movement process. This view largely fell from favor in the 1990s and it is now widely accepted even within TG that word-formation is confined to the lexicon.

There are also questions about the relation between syntax and phonology. It has sometimes been proposed within TG that certain movement processes apply within the phonological component. For example, Chomsky (1995, p. 368) proposes that verb-second order in German is a result of a rule applying within the phonological component. The following examples illustrate this phenomenon:

Ich las schon letztes Jahr diesen Roman. (19a)

I read already last year this book

Diesen Roman las ich schon letztes Jahr. (19b)

this book read I already last year

Schon letztes Jahr las ich diesen Roman. (19c)

already last year read I this book

'I read this book already last year.'

Each example has a different constituent in initial position, but all have the verb in second position. It

has also been assumed in much work in HPSG that linear order is solely a property of phonology in the sense that it is not words and phrases but only their phonological properties that are ordered.

Questions also arise about the relation between syntax and the lexicon. Within TG a central issue is where the insertion of lexical items into syntactic structures applies. It has often been assumed that it applies before any movement process. However, it has sometimes been proposed that some lexical insertion may take place after movement. Within HPSG, where lexical categories are quite complex, there are important questions about how generalizations about the categorial makeup of words can be captured. Considerable use has been made of lexical rules deriving lexical entries from lexical entries. More recently, it has been argued that most generalizations can be captured if words are classified in terms of a number of hierarchies of lexical types from which they inherit properties. Thus, 'chased' might be classified as both a transitive verb and a past tense verb and combine the properties of these two types (see Koenig 1999).

There are further issues about the scope of syntax. Should grammars include information about the contexts in which constructions are appropriate? For example, should a grammar include the information that (19) with no overt object following 'beat' is only appropriate in recipes?

Beat until stiff. (20)

It has generally been assumed that such information is something separate interacting with purely grammatical information (see, for example, Culy 1996). However, a number of researchers have argued that it is inseparable from purely grammatical information (see Hudson 1996, Paolillo 2000). Should grammars incorporate statistical information about how likely certain constructions are to occur? For example, should a grammar incorporate the information that (21a) with a clause in subject position is less likely to occur than (21b) with the clause in final position?

That Kim was there is odd. (21a)

It is odd that Kim was there. (21b)

Traditionally, statistical facts about syntactic structures have been seen as a matter of performance, but Abney (1996) argues that such information is part and parcel of grammars.

6. Some Syntactic Phenomena

There are many unresolved issues in generative syntax but a great deal has been learned about both the universal syntactic properties of natural languages and the ways in which they can vary in their syntax.

A major focus of research has been clause structure and a lot is known about the kinds of clause structure that a language may exhibit and about what kinds of analyses might be appropriate. This includes such

matters as the order of subject, verb, and object (see (13)–(15), the realization of tense, mood, and negation, agreement, and case-marking, and the relation between main and subordinate clauses. German, which has verb-final order in subordinate clauses, is relevant here. The following subordinate clause contrasts with the examples in (19):

dass ich schon letztes Jahr diesen Roman las (22a)
that I already last year this book read
'that I read this book last year'

There has also been a great deal of research on noun phrases and a lot is known about such matters as the realization of definiteness, the positioning of adjectives (which normally precede the noun in some languages, e.g., English, but normally follow in others, e.g., Welsh), and the positioning of relative clauses (which follow the noun in English and most European languages but precede in Turkish, Japanese, and Korean).

Perhaps the most important focus of research in generative syntax has been the various kinds of non-local dependencies which natural languages exhibit, which were largely unnoticed in pre-generative work. An important example is the dependency between a clause-initial interrogative element like 'who' and the associated gap which is a feature of many languages. A simple example is (21) in which there is a gap in object position.

Who did Kim annoy? (23)

It has been known since the 1960s and especially since Ross (1967) that these dependencies are subject to various constraints. For example, while (23) is fine, (24) with a gap following 'and' is ungrammatical.

* Who did Kim annoy Lee and? (24)

There are important differences between languages in this area. English allows a gap in prepositional object position. Hence both the following are possible:

Who did you talk to? (25a)

To whom did you talk? (25b)

However, most languages do not allow a gap in prepositional object position. The following Polish examples are typical.

* Kim rozmawiałeś z? (Polish) (26a)

whom you-talked with

Z kim rozmawiałeś? (Polish) (26b)

with whom you-talked

In contrast, English and many other languages do not allow a gap in subject position in a subordinate clause introduced by a complementizer. Hence, the following is ungrammatical:

* Who did you say that wrote this book? (27)

However, some languages do allow this. Thus, the following Italian example is grammatical:

Chi hai detto che ha scritto questo libro?
(Italian) (28)

who have-you said that has written this book

'Who did you say wrote this book?'

As the translation makes clear, an English example is grammatical if there is no complementizer. See Roberts (1997, Chap. 4) for discussion of the extensive work on these matters.

Another important dependency is that between a reflexive pronoun such as English 'himself' and its antecedent, the expression from which it derives its interpretation. In English, while (29a) is acceptable, (29b) is not.

John criticized himself. (29a)

*John said Mary criticized himself (29b)

Thus, the antecedent must be quite close to the reflexive. In other languages, however, a reflexive can be further from its antecedent than in English. For example, in the following Japanese sentence, the antecedent of the reflexive 'zibun' can be either 'Ziro' or 'Taro'.

Taroo-ga Hanako-ni [Ziroo-ga zibun-o
(Japanese) (30)

Taro-NOM Hanako-to Ziro-NOM self-ACC

hihan-sita]-to itta.

criticized-COMP said

'Taro said to Hanako that Ziro criticized self.'

Hanako is not a possible antecedent because it is not a subject. For discussion of these matters, see Roberts (1997, Chap. 3).

Non-local dependencies like these are likely to remain a major focus of research in generative syntax for the foreseeable future.

7. Acquisition and Processing

As has been noted, it is generally accepted within generative work that syntax is concerned with I-language, the cognitive system underlying ordinary use of language. It follows that a variety of data are relevant, for example, facts about acquisition, facts about processing, and facts about pathology.

Acquisition has been a major concern within TG. Since about 1980, it has been argued that the language faculty consists of a set of principles to which all languages conform and a set of parameters which allow a limited amount of variation between languages. For example, it is commonly assumed that there is a parameter distinguishing languages like English, in which interrogative elements appear in initial position, from those like Japanese, in which they appear in the same position as corresponding non-interrogative elements. The following examples illustrate:

John gave the book to Mary. (31a)

Who did John give the book to? (31b)

John-wa Mary-ni sono hon-o

John-TOP Mary-DAT that book-ACC

agemasi-ta-ka. (Japanese) (32a)

give-PAST-Q

'John gave the book to Mary.'

John-wa dare-ni sono hon-o

John-TOP who-DAT that book-ACC

agemasi-ta-ka? (Japanese) (32b)

give-PAST-Q

'Who did John give the book to?'

Within this framework, language acquisition is largely a matter of setting parameters. A great deal of work on the acquisition of syntax has drawn on these ideas. However, some are skeptical. There are two reasons for this. First, relatively little progress has been made towards a plausible set of parameters even for the central or 'core' phenomena of syntax, and languages have a wide range of noncore phenomena, which are also acquired (Culicover 1999). Second, it is clear that setting a parameter is a much more complex matter than it was originally thought to be (Fodor 1998). Nevertheless the idea remains a potentially important one.

Other frameworks have been more concerned with language use. It has been argued that HPSG receives some support from what is known about human language processing. HPSG is a constraint-based framework, in which all rules and principles are on a par and none takes precedence over any other. Pollard and Sag (1994, pp. 11–12) argue that this permits an explanation for some important features of human language processing. They highlight four features. First, it is highly incremental in the sense that 'speakers are able to assign partial interpretations to partial utterances.' Second, it is highly integrative in the sense that 'information about the world, the context, and the topic at hand is skillfully woven together with linguistic information whenever utterances are successfully decoded.' Third, '... there is no one order in which information is consulted which can be fixed for all language use situations.' Finally, it consists of various kinds of activity: 'comprehension, production, translation, playing language games, and the like.' They argue that these features are unproblematic for constraint-based grammars but pose serious problems for other sorts of grammars.

Facts about acquisition and processing are likely to be of continuing importance for the evaluation of proposals within generative syntax.

Genes and Behavior: Animal Models

Explaining behavior in genetic terms is no small task. Behavior draws on the activities of a wide range of genes acting at many different times in an individual's life. Model organisms have provided insight into the role of genes in behavior that have major implications for humans. Many of the mutations and genetic variants (alleles) that affect behavior in *Drosophila* and mice have proved to be subtle changes in genes that, when more severely mutated, produce wider ranging effects. Studies of mutants induced in the laboratory have identified a variety of genes that affect behavior:

genes that regulate other genes (transcription factors), regulatory enzymes (protein kinases), and signaling molecules in the brain (neuropeptides and receptors). Their study has made major contributions to our understanding of biological rhythms, learning, memory, and social behavior, and has helped explain newer findings on naturally occurring variants in behavior.

1. Introduction

Unitary explanations for human behavior have a dismal history in the modern world. Whether economic, cultural, psychological, or genetic, attempts to reduce human behavior to a single influence inevitably fail to give a full account and have often produced distortions with unfortunate political consequences. Charting the relationship between genes and behavior can therefore be a perilous activity. The challenges are many: the difficulty of defining genetic and nongenetic factors, the difficulty of understanding the interactions among these many factors, the many steps that intervene between the expression of a gene and the manifestation of a behavior, and the inescapable fact that each individual is the unique product of a series of historical accidents. Historical uniqueness also applies to nonhuman biological individuals. It is a hallmark of the biological world due to the fact that no particular combination of genes and experiences is ever replicated exactly in nature.

Studies of genes and behavior in model organisms offer one way out of this conundrum. To begin with, it is far easier to control environmental conditions and genetic heterogeneity in the laboratory, and such studies are generally undertaken keeping environmental conditions as uniform as possible and genetic makeup as well defined as possible. But this would be no help if the phenomena and principles are fundamentally different from those of humans. Fortunately, they appear to be similar by an ever-increasing number of criteria. One of the most striking outcomes of modern biology and the sequencing of genomes is the similarity of genes between distantly related creatures. The fruit fly *Drosophila melanogaster* and humans share a great many of the same genes in common. Similarly, they share considerable conservation of metabolic and signaling pathways at the cellular level. Most strikingly, and most relevant for this discussion, there is growing evidence for conservation at the level of behavior and its molecular mechanisms. This has been shown most convincingly, thus far, for several behaviors in *Drosophila*: circadian rhythms (Young 1998), learning and memory (Dubnau and Tully 1998), and most recently sleep (Greenspan and Ferveur 2000). Thus, there is good reason to believe that the characteristics, interactions, and contributions of genes in the behavior of model organisms will provide important guidelines for how to think about the role of genes in human behavior.

Traditionally, there have been two separate, and often hostile, approaches to behavior genetics in model organisms: the measurement and manipulation of naturally occurring variation in laboratory or wild-caught strains, and the isolation and manipulation of newly induced mutations. The former assayed the extent of relatively mild mutational variation that survives in the world and exerts effects on behavior, without being able to know the identity of any of the genes or their mechanism of action. The latter concentrated exclusively on identifying genes and mechanisms subserving particular behaviors, but did so by producing relatively drastic genetic lesions that did not reflect the permissible variation that would have been worked on by natural selection. Both have been relevant to humans, but a synthesis between the two, made possible by recent advances in molecular biology, holds the most promise for useful insights. In this article, a few salient examples of gene effects on behavior are described as illustrations of general principles that are emerging.

2. Severe Single-gene Mutants

2.1 Circadian Rhythms

The clearest contribution single-gene mutants have made is in the realm of identifying individual genes that are central to behavioral mechanisms. The unraveling of the cellular mechanism of the circadian clock began with the discovery of the *period* gene through the isolation of long-day, short-day, and arrhythmic mutants in *Drosophila* (Fig. 1; Konopka and Benzer 1971) and proceeded with the isolation and cloning of additional mutants in flies, fungi, and mice (Young 1998). What has emerged is a picture of the circadian clock as a feedback loop in which each cell counts out its own 24 hour period by means of an oscillating cycle of gene readout in which some of the products accumulate up to a point, then begin to dampen their own synthesis through a series of time delays between the various stages of gene expression: transcription, translation, and import back into the nucleus (Fig. 1). This serves as the central regulator for specific implementation of rhythmic activities. The cellular mechanism of the circadian clock, as well as the clock's phenomenology, appears to be universal in the biological world and many of the actual genes involved, such as *period*, are well conserved between flies and mammals. The human relevance is thus transparent.

2.2 Learning and Memory

Learning and memory have many features common to flies, rodents, and humans. Behaviorally, all are

Figure 1

Top: circadian locomotor activity in normal *Drosophila* and in mutants of the *period* gene as measured in an activity monitor in the absence of a day/night cycle of light and darkness. Heavy traces represent activity, with the clock's day length indicated underneath (Source: *Proceedings of the National Academy of Sciences USA* 68: 2112–6. Reproduced with permission).

Bottom: conservation of molecular mechanisms of the circadian clock between flies and mammals. PER = *period* gene, TIM = *timeless* gene, CKIε = casein kinase Iε gene (Source: *Science* 2000 288: 451–3. Reproduced with permission)

capable of associative conditioning and the memory that is induced shows multiple phases that can be distinguished by pharmacology and by training regimen (Dubnau and Tully 1998). In the fly, learning takes the form of distinguishing between two odors and avoiding the one that has previously been paired with electric shock. Long-term memory is produced by repeated training trials separated by suitable time intervals. The original *Drosophila* learning mutant, *dunce* (Dudai et al. 1976), is defective in initial acquisition as well as in subsequent retention of the learned behavior (Fig. 2). Care was taken to ascertain that these mutant flies were normal in all other relevant

faculties that are required for the learning task: olfaction, locomotor activity, and shock reactivity.

The product of the *dunce* gene was subsequently identified as an enzyme that is part of the signaling cascade in nerve cells that utilizes the intracellular messenger molecule cyclic AMP (Fig. 2). The gene encodes a cAMP-phosphodiesterase, the enzyme that degrades cyclic AMP. Mutations in other components of this signaling system, *rutabaga* in the synthetic enzyme (adenylate cyclase), and *Dco* and *RI* in the key enzyme regulated by cyclic AMP (cAMP-dependent protein kinase), were subsequently shown to also affect learning and memory in the fly (Dubnau and Tully

Figure 2

Top: the cAMP signaling pathway in memory formation. AC = adenylyl cyclase (*rutabaga* gene), PDE = cAMP phosphodiesterase (*dunce* gene), PKA = cAMP-dependent protein kinase (*DCO* and *RI* genes), CREB = cAMP-response-element-binding protein (*dCREB* gene) (source: *Nature Neuroscience* 1998 1: 543–5. Reproduced with permission). Middle: memory is consolidated via distinct phases that are genetically and pharmacologically dissectable in *Drosophila* and in mammals: short-term memory (STM), middle-term

1998). The cyclic AMP signaling system had already been implicated in neuronal plasticity as central to the mechanism that modifies efficacy at synapses in the circuitry underlying learning. The isolation of mutants affecting the system from unbiased, open-ended mutant screens and the demonstration that they affected classical conditioning in the intact animal gave universality to the finding. Mouse mutants in the synthetic enzyme (adenylate cyclase) show analogous deficits in learning (Silva et al. 1998). The relevance to humans has been borne out by the fact that there are currently several memory enhancement drugs in clinical trial that target cAMP phosphodiesterase.

As additional mutants accumulated, comparison of the time course of memory decay revealed some interesting differences between them (Fig. 2), suggesting that they differentially affected memory retention. This suggestion received major support from studies of another component of the cAMP signaling system: the *Creb* (cAMP-response-element-binding) protein that regulates genes induced by cAMP. *Creb* exists in both repressor and activator forms. A repressor form of the gene, when engineered to be expressed in the fly just prior to training, completely blocks the formation of long-term memory while permitting normal short- and medium-term memory (Dubnau and Tully 1998). In contrast, an activator form of the gene, when engineered to be expressed just prior to training, produces long-term memory after a single trial, in contrast to the usual 10 trials with intervals that are required to induce long-term memory (Fig. 2). These findings not only placed the differential genetic effects on memory phases on firmer ground, they were also subsequently extrapolated to mice and rats (Silva et al. 1998). A *Creb* mutant in the mouse that reduces, but does not eliminate, repressor activity fails to form long-term memory in a fear-avoidance paradigm. Analogous results have been obtained in the rat after injection of a *Creb* gene blocker (anti-sense RNA) to specifically reduce levels of the protein.

A variety of other mutants disrupting learning that also affect synaptic efficacy have also been obtained in the fly and mouse, including those affecting other regulatory enzymes (calcium/calmodulin-dependent protein kinase, *fyn* kinase) and receptors (NMDA and acetylcholine). The studies of the cAMP cascade stand out, however, for the depth to which they have taken the analysis through their insight into the mechanism of differential memory phases.

memory (MTM), anesthesia-resistant memory (ARM), and long-term memory (LTM) appear sequentially, and each has a progressively slower rate of decay (source: *Trends Neuroscience* 1995 18: 212–7). Bottom: a genetic model of information flow showing where in the pathway single gene mutant and pharmacological disruptions have their primary effects (source: *Cell* 1994 79: 35–47. Reproduced with permission)

2.3 Social Behavior

Genetic studies of social behavior have great relevance for humans and for considerations of human evolution. A productive avenue into this question has been taken in rodents, based on neuroendocrinological studies of the behavioral effects of oxytocin and vasopressin. Administration of these hormones produce complementary effects on a variety of behaviors including affiliative, sexual, maternal, territorial, and aggressive behavior as well as on social memory (Young et al. 1998). The detailed neural mechanisms for the hormones' actions have yet to be elaborated. A mouse mutant that lacks oxytocin altogether (*Oxt*^{-/-}) shows a distinct deficit in social memory as reflected by male olfactory investigation of a female in repeated exposures. The effect is more selective than predicted from the range of effects when oxytocin is administered. Moreover, *Oxt*^{-/-} mutant mice are normal for olfactory responses to other, nonsocial odors, and normal for learning tasks unrelated to this social behavior.

An increase in aggression between males was also observed in the oxytocin-deficient mice. This observation falls into line with a growing number of other mouse mutant studies reporting increases in aggression. These range from mutants in receptors for serotonin or adenosine, to synthetic enzymes for the neurotransmitters GABA or nitric oxide, to regulatory enzymes (calcium/calmodulin-dependent protein kinase II) to cell adhesion molecules. In contrast to mutants of circadian rhythms or of learning and memory, there seem to be a great many genetic lesions that produce aggression in mice. When one encounters such promiscuity in genetics, it is usually diagnostic of a system that is subject to many nonspecific kinds of disruption, with all of the caveats to interpretation that accompany effects on such a system, as opposed to a sensitive indicator of key mechanistic components.

2.4 Range of Action of Behavioral Genes

The foregoing examples highlight the mechanistic insights that have been gained from behavioral studies of laboratory-induced mutants. An important criterion for these studies was the relative refractoriness of the behavior to mutational disruption: mutations in most genes do not affect these behaviors. The question then arises of the relative specificity of these genes to the behaviors they disrupt. Are these 'genes for' behaviors such as rhythms, memory, or social life, as have often been alluded to in evolutionary discussions of behavior (e.g., Wilson 1978)? For the mutants described above, as well as for the vast majority of behavioral mutants studied in both flies and mice, the answer appears to be negative. By and large, the genes that produce behavioral mutants are not limited to affecting only one behavior or only one aspect of the

animal. They exert influences over many facets of the organism's biology (the genetic term for this is 'pleiotropy').

The archetypal circadian rhythms gene, *period*, regulates the song produced by a male fly during courtship as well as its 24-hour rhythms (Greenspan and Ferveur 2000). The male's song, produced by vibrating the wing, consists of a series of 'pulses' which sound like bumps occurring at the rate of about 30 per second. The rhythm lies in the slight but regular variation in the interval between pulses (Fig. 3) as the male gradually increases then decreases this interval to produce a smoothly wavering song over a period of approximately 60 seconds. Female flies respond to the male's song by becoming more receptive to their courtship advances. Mutants in the *period* gene that affect the circadian rhythm have corresponding effects on song rhythm such that long-day mutants have an 80-second rhythm, short-day mutants have a 40-second rhythm, and arrhythmic mutants have no regular rhythm (Fig. 3).

The *period* mutant also affects timing on scale greater than the 24-hour period: short-day and long-day mutants have a shorter and longer developmental time course, respectively, from egg to adult compared to normal controls. These effects of *period* occur on timescales an order of magnitude larger (10 days) or several orders of magnitude smaller (60 seconds) than the 24-hour clock. Distant as they are from the circadian timescale, they are timing mechanisms nonetheless and therefore not outside of the realm already affected by the mutants. It remains a mystery, however, as to how the relatively slow mechanism of feedback onto gene expression (Fig. 1) can also regulate a 60-second rhythm. One clue comes from a more divergent consequence of *per* and several other rhythm mutants that was revealed in pharmacological studies of cocaine responsiveness, in which they fail to become sensitized. There is no circadian or timing-dependent aspect to this phenomenon. Instead, it appears to involve a different use of their function as gene regulators: induction of the enzyme responsible for sensitization fails to occur in the mutants.

Mutants affecting learning and memory are no less wide-ranging. The *dnc* mutation produces sterility in female flies, defects in embryonic development, and shorter lifespan. The most severe *Creb* mutants are lethal in both flies and mice. Finally, *Oxt*^{-/-} female mice are defective in lactation, as well as in infant vocalization.

The conclusion that genes producing behavioral mutants are wide-ranging in their effects (pleiotropic) is based on a large enough sampling of mutants from two different organisms to consider it likely to be the rule rather than the exception (Hall 1994, Pflugfelder 1998, Mouse Knockout & Mutation Database, <http://research.bmn.com/mkmd/>). It would be a mistake, therefore, to ignore it in analyses of how genes affect behavior, or in considerations of what

Figure 3

Rhythmic oscillations of the courship song of normal (per^+) male *Drosophila melanogaster* and short-day (per^s), long-day (per^l), and arrhythmic (per^0) mutants of the *period* gene. The song consists of pulses of sound lasting 33–7 milliseconds (ms) produced by vibration of the wing. The interval between these pulses (interpulse interval, IPI) oscillates regularly with a periodicity (τ) indicated in seconds (s) (source: *Proceedings of the National Academy of Sciences USA* 1980 77: 6729–33. Reproduced with permission)

kinds of behavioral variation are evolutionarily permissible. A sobering conclusion that emerges from this recognition is that the path from gene to behavior is extraordinarily complex, winding its way through all possible levels of biological organization, from gene regulation through cellular biochemistry, through communication between cells, through large-scale patterns of activity in the nervous system, finally emerging as the manifest behavioral output itself.

3. Mild Natural Variants

Natural variation in behavior exists between and within species, and provides a major substrate for natural selection. Divergence in behavior between species is thought to be a critical component of the speciation process itself, whereas behavioral variants within a species provide it with the flexibility needed to weather the unpredictability of external conditions. Until recently, the identity and mechanistic nature of

these behavioral variants has been a black box. Analyses were confined to statistical treatments of overall behavioral variation (e.g., Ehrman and Parsons 1981). A growing list of these variants has now been characterized molecularly and functionally. As foreshadowed by the experience with laboratory mutants, many have proved to be subtle variations of genes that are capable of more severe and wider ranging effects.

3.1 Differences Between Species: Biological Rhythms

The courship song produced by *Drosophila* males is species-specific and plays a role in species recognition for mating (Greenspan and Ferveur 2000). The courship song of *Drosophila melanogaster* differs from that of the closely related species *Drosophila simulans* in several parameters, the most important of which is its rhythmic oscillation (see Sect. 2.4). The *D. melano-*

Figure 4

Anatomical distribution of the V_{1a} vasopressin receptor in the brain of the montane vole (top) and the prairie vole (bottom). Binding is more intense in the lateral septum (LS) of the montane vole but not the prairie vole, and in the diagonal band (DB) of the prairie vole but not the montane vole. Similar differences exist throughout the brain (source: *Nature* 1999 **400**: 766–8. Reproduced with permission)

gaster oscillation has a 60-second period, whereas the *D. simulans* oscillation has a 35-second period. This rhythmic difference is due to a subtle difference in the sequence of the *period* gene between *D. simulans* and *D. melanogaster*: a short segment of the protein coding region that contains repeats of the amino acid pair threonine and glycine (Fig. 3). A *D. simulans period* gene transferred into *D. melanogaster* that lack a *period* gene confers a characteristic *D. simulans* song rhythm (Wheeler et al. 1991). More specifically, a synthetic gene consisting of the entire *D. melanogaster period* gene, except for a segment of *period* from *D. simulans* consisting of a small region that is highly variable among many *Drosophila* species, also gave the same characteristic *D. simulans* song (Fig. 3). The remarkable feature of this finding is that one portion of the sequence was capable of diverging in a species-

specific manner, while the rest of the gene stayed constant enough to retain the normal 24 hour circadian rhythmicity.

3.2 Differences Between Species: Social Behavior

Differences in social behavior are marked in the animal kingdom even between closely related species. Two species of North American vole illustrate this point. The prairie vole (*Microtus ochrogaster*) is monogamous, biparental, and highly social. They contrast with the montane vole (*Microtus montanus*), which is promiscuous, maternal, and minimally social (Young et al. 1998). The hormones oxytocin and vasopressin exert complementary effects on these behaviors in the

Figure 5

Top: latitudinal cline in distribution of the (Thr-Gly)₁₇ (dark gray) and (Thr-Gly)₂₀ (light gray) alleles of the *period* gene. The (Thr-Gly)₂₀ allele, which is more prevalent in the north, is more robust in its temperature compensation. Numbers indicate chromosomes tested (source: *Proceedings of the Royal Society of Biological Science* 1992 **250**: 43–9. Reproduced with permission). Bottom: temperature compensating ability at 18°C (box) and 29°C (arrowhead) of alleles of the *period* gene differing in the length of their Thr-Gly repeats. The arrow reflects the change in direction of the period at 29°C. The (Thr-Gly)₂₀ variants show almost identical periods at the two temperatures (source: *Science* 1997 **278**: 2117–20. Reproduced with permission)

prairie vole, similar to their effects in rats and mice (see Sect. 2.3). Moreover, the anatomical distribution of oxytocin and vasopressin receptors in the brain differs markedly between the two vole species (Young et al. 1999).

Vasopressin administration stimulates affiliative behavior in prairie voles but not in montane voles, nor in mice. When a prairie vole vasopressin receptor gene (V_{1a}) was transferred into mice, thereby creating an anatomical distribution similar to that of the prairie vole, the mice began to exhibit affiliative behavior in response to vasopressin (Fig. 4). This result argues that changing the pattern of V_{1a} distribution is sufficient to alter this behavior. This interpretation is further supported by the fact that the V_{1a} receptor genes are virtually identical between the two vole species that differ in affiliative behavior, except for the presence in prairie voles of a small segment in the region of the gene that is likely to regulate its expression. The presence of this DNA segment correlates well with behavioral and anatomical features of two other species, the pine vole (*Microtus pinetorum*), which is like the prairie vole behaviorally as well as in its anatomical and molecular characteristics of V_{1a} , and the meadow vole (*Microtus pennsylvanicus*), which is like the montane vole in all of these respects. Thus, it appears that subtle evolutionary tinkering with the expression pattern of the vasopressin receptor V_{1a} may account for some of the differences in social behavior between these rodent species.

3.3 Differences Within Species: Circadian Rhythms

If the genetic differences underlying behavioral variation between species are subtle, then those underlying variation within species are downright esoteric. The segment of the *period* gene that was sufficient to transfer a *D. simulans* courtship song rhythm into *D. melanogaster* also varies within the *melanogaster* species. Two versions (alleles) of the gene predominate: one containing 17 repeats of the pair of amino acids threonine and glycine (Thr-Gly)₁₇, and one containing 20 repeats (Thr-Gly)₂₀ (Costa and Kyriacou 1998). These two alleles are nonrandomly distributed in the wild, following a north-south gradient (known as a 'latitudinal cline') from northern Europe down to North Africa with (Thr-Gly)₂₀ predominating in the north and (Thr-Gly)₁₇ predominating in the south (Fig. 5). Distributions of this sort are traditionally explained as an adaptive response to climatic variation.

If these variants are undergoing selection, then the functional differences between them become relevant. A clue to such a functional difference was seen in tests of temperature compensation, one of the distinctive features of circadian rhythms which allow cold-blooded organisms to maintain their 24 hour cycle at

different temperatures. Flies carrying the northerly (Thr-Gly)₂₀ allele exhibit more robust temperature compensation than those with the more southerly (Thr-Gly)₁₇ allele (Fig. 5). The temperature range is much greater in the north and presumably imposes greater demands on the temperature-compensating ability of the clock. The size of the effect is small, perhaps reflecting a tradeoff between the temperature compensation and conservation of the overall 24 hour rhythm.

3.4 Differences Within Species: Foraging Behavior

Most natural variation in behavior is not primarily attributable to any single gene. Where multiple genes contribute, the effect often disappears when they are separated from each other in the crosses required for genetic mapping. An exception to this trend is the *foraging* gene that affects food search behavior by *Drosophila* larvae.

Natural populations of *D. melanogaster* harbor two larval types: rovers, who search widely for food, and sitters, who do not (Sokolowski 1998). The difference is not merely locomotor because it is expressed only in the presence of food. Genetic mapping revealed it to be due primarily to a single gene, *foraging*, and molecular analysis showed it to be an enzyme involved in regulating many physiological processes, cGMP-dependent protein kinase (Fig. 6). Severe mutations of the *foraging* gene are lethal. The detailed mechanism through which the enzyme alters neuronal and behavioral activity is not known, but it appears to regulate neuronal thresholds.

A gene whose product has as wide-ranging functions as the enzyme encoded by *foraging* must have severe constraints on the kinds of variation that are viable and permissible. The explanation, in this case, appears to be that the magnitude of the natural enzyme variation is relatively small: rovers have 12 percent more activity of the enzyme cGMP-dependent protein kinase than sitters and the levels of its protein and mRNA are correspondingly higher in rovers vs. sitters (Osborne et al. 1997). This small increase thus appears to be sufficient to make a very distinctive difference in behavior, while not seriously impairing viability or obligate functions of the gene.

3.5 Genetic Basis for Selected Behaviors

Artificial selection in the laboratory has been the conventional method for detecting the presence of naturally occurring genetic variation in behavior (Ehrman and Parsons 1981). While such variation has been clearly demonstrable in virtually every behavioral selection attempted, from maze learning in rats to

Figure 6

Top: larval foraging behavior of sitter and rover variants in *Drosophila*. Records of the trail left by larvae on a petri dish covered with yeast. Bottom: Bimodal distribution of sitter (S/S) and rover (R/R) larvae in a natural population of *Drosophila* (source: *Behavioral Genetics* 1980 **10**: 291–302. Reproduced with permission)

gravity response in *Drosophila*, there has been no way to identify any of the relevant genes. The behavioral differences are generally due to the contribution of many genes, usually of rather small effect, and thus refractory to conventional mapping techniques. Only their approximate number and putative interactions could be estimated from statistical analyses of selected lines and of F1, F2, and backcross progeny. The advent of QTL mapping (quantitative trait loci) using a widely distributed set of DNA markers has improved the prospects for mapping of such polygenic traits, but significant difficulties still attend the identification of the contributing gene itself.

The identification of natural variants in the *foraging* locus created the possibility of testing directly its response to selection under conditions likely to be relevant to its role in the wild: differences in population

density. In two different experiments, strains of flies mixed for rovers and sitters were cultured at high or low larval density for over 250 generations. In both cases, the resulting high-density strains had become predominantly rover in behavior and the low-density strains predominantly sitter (Sokowloski 1998). That is, selection had eliminated the vast majority of one *foraging* allele from each population.

These findings contrast with those on intraspecies variants of the *period* gene, where the possibility of selection between alleles was inferred from their geographical distribution and made more plausible by the subtle functional differences between alleles. The conditions necessary to impose selection on the *foraging* locus are easier to imagine and implement, and the outcome leads to the conclusion that being genetically rover is advantageous under crowded

conditions, whereas being genetically sitter is advantageous under conditions of low density.

The most common sort of selection experiments have also been the most refractory to analysis. The ability to analyze the genetic basis of the strains whose behavior results from selection for variation in many genes is likely to improve with the advent of genome-wide capabilities to measure differences in gene activity (White et al. 1999). This will likely make it feasible to identify genetic differences between selected strains or natural variants based on detecting asymmetries in the activity patterns of specific genes.

4. Implications for Humans

The foregoing discussion highlights explicit and implicit aspects of the relevance to humans of gene/behavior studies in model organisms. Explicit is the conservation of function (e.g., *period* for circadian rhythms, *Creb* for long-term memory), as well as the wide-ranging nature of the genes involved. Implicit is the importance of specific context in any given gene's effect on behavior and the humility with which the question of genetic influences on behavior must be approached.

4.1 Promiscuity of Behavioral Genes

The breadth of action of the genes influencing behavior has significant implications for speculation about human behavior and its evolutionary origins. The extent to which a gene can vary is constrained by how widely its effects will radiate through the organism. For genes with wide-ranging (pleiotropic) function, this means that variants with severe effects on the gene's function are likely to have deleterious consequences. In this light, evolution looks like a balancing act, selecting for genetic variants that do the most to help the organism without doing too much harm. Sometimes this may take the form of a highly restricted alteration in a gene (e.g., anatomical distribution of V_{1a} in prairie vole vs. montane vole) and other times as a tradeoff between utility and loss of fitness (e.g., adult sluggishness in sitter). An important implication of this point is that some traits will be carried along for no reason other than their connection to some other effect of the same gene. A further corollary is that not all existing traits have been selected for themselves, and thus cannot be automatically assumed to have adaptive value.

4.2 Context

The nature/nurture dichotomy is the traditional way to describe the putative role of context in affecting gene action, but it only conveys one axis of the

problem. Context is as much genetic, consisting of the particular constellation of alleles that an individual possesses, as it is nongenetic, consisting of the myriad environmental factors, both physical and social, that an individual experiences in a lifetime. Interactions between the two further complicate the matter. This means that different alleles of a given gene will not have the same effect in all contexts. A clear example of this was described earlier in the differential ability of two naturally occurring *period* alleles to compensate for temperature fluctuations (see Sect. 3.3). The (Thr-Gly)₁₇ allele makes the individual more sensitive to its external environment than (Thr-Gly)₂₀. This has important implications for analysis of the genetic contributions to particular behaviors (e.g., heritability).

The effect of an allelic variant on a behavior is also heavily dependent on the genetic context. This is known throughout the genetics literature as the sensitivity of a mutation to 'genetic background.' Genetic background is simply another way of describing the particular constellation of alleles at other loci present in the individual. This is exemplified in the interaction between alleles of the *foraging* locus and those of the *Chaser* locus, a gene identified based on the ability of certain of its alleles to convert sitters into rovers. In other words, mild alleles of the sort that occur naturally are even more susceptible to variations in genetic context than severe alleles.

4.3 Testability

Human genetics is primarily a correlative science. This applies as much to behavioral genetics as to any other variety. Hypotheses can be tested against observational data, but actual manipulations or 'test crosses' cannot, of course, be carried out. One of the principal virtues of model organisms, therefore, is experimental testability of gene function and interaction. Given the increasing evidence for conservation of genetic function between species as distant as *Drosophila* and mammals, they represent an important contribution to understanding and interpreting possible genetic influences on human behavior. One of these contributions should be a sense of humility before the problem. As the foregoing discussion elaborates, the road from gene to behavior is neither simple nor direct, and is difficult enough where experimental testing is possible. The difficulties are multiplied for natural variants because of the subtlety of their effects and their consequent elusive nature.

The universal importance of context in the action of genes on behavior presents further obstacles to a simple formulation. If combinations of alleles will give different effects due to interactions with each other and with environmental variables, then the problem takes on the aspect of an infinitely sliding scale. Whenever one variable is changed, the relative effect of many of the others may also change. This mallea-

bility is no doubt a source of robustness in biological systems, as well as a source for evolutionary change. Understanding it remains one of the central questions in the behavioral sciences.

Genes and Culture, Coevolution of

Cultural transmission can be roughly defined as the transfer of information between individuals by social learning. Genes used to be—and for most species still are—the only means available for the accurate transfer of information across generations. In species where cultural transmission has developed, notably the human, interactions can occur between the two inheritance systems. Gene-culture coevolution refers to the evolutionary phenomena that arise from these interactions.

1. Quantifying Cultural Evolution

The principles of genetic evolution are well established. By contrast, cultural evolution is more contentious. The information that forms the basis of culture is transmitted by social learning—instruction by, or imitation of, other individuals. This information must somehow reside in the brain, but it is unclear how this is achieved. Nevertheless, just as significant insights into genetic evolution were obtained before DNA was identified as the genetic material, cultural evolution can be studied without waiting for definitive progress in cognitive science.

Central to the modern treatment of cultural evolution is the concept of a ‘meme’ (Dawkins 1976; also ‘culturgen’ of Lumsden and Wilson 1981). The meme is defined, in analogy with the gene, as a unit of information that is transmitted by social learning. Surnames are a good example of a meme that is highly congruent to a gene. Surnames are well-defined units that in many societies are transmitted from father to son, just like a gene on the Y chromosome. However, most memes cannot be delimited as precisely, so that copies of the same meme in two individuals may differ in content. Consider the ambiguity of ‘how to use a personal computer.’ In addition, although the meme is defined as information, it is usual to regard as a meme the more readily observable behavior that the information regularly induces.

Memes also differ from genes in that there is a multiplicity of transmission pathways. ‘Vertical’ transmission from parents to their children and ‘horizontal’ transmission between individuals of the same generation have received the most attention.

The classical, although by no means the first, quantitative study of horizontal transmission is due

two rural sociologists, Ryan and Gross (1943), who investigated the spread of hybrid seed corn. This striking technical advance in agriculture was introduced to Iowa farming communities in the late 1920s. Ryan and Gross learned through retrospective interviews when each farmer had adopted this innovation. By the time these interviews were conducted in 1941, adoption was almost complete. The cumulative number of adopters follows an S-shaped curve, which resembles the logistic curve. It is not known whether this resemblance is more than superficial.

The study of vertical transmission begins with Feldman and Cavalli-Sforza (1976). Assume two alternative memes, such as whether or not salty foods are eaten habitually. In general, denote the alternative memes by H and h . Then, the four possible combinations for husband and wife are $H \times H$, $H \times h$, $h \times H$, or $h \times h$. If children acquire their memes by vertical transmission—by social learning from their parents—the four types of families should produce different frequencies of H and h children. More specifically, if the probabilities of an H child in the four types of families are b_3, b_2, b_1 , and b_0 , respectively, then the inequalities $b_3 \geq b_2$, $b_3 \geq b_1$, $b_2 \geq b_0$, and $b_1 \geq b_0$ should hold. A survey of Stanford University students and their parents showed that, for the example of habitual salt use, $b_3 = 60$ percent, $b_2 = 36$ percent, $b_1 = 65$ percent, and $b_0 = 26$ percent, suggesting a fairly strong maternal influence (Cavalli-Sforza and Feldman 1981).

Cultural evolution is said to occur when the frequency (proportion) of a meme in a population changes. Memes are in principle subject to the same evolutionary forces as genes—the analog of mutation, random drift, natural and sexual selection. For example, the meme for habitual salt use may raise mortality and as a result be selected against. On the other hand, an important force acting on memes to change their frequencies, but one not normally applicable to genes, is transmission bias. The spread of hybrid seed corn in the Iowa communities is an example of cultural evolution by transmission bias, since nonadopters are more likely to be converted to adopters than vice versa.

Having briefly described cultural evolution, let us now consider in detail two well-documented instances of an interaction between genetic and cultural evolution. Many more case studies of gene-culture coevolution are discussed in books by Lumsden and Wilson (1981), Boyd and Richerson (1985), and Durham (1991).

2. Adult Lactose Absorption and Drinking the Milk of Domesticated Animals

Perhaps the paradigmatic example of gene-culture coevolution is the process whereby the genetic ability of adult humans to digest lactose (adult lactose

absorption) became associated with their consumption of animal milk.

The fresh milk of domesticated animals, such as goats, camels, and cows, has been an important food in northern Europe and in pastoral societies for about 5,000 to 6,000 years. By contrast, animal milk is not traditionally used by hunter-gatherer and nondairying agricultural groups.

Milk contains a sugar, lactose, which must be digested by the enzyme, lactase, before it can be absorbed in the small intestine. All normal infants have high lactase activity, but during development the majority of individuals experience a drop in lactase activity, which is fully manifest by school age. Hence, adults are of two types—lactose absorbers who have high lactase activity, and lactose malabsorbers who have low lactase activity. Data from families and individuals of mixed ancestry indicate that adult lactose malabsorption is inherited as a simple Mendelian recessive.

When milk is consumed in quantity by a lactose malabsorber, the lactose passes undigested into the colon. Symptoms of intolerance such as severe diarrhea can result. Malabsorbers may also be less efficient at absorbing the calcium in milk.

Many researchers have noted the following pattern. First, populations with high frequencies of absorbers were traditionally dependent on animal milk. Second, populations not known to have used milk have low frequencies of absorbers. The highest frequencies are observed in northern Europe among the Finns, Danes, and Germans. Comparable frequencies are seen among the nomadic tribes of the north African and Arabian deserts, such as the Beja, Tuareg, and Jordanian Bedouin. On the low end are groups like the Japanese, the Pima Indians of Arizona, and the Yoruba of central Africa, none of which have a history of dairying. Although the covariation is impressive, it is not the case that all dairying populations have a high frequency of absorbers, and numerous 'exceptions' can be found around the Mediterranean. Hence, populations with a high frequency of absorbers apparently form a subset of those with a history of milk use.

Lactase activity drops at weaning in nonhuman mammals, suggesting that our ancestors were also malabsorbers. This inference and the above observations led to the proposal of the 'culture-historical' hypothesis, which posits that lactose absorbers gained a selective advantage when children and adults began to drink the milk of domesticated animals (Simoons 1970, McCracken 1971, Kretchmer 1972). Hence, the frequency of absorbers increased by natural selection in populations that had access to animal milk—or at least in some of them.

A variant of the culture-historical hypothesis is the 'calcium absorption' hypothesis (Flatz and Rotthauwe 1973). Whereas the former attributes a general nutritional advantage to the use of milk, the latter claims

that calcium was all important. Recall that high frequencies of absorbers are observed in northern Europe. Here, solar radiation is weak, and the calcium in milk may have provided protection from rickets.

A different hypothesis called the 'reverse cause' argument suggests that dairying was adopted by precisely those populations that could tolerate lactose. The genetic differentiation of human groups is assumed to have occurred before the invention of dairying by some process unrelated to milk use. In particular, drinking milk is not assumed to have conferred a selective advantage.

The two major proposals, the culture-historical hypothesis and the reverse cause argument, thus differ in the temporal priority given to cultural or to genetic change. (A third possibility is that they occur together, in which case the process would be truly coevolutionary.) However, the prevailing view in modern anthropology is that the genetic differences (if any) among human populations are not the cause of the cultural differences among those populations. In particular, the claim that a preexisting genetic contrast, such as in the prevalence of lactose absorbers, would have produced divergent cultural evolution is anathema. Hence, the reverse cause argument, in straying from dogma, has already acquired one strike against it.

More substantively, Holden and Mace (1997) have recently used phylogenetic comparative methods to show that the cultural evolution of milking probably preceded the genetic evolution of lactose absorption. In a sense, this outcome is anticipated by the fact noted above that a high frequency of absorbers is observed in only some of the dairying populations and in none of the nondairying ones. In addition, this analysis reveals that statistical evidence for the calcium absorption hypothesis is weak. Instead, the parsimonious explanation is that northern European populations are similar in having high frequencies of absorbers because they share a relatively recent common ancestral population. On the other hand, the culture-historical hypothesis is supported by a global phylogenetic analysis.

In the previous section, it was explained how a useful innovation may spread by horizontal transmission. Presumably, drinking the milk of domesticated animals can be regarded as a useful innovation, at least for absorbers. Hence, in societies where domesticated animals were available, as short a time as one generation may have sufficed for dairying to become established. If so, the claim that milk use spread first and lactose absorption evolved later may be valid.

Against this, however, the possibility must be entertained that drinking milk was an unattractive option to a society dominated by lactose malabsorbers. In other words, there may be a genetically determined transmission bias against milk use among malabsorbers. Studies conducted in modern industrial

societies reveal little evidence of a clearcut difference in preference for milk between absorbers and malabsorbers. This may be because the availability of many foods, and especially the presence of lactose as an additive, makes it difficult for malabsorbers to associate the symptoms of intolerance with the ingestion of milk. By contrast, in traditional societies where food choices are limited, a difference in preference may be easier to demonstrate.

3. Recessive Hereditary Deafness and Sign Language

The incidence of profound childhood deafness is about one in 1,000. About one half of these cases is hereditary, with recessive genes in particular being responsible for about one third of the total incidence. Estimates of the number of recessive genes range from five to more than 30 depending on the population. Homozygosity for (having two copies of) any one of these genes results in deafness. Among the nongenetic causes are maternal rubella, neonatal jaundice due to rhesus incompatibility, and otitis media.

Sign languages are the naturally occurring forms of linguistic communication among the profoundly deaf. A sign language is not a collection of gestures. Rather, grammatical rules govern the production of words and the expression of thoughts. There are many sign languages just as there are many spoken languages. Sign languages are natural languages, whose origins cannot be determined and which have existed in the deaf communities possibly for many generations.

When deafness is recessive, an affected child may be born to normal heterozygous (having one copy of a gene for deafness) parents. In fact, about 90 percent of deaf children have hearing parents. A hearing child of hearing parents will learn the spoken language used by the parents. Vertical transmission plays an important role in the transmission of a spoken language across generations. By contrast, a deaf child of hearing parents usually cannot learn the local sign language from the parents, simply because the latter do not know it. Hence, the transmission of a sign language across generations is complicated by the fact that a significant fraction of profound childhood deafness is caused by recessive genes. Aoki and Feldman (1991), therefore, suggest that a sign language is a good example of a meme whose transmission and social distribution are subject to strong, if indirect, genetic constraints.

Another factor that interferes with the vertical transmission of a sign language is natural selection against the deaf. Selection is apparently due, not to higher mortality, but to lower marriage and fertility rates among the deaf. In the 1950s a deaf person in Northern Ireland or Japan could expect to have about 30 percent as many children as a hearing person. These observations suggest that a sign language cannot

persist under vertical transmission alone. This prediction is supported by a simple model, which is presented below to illustrate some of the principles of gene-culture coevolution.

Assume the following: (a) One gene causing deafness segregates in the population. There are two alleles (alternative states of a gene), the normal allele, and the mutant allele that causes deafness when homozygous; (b) Nongenetic causes of deafness are ignored; (c) The deaf suffer a higher mortality than the hearing, which is contrary to fact, but has approximately the same evolutionary effect as lower nuptiality or fertility. The relative viability of a deaf person is v ; (d) The recessive allele causing deafness arises by mutation in each generation; (e) Deaf persons tend to marry other deaf persons. The rate of assortative mating is m ; (f) Only the deaf use sign language. Sign language is transmitted vertically from signing parent(s) to deaf children. A deaf child acquires sign language with probability c , kc , or 0 depending on whether there are two, one, or no signing parents. The correspondence with the parameters of Sect. 1 is $b_3 = c$, $b_2 = b_1 = kc$, $b_0 = 0$. When the child is hearing, $b_3 = b_2 = b_1 = b_0 = 0$.

Assumptions (a)–(e) and assumption (f) determine the dynamics of the gene for deafness and the meme for sign language, respectively. Together, they constitute a model for the coevolution of genes and culture. When the strong force of natural selection and the weak force of mutation balance each other, the allele causing deafness will exist at a low equilibrium frequency. The dynamics of the frequency of signers, x , can then be approximately described by the following recursion equation, where the prime indicates the value in the next generation.

$$x' = 2kcvmx \quad (1)$$

Equation (1) is valid when the mutation rate and the frequency of signers are low, which are realistic assumptions.

Clearly, the frequency of signers will decrease and sign language will be lost if $2kcv m < 1$. On the other hand, sign language can persist if $2kcv m > 1$. Estimates of the strength of natural selection and of the rate of assortative mating are available for Japan and Northern Ireland. For example, in Japan in the 1950s, $m = 62$ percent and $v = 30$ percent. Substitution gives $2kcv m = 0.37 \times kc$. This is smaller than one, because the vertical transmission parameter, kc , cannot exceed one.

Thus, this simple coevolutionary model suggests that a sign language cannot be maintained in a deaf community by vertical transmission alone. Some linguists invoke horizontal transmission at schools for the deaf, where naive deaf children can learn from classmates who were fortunate enough to have deaf signing parents.

Genes and Languages

In a study by Cavalli-Sforza et al. (1988), the spread of anatomically modern man was reconstructed on the basis of genetic and linguistic pieces of evidence: the main conclusion was that these two approaches reflect a common underlying history, the history of our past still frozen in the genes of modern populations. The expression ‘genetic history’ was introduced (Piazza et al. 1988) to point out that if today we find many genes showing the same geographical patterns in terms of their frequencies, this may be due to the common history of our species. A deeper exploration of the whole problem can be found in Cavalli-Sforza et al. (1994). In the following, some examples will be shown of structural analogies between linguistic and genetic geographical patterns that supply complementary information. It is important to emphasize at the outset

that evidence for coevolution of genes and languages in human populations does not suggest that some genes of our species determine the way we speak; this coevolution may simply be due to a common mode of transmission and mutation of genetic and linguistic units of information and common constraints of demographic factors.

1. *The Genetic Analysis of a Linguistic Isolate: The Basques*

The case of the Basques, a European population living in the area of the Pyrenees on the border of Spain and France who still speak a non-Indo-European language, is paradigmatic. What are the genetic relations between the Basques and their surrounding modern populations, all of whom are Indo-European speakers?

Almost half a century ago it was suggested (Bosch-Gimpera 1943) that the Basques are the descendants of the populations who lived in Western Europe during the late Paleolithic period. Their withdrawal to the area of the Pyrenees, probably caused by different waves of invasion, left the Basques untouched by the Eastern European invasions of the Iron Age. In their study of the geographic distribution of Rh blood groups, Chalmers et al. (1948) pointed out that the Rh negative allele, which is found almost exclusively in Europe, has its highest frequency among the Basques. Chalmers et al. hypothesized that modern Basques may consist of a Palaeolithic population with an extremely high Rh negative frequency, who later mixed with people from the Mediterranean area. In more recent times it was suggested (Bertranpetit and Cavalli-Sforza 1991) that the immigrants might have been the Neolithic farmers who came from the Near East and whose modern descendants have a very low frequency of the Rh negative allele.

In summary, genetic analyses have produced the following conclusions:

(a) If Basques originally settled in a large area including the Pyrenean mountains, we can postulate that the genetic differentiation of modern Basques from the neighboring French Béarn population occurred, at the latest, during the Roman period, about 2,000 years BP.

(b) On the assumption that genetic differences are proportional to the times when populations separated (which is strictly valid only when one mechanism of genetic change, technically called genetic drift, is the major cause of differentiation), it seems very plausible that genetic differentiation of Basques from European samples occurred before Celtic people settled in France and originated the French population (about 2,600 years BP). In fact recent analyses of mitochondrial DNA support the idea that the Basques are the descendants of a Paleolithic population (Richards et al. 2000).

(c) The linguistic hypothesis originally put forward by Trombetti (1926) that Basques share a common ancestry with the modern Caucasian speaking people living in the northern Caucasus (see Ruhlen 1991) is in agreement with the genetic evidence: the ancestors of modern Basques could have shared a common genetic origin with populations from the Middle East at the latest before the Neolithic introduction of agriculture in Europe (ca. 6,000–5,500 years ago).

2. *From Basque to Ligurian and Etruscan*

The population and language name ‘Basque’ is interesting by itself. The Basques call themselves *Euskaldunak*: the term ‘Basque’ derives from *Vascos*, a Spanish word. The geographical distribution of the place names ending with the suffix *asc* includes a large region where such place names are significantly represented, from the southwest of France to the Po river delta in Italy. The number of place names whose origin is documented in historical records before 1850 is about 250, and there is general agreement among linguists to associate this suffix with a pre-Indo-European *Ligurian* substratum. Place names are generally very conservative, being notoriously resistant to ethnic stratification; conquerors may impose a language on invaded populations, but usually if they modify place names, they do not change them entirely. The presence of these place names in the Alpine region between Italy and the Swiss Italian-speaking region but not in the region north to the Po River is peculiar.

The linguistic interpretation of this kind of geographical distribution—one linguistically homogeneous area surrounded by two marginal areas with the same linguistic characters—was proposed by the Italian scholar Bartoli (who together with G. I. Ascoli, Trombetti, and Terracini pioneered the new discipline called ‘linguistic geography’) at the beginning of the twentieth century. One of the so-called Bartoli rules says: if a central area is linguistically homogeneous and is surrounded by marginal areas which are linguistically different from the central one but equal between themselves, the language of the marginal areas is almost always older than that of the central area. In fact, the distribution of place names of Ligurian origin surrounds a region of Celtic substratum that flooded any pre-Indo-European relic. Claimed to be among the most ancient ethnic groups of Western Europe, the Ligurians’ original domain far exceeded the boundaries of the modern Italian region bearing their name.

The case of Ligurian is different from that of Basque because the latter is still spoken today while the former can possibly be detected as a linguistic relic (substratum) in the modern dialect spoken by the inhabitants of the relevant region of Italy (‘Liguria’). Although the non-Indo-European nature of the Ligurian language has been debated because of the

very small number of glosses dating at least before the Celts occupied most of the Po river valley in the early sixth century BC, nobody doubts the non-Indo-European origin of the Etruscans (Pallottino 1975), and a natural question is whether we are able to recognize in today's Tuscans the fingerprints of their ancestors' genes. Apart from the number of genetic samples which have to be tested to supply enough information, the Tuscan dialect spoken today certainly cannot be defined as a non-Indo-European or a pre-Roman language: quite the reverse, it was adopted as the 'true' Italian language. What happened is that the transition from Etruscan to Latin was so difficult, the innovation so remarkable, that the process of nearly complete language substitution produced deep subconscious reactions by the speakers, and the effect of these reactions to innovation can be detected as 'fossils' in the language substratum of their descendants: the more different the languages of the conquerors and the conquered populations, the more recognizable these fossils are.

Genetics can be of great help in recognizing these fossils and possibly the population where they originated for at least two reasons. The first is that the transmission of genes is a much slower process than the transmission of a cultural trait such as a linguistic item; therefore genes can keep their identity for a longer time. Second, genetic evolution is very much dependent on population sizes. While it is perfectly legitimate to suppose that a few people can impose their language on large populations—as the Romans in fact did over the 'Romance' Europe—it is much more difficult to think of the same process in genetic terms. A few well-organized people can subdue a whole population, but it is unlikely that they would overwhelm the resident gene pool. It is reasonable to suppose that the Romans subdued the Etrurian inhabitants, but a part of the latter's probable descendants still preserve Etrurian genes. With new DNA markers, and testing of the relevant bone fossils, a better picture of the relationship between Romans and Etruscans might emerge.

3. *Co-evolution of Genes and Languages: The Origin of Indo-European*

Barbujani and Sokal (1990) found a correlation between linguistic and genetic boundaries in Europe. In the majority of cases (22 out of 33) there were also physical barriers that may have caused both genetic and linguistic boundaries. In nine cases there were only linguistic and genetic boundaries but not physical ones: three of them (northern Finland vs. Sweden, Finland vs. the Kola peninsula, Hungary vs. Austria) separate Uralic from Indo-European languages. It remains to be determined whether in these cases linguistic boundaries have generated or

enhanced genetic boundaries, or if both are the consequence of political, cultural, and social boundaries that have played a role similar to that of physical barriers.

The problem of the origin of the Indo-European linguistic family and of the people speaking its languages has roused much more interest over the last years than in earlier times partly owing to the book by Renfrew (1987), who suggested that farmers, beginning to spread from Anatolia around 9,000 years ago, spoke Indo-European languages. His hypothesis was based on the suggestion originally put forward by Ammerman and Cavalli-Sforza (1984) that the spread of Neolithic farming from the Fertile Crescent was due to the spread of the farmers themselves and not only of the farming technology, and on the consideration that migrating people retain their language, if at all possible. Renfrew's hypothesis was criticized by most Indo-European linguists (for a review, see Mallory 1989, Lehmann 1993, pp. 283–8) and did not fare well when contrasted with earlier hypotheses, now identified with the name of another archaeologist, Marija Gimbutas (1985), that Indo-Europeans migrated to Europe from the Pontic steppe area of south Russia from Dniepr to the Volga (which she called 'Kurgan' from the Russian name of mounds covering the graves), beginning with the early Bronze Age, that is, around 5,500 years ago.

Genetic data cannot give strong evidence on dates of migration, especially since the 'Kurgan' area, one of the largest pre-historic complexes in Europe, probably remained very active in generating population expansions for a long time after the Bronze Age. In that area we find at c. 6,000 years ago the Sredni-Stog culture, later (5,500–4,500 years ago) the Yamnaya cultures (formerly called pit-grave cultures) which stretched from the Southern Bug River over the Ural River and which dates from 5,600 to 4,200 years ago. From about 5,000 years ago we begin to find evidence for the presence in this culture of two and four-wheeled wagons (Anthony 1995).

Genetic data on European populations using blood typing (Piazza et al. 1995) and Y-chromosome DNA markers (Semino et al. 2000) have strongly supported a center of radiation in the Ukraine. It has been suggested (Cavalli-Sforza et al. 1994, Piazza et al. 1995) that the hypotheses of Renfrew and Gimbutas should not be treated as mutually exclusive; they may be compatible, as Schrader anticipated as long ago as 1890: 'the Indo-Europeans practiced agriculture at a site between the Dniepr and the Danube where the agricultural language of the European branch was developed' (quoted from Lehmann 1993, p. 279). The settling of the steppe by Neolithic farmers must have occurred after the beginning of their migration from Anatolia, and if the expansions began at 9,500 years ago from Anatolia and at 6,000 years ago from the Yamnaya culture region, then a 3,500-year period elapsed during their migration to the Volga–Don

region from Anatolia, probably through the Balkans. There a completely new, mostly pastoral culture developed under the stimulus of an environment unfavorable to standard agriculture, but offering new attractive possibilities. Our hypothesis is, therefore, that Indo-European languages derived from a secondary expansion from the Yamnaya culture region after the Neolithic farmers, possibly coming from Anatolia and settled there, developing pastoral nomadism.

A new analysis of the problem has been given in an unpublished analysis (Piazza et al. n.d.) of a set of lexical data (200 words) in 63 Indo-European languages published by Dyen et al. (1992). From a linguistic distance matrix whose elements are the fraction of words with the same lexical root for any pair of languages and its transformation to make the matrix elements proportional to time of differentiation, we were able to reconstruct a linguistic tree.

The root of the tree separates Albanians from the others, with a reproducibility rate (the error in reconstructing the tree) of 71 percent. The next oldest branch is Armenian. The simplest interpretation is that the language of the first migrant Anatolian farmers survives today in two direct descendants, Albanian and Armenian, which diverged from the oldest pre-Indo-European languages in different directions but remained relatively close to the point of origin.

If we give to the first split the time depth of the beginning of the expansion of the pre-Indo-European Anatolian farmers, about 9,000 years ago, we can then calculate that the origin of the European branch dates to about 6,000 years ago. The four major branches (pre-Celtic, pre-Balto-Slavic, pre-Italic, pre-Germanic) may correspond to some extent to different migratory waves, but archaeological dating is too scanty to provide unambiguous associations. It is reasonable to suggest that a first migration corresponds to the first branch, the pre-Celts (6,000 years ago, according to the tree), who settled first and went further west. Their only linguistic remnants are still alive today at the extreme of their original range. They profited from being among the first to develop an Iron Age culture, and were able to develop a wide community that spoke their language. Before Roman rule they spread to half of Europe, extending from Spain to France, most of the British Isles, northern Italy, and central Europe.

A detailed description of the other possible expansions will be found in the original paper (for a summary, see also Cavalli-Sforza 2000). In this context it is more interesting to explore how the linguistic lexical data analyzed above correlate with genetic data. The gene frequency geographical maps of the 95 blood type gene frequencies published and analyzed in Cavalli-Sforza et al. (1994) are interpolated at the geographical centers of gravity of the areas where each of the 63 languages is spoken. By taking into account

the spatial autocorrelation of both—linguistic and genetic—sets of data, the following results are obtained: (a) the correlation between genetic and linguistic variables is 69 percent and is statistically significant; and (b) since there is a possible effect of the geographical distance in explaining this correlation, the partial correlation between linguistic and genetic data, given constant geographical distances, has been calculated. The resulting value of 27 percent is still statistically significant and gives evidence for a correlation between genes and languages in Europe that is not only due to the effect of the geographical distance.

4. *Towards a Global Perspective*

More than 5,000 languages are spoken today in the world, and it does not take a linguist to recognize that some languages are more closely related than others due to history. The official origin of historical linguistics can be dated to 1786, when the English judge Sir William Jones advanced the idea that Sanskrit, a classical language in India, Greek, Latin, and possibly Celtic and Gothic (the ancestor of Germanic languages) shared a common origin. These old languages were the first members of a family of languages that would become known as the 'Indo-European' family (or 'phylum'). As Indo-European is the earliest and best studied linguistic family, coevolution of genes and languages has been documented. Since the eighteenth century, however, many other linguistic families or superfamilies have been recognized. The most complete classification on a world basis was proposed by Ruhlen (1991) who lists 17 linguistic families (Khoisan, Niger-Kordofanian, Nilo-Saharan, Afro-Asiatic, Caucasian, Indo-European, Uralic-Yukaghir, Altaic, Chukchi-Kamchatkan, Dravidian, Sino-Tibetan, Austric, Indo-Pacific, Australian, Eskimo-Aleut, Na-Dene, Amerind).

The reconstruction of the relationships above the family level is hotly debated among historical linguists who have yet to agree on the existence of a single tree linking all the existing language families, that is on the possible differentiation of modern languages from a single ancestor language. Even unification at a lower level such as that of the (pre-Columbian) American languages proposed by Greenberg (1987), who grouped them into just three macro-families (Eskimo-Aleut, Na-Dene, and Amerindian), has been strongly opposed by the majority of American linguists. Interestingly, Greenberg's proposal seems to agree with the analysis of genetic markers in extant Native Americans (Cavalli-Sforza et al. 1994) and these three families seem to identify three major migrations suggested by archaeological data. Amerindian speakers appear to have come first (between 30,000 and 15,000 years ago according to genetic data), followed by Na-Dene

speakers and finally Eskimo-Aleut (both in a period between 15,000 and 10,000 years ago). It must be said, however, that at a finer level of classification contemporary Amerindian speakers show high genetic variability, and this is not easy to reconcile with linguistic taxonomy.

Even without an agreed genealogy of the linguistic families covering all tongues spoken today, it is relevant to note the impressive one-to-one correspondence of the genetic phylogeny of the world populations with the classification into the 17 large linguistic families listed above (Cavalli-Sforza et al. 1988). This correspondence is expected because there are important similarities between the evolution of genes and languages. In either case: (a) a change which first appears in a single individual can subsequently spread throughout the entire population (for genes they are called mutations; they are rare, are passed from one generation to the next and can, over many generations, eventually replace the ancestral type; linguistic innovations are much more frequent and can also pass between unrelated individuals); and (b) the dynamics of change is affected by the same demographic pressures, isolation, and migration. Two isolated populations differentiate both genetically and linguistically because isolation, which could result from geographic, ecological, or social barriers, reduces the likelihood both of marriages and cultural exchanges and, as a common result, reciprocally isolated populations will evolve independently and gradually become different. Both genes and languages will drift apart regularly over time, the former slowly, the latter much more quickly.

In principle, therefore, the linguistic tree and the genetic tree of human populations should agree since they reflect the same history of population splitting and subsequent independent evolution. The different rate of change, however, is a major source of divergence: one language can be replaced by another in a relatively short time. In Europe, for example, Hungarian is spoken in a land surrounded by Indo-European speakers but it belongs to the Finno-Ugric subdivision of Uralic. At the end of the ninth century AD, the nomadic Magyars left their land in Russia and invaded Hungary. The number of conquerors was probably less than 30 percent of the conquered population so that their genetic contribution was limited, but they imposed their language on the local Romance-speaking population. Today all Hungarians speak a Uralic language, but barely 10 percent of their genes can be attributed to the Uralic conquerors. Generally it is intuitive that the total substitution of one language for another occurs more easily under the pressure of a strong political power of the newcomers, as witnessed in the Americas. The case of Basques, on the other hand, shows that separate languages spoken in nearby countries can remain relatively unaffected for thousands of years, even when their genes experience a partial substitution.

It is remarkable that, despite the above sources of confusion, the correlation between genes and languages has been maintained through the centuries until today and is still statistically significant. The ties between biology and linguistics were already evident since the times of Darwin, who in chapter XIV of his *The Origin of Species* wrote:

If we possessed a perfect pedigree of the mankind, a genealogical arrangement of the races of man would afford the best classification of the various languages now spoken throughout the world; and if all extinct languages, and all intermediate and slowly changing dialects, were to be included, such an arrangement would be the only possible one. Yet it might be that some ancient language had altered very little and had given rise to few new languages, whilst others had altered much owing to the spreading, isolation, and state of civilization of the several co-descended races, and had thus given rise to many new dialects and languages. The various degrees of difference between the languages of the same stock, would have to be expressed by groups subordinate to groups; but the proper or even the only possible arrangement would still be genealogical; and this would be strictly natural, as it would connect together all languages, extinct and recent, by the closest affinities, and would give the filiation and origin of each tongue.

The increasing resolving power of modern genetic data makes it possible to follow Darwin and to use the genetic phylogeny of our species to infer the earliest branches of a hypothetical linguistic tree. The most comprehensive genetic phylogeny reconstructed in Cavalli-Sforza et al. (1988) was used by Ruhlen (1994) to draw the tree of origin of human languages (some reference dates from genetic and archaeological evidence have been added). The oldest linguistic families must be African: Khoisan is probably the oldest and Afro-Asiatic the most recent, while Niger-Kordofanian and Nilo-Saharan believed by some linguists to descend from an ancestor tongue, and the Congo-Saharan, were probably spoken at an intermediate time. A more exhaustive discussion of this hypothetical tree can be found in Cavalli-Sforza (2000). As the genetic data improves with the inclusion of more representatives from those geographical areas of the world where the sampling is still scanty, the tree will be more complex but it is likely that its main features will remain unchanged.

In conclusion, our present genome keeps the record of its past evolution with an impressive richness of detail that is also reflected by our languages. Genes and languages contribute to the understanding of human history by highlighting human diversity; both are instrumental in giving some of the silent voices of our past a chance to be heard.

Genetic Counseling: Historical, Ethical, and Practical Aspects

Genetic counseling is one of the most important direct applications of human genetic knowledge. Genetic counseling refers to the totality of activities that (a) establish the diagnosis of genetic disease, (b) assess the occurrence risk, (c) communicate to the patient and family the chance of recurrence, (d) provide full and unbiased information within a caring relationship regarding the many problems raised by the disease and its natural history, including the potential ethical conflicts as well as the medical, economic, psychological, and social burdens, and (e) provide information regarding the reproductive options to be taken, including prenatal diagnosis, and refer the patients to the appropriate specialists. Genetic counseling should offer guidance but will allow those being counseled to arrive at their own choices, both before and after genetic procedures (Vogel and Motulsky 1997; World Health Organisation [WHO] 1998).

1. Paradigm Development and Concepts of Genetic Counseling

Pre-scientific knowledge of heritability in humans dates back to the early Greek physicians and philosophers and it can be assumed that there have been practical measures, including advice to individuals and couples as to how to use such knowledge (Vogel and Motulsky 1997). The idea of an improvement of mankind by rationalized mate selection was a major aspect of ancient and Renaissance state and social utopias (Plato, *Politeia* (about 374 BC); Thomas More, *Utopia* (1516); Fra Tomaso Campanella, *The City of the Sun* (1623)). In the medical literature of the eighteenth and nineteenth centuries, reports on the familial recurrence of particular disorders begin to accumulate. An early and noteworthy example is the book of the English physician Joseph Adams (1756–1818) *A Treatise on the Supposed Hereditary Properties of Diseases* (1814), where an attempt is made to lay out the fundamentals of genetic counseling in affected families.

Towards the end of the nineteenth century, two paradigms established human genetics as a science. Gregor Mendel (1822–1884) founded the concept of the gene as the basic factor of inheritance (1866), while Francis Galton (1822–1911) introduced statistical

Table 1
Paradigm shifts in applied human genetics

Paradigm	Basis	Goal	Measure
Eugenics	Emotionally carried social utopia	Improvement of the gene pool	Directiveness, compulsion, coercion
Prevention	Rational calculation	Reduction of individual suffering, economic distribution of resources	Paternalism
Psycho(socio)-biology	Complex interaction between counselor (doctor) and client (patient)	Help in individual decision making	Empathy, nondirectiveness

methods to investigate and interpret the familial clustering of traits and thus founded the biometrical paradigm. Until the present, biometrics and Mendelian genetics have remained the basis of risk determination as the naturalistic component of genetic counseling. Galton coined the term 'eugenics' and favored measures to enhance propagation of individuals with supposedly high genetic qualities (positive eugenics). In Germany, around the turn of the nineteenth to the twentieth century, Wilhelm Schallmeyer (1857–1919), Alfred Hegar (1830–1914), and Alfred Ploetz (1860–1940) developed the idea of negative eugenics, a concept of decreasing the number of offspring of individuals with supposedly below average hereditary qualities, or of preventing congenitally diseased individuals altogether, with the aim of improving the gene pool of future generations and especially that of the presumed superior Nordic race (see Ploetz 1895).

In many countries during the first half of the twentieth century, positive and negative eugenics formed the ideological basis of state-enforced measures to exert reproductive control over individuals. Between 1911 and 1930, 24 US states proclaimed sterilization laws and eugenic thought also played a role in the enactment of restrictive immigration laws. In Europe, Denmark was the first country to proclaim a Law on Genetic Hygiene (1929), in which voluntary sterilization for genetic reasons was regulated. In Germany, the Law for the Prevention of Congenitally Diseased Progeny (1933), followed by a series of other laws and decrees, mandated and organized the sterilization of individuals with certain diseases, which were thought to be genetically determined. In Germany, eugenics, racial hygiene, and National Socialist ideology formed a gloomy alliance. The involvement of German geneticists in coercive measures and eventually the Holocaust to sections of the population that were declared to be inferior has been well documented by Müller-Hill (1997). It is beyond doubt that this historical burden strongly influences the current debate on ethics and genetics in Germany and elsewhere.

From about 1930 onwards, the eugenic movement outside Germany began to lose power, but it was not

until the 1950s that the population-directed eugenic orientation was slowly replaced by a medically oriented practice with genetic disease prevention as a major focus. Nevertheless, eugenic thinking, whether acknowledged or not, has continued to play a role until the present time, especially outside the Western world (Wertz 1997). When, in 1947, Sheldon Reed coined the term 'genetic counseling,' it became clear that eugenics and what was then understood to be genetic counseling, were no longer identical. According to Reed, 'genetic counseling is a type of social work entirely for the benefit of the whole family without direct concern for its effect upon the state or politics' (1974). This definition marks a change of paradigm in applied human genetics, away from the concern about the genetic make-up of the population and towards the attitude that decision-making with regard to genetic risks should be left to the individual, even if this may create or increase social costs or worsen the gene pool. Thus, one of the fundamental ethical principles in medicine, the respect for the autonomy and self-determination of persons, is also the cornerstone of genetic counseling.

Genetic counseling has thus gone through three overlapping historical phases (Table 1). First, the eugenics phase, mainly rooted in England, the United States of America, Scandinavia, and Germany, was based on the social and biological utopia of general mental and physical health and the optimization of humankind. In order to attain these goals, depending on political circumstances, directive measures including direct and indirect coercion were applied. Eugenics was scientifically ill-founded, and the definition of inferior or superior genetic qualities a matter of ideology. Second, the preventive-medical phase laid its emphasis on the reduction of individual suffering through the prevention of genetic diseases and disabilities, in order to economize rare medical resources. It was founded on the rational calculation that any means towards that end would find acceptance as being in the immediate interest of the individual. Strategies were those of benevolence, authority, and paternalism. Third, in the psycho-(sociobio-)logical phase, the focus of genetic counseling is to help the individual or the family to manage a problematic

situation caused by genetic disease. The basis of this help is a complex interaction between the counselor (a specialized physician or a non-medically trained expert) and the client (patient) in a nondirective process of communication. Help is provided with the understanding that genetic diseases are often associated with special psycho-social problems and ethical conflicts which deserve to be managed individually. Thus, any direct or indirect coercive influence is to be avoided. Nondirectiveness has become a basic concept of genetic counseling, to which a majority of counselors worldwide feel obliged (Wertz 1997).

The history of genetic counseling shows that its purpose has always been value-determined and has never been seen outside the context of social politics in which it was embedded. In countries that acknowledge human rights as defined in the democratic state theories of the eighteenth century, the only defensible position is that of the autonomy of the individual to make decisions regarding genetic counseling and genetic diagnosis, and to draw consequences for life and family planning. The healthcare system, on the other hand, carries the ethical obligation to provide full information and the tools that may enable the individual, depending on the state of knowledge, the emotional situation, and moral positioning, to make use of that information.

1.1 Excursus: Ethics and Genetic Counseling: The Respect for Personal Autonomy

Today the term 'eugenics' is sometimes used to describe the cumulative result of individual choices after genetic counseling, especially in view of reproductive choices. The decreasing prevalence of births of children with Down Syndrome in Western Europe, especially in the UK, may be regarded as a result of individual choices to undergo prenatal diagnosis and subsequently to terminate a pregnancy after a positive test result. Whether this type of individual eugenics is socially desirable and a benign development has been discussed with some controversy by Wertz (1998). Critics argue that free, autonomous choices (after genetic counseling) not only depend on surrounding social, cultural, and other factors, but also on the full and honest presentation of information in genetic counseling, i.e., on access to valid information. In the absence of correct and unbiased information, free choices are not possible and are compromised, and information and genetic counseling becomes a means of furthering attitudes and goals of health professionals. A worldwide survey of 2,091 genetics professionals in 36 nations conducted by Wertz (Nippert and Wolff in Germany) suggests that eugenic thought underlies the perception of the goals of genetics and genetic counseling in many countries. In developing nations of Asia and Eastern Europe especially, directive counseling is practiced to influence individual

decisions. Intentionally pessimistically biased information is routinely provided after positive results from prenatal diagnosis in order to avoid the birth of affected children (Wertz 1998, Cohen et al. 1997). The data from this survey suggests that the concept of non-directive counseling found in English-speaking nations and Western Europe is an aberration from the rest of the world.

2. Indications for Genetic Counseling

In medicine in general, a measure is 'indicated,' when, after weighing up the risks and benefits, it appears medically required. This definition is hardly applicable to genetic counseling, because the recognition of risks and benefits of knowledge, as well as any actions that may result from such knowledge, will emerge only in the counseling process itself, and their appraisal is often more strongly determined by individual life circumstances than by medical judgment. On the other hand, the professionalization of genetic counseling, as a specialization within medicine, and jurisdiction in regard to correctness and completeness of any medical advice, have brought about a core service that every counselee may duly expect to receive: A scientifically founded statement regarding the etiology and the (recurrence) risk of a genetic condition, comprehensive information and counseling regarding diagnostic options, and referral to preventive, therapeutic, and/or socially alleviating measures.

Generally speaking, an indication for genetic counseling is given whenever an individual regards it as a means to help solving a personal problem related to an existing or suspected genetic risk. Table 2 summarizes the most frequently encountered situations. With increasing awareness of old and novel pre- and post-natal methods of genetic diagnosis, genetic counseling is increasingly sought by individuals with genetic risks not immediately apparent to themselves. Concerns,

Table 2
Indications for genetic counseling

-
1. Birth of a child with congenital disease or disability
 2. One or more relatives suffering from (suspectedly) genetic disease or disability
 3. Affected counselee
 4. Consanguineous couple
 5. Recurrent miscarriage
 6. Infertility
 7. Mutagenic influences
 - 7.1 Advanced maternal age
 - 7.2 Pre- or postconceptional mutagen exposure
 8. Teratogenic exposure
 - 8.1 Infections
 - 8.2 Drugs
 - 8.3 Alcohol
 - 8.4 Radiation
-

including moral doubts, may have been raised, for example, by offers of prenatal screening (maternal serum marker and ultrasound screening), or carrier detection, within or outside the framework of a defined screening programme, because such offers may bring up the question of termination of the pregnancy.

3. The Counseling Process

According to a statement issued by an Ad hoc Committee on Genetic Counseling of the American Society of Human Genetics, genetic counseling is a communication process which:

deals with the human problems associated with the occurrence or risk of recurrence of a genetic disorder in a family. This process involves an attempt by one or more appropriately trained persons to help the individual or the family to 1. comprehend the medical facts, including the diagnosis, the probable course of the disorder, and the available management; 2. appreciate the way heredity contributes to the disorder and the risk of recurrence in specified relatives; 3. understand the options for dealing with the risk of recurrence; 4. choose the course of action which seems appropriate to them in view of their risk and their family goals and act in accordance with that decision; 5. make the best possible adjustment to the disorder in an affected family member and/or to the risk of recurrence of that disorder (Fraser 1974; Ad hoc Committee on Genetic Counseling 1975).

The counseling process is usually initiated by clarifying the counselee's motivation for consultation. What is the background to the problem, and what are the expectations? The counselor should explain, in general terms, what genetic counseling can achieve, and where its limits lie. This is important, because expectations are frequently unrealistic. It needs to be explained, for example, that it is technically not possible to exclude any kind of genetic risk, or to guarantee a healthy child. The next step is to record the personal and family medical history in the form of a genealogical tree, encompassing at least all first and second degree relatives. This is followed by providing information regarding the most important medical facts concerning the disease in question (natural history of the disease, the likely degree of suffering it may confer, its treatability) as well as the likelihood of its occurrence or recurrence. It is important to give unbiased, objective information. During the later phases of the counseling process, the counselor will often return to this information in order to relate it to the personal views of the counselee. The 'prior' risks for a genetic condition as deduced from its pattern of inheritance (monogenic dominant or recessive, autosomal or sex-linked, co-determined by several genes and/or the environment) may be modifiable by genetic diagnostic tests so that a 'posterior,' usually more precise, risk figure emerges. Ever more often, with the Human Genome Project nearing its completion and

concomitant technical developments becoming routine practice, firm confirmation or exclusion of carrier status for any particular genetic disposition will be the rule, rather than the exception. Nevertheless, the phenotypic outcome will often be variable, due to environmental factors and complex interactions between genes. In the counseling process, the resulting uncertainty needs to be explained and worked upon with great care. Without thoroughly understanding the chances and limits of genetic testing, an informed consent to any such procedure cannot be attained. Informed consent is generally held to be the prerequisite for any genetic testing. The decision whether to make use or not of diagnostic offers can only be made sensibly in a highly personalized context, so that genetic counseling is required to be nondirective (Wolff and Jung 1995).

During the counseling process it may be necessary to make a physical examination of the counselee and/or of family members in order to search, for example, for early signs of manifestation of a late-onset disorder or for microsymptoms of a disease. The impact of such examination needs to be explained beforehand, because counselees and their family members may wish to help clarify genetic risks for others, but not necessarily for themselves. It is sometimes difficult to decide to what extent information from the family history which may confer a genetic risk to the counselee needs to be discussed, if this information has not been central to the counselee's motivation for consultation. This is particularly delicate when no therapeutic or preventive options exist. If they do, however, the counselee has a right to comprehensive information and counseling.

4. The Determination of Genetic Risks

The determination of genetic risks in any individual case is the essential naturalistic component of genetic counseling. It requires expertise in general and human genetics, including formal (mathematical) genetics, population genetics, and clinical genetics, as well as an awareness (attainable in this fast-moving field only through continuous further self-education) of novel developments, especially in the differential genetic diagnosis. In the following discussion, we provide a summary of the most important groups of conditions where a risk assessment is often sought and a brief outline of risk provision. Often, the prior genetic risks need to be modified by using information from the pedigree or genetic tests (conditional probabilities). By employing Bayesian methodology this information can be used to arrive at posterior (final) risks (Harper 1998).

If a disease is (mainly) due to the effect of a single gene, the phenotype may be inherited in a recessive or a dominant fashion. The disease may manifest itself in a sex-dependent way, if the causative gene is not

located on the autosomes (the chromosomes shared by both sexes in equal number) but rather on the sex chromosomes (X and Y). In an autosomal-recessive condition, the recurrence risk in a sibship is 1/4, but usually low (less than 1 percent) for second-degree relatives. If a parent has an autosomal-dominant condition, there is a 50 percent chance that each child will also carry the disease-causing mutation. If neither parent has a condition that is known to be autosomal-dominant, the recurrence risk in a sibship is usually negligible, because the presumption is that a spontaneous mutation has occurred in the germ-line leading to the affected individual. In X-linked recessive disease, if the mother is a carrier, half of all her sons will develop the full clinical picture, and half of her daughters will be carriers. Mothers and daughters are usually unaffected or exhibit symptoms to a lesser degree (due to non-randomness of X-inactivation during early development). In Y-linked disease (such as sub-fertility), the trait is passed on from fathers to sons. In both recessive and, most notably, dominant conditions, the inheritance patterns may be obscured by variable penetrance (proportion of carriers manifesting the phenotype at all) and expressivity (degree of disease severity). Greatly reduced penetrance and expressivity, i.e., where only a small fraction of carriers suffer from the condition, leads to the concept of genetic predisposition (susceptibility) for disease, which may be modulated by other genes or environmental factors. Polygenic and multifactorial inheritance are the etiology of most of the common diseases (such as coronary heart disease, obesity, diabetes mellitus) and the majority of cases of birth defects. In these categories, empirical risk figures apply. Numerical chromosomal aberrations are usually sporadic, with a low empirical recurrence risk in a sibship, but may also run in families, e.g., structural aberrations, such as translocations, which may be inherited as balanced or unbalanced in offspring in a more or less apparent Mendelian fashion.

5. Genetic Counseling in the Social Context

How have genetic counseling and its supposed high standards fared in common practice? Throughout the world and even in Europe, there is a huge variance in the professional identity and training of providers of genetic counseling services. In Germany, most counseling services are provided by physicians who are specialists in medical genetics (Nippert et al 1997) and in the UK, genetic counseling is provided primarily by nurses (Raeburn et al 1997), whereas in the US and Canada a substantial amount of genetic counseling is provided by counselors trained to the master's degree level. This implies that practice differs between countries. Surveys which compare the attitudes of genetic service and counseling providers have revealed a remarkable difference in attitudes and values. An

international survey carried out in 37 nations in 1994–1995 found that, in most of the surveyed countries, genetic counseling, especially in the context of prenatal diagnosis (PD), is directive in that the counselor provides the client with intentionally slanted information in order to influence the client's decision (Wertz 1998). The survey shows that, depending on the diagnosed conditions of a fetus, on the culture's view of the condition, and on the counselor's personal view about the morality of abortion, he or she deliberately provides more optimistically or pessimistically biased information.

Although published policies and guidelines exist (Fraser 1974, German Society of Human Genetics 1996, Andrews et al 1994, WHO 1998, Fryer and Lister Cheese 1998, Holtzman and Watson 1997), the type of information and the way information is communicated vary within countries, and standard practices can hardly be found. Obviously genetic counseling practices are shaped by the characteristics of the various healthcare systems, as well as by the personal characteristics of the counselor, such as sex, professional expertise, and type of employment. The process and outcomes of genetic counseling have been documented by a few empirical studies (Sorenson 1992). The outcomes have been defined primarily on the basis of patient knowledge and patient satisfaction, but so far have hardly paid any attention to the social aspects of the information (Clarke et al 1996). Concern has been voiced that in the future more counseling will be provided by professionals not trained in genetics. Although there is insufficient empirical evidence that genetic counselors successfully achieve autonomous, informed decision-making, research from Europe and the US suggests that non-geneticists do not set a high value on providing information that allows informed decision-making before undergoing tests such as prenatal diagnosis (Dodds 1997).

With the development of more new molecular tests, implementation of these tests in various fields of medicine will drive the diversification of genetic counseling practice. Neither general healthcare providers nor non-genetics specialists have sufficient professional education and expertise in genetics, molecular testing, and genetic counseling to perform this task (Holtzman and Watson 1997). How to target the education for providers via medical curricula and continuing education remains an unsolved challenge. So far, no country has developed any strategy or has made any far-reaching efforts. Genetic specialists are arguably the most valid source for providing the needed expertise and information for their medical colleagues to facilitate their understanding of basic genetic principles and the application of molecular testing, including pre- and post-test counseling, in clinical practice. However, the more genetics becomes part of general medicine and the more genetic testing is introduced into the various specialty areas, the more the task to provide information and to interpret test

results will fall on primary care physicians and non-genetics specialists. Probably the future of genetic services will be provided in the way envisaged by Wertz:

It is perhaps more likely that most genetic services will be provided in the same manner as other types of medicine. In managed care systems this may mean hurried, assembly-like encounters that focus on tests and treatments rather than on providing information and counseling. Most primary care providers may be ill-equipped to provide information and counseling needed in any case ... Many will wonder why genetics was ever expected to produce superior provider-patient relationships, to uphold superior ethical standards, or to allow greater patient autonomy than other fields of medicine (1997, p. 343).

Most likely the future of genetic testing and counseling will be shaped by economic interests, because of the need for financial returns on heavy investments made in the field of molecular testing, by reimbursement practices, and by the extent to which national healthcare policies will encourage genetic testing. It remains unclear whether the main ethical concepts attached to genetic counseling, such as nondirectiveness, individual autonomy, and greater equality in the doctor-patient relationship, will survive or will wither away during the integration of genetic tests into routine medical practice. Hopefully genetic counseling will retain some of its best elements, namely respect for patients' rights to valid, non-slanted information and for patient autonomy in reproductive decision-making.

Genetic Engineering

The term 'genetic engineering' stands for human alteration of the genetic code of an organism, so that its biosynthetic properties are changed. The major applications are for the industrial production of desired peptides or proteins, or to alter the biological capabilities of the organism. These techniques have

been used to develop crops with agronomically useful changes, such as pest resistance and ripening properties that allow for shipment. Surprising results have been obtained by silencing genes in experimental organisms, as well as the production of animal models of human disease by deriving strains of animals with mutated human genes. Much attention is being given to the production of products and methods to modify an individual's cells to treat human disease. Although the majority of activity at the present time is directed toward traits governed by a single gene, commercial and academic investigators are hopeful that complex diseases and behavior can also be modified.

1. Biological Background

The technology has developed in the context of our understanding of genetics. A vital property is the production and maintenance of variability in populations. One of the mechanisms that produces such variability is recombination. Information for a number of peptides as well as the controlling mechanisms for their synthesis are inherited together on a single chromosome. In diploid organisms, exchanges between homologous chromosomes is an important source of variation. This process occurs in the context of DNA replication, including the enzymatic unwinding of the double helix and synthesis of the new, complementary chain of nucleic acids.

Cellular properties may be altered by external mechanisms. One of the first systems that was extensively studied, and provided the tools that are currently used, is the phenomenon of infection of bacteria by bacteriophages, the bacterial viruses. The usual direction of events is followed. The message is coded in the DNA sequence. It is then transcribed into the sequence of the intermediate messenger RNA molecules, and then translated into protein. In the lytic cycle, the viral DNA instructions are used to synthesize new viral DNA and protein that can assemble into new viral particles that destroy the cell and are then released into the environment to infect other host cells. In the lysogenic cycle, the DNA of the virus integrates into the host DNA. In addition, there are a number of other particles called plasmids, which can transfer genetic information from one bacterium to another. They are small, circular DNA molecules that replicate independently of the DNA of the host bacterium. Their role is particularly prominent in the transmission of antibiotic resistance. Most animal viruses are similar to the lytic cycle of bacteriophage, however, there are a number of viruses that can become latent. There is also agents like the retroviruses, whose genome gets transcribed into the host DNA, thereby changing cellular properties. Some of these agents will also incorporate host DNA into their sequences, and then capable of transmitting this sequence into a new host.

The tools that allow us to transfer genes from one organism to another are the *restriction* endonucleases. These enzymes are found naturally in bacteria and protect them from infection by breaking down foreign DNA. They are chemically very specific, only working on specific palindromic sequences. Consequently, the kind of infection discussed in the last paragraph can only occur if the bacteriophage sequence does not contain elements that will be broken down by the host bacterial system of endonucleases. A number of different enzymes are found in different bacterial species, and the enzymes referred to by an abbreviation of the bacterial species name and a number. Similarly, there are enzymes that are used to connect fragments, the ligases (Griffiths et al. 1996).

2. Cloning Genes

All of the manipulations of genetic engineering require multiple copies of the DNA sequence or gene of interest. The original methods of getting multiple copies relied on bacteriophage or plasmid vectors to introduce the foreign DNA into bacteria to produce these copies, as each modified cell produces multiple copies, and the bacterial culture itself increases. This is done by first physically isolating the vector, opening its DNA with a restriction enzyme and binding in DNA from the organism being studied that has also been cleaved with a restriction endonuclease. A new population of bacteria is then infected with the altered vector. Given an appropriate way of selecting the population of bacteria so that it uniformly has the DNA of interest multiplying within, one can isolate a large population of vector molecules with the desired sequence, which is then freed by enzymatic cleavage once again.

Fragments of DNA are identified by physically separating them by electrical charge and molecular weight through gels. The DNA of the vectors and bacteria are generally in the range of one to ten thousand base pairs, and there are a sufficiently small number so that the fragments can be identified with a simple staining technique, usually a compound that binds to DNA and fluoresces under ultraviolet light. The larger quantity of fragments that would be isolated from more complex organisms produces a smear with such dyes, so the base-pairing property of DNA, the obligate pairing of adenine with cytosine and guanine with cytosine that allows for both recognition and synthesis of the linear sequence, is used to identify the same sequence on the gel by labeling a known fragment with an isotope or fluorescent dye. The labeled molecules are called probes. This is also the basis for identifying genetic variation in organisms, either for basic studies or identification of mutations associated with disease.

Isolation of fragments produced by digestion with several enzymes, used both singly and in combination,

allows for the construction of a physical, restriction-fragment map. Smaller fragments may be replicated, followed by the chemical analysis of the base sequence within fragments which are then assembled into the final base sequence of the gene. Once the sequence is known, production of useful amounts of a region of DNA may now be done enzymatically *in vitro* with the polymerase chain reaction (PCR). In this technique, the region between two primers, one from each strand of the final DNA molecule is copied in a logarithmic fashion by a heat-resistant DNA polymerase from a small amount of genomic DNA (it has been done with single cells), using multiple heating and cooling cycles. This technique is also used in diagnostic work (Strachan and Read 1996).

3. Modifying Cells to Produce Proteins

A number of strategies have been used to produce large amounts of a peptide or protein. Multiple techniques have been necessary because of the different kinds of cells that have been used. The production of human insulin, one of the earlier products produced commercially, is a useful model that is an example of expression cloning. The sequences for the A and B chains were introduced into separate vectors in sequence with a bacterial promoter (a signal to turn a gene on) and the enzyme β -galactosidase that produces colored bacterial colonies. This arrangement is necessary because bacteria will not just produce the human protein if only the structural gene is introduced. The bacteria are tricked into producing a fusion protein: a bacterial β -galactosidase with a human insulin chain sequence at the end. After selecting the colonies by color, mass cultures are produced from which the fusion proteins can be purified. The normal insulin dimer is then produced chemically by removing the β -galactosidase, purifying the chains, combining the chains and allowing them to refold and form the sulfide bridges between the two chains.

Expression cloning in bacteria works well if the peptide or protein is composed entirely of the amino acid sequence. Many functional proteins contain specific carbohydrate groups at precise locations on the chain that are attached after translation. These modifications are different in different classes of organisms, so techniques using yeast, plant, cultured insect, other mammalian, or human cells have been used to make the complete molecule. Another problem that is addressed in this approach is the elimination of bacterial toxins that cannot be removed from the desired protein product mixture. The engineered DNA can be introduced into these cells by a variety of methods. The physical techniques like electroporation, which uses an current to move the DNA inside, or coating various kinds of particles, like gold, with the DNA and then bombarding the cells to get the DNA inside has a chemical parallel in the use of calcium salts

and heat. Artificial yeast chromosomes have been produced to move gene constructs. For the cultured insect cells, modified Bacloviruses are used (these are viruses that have invertebrate hosts). In mammalian systems, several viruses have been used, including retroviruses (the class of agents involved in acquired immunodeficiency and tumor transformation in experimental organisms), adenoviruses (agents that typically produce respiratory disease, however, some strains are capable of producing more severe systemic disease), and herpes simplex.

The goal of expression cloning is to produce large amounts of protein that can be purified more easily, and in much larger amounts than is possible using chemical techniques starting with cells from the normal tissue. On the research laboratory scale, the three-dimensional structure of the whole protein or the active region can be determined by a combination of nuclear magnetic resonance and x-ray crystallography. This information is useful for understanding function or designing small molecules that are expected to have pharmacological actions. This is then one element of the strategy in rational drug design. If the protein is to be used as a product, the growth of the modified cells has to be done on an industrial scale that is an engineering problem similar to that used in the production of a number of antibiotics (Glick and Pasternak 1998).

4. Modifying Organisms

An organism that has been engineered so that it has a gene from another species integrated into its genome is called a transgenic organism. These techniques have been used to produce plants and animals expressing mutated genes of that species to study function, with mutated or genes introduced from another species with desired agronomic properties, as models of human diseases, and to produce therapeutic products. There is a large and continuously growing literature of studies in the mouse.

Two procedures have been widely performed in mice: the interruption of a mouse gene to eliminate its function, for which the term knockout has been used, and introduction of a transgene. The 'standard' procedure employs classical, cellular, and molecular genetic techniques. The gene to be studied is first cloned, and then introduced into a targeting vector in such a way that the coding sequence of the gene is interrupted by the neomycin resistance gene. The vector also has the thymidine kinase gene from herpes. Embryonic stem cells are obtained from a brown mouse and placed in culture. The cells are then exposed to the vector. There are three possible outcomes. The vector does not insert at all, the whole construct inserts at random in a chromosome, or only the desired coding sequence and the neomycin resistance gene insert into the normal location on the chromosome.

Treating the cells with a neomycin analogue and the antiviral agent ganciclovir will kill all of the cells except the ones with the integrated sequence. The surviving stem cells are injected into the blastocyst stage embryo of a black mouse and placed in a surrogate mother. If a chimera is formed, it will have a coat of two colors. The chimeras are mated with black mice, and their brown offspring tested for the modified gene. Those that are heterozygous are mated, and one of four will be homozygous for the modification.

In addition to the introduction of genes into stem cells by vectors, injection of the desired sequence has been done by some of the physical methods discussed earlier such as electroporation, coated gold particles, and salt precipitation. Some transgenics have been derived from direct injection of the plasmid into the egg.

The production of genetically identical organisms, cloning in the original sense, was first done in amphibians by nuclear transplantation into fertilized ova from which the original nucleus was removed. This was done widely in mammals by using embryonic cells as the nuclear donor. The production of the sheep named Dolly was noteworthy because the donor nuclei were obtained from adult mammary cells that were maintained in cell culture. This precipitated a round of discussion about the feasibility and the desirability of doing this in human beings. The claim was made that this would be an alternative for infertile couples, and therefore acceptable. It is necessary to point out to people who would propagate themselves for narcissistic reasons that the derived individual would not be absolutely the same because of the developmental environment, both before and after birth (Hubbard and Wald 1997).

Another possible use of this technology that has been proposed is the therapeutic cloning of replacement tissues or organs. Cells would be biopsied from the eventual recipient and placed in culture. Nuclei from these cells would be transplanted into eggs from which the nuclei have been removed; these eggs will be allowed to develop to the blastocyst embryonic stage for the isolation of embryonic stem cells that are treated to produce the desired cell types. This avoids the problem of using fertilized eggs, but still involves the use of human eggs and early embryonic stages (Gurdon and Colman 1999).

5. Gene Therapy

The goal of gene therapy is to provide a functional protein to an individual whose genotype leads to a disease because the protein is missing or modified so that it is not functional. There are two potential modes. In germ-line therapy, the modification would be heritable, and the individual's offspring potentially would not be affected. In somatic cell therapy, only the treated individual would have the modification. There

have been many arguments against germ-line therapy including our inability to know whether potentially harmful changes in the sequence have been made inadvertently. All of the trials to date have been in somatic cells for the treatment of inherited disease and cancer by control of cell death.

Two strategies are being attempted. For those disorders for which bone marrow transplantation has been effective, the gene is introduced into marrow cells, the population of which is then expanded and infused into the patient. The techniques for gene introduction are similar to the ones previously discussed: viral vectors and chemical or physical techniques. An immune deficiency disorder, adenosine deaminase deficiency, was the first attempt reported. Although the modified cells express the enzyme, repeated infusions of treated cells have been necessary, and the patients have continued to receive chemically modified enzyme, so it is not clear whether or not gene therapy alone is sufficient.

Other trials have used viral vectors to treat target organs, such as the lung in cystic fibrosis. The therapeutic trial of an adenovirus-mediated transfer of a gene to the liver has received general media attention because of the death of a participant. Evidently, other participants in gene therapy trials have died, although it is not clear how many of those deaths are a result of the procedure (Strachan and Read 1996).

6. Applications to Behavior

The application of these techniques in behavior is loaded with scientific, ethical, and legal complications. Part of the problem stems from the very human desire to have a simple answer to a complex problem. Genetic, environmental, and developmental factors interact to produce behavior, and it is difficult to distinguish the role of each component. One should ask if it is even desirable to do this, because of the mixture of potential benefit and risk. It is clear that each behavioral trait is heterogeneous. There may be families where a single major gene is responsible, and a particular drug, expressed protein or even gene therapy could work, but in the more usual instance of several genes and environmental factors, it is unlikely that such a unitary approach would work. The promise of a solution to disease problems by definition of molecular mechanisms has been difficult to achieve. We still do not have an answer in the case of sickle cell anemia, the first disorder to be described in this manner. Common behavioral traits would be more difficult because of the interactions.

Because of the Human Genome Project, it is likely that a number of genes will be discovered that contribute to the development of a number of behavioral characteristics. The technology therefore will create the possibility of diagnostic tests for the presence of variants at these genetic loci that might be involved in diagnostic confirmation, or even asymp-

matic screening without necessarily having the ability to safely and ethically treat those in whom the genetic variant is identified. Furthermore, since it is well known that the genotype does not always predict the phenotype even for such things as emphysema associated with a variant α -1-antitrypsin, one should question this approach with respect to behavioral characteristics (Hubbard and Wald 1997).

Using genetic information to design pharmacologically active agents will probably be useful for drugs interacting with receptors influencing neural function. A similar problem arises here. Will the intervention be beneficial to someone who is suffering or will it be used to control individuals who are designated by those in authority to be deviant? Modifying the environment to enhance development is effective and poses less of a biological risk than drugs or gene therapy (Duyne et al. 1999). The relative economic costs are unknown, but the human ramifications are immense.

Genetic Factors in Cognition/Intelligence

Research has not only established the importance of both genetic and environmental influences on human intelligence, but has also begun to examine how genes

shape intellectual development and the relationship among different cognitive skills (e.g., verbal and performance ability). Additionally, researchers have begun to search for DNA markers associated with human cognitive ability. This article will not only examine these new research directions, but will also discuss the implications of these findings in the context of the environment.

1. Behavioral Genetics, Genes, and Intelligence

One of the major misconceptions about behavioral genetics is that the purpose of this research is to examine whether genes *or* the environment is operating. Instead, behavioral genetics assumes that differences in intelligence, for example, are due to differences in genes, the shared family environment (the environment that family members share, such as socioeconomic status), the nonshared environment (the environment that makes family members different, such as differential parenting and different experiences), and error. Genetic influences on intelligence are statistically significant, averaging around 50 percent when collapsing across all available twin and adoption studies (see Brody 1992 for a review). In other words, genes account for roughly half of the measured variability in intelligence.

2. Beyond Heritability

While a heritability of 50 percent is important in terms of the nature/nurture debate, finding that intelligence 'is both' genetic and environmental (the other 50 percent has to be due to nongenetic influences) in and of itself does not elucidate *how* genes influence the development of human intelligence. Behavioral genetics has begun to move beyond heritability and, as a result, has reported findings that fundamentally change how we think about the development of intelligence.

2.1 Genes Become More, Not Less Important With Age

A common assumption is that genes become less important with age, as environmental influences 'add up' to shape cognitive performance. Behavioral genetic results suggest that the opposite is the case. Although genes account for 50 percent of individual difference in intelligence collapsed across all studies, heritability appears to vary with age, starting at around 40 percent in early childhood, rising to 60 percent in early adulthood, and to 80 percent in later life (see Plomin et al. 1997). More recent evidence suggests that the genetic influences on intelligence may decline to around 60 percent in old age (Finkel et al. 1998, McClearn et al. 1997).

Genes in childhood Genes in adulthood

Figure 1

Genes are largely shared across development, but there is also genetic specificity across different ages

2.2 Genes Drive Stability, But Are Not Invariant Across Development

Another new research question addressed by genetic methods is the extent to which the genes that influence cognitive abilities at one age are the same genes that influence cognitive abilities at later ages. Are genes relating to intelligence immutably 'on' from birth, or do different genes turn on and off across development? Results (see Plomin et al. 1997) suggest that genes are largely stable, with some genetic change across development (see Fig. 1). In contrast, the environment is largely responsible for the changes in intelligence across development.

2.3 Genes Also Drive The Correlation Among Different Aspects of Cognitive Ability

One of the most interesting 'new directions' in behavioral genetics research involves the examination of how genes influence different aspects of cognitive ability. Are the genes that influence verbal skills the same as those that influence spatial ability or are verbal and spatial skill each influenced by different genetic processes? This debate, often called the molarity vs. modularity debate, has important implications for cognitive neuroscience. A molar system is one in which different aspects of cognitive ability, such as verbal ability, spatial ability, perceptual speed, and memory, are all influenced by a common set of genes. A modular system, in contrast, holds that genes function independently across different cognitive skills. In multivariate behavioral genetics, this degree of overlap is often measured by a genetic correlation. A high genetic correlation suggests almost complete overlap while a low genetic correlation suggests genetic independence. Behavioral genetic studies suggest that the genetic correlation approaches 1.0, suggesting

Genes for verbal ability Genes for spatial ability

Figure 2

Genes are largely shared across different measures of cognitive ability

almost complete genetic overlap (see Petrill 1997). The genes that influence spatial ability, for example, are largely the same genes that influence verbal ability (see Fig. 2). Genes are the 'tie that binds' different cognitive skills while the discrepancy between different cognitive skills (e.g., certain people may be better at verbal as opposed to spatial skills) is due largely to the environment.

2.4 Molecular Genetics and Intelligence/Cognition

One of the most quickly developing areas of behavioral genetics involves the search for DNA markers associated with human cognitive ability. For example, the APOE-4 marker is associated with a four-fold increase in risk for developing late-onset Alzheimer's disease (Breitner et al. 1998). Another notable example is the continuing research on the association between DNA markers on Chromosome 6 and reading disability (see Gayan et al. 1999).

While these markers are important in that they show that differences in the human cognitive system are associated with specific DNA markers, these studies do not necessarily show that individual differences in healthy, normally distributed cognitive functioning are influenced by these same DNA markers. A study called the IQ-QTL Project is attempting to search for DNA markers associated with intelligence. In 1998 this study yielded the first replicated DNA marker associated with intelligence (Chorney et al. 1998) and is expected to complete a full genome scan, likely yielding other markers for intelligence.

3. Implications

Taken together, these data not only suggest that genes influence the development of intelligence, but that intelligence develops differently than once thought.

Genes become more, not less important as the age of the sample increases. Genes influence the correlation among measures of intelligence, both across time and across different measures of cognitive performance. Additionally these behavioral genetic results, although indirectly measured through twin and adoption studies, are beginning to be tied to specific DNA markers. What are the implications of these data?

3.1 DNA Markers Will Likely Be General In Effect

Although the search for DNA markers is in its infancy, it is likely that the first decade of the twenty-first century will yield a set of DNA markers that account for a significant proportion of the variance in intelligence. Given the fact that twin and adoption research suggests a great deal of genetic overlap, it should be expected that DNA markers will cut across different cognitive skills, and will be stable over time. This 'molar' focus will become increasingly important as researchers turn from simply trying to find markers associated with cognitive ability to attempting to delineate the mechanism by which genes influence complex cognitive skills.

3.2 The Environment Is Also Important

A significant heritability estimate, genetic correlation, or DNA marker associated with intelligence does not mean that intelligence cannot be modified by the environment. For one, the environment is an important determinant of individual differences in intelligence, especially in childhood (the heritability of intelligence is roughly 40 percent, which means that the other 60 percent has to be due to nongenetic influences). More importantly, although heritability describes why individuals differ within a group, it does not examine average increases in ability or average differences in ability between groups. Although genetic influences account for 90 percent of the individual differences in height, for example, the height of the average person has increased, presumably due to an average improvement in the environment. Similarly, although the heritability of IQ has remained stable across the 80+ years that twin studies have been conducted, the measures used to measure IQ have been restandardized numerous times. The average IQ, although set to be 100 on a particular test, increases over time. Put another way, if a random sample of children in 1999 were given an intelligence test standardized in 1920, the average IQ would be significantly greater than 100 (Flynn 1998). Thus, behavioral genetic methods tell us 'what is' for a specific population at a specific time, not 'what will be' or 'what should be' (Plomin and Petrill 1997).

In fact, some of the most important discoveries about the relationship between the environment and

intelligence have come through behavioral genetic research. As stated earlier, behavioral genetics separates the environment into that which is shared by family members and that which is not shared by family members. Thus, behavioral genetic methods allow the examination of environmental effects that operate between families (shared environment), and environmental effects that operate within families (nonshared environment). The same behavioral genetic studies that suggest increasing heritability and high genetic correlations also suggest that the most pervasive environmental influences across the lifespan are non-shared. In other words, the most important environmental effects are those that make family members different from one another. Behavioral genetic studies are currently attempting to identify these nonshared environmental influences.

4. Summary and Conclusions

Genetic influences *are* important to understanding intelligence. However, the environment is also important. Intelligence tests are not a veridical window into genetic potential nor are they indices of environmentally driven learning. Intelligence is defined by measures of behavior and is thus subject to both genetic and environmental effects. The key issue is understanding how genes and environment work together to yield cognitive development.

Genetic Screening for Disease-related Characteristics

1. Introduction

Although one could imagine genetic screening for human characteristics that are not disease-related, in what follows we will restrict ourselves to disease-related screening. Furthermore, although disease-related screening could serve other purposes than the benefit of the participants, e.g., scientific or economic motives, we consider here only screening that has as its main goal the interest of people. So we place genetic screening in the medical perspective, where it is a component of community genetics, the application of medical genetics to the benefit of large numbers of people.

2. Definition

Genetic screening is the application of a test on people for the systematic early detection or exclusion of a hereditary disease, a genetic predisposition to a disease, or to determine whether a person carries a predisposition which may produce a hereditary disease in their offspring (Health Council of the Netherlands 1994). Testing is not restricted to the study of DNA or chromosomes, but includes the use of any test which is designed to detect and exclude hereditary disease, predisposition, or carrier state. Early detection means that the testing is applied to those who have not (yet) sought medical aid because of physical signs, symptoms, or anxiety. So it is typically the care system that takes the initiative. The word 'systematic' in the definition implies that screening is offered to all people in a predefined target group, e.g., neonates or pregnant women.

2.1 Terminology

Genetic screening shares its terminology with epidemiology and genetics. A test result is called positive when it points to the presence of the feature sought

after. Similarly, a result is said to be negative when it indicates the absence of the feature. Both results, however, may be true or false. A test result, for instance, is called false positive if it indicates that the feature looked for is present while in reality it is absent. The probability that a certain test result is true or false depends on the prevalence of the feature and two test characteristics: sensitivity and specificity. Sensitivity refers to the proportion of cases in which the presence of the feature is identified by the test. Specificity is the proportion of cases in which the absence of the feature is correctly identified by the test. The predictive value of a test result, either positive or negative, indicates how often that test result is correct.

As to the terminology of genetics the reader is referred to other articles. An exception is made for the term 'penetrance.' Penetrance is the frequency of cases in which a particular genotype comes to expression.

3. Characteristics of Genetic Screening

As with other types of medical screening, diagnostic confirmation of a positive screening test is an integral part of the screening procedure. Unlike other types of screening, however, genetic screening looks for stable characteristics of the participants. So in general, once an individual is tested, repetition of the test is not needed. In screening for infectious diseases or cancer, the majority of participants, namely the true negatives, the false positives, and the cured, have to return for subsequent testing after a set time period.

The stability of the genetic characteristics also makes it possible to predict disease long before it would become manifest without intervention. In principle this lead time (time until disease becomes manifest) can be lifelong, or with prenatal diagnosis even longer. It is clear that this is an unwanted situation unless interventive measures are more effective when they are started early.

A further characteristic of genetic screening that differentiates it from other types of medical screening is that a positive test result may frequently have consequences for the family members. This does not apply to all types of genetic screening. For instance, finding a fetus with a regular trisomy 21 Down syndrome does not increase the risk for sisters of the pregnant woman, since this is a spontaneous mutation. But finding through screening that someone carries, for example, two mutations of the gene involved in hemochromatosis puts his or her siblings immediately at a 25 percent risk of having the same mutations (Worwood 2000). They may be grateful to know this since manifestations of this iron overloading disease can be prevented effectively by regular bleeding, but the point here is that one's decision to participate in a genetic screening program is to some extent a decision involving family members who might have preferred to make such choices themselves.

4. Target Groups

The target groups for genetic screening may consist of individuals or couples. Screening newborns for phenylketonuria (PKU) or young adults for hemochromatosis are examples where the individual is the target. In both cases the goal of identifying these persons is to offer timely intervention (dietary measures prevent the development of mental retardation in PKU, and bleeding prevents the iron overloading in hemochromatosis). Other examples are screening for other inborn errors of metabolism, congenital hypothyroidism (CHT), and familial hypercholesterolemia.

Screening for carrier status of autosomal recessive diseases such as cystic fibrosis, thalassemia, and Tay-Sachs disease can be offered to individuals, but because being a carrier is only significant when the partner is a carrier too, screening for carrier status can also wait until a partner has been found and reproductive issues arise. In this case the couple rather than the individual is the target. When both partners of a couple are carriers (for the same disease) their children are at 25 percent risk for the disorder.

Screening during pregnancy may be targeted at characteristics of one to three individuals. First, the fetus may be studied directly, for instance when ultrasound is used for the detection of congenital anomalies in general or nuchal translucency (an indication for the existence of Down's syndrome) in particular. Second, the screening may involve the pregnant woman first, such as is the case with maternal serum screening, e.g., triple test. In case of a positive test result the fetus becomes involved in a definitive diagnosis. Third, both the pregnant woman, her partner, and the fetus may become involved. This is the case with couple screening in pregnancy.

4.1 Timing

As hinted at above, apart from determining who should be screened, it is important to define the best moment for screening within the lifetime of the individual or couple. The earliest possibility is pre-implantation genetic screening (PGS) in case of *in vitro* fertilization (IVF). With pre-implantation genetic diagnosis (PGD), one is looking for a disorder for which this particular embryo has a particular high risk, while in PGS the embryo at stake has a not much higher risk than other pre-implantation or IVF embryos. PGS for chromosomal anomalies, for instance, would be very helpful to select the embryos with the highest chance of survival.

Prenatal screening, newborn screening, and adult screening are discussed above. Some people advocate screening in high school. Couple screening can be performed premaritally, preconceptionally, and prenatally. Premarital screening is perhaps the best choice in cultures where selection of marriage partners is

done by third parties, without involving the partners at all. Compulsory premarital screening, after the partners have matched, as is the case for thalassemia in Cyprus, infringes personal autonomy. Preconceptional screening is characterized by difficulties of reaching the target group in time. So the majority of couple-screening programs target pregnant women (and their partners).

4.2 Taking Advantage of Family Structure

Cascade screening is a special type of genetic screening. Starting from an individual with the characteristic of interest (the proband), one offers screening to his or her first-degree relatives. Once the relatives with the same characteristic have been identified, their first-degree relatives are also offered screening, and so on. This type of screening is suitable for dominant disorders, such as familial hypercholesterolemia, and for X-linked disorders with high penetrance and low mutation rate. It has, however, also been proposed for the detection of couples who are carriers of an autosomal recessive disease such as cystic fibrosis. The disadvantage there is that only a small proportion of at-risk couples can be identified in this way. So, screening without taking the family structure into account is a better option. A combination of non-cascade and cascade screening may, however, be very efficient.

4.3 Other Technicalities

In many cases it is not possible or feasible to have a test which is 100 percent sensitive or specific. The lack of perfect specificity can be countered by subsequent diagnostic workup. When the screening involves a DNA test, specificity is usually very high. If in the cascade approach family members are tested for the same mutation as has been found in the proband, sensitivity is also very high. In case of a test with imperfect sensitivity (e.g., 90 percent), the imperfection is multiplied in couple screening (81 percent).

Couple screening has many modalities (ten Kate et al. 1996). One may test one partner first, and only if this first partner tests positive, test the other partner (single entry or step-wise screening), or one may test both partners always (double entry). One may also decide to screen partners of carriers for more mutations than is feasible in the initial screen. One may sample both partners simultaneously or stepwise. One may give complete results, or only tell the couple whether they are both carriers or not.

5. Psychosocial Impact of Genetic Screening

The purpose of genetic screening is to provide people with information about their risks and the options available to them to avoid the birth of an affected child or to take preventive measures in case of a serious

disease. Genetic screening seems especially advantageous when intervention measures are available. For instance, for women with a high risk of hereditary breast cancer, confirmation that they are carriers makes it possible for them to take preventive measures such as participating in an intensive screening program for early detection of the disease. Because the potential impact of genetic screening is considerable, the advantages as well as the disadvantages of genetic screening should be considered carefully before deciding to offer a specific screening program routinely.

The availability of genetic screening may also have its drawbacks. Although the available choices would appear to increase people's control over their own destiny, they are actually experienced by many as an additional burden. An indication of the perceived difficulty of decisions is the finding that although most people at risk for a genetic disease say they intended to be tested in the future, many are not (e.g., Lerman et al. 1996). Some people might prefer the uncertainty of not knowing above the certainty that, for instance, they will develop a serious disease for which there is no cure, such as Huntington's disease. In addition, with the increasing possibilities and availability of genetic screening, more and more people, some with a very low risk for chromosomal abnormalities who first did not consider screening, are now confronted with the choice to undergo screening. In many countries young pregnant women with a low risk of having a child with Down's syndrome are offered prenatal screening. If they choose screening, they must cope with the possibility of a positive screening result and the implication that confirmation is needed with invasive diagnostics such as amniocentesis that itself carries a risk of miscarriage. When they decide against screening, they must deal with the feelings that they could have done otherwise in case things turn out badly and the child is affected.

The decision for or against screening is not only complicated emotionally but also cognitively. Genetic risk information is complex and replete with uncertainties, associated not only with the hereditary nature of the disease but also with (un)informativeness of the test results, the effectiveness of preventive measures, and the variability of expression of the disease (incomplete penetrance). For example, when a woman is diagnosed as 'at risk' for breast cancer based on family history, there is only a 30 percent chance that DNA testing will result in a conclusive test result. If a woman is a carrier of the breast cancer gene, she has an increased risk of getting breast cancer: 7 out of 10 women who are carriers will get breast cancer before the age of 75, and 3 of them even before 40. There is a 3 in 10 chance, however, that a woman who is a carrier will not get breast cancer. This is complicated information and difficult to integrate to make the decision about testing (e.g., Bottorff et al. 1998). Providing information about genetic risks of, e.g., breast cancer is considered an important component

of genetic education and genetic counseling. The importance attributed to risk information is illustrated by the fact that recall of risk information and understanding of probabilities are considered central measures of the effectiveness of genetic counseling. The underlying assumption that accurate perception of risk could help people to make informed and individual decisions seems to be based on the principle of the autonomous and rational decision maker. From this perspective the most important goal of genetic education and counseling is to provide people with all relevant information in an understandable way. It is therefore important to find the best format to communicate risks and to stimulate a rational tradeoff of pros and cons of several options. Research has shown, however, that people find it difficult to understand risks and to make rational tradeoffs. It has been shown that knowledge of actual population risks of, e.g., breast cancer is far from adequate. People either underestimate or overestimate the risk and often fail to make a distinction between the population risk and their own risk. Genetic counseling has been shown to improve accurate risk perception, although the majority of women still have an inaccurate perception after counseling (e.g., Cull et al. 1999).

In the case of screening for a hereditary disease, the decision to screen is complicated by the potential impact that test results could have on family members. As has been pointed out, genetic screening may have implications for family members and may put familial relationships under pressure. For example, one sister may want to know more about the hereditariness of breast cancer while another sister might prefer not to know. The same goes for couples when there is no agreement as to whether to test for carrier status for, e.g., cystic fibrosis.

If the decision is made and test results become available, these need to be interpreted. Mostly, test results also involve uncertainties. A positive test result after prenatal screening for Down's syndrome means that the risk of having a child with Down's syndrome is higher than 1 in 250. A decision then must be made whether or not to confirm this chance estimate with invasive diagnostics whereby the extra information must be traded off against the risk of a miscarriage. Screening and waiting for the results have an emotional impact on people. Receiving test results, whether they are positive or negative, is also emotionally stressful. Many low-risk people are likely to undergo testing for reassurance and hope for a good result. Most of them will receive a negative test result. For those who perceive themselves as being at risk this is reassuring, but the news will perhaps be learned at the expense of knowing that they were at risk in the first place. It has been shown that anxiety exists even after negative results of prenatal screening (Green and Statham 1996). Learning what could go wrong without the possibility of ruling out all possible defects makes women more aware of birth defects and affects their

sense of vulnerability. Testing for carrier status of cystic fibrosis involves a large number of mutations but it is practicable to test only for the most common. If tested negative, the carrier status of cystic fibrosis, therefore, cannot be ruled out completely and no complete reassurance can be given that one is not a carrier. Even if testing implies that the person is not at risk, some members of risk families for, e.g., Huntington's disease find it difficult to cope with a future that no longer includes the expectation of getting a serious disease. An explanation for these negative feelings after being tested negative is that being at risk for this serious disease was part of one's identity which then needs to be changed (Tibben et al. 1997).

A positive screening test is obviously upsetting even if it turns out to be false. Women having diagnostic tests as a result of a positive screening test have been shown to be especially anxious compared to women who chose amniocentesis directly. Most of these women will be shown not to carry a child with Down's syndrome, and their anxiety can be considered to be unnecessary. Testing positive as a carrier of a recessive disease such as cystic fibrosis without actually having the disease can affect one's view of and one's optimism about the future. Being identified as a carrier for a genetic disease may affect how an individual perceives him- or herself and how he or she is perceived by others. Being tested positive for a disease for which there is no cure (such as Huntington's disease) also affects one's view on the future. Because nothing can be done to prevent the disease, this knowledge will not be considered as useful by all people (Keenen 1996). As more genetic conditions become diagnosed before any cure is in sight, more and more individuals will be added to the at-risk pool many years before a cure is possible. Some people may even be at risk their whole life for a condition they will never develop. It is therefore important to determine for which conditions and for whom genetic testing should be available.

It could be argued that at the basis of many of the problems or possible negative effects of genetic screening described above is a poor understanding of genetics, the tests, and the meaning of test results. It is therefore very important that the public as well as people with an at-risk status learn more about genetics, what it means to have some abnormal genes, how best to make a decision, what it means to have a positive screening result, etc. Professionals should learn the best way to provide genetic information in such a way that people can make a balanced decision for or against genetic screening and be able to cope with the test results so that the advantages of screening will be maximized and the disadvantages minimized (Schwartz et al. 1999).

6. Criteria

There are many genetic, medically relevant characteristics for which, in theory, screening could be started

now. There will be many, many more in the future. It is quite clear that it is not desirable to screen for all these characteristics, and careful selection is needed. Apart from potential benefit, potential harm should be considered. Harm could be physical, psychological, social, or otherwise. Not only the effects of screening on the participants should be taken into account, but also the effects on nonparticipants.

Many individuals and groups have worked on the development of criteria that should be fulfilled for screening in general (EUROGAPPP PROJECT 1999–2000, Holtzman and Watson 1997, Nuffield Council on Bioethics 1993). Some countries have also developed specific legislation. It is widely recognized that every individual screening program should be tested to see if it reaches appropriate standards.

Basically, the information that is needed for this test can be grouped into three sets. The first set concerns what is known about the disease or characteristic and about the screening program (state of knowledge). The second set concerns the advantages and disadvantages arising from the screening, and the third set is about the guarantee of autonomous decision.

The disease should be well delineated. Its general course should be clear but also the amount of variability in its course. The effects of intervention should be known. A reliable test should be available with known sensitivity, specificity, and predictive value. The screening program should be described in detail, including the availability of intervention and follow-up. Privacy protection, and permanent quality control of all aspects of the program should be ensured.

Practical courses of action should be available for the participants, such as preventive measures or reproductive choices. The psychological and social effects should be known for the participants and nonparticipants in general, but also and in particular for those among the participants who are faced with a positive test and those among the nonparticipants who are confronted with the disease in themselves or in a child. Also, more remote effects on society should be considered, e.g., on the amount of support for handicapped people. Finally, the financial costs of the program should be taken into account and alternative strategies to combat the health problem should be considered. All this information should make it possible to compare and weigh the benefits and drawbacks of the program. The final balance should be clearly biased towards the benefits.

Participation in the screening program should be voluntary and based on good-quality information and informed consent. People should be given enough time to reach a balanced decision. This requirement may be difficult to realize in prenatal and neonatal screening, but every effort should be made to inform pregnant women about the decision to come as early in pregnancy as possible. People should have ample opportunities for pre-test consultation. People should

not be taken by surprise (as in opportunistic screening).

It is desirable to have an authority to supervise all (genetic) screening programs in a country or larger region. Criteria should be the same for screening programs offered by nonprofit organizations and commercial firms. As more and more tests become available, problems inherent in multiple testing arise. Multiple testing increases the frequency of false negative and false positive results and augment the difficulty of giving sufficient information to reach a balanced decision.

The complexity of genetic screening makes it a multidisciplinary area, involving medical doctors, laboratory specialists, epidemiologists, psychologists, sociologists, jurists, ethicists, patient organizations, and representatives of the community.

Genetic Studies of Behavior: Methodology

The phrase 'methodology in genetic studies of behavior' is intended to cover any scientific analysis of behavioral phenomena that includes biometric genetic information. Human beings have multiple thousands of genes—specific DNA sequences on specific areas of the chromosomes—and each gene represents a specific sequence of amino acids that creates RNA for the formation or coding of specific proteins. Different versions of a gene appear as a pair of *alleles* at a specific position or *locus*, and a specific collection of alleles are labeled a *genotype*. While over 99 percent of all genes in humans are identical to the corresponding genes in all other humans, the other 1 percent are important because they are thought to lead to individual differences in both genotypes. Human beings exhibit multiple thousands of observed behaviors and any well-defined subset of these behaviors is labeled a *phenotype*. In these terms, the methods of genetic analysis of behaviors are used to clarify and improve our understanding of the relationships among particular variations or combinations of genotypes and particular variations or combinations of phenotypes.

Genetic methods and analyses have roots in the nineteenth century, specifically in Charles Darwin's well-known ideas on evolution and Gregor Mendel's work on the mechanisms of heredity in plants. Many techniques used in genetic analyses of behavior were initiated in the agricultural sciences to better control the size and health of plants and animals, further developed in the medical sciences to understand and control sources of disease, and are now routinely used in large-scale family studies to better understand many

behavioral phenomena. Most of the latter methods described here stem from the classical nineteenth century work of Sir Francis Galton on the measurement of individual differences in physical and mental characteristics (Johnson et al. 1985).

In this article, we discuss some historical background, we focus on contemporary methodological issues, and we emphasize the methodological unity of most current genetic approaches. We do not deal with important contemporary issues about the use of genetic information (i.e., genetic testing and screening, ethical use of genetic information, human cloning, genetically altered food, etc.).

1. Classical Methods in Genetics and Behavioral Studies

From a historical point of view, human genotypes have been very difficult to measure and have often been treated as unobserved or latent attributes. Analyses of family trees or 'pedigrees' were among the first scientific evidence provided to clearly establish that aspects of human behavior are influenced by genetic variation. Figure 1 is a chart of a family tree or 'pedigree' from Galton of the inheritance of hemophilia in the family of the English Queen Victoria, Prince Albert, and their descendants. The pedigree method has been used to establish whether given disorders (e.g., hemophilia) run in families and, if so, what kind of inheritance (dominant or recessive, autosomal or sex-linked) best fits the observed pattern,

for example hemophilia was found to be a sex-linked characteristic carried on the X chromosome. In another well-known example, clinical research on mental retardation, especially research showing the effects of inbreeding and the genetic cause of Down syndrome, has established the role for genetic regulation of impaired intellectual functioning (for references see Dixon and Johnson 1980, McArdle and Prescott 1996).

Findings from clinical disorders led researchers to investigate whether genetic factors might regulate aspects of behavior within the normal range of variation. Early evidence for genetic effects on normal

Figure 2

The results from Robert Tyron's (1940) selective breeding for maze learning over 20 generations of rats (from McGill 1965, p. 75)

Figure 3

A path analysis model of inheritance of coat-pattern in guinea-pigs (from Sewall Wright 1920)

behaviors came from selective-breeding studies with non-human animals. Figure 2 is a plot of results from the well-known selective-breeding studies of Tolman, Jeffress, and Tryon (Tryon 1940 as reported by McGill 1965). In these studies a heterogeneous stock of rats was tested on learning tasks in an automatic maze. The observed performance in these learning tasks led the experimenters to classify each rat into one of two groups—'dull' or 'bright'—within which the rats were allowed to mate and produce offspring for the next generation. After accounting for some deleterious effects (e.g., inbreeding and regression), these investigators showed that after successive selection of relatively few generations this behavioral selection led to distinct strains of 'maze-bright' and 'maze-dull' rats. With no change in rearing environments, these experiments provided direct evidence for the role of genetic components in learning.

Galton also initiated large-scale studies based on family resemblance. He studied physical features (e.g., height) in parents and children and reported the law of 'filial regression (reversion) towards mediocrity' better known as 'regression to the population mean.' He also studied intellectual achievement and reported that individuals born to higher social classes attained higher educational and social standing than individuals born to lower classes. These family studies were not controlled experiments, so scientific inferences about the separate impacts of changing genotypes and changing environments remained obscure. Selective breeding experiments were impossible with human populations for ethical reasons. Nevertheless, experimental concepts derived from animal research gradually led to creative use of a novel class of methods

based on correlations observed among atypical groups of families—'twin studies,' 'adoption,' 'half-sibs,' and other 'genetically informative' family groupings were discussed in the early twentieth century by many researchers including Thorndike, Siemans, Merriman, and Fisher (see Spector et al. 2000).

Multivariate statistical methods were developed to accommodate unobserved or latent genotypes. Figure 3 is a path diagram from the classical work of geneticist Wright (1920) showing a complex system of influences. Here Wright suggested the environmental factors (*E*) were mixed with the heredity influences (*H*) together with 'Chance' factors (and those labeled *D*), and all were required to account for the 'coat-pattern' of a guinea-pig litter. More complex models of inheritance were defined by the quantitative rules of Mendelian inheritance and the factors of the correlation decomposition of the statistician R. A. Fisher and later by many other including R. B. Cattell, and J. Jinks and D. Fulker (see Falconer and Mackay 1996).

Advanced versions of these genetic methods are now widely used in behavioral research. The search for specific genetic abnormalities linked to behavioral disorders continues at a rapid pace in research from the Human Genome Project (e.g., Strachan and Read 1995). Genotypes are now directly related to behaviors using experimental techniques based on direct manipulation of the genome in model organisms, as well as statistical techniques of linkage and association (Elston 1998). In advanced statistical studies, substantial progress has been made in the use of mathematical and statistical techniques for studies of family resemblance based on latent genotypes and latent phenotypes (McArdle and Goldsmith 1990, Neale and

Cardon 1992). In the next four sections we highlight contemporary issues in these methodologies and present some issues for future research.

2. Contemporary Experimental Methods with Measured Genes

The last decade of the twentieth century has seen a revolution in molecular genetic methodology. Techniques based on recombinant DNA methods permit direct measurement and experimental manipulation of variations in genotype or gene expression. It is useful to divide these techniques on the basis of whether they primarily use information about a gene's position within the genome, a gene's function, a gene's DNA sequence, or a gene's protein product to develop our understanding about the genetic influences on behavioral characteristics.

Studies based on positional information are usually aimed at the long-term goal of positional cloning of the gene or genes that influence some trait (Burmeister 1999, Schork and Chakravarti 1996). In positional cloning, one capitalizes on the fact that Mendel's law of independent assortment does not hold for genes that are physically near each other on the same chromosome, so genes do not assort randomly. Rather they tend to co-segregate within families to a degree that is monotonically and directly related to their physical proximity to each other on a chromosome. A genetic marker is a specific physical location on a strand of DNA. If co-segregation is observed between a genetic marker and a phenotype, it is reasonable to conclude that the marker is physically close or linked to a gene influencing the phenotype. When this co-segregation is examined as an association between markers and phenotypes within families one is generally testing for linkage. When this co-segregation is examined as an association between markers and phenotypes across nominally unrelated individuals one is often testing for linkage disequilibrium (Elston 1998).

There are many types of studies that use positional information to find genes influencing traits in non-human animals (e.g., Lynch and Walsh 1998). Selective breeding studies with measured genes are the conceptually simplest method used to locate genes influencing traits. These studies are based on measurements of the frequencies of alleles at genetic loci in an outbred population. Any loci exhibiting statistically significant changes in allele frequency over generations are either locus influencing the trait or linked to loci influencing the trait.

A more complex but efficient method uses recombinant inbred strains. Once several inbred strains are produced, one animal from each line can be genotyped at a set of marker loci. Because all animals within a strain have the same genotype, it is only necessary to genotype one animal within each strain to

know all animals' genotypes. At each locus of interest, one simply tests whether the different lines (i.e., AA vs. BB genotypes) have different phenotypic outcomes. If significant differences are found, this is evidence that the locus under study either causes variation in the phenotype or is linked to a locus that causes variation in the phenotype. In certain situations, the use of inbred strains can be quite efficient in terms of both genotyping and phenotyping costs. More complex methods involve intercrosses between inbred strains, multipoint analyses with simultaneous uses of multiple markers, multivariate analysis of multiple phenotypes, selective sampling, and other enhancements.

One limitation of all approaches based on positional information is that they only work with existing variation within a gene, that is, they do not tell us what genes are fundamentally important to a phenotype when all individuals within a population have the same alleles at that gene. In one kind of experimental approach, molecular geneticists are now able to alter or remove particular genes and observe the behavioral effects. One of the most common types of induced mutation studies is the development of a 'knockout' animal where a specific targeted gene is disrupted or 'knocked-out.' Another type of study is based on the use of random insertion clones—expressed sequences tag (EST) acting as a molecular homing device—to disrupt genes throughout the genome. Another type of direct genetic manipulation is referred to as the generation of a 'transgenic' model where additional genetic material or a new gene is inserted into an animal. A final approach to studying gene function uses microarrays, small silicon chips, which have been set up to simultaneously measure the amount of expression of literally thousands of genes. This approach is permit study the circumstances under which certain genes come in to play and, in future research, may permit analyses of multiple interactions of measured genes with measured environments.

3. Contemporary Statistical Methods Based on Measured Genotypes in Humans

In human studies, one classical way to find genes that influence behavioral traits is to look for cytogenetic anomalies among rare individuals with respect to those traits (see Dixon and Johnson 1980). If a cytogenetic anomaly affects a large segment of the chromosome (i.e., missing, transposed, or present in extra copies), and it can be detected in the individuals, then it is plausible that the genomic region of the anomaly harbors a gene influencing the trait. While this method may provide a good starting point for further study, most behaviors are not marked by discontinuity, are not related to abnormality, and cannot be examined in this simple way.

In the method known as linkage analysis, associations (e.g., correlations) between transmission of a

measured allele and some measured phenotype are studied within families (Elston 1998). The variety of methods for testing for linkage in human studies is now quite large, but the prototypical study is the sib-pair study. Two classes of tests are commonly applied to quantitative genetic information. Neither relies on the assumption of a particular genetic model (Elston 1998) and both are based on allele sharing at marker loci (Lander and Schork 1994). Covariance-based tests are based on standard statistical principles and are commonly used (Allison et al. 2001). Under the null hypothesis of no linkage between a marker and a quantitative trait locus (QTL), there will be no association between the number of alleles a sib-pair shares identical by descent (IBD) and their degree of phenotypic similarity for the traits under study. In contrast, when there is linkage between the marker and the QTL, there will be a positive association between (a) the number of alleles a pair shares IBD and (b) the degree of phenotypic similarity of the pair. Thus, by evaluating whether there is evidence of positive covariance between IBD and phenotypic similarity one can test for linkage. Another class of tests is based on inferring such association by observing a departure of the 'marginal' distribution of IBD from its null expectation in samples of sib-pairs that have been selected on the basis of their intra-pair phenotypic similarity or dissimilarity.

One of the key issues in both human and non-human genetics, particularly linkage analysis with large numbers of candidate genes, is the determination of an appropriate threshold for statistical significance given the enormous amount of multiple testing conducted (Lander and Schork 1994). Although no definitive consensus now exists, probability or p -values greater than about 10^{-4} are rarely taken as compelling evidence for a linkage effect. Reports of p -values smaller than 10^{-4} are common and are often persuasive. However, as in any statistical model, these p -values are calculated under various untested assumptions (e.g., distributional assumptions, accuracy of genotyping, accuracy of phenotyping, independence of observations) and the test procedures may lead to empirical Type I error rates which exceed (or fall below) nominal alpha levels (e.g., Allison et al. 1999). It follows that small p -values alone should not be taken as convincing evidence for a linkage finding in the absence of additional evidence. Researchers look for careful documentation of the statistical robustness of the finding (e.g., bootstrap and sensitivity analyses), replication in an independent data set, or confirmation through independent methods such as gene knockouts in animal models.

Perhaps the chief limitation of linkage analysis in the context of human studies is low statistical power. For example, to detect a QTL explaining 5 percent of the variance in a phenotype would usually require that one study, or at least screen, thousands of sibling pairs. The reasons for this low power are manifold, but

chief among them is the fact that in linkage analysis in humans, one is generally not examining the direct effect (in terms of mean displacement) of different alleles at a QTL, but rather the variance explained by the QTL (i.e., a variance component). In addition, this is only an indirect estimate based on the observation of IBD scores at a marker allele, and these alleles are only partially correlated with IBD scores at the QTL. This being the case, initial analyses focus on a simple test of mean differences in phenotype by genotype at a putative QTL; such a test is referred to as an 'association test' in the human genetics literature. Under most circumstances, association tests will be enormously more powerful than linkage tests when one has the polymorphisms of the actual QTL in hand. The typically greater power of association tests has led some to suggest that linkage analyses be replaced by association tests, but this position has led to controversy (e.g., Risch and Merikangas 1996).

One special concern comes from the need to control for background correlations or other confounding, usually referred to as admixture or population stratification in the context of human genetic studies. These confounds arise from the fact that the effects of alleles at any one locus may be stochastically dependent upon the effects of alleles present at another locus even if these two loci are not physically linked on the same chromosome. To avoid the inappropriate conclusions that could stem from such confounding, Spielman et al. (1993) developed what is termed the transmission disequilibrium test (TDT). In the TDT, one counts the number of times a particular allele is transmitted to an offspring affected with the disease from a parent that is heterozygous at the marker locus. If a particular allele is transmitted from a heterozygous parent (i.e., a parent that has two different alleles at the candidate locus) more than 50 percent of the time (i.e., the chance expectation) this is evidence that, not only is that allele associated with the disease, but that it is also linked to a locus which causes the disease. This is because, under ordinary circumstances, each allele a parent has at a genetic locus has an equal (50 percent) chance of being transmitted to an offspring, so any difference from this expectation is evidence of both linkage and association. Since then, numerous extensions of the TDT approach have been developed for both qualitative and quantitative traits (e.g., Allison 1997, Allison et al. 1999).

4. Contemporary Statistical Methods Based on Latent Genotypes in Humans

The vast numbers of human genotypes are very difficult to measure and are necessarily treated as latent attributes. This is especially true when a complex of influences and a complex of outcomes are considered. In behavior genetics and genetic epidemiology

all statistical methods utilize classical biometric genetic theory to define and specify the relations among the underlying components thought to represent a continuously distributed trait (e.g., Falconer and Mackay 1996). Most models start by asserting that individual genes combine to produce the underlying genotype. Furthermore, these genes are assumed to be: (a) numerous or 'polygenic,' (b) additive in effect, (c) segregating independently (i.e., the probability of receiving one gene is independent of the probability of receiving others), (d) not sex-linked (i.e., located on the X or Y chromosomes), and (e) not influencing characteristics used for spousal selection.

These biometric assumptions are important because they lead to statistical expectations about the observed correlations among pairs of relatives. If all resemblance between relatives in a family is due to genetic sources, the correlations between their observed phenotypic scores are expected to be proportional to the correlations between their genotypic backgrounds, and unrelated individuals would be uncorrelated. More specifically, the genotypes of first-degree relatives correlate (on average in a large sample) at $1/2$. First-degree relatives include fraternal (also called dizygotic or DZ) twins, ordinary siblings, and parent-child relationships. The genotypes of second-degree relatives (grandparents-grandchildren, aunt-niece, half-siblings) are expected to correlate $1/4$, and the third-degree relatives (cousins) at $1/8$, etc. Unrelated individuals living together, such as stepsiblings or parents and their adopted children would be expected to have zero genetic correlation. In the special case of identical (monozygotic or MZ) twins, the genotypes are considered identical and correlate 1.0. Of course, the adequacy of inferences from the sampling of people that are related or unrelated is a major concern of behavior genetic researchers.

Nongenetic influences are often considered as well. In some models the similarity in behavior is expected to be correlated with the similarity in relevant environments (e.g., home of rearing or social background). If true, the highest correlations would be found in scores from twins and similar-aged siblings, lower correlations from parents and children, and still lower correlations from related individuals who have not lived together. Thus, under a purely environmental hypothesis, adoptees should be as similar to their adopting parents and siblings as any other children, and related individuals living in different environments would have scores with no correlation. A model that includes both genetic and environmental sources of familial resemblance would produce estimates intermediate between these other two. All such models can include measurement error and the influence of experiences unique to particular individuals, so even MZ twins living together are not expected to have scores that correlate perfectly.

Different family data permit different assessments of the theoretical components. Figure 4(a) illustrates

this kind of latent path model for a 'family' design. In this model, additive genetic and shared environmental sources of resemblance are confounded, that is, any interpretation of family resemblance cannot be partitioned into separate additive genetic scores (A) and common family environment scores (C). In the adoption design of Fig. 4(b) these A and C components are (theoretically) separable, and the only source of parent-child resemblance is through cultural transmission, resulting in an estimate of common family effects. By comparing differences in resemblance among family members in the adoptive versus biological family designs, an estimate of the additive genetic (A) contribution to the phenotypic deviation is obtained.

Figures 4(c) and 4(d) show models for resemblance between siblings or fraternal (DZ) twins and identical (MZ) twins. In this kind of model, pairs of DZ twins and pairs of full siblings are assumed to have the same genotypic correlation, even though the siblings can differ widely in chronological age. Unlike the family and adoption models, here we cannot estimate the effects of assortative mating based on the correlation between A and C . In most twin models these correlations are assumed to be zero although fixed estimates from other sources can be inserted. Using these assumptions, the twin design can provide estimates based on the difference between the resemblance between MZ and DZ pairs. The special case of MZ twins raised apart (MZA) is important because, in theory, these data permit a complete separation of these latent components.

Structural equation models developed in several areas of science are used in behavior genetics to organize, estimate, and test aspects of these theories of underlying influences (McArdle and Goldsmith 1990, Neale and Cardon 1992). In some recent models an observed phenotype (P) is often cast as a simple combination of true scores (T) and error of measurements (W). Behavioral genetics models go further and include unobserved variables representing the biometric hypotheses: Additive genetic scores (A), non-additive genetic scores (D), common family environments (C), other nongenetic (E) components, and possibly other complex sources. The goal of the structural analysis is independently estimate the total impact (contribution to the variance) of the separate components using the available data from relatives. The statistical basis of the models relies on features common to many scientific analyses—maximum likelihood estimation and likelihood ratio comparisons (e.g., chi-square tests). A sequence of nested statistical tests is routinely used to examine the necessity of each latent component and confidence boundaries can be created.

After specific model coefficients are estimated at a specific value, it is possible to standardize the unobserved variables, assume the latent scores (A , C , and E) are uncorrelated (orthogonal), and calculate the

Figure 4

Latent variable path models for the analysis of family resemblance (from McArdle and Prescott 1996). (Note: In these diagrams: (1) Squares are used to represent observed or measured variables. (2) Circles are used to represent unobserved or theoretical variables (3) One-headed arrows are used to represent fixed regression coefficients. (4) Two-headed arrows are used to represent estimated variance or correlation coefficients.)

unobserved genetic variance. In order to compare results for phenotypes with different measurement scales, it has become common to calculate the 'heritability' ratio—the unobserved additive genetic variance divided by the observed phenotypic variance ($h^2 = V_a/V_p$). This kind of calculation may or may not take into account the common family environment, other genetic factors (dominance, epistasis), and is limited by the sample phenotypic variance. In most published research this sample statistic (h^2) is reported and the utility of this routine practice has been seriously questioned (e.g., Gottlieb 1997, Wachs 1999, Hooper in Spector et al. 2000).

There has been a great deal of recent progress towards addressing more complex problems and creating methods that permit the study of more complex patterns of influences. Contemporary behavioral genetic methods do include the possibility of evaluating these more complex patterns of influence, including: parent to child environmental transmission of shared effects, further decomposition of the non-shared environments, the correlation between spouses, and the separation of measurement error via multiple phenotypes. The possibility of a correlation between A and C variables is an important feature of contemporary models. These correlations can be meaningful

but they often cannot be estimated without more extensive data collections and more complex models. In this recent work, parameters for all effects are estimated by assuming the model parameters are invariant over all the multiple groups of Fig. 4. Other important model features include nonadditive genetic effects such as dominance (nonadditive effects of alleles at the same locus) and epistasis (nonadditive effects of genes at different loci) and the general utility of mean intercepts, subject sampling corrections, and multivariate phenotypes (see McArdle and Goldsmith 1990, Neale and Cardon 1992, McArdle and Prescott 1996).

5. Future Issues in Genetic Methods for Behavioral Studies

As with any methodology, there are both strengths and weakness of the genetic methods discussed here. Direct gene measurement permits usually strong experimental designs—in gene association analyses, the appropriate dependent variable is phenotype and the appropriate independent variable is genotype. However, in most studies the genotype is a nearby marker and not the gene of interest. This produces several

unresolved questions that generate skepticism about the value of association tests: (a) Can candidate loci and polymorphisms be identified with sufficient confidence to be useful? (b) Can enough separate polymorphic loci be studied to do genome-wide association studies when candidate loci cannot be confidently identified on an *a priori* basis? (c) Can confounding by population admixture/stratification be controlled? (d) Will applied investigators conduct association studies with adequate rigor even when the tools are available to them?

The challenge of creating hypotheses about candidate genes must be acknowledged, but this is more a limitation than a flaw of the method. The availability of sufficient markers when one wants to go beyond prespecified candidate genes, the ability to economically assess a large number, and the ability to determine how large that number needs to be are currently being addressed by many researchers. The occasional lack of rigor in the conduct of association studies should not be trivialized, but is a problem that potentially affects all areas of research.

There is ongoing research in trying to understand genes and their role in producing phenotypic effects by studying the more complete gene sequence and gene-protein structure. This latter field is often referred to as proteomics and is one of the most active fields in molecular biology at the beginning of the twenty-first century. These methods will become increasingly important in the future and, moreover, will be combined with studies involving information about gene position, gene function, and behavioral measurements to provide a much richer picture about the way genes work to produce their effects. In these more detailed analyses of measured genes we may also be able to study about how gene-protein functions are stimulated by specific environments.

In a similar vein, the statistical methods for latent genotypes rest on assumptions that may not be reasonable representations of the underlying mechanisms, and some of these assumptions are not testable. Statistical biases arise in adoption studies when the effects of selective placement lead to a correlation between the genotypes of the biological and adoptive parents. In twin data, positive assortative mating leads to underestimates of additive genetic effects and overestimates of downward and common family effects. In addition, the standard twin model assumes that both kinds of twins experience similar environments to an equal degree, but the similarity of MZ pairs is in part due to sharing a more similar common environment, the additive genetic effects will be raised spuriously.

But other modeling assumptions are more fundamental and problematic. For example, the classical models above routinely assume no interaction of the genetic and non-genetic components, initially because these additional components are hard to estimate without detailed measurements of both the genotypes

and the environments. Similarly, the concept of genotypes as immutable characteristics with asymmetric direct effects on phenotypes is often challenged. Researchers often suggest that both genes and the environments play an important role in creating constraints on developmental processes (e.g., Waddington 1962, Gottlieb 1997, Wachs 1999).

More complex genetic methodologies are needed to answer these complex questions about complex human characteristics. These are not questions that can be simply answered in terms such as, 'we have found the gene(s) *Q* for behavior(s) *P*,' or, 'recent twin research shows *P* is largely genetic.' Further answers for the questions raised here will, no doubt, combine the best aspects of both measured and latent genotype approaches. Recent research demonstrates the natural convergence of QTL analysis and latent variable structural models (e.g., Neale in Spector et al. 2000). Newer models are likely to include basic information about the phenotypic outcomes in terms of multivariate measurement models combined with longitudinal dynamic modeling.

A clearer understanding of the methods, models and results from these newer analyses may illuminate the complexity of genetic theory and behavioral theory, as well as the appropriateness of scientific inferences that can be made from such studies. We are given pause when we consider that, even after the entire human genome is accurately mapped, we will still be confronted with an enormously complex set of analytic problems—of linking genotypes to proteins, and proteins to physiology, and physiology to basic levels of behavior, and basic behaviors to more complex ranges, constraints, and the resulting limitations on multiple behaviors. The prior methodological advances have carried us very far, but we now look forward to the future development of novel methods for these monumental tasks.

Genetic Studies of Personality

Genetic studies of personality focus on (a) evaluating the extent to which genetic influences are important

for individual differences in personality traits and (b) demonstrating whether or not specific genes are associated with personality traits. The thought that genetic effects may be important for personality is not new. Indeed, many cultures have sayings, for example, in Swedish and English, 'the apple does not fall far from the tree,' which suggest that genetic effects are important. Formal studies of genetic effects on personality started with Sir Francis Galton, who examined familial similarity for a variety of human characteristics. During the twentieth century, multitudes of behavioral genetic studies of personality have quantified the relative importance of genetic effects. Genetic differences among individuals account for on average 40 percent of the variance (individual differences) observed in most personality traits. Many specific genes are likely to be associated with personality, each with small effects.

1. Behavioral Genetic Studies of Personality

Twin, family, and adoption studies have been the primary source of information on the relative importance of genetic effects ('heritability') for personality. Behavioral geneticists study the similarity of individuals who share genes and environments to different degrees to quantify heritability. In the classical twin study, identical twins share all of their genes in common whereas fraternal twins share on average only half of their segregating genes in common. Thus, if genetic effects are important for a personality trait, identical twin pairs should be twice as similar as fraternal twin pairs. Similarity between parents and offspring or among siblings may also indicate the influence of genetic effects. The importance of the shared rearing environment can be evaluated by assessing the similarity of adoptees and their adoptive parents. Environmental influences can also be individual specific, or 'non-shared,' i.e., contributing to differences among family members. Behavioral geneticists typically apply structural equation modeling techniques to paper and pencil self-reports of personality when estimating heritability and the importance of shared and non-shared environmental influences (see *Genetic Studies of Behavior: Methodology; Genetics of Complex Traits Through the Life Cycle*).

1.1 Univariate Results

Most genetic studies of personality are based on very large twin and family samples. Personality has been assessed on over 50,000 pairs of twins in the national twin registries in Australia, Finland, Norway, Sweden, and The Netherlands, on volunteer twin registries in the USA, and on the 30,000 individuals in the Virginia study of twins and their families. Numerous smaller twin, family, and adoption studies have also been performed. Many of the studies (particularly those in

the national twin registries) have assessed personality, using versions of the Eysenck Personality Inventory. However, during the 1980s and 1990s increasing amounts of data have become available concerning other personality inventories, such as the Five-Factor Model of Costa and McCrae (McCrae and Costa 1987) and the Seven-Factor Model of Cloninger (Cloninger 1998).

Remarkably, there is considerable consensus across studies and cultures. Genetic effects account for on average 35–40 percent of the variation in personality traits such as neuroticism and extraversion. (In other words, the heritability of these traits is 0.35–0.40.) Evidence from studies of twins reared apart and adoption studies indicate that shared environmental influences account for another 5–10 percent of the variation in most personality traits, and the remaining variation is individual specific or ‘non-shared’ environmental variation. In other words, people differ for personality. Most of the individual differences we observe are due to individual specific experiences not shared by other family members and about 40 percent of the differences are due to genetic differences among us. The extent to which family members are similar to one another reflects primarily their genetic similarity, and only in part being raised in the same home.

There is some heterogeneity in genetic effects on personality. Traits related to extraversion, such as impulsivity, openness to experience, and sensation seeking tend to have slightly higher heritability estimates than those related to neuroticism and instability. Furthermore, the genetic influences for the extraversion-related traits may in part be operating in a nonadditive manner. That is, there may be interactions within or between genetic loci, such that the effect of one gene may depend on another gene. The latter effect, known as epistasis (see *Genetics of Complex Traits Through the Life Cycle*), may complicate efforts to identify specific genes that are of importance for personality traits.

Heritability estimates may be on average 40 percent for most personality traits, but there are traits for which genetic effects are of less importance. Examples of these are ‘agreeableness,’ ‘guilt,’ feelings of control over ‘luck,’ and ‘cynic hostility.’ For these measures, familial similarity is primarily due to environmental influences shared by family members rather than genetic similarity.

1.2 Genetic Influences on Stability and Change

There has been a great deal of controversy as to whether personality is stable throughout the lifespan. Some developers of personality inventories argued that finding significant heritability for personality would support hypotheses of stability in personality. Their argument rested on the misconception that if genetic effects are important they are immutable and

do not change. Despite the fact that humans are born with a full complement of genes, not all genes may be operating at all phases in life. Some genes turn on and others turn off at various transitional periods, while others may react dependent on external stressors. On the other hand, some genes may have a long-term effect that is stable across the lifespan (see *Genetics of Complex Traits Through the Life Cycle*). Thus, the issue of genetic contributions to stability for personality is empirically testable.

During infancy, there is less stability in temperament than is typically reported for adulthood. Nevertheless, results from longitudinal twin studies indicate that the moderate stability observed for infant temperament is influenced in part by genetic effects. During childhood, genetic effects are also important contributors to phenotypic (i.e., observable) stability. Longitudinal studies of adult twins confirm findings of substantial phenotypic stability in personality. Furthermore, the genetic effects themselves are very stable, i.e., the same genes appear to be influencing personality throughout adulthood. Nonetheless, genetic and environmental influences are equally important for phenotypic stability. Even though the genetic effects themselves are very stable, they are relatively less important than environmental effects, and thus the net influence on stability is reduced. Environmental effects are the most important influences on change. Thus, genetic influences on personality contribute to stability rather than to change. However not all personality stability can be explained by genetic influences alone.

1.3 Structure of Personality

Developments in theories of personality have been paralleled with developments in statistical analyses of genetically informative data. During the 1980s and 1990s, the three-factor approach to personality was gradually extended to the five-factor theory and the seven-factor theory (McCrae and Costa 1987, Cloninger 1998). The factor analytic approach generally applied at the phenotypic level is also applicable at the level of genetic and environmental influences. The question to be addressed is whether there is a genetic factor structure or an environmental factor structure that is similar to the phenotypic factor structure. Do genetic or environmental effects mediate the associations among various aspects of personality? This line of analysis has only recently been applied and promises to be an important area for future research concerning the structure of personality.

1.4 Genetic Mediation of Associations with Personality

Health psychologists have demonstrated that personality is important for health outcomes (such as

cardiovascular disease, cancer, and osteoarthritis) and response to treatment such as recovery from surgery. Current research efforts are focusing on the extent to which genetic and environmental effects mediate the associations between personality and health outcomes. By evaluating these associations, much can be learned about the mechanisms by which personality affects health. For example, neuroticism in young adulthood is predictive of joint pain and osteoarthritic symptoms some 25 years later in midlife. Genetic influences in common to neuroticism and joint pain and shared familial environmental influences mediate this association. There are no genetic influences unique to joint pain. Because neuroticism preceded the joint pain, it is likely that genetic effects are important for neuroticism which in turn influences joint pain and osteoarthritic symptoms through response to stress, immune, and inflammatory processes (Turk-Charles et al. 1999).

2. Molecular Genetic Associations with Personality Traits

The second major approach to the study of genetic influences on personality is to test whether specific genetic variants, or alleles, are associated with mean level differences in personality traits. Because personality traits are most often continuous measures and heritability analyses suggest that these traits are polygenic, the challenge is to find genes of medium effect size that influence personality levels. These genes are known as Quantitative Trait Loci or QTLs. Most efforts to identify which genes may be associated with personality traits are currently focusing on genes involved in neurotransmission, such as dopamine receptor genes and serotonin receptor and transporter genes. Many of the findings are only preliminary, and often with contrasting results or lack of replication in other studies or populations.

Finding genes that have relatively small effects will present great challenges to behavioral and genetic scientists, for several reasons. First, because many genes are likely to be involved, each with a small effect, very large sample sizes will be necessary to obtain sufficient statistical power. Second, many of the genes may be interacting with other genes, a phenomenon known as epistasis. For example, a particular allele for gene A may only influence personality negatively if a specific variant of gene B is present. Preliminary findings from large population-based studies suggest that some epistasis exists for personality and genes in the dopaminergic system. Third, there may well be substantial interactions between genes and environments that hamper the potential to find genotypic or even environmental associations. The impact of negative life events is greater in individuals with a genetic susceptibility to major depression, suggesting an interaction between genetic and environmental influ-

ences. Similarly, the effects of some allele may be enhanced or reduced depending on environmental circumstances. Again, large samples with genetic and detailed environmental characterization will be necessary to delineate the respective roles of genes and environments. In this fashion, scientists will come closer to understanding not only how much, but how genes influence personality.

3. Future Directions

Behavioral genetic analyses have provided a firm foundation for further studies on genetic influences on personality. Genetic influences are indeed important, and appear to be important for stability rather than change in personality. Further analyses of the genetic and environmental architecture of personality will expand our understanding of the associations within and among domains, such as the structure of personality and how personality influences health and other behavioral outcomes. Now that the Human Genome Project has provided a genetic map, the challenge to scientists will be to understand the function of the residents at the 30,000 addresses. Many genes, each of small effect, in interaction with each other and in interaction with the environment, are likely to influence variation in normal personality.

Genetic Testing and Counseling: Educational and Professional Aspects

The sequencing of the human genome has enabled scientists to accelerate substantially the rate of discovery of gene mutations associated with disease. As these discoveries continue to stimulate the development of clinical genetic tests for disease susceptibility, there is a growing need to effectively educate and counsel individuals about the implications of this information. Genetic counseling is the professional practice established to provide this service. The unique familial aspects of genetic susceptibility and conditions have led to the development of medical genetics counseling subspecialties in medicine and nursing, as well as specialized master's degree programs in genetic counseling. While primarily a health communication process, genetic counseling also involves the discussion of relevant psychosocial issues. Thus, it may best be described as psychoeducational. Genetic counseling providers communicate with individuals and their relatives to improve their technical understanding of the cause of genetic conditions and genetic risk. In addition, they address feelings and coping strategies related to the condition and provide support in making preventive, reproductive, and other health-related decisions.

1. Genetic Counseling

1.1 The Role of Genetic Counselors

Members of families with inherited disease often ask not only why the condition occurred, but also why it happened to them. They seek an opportunity to find personal meaning in the senseless nature of it, and search for ways to live with the risk of future disease (Kessler 1979). In this sense, many of the psychological issues associated with inherited diseases are not unique. However, the shared, familial nature of genetic risk raises additional issues that are distinctive. Inherited risk implies that what is a health risk to one individual may also be a risk to their biological relatives. In addition, when a client seeks information about inherited patterns of disease risk, it may have unanticipated consequences. Information previously kept private (such as nonpaternity or adoption) may be revealed, producing enduring effects on family relationships. Yet there also may be potential harms from failing to disclose genetic information. Individuals who remain uninformed of their risk of a preventable disease, such as advanced-stage colorectal cancer, may suffer needless morbidity or mortality.

Because of their training and expertise, genetic counselors are uniquely positioned to assess and explain the genetic nature of a disease and to address its implications. The process aims to be therapeutic in

exploring with clients their feelings of guilt, shame, fatalism, or social isolation. Genetic counseling requires health care practitioners with expertise in medical genetics, knowledge of the disease for which the individual is at risk, effective communication skills, and short-term therapeutic counseling skills.

1.2 Genetic Counseling as a Profession

Until recently, genetic counseling focused primarily on risks for and consequences of rare conditions. Consequently, there are few genetic counseling providers worldwide. Also, because most of the evidence concerning the inherited causes of many diseases is relatively new, the practice of genetic counseling is only about 50 years old (Resta 1997). The short history of the field is reflected in the limited, but growing empirical evidence concerning the process of genetic counseling and its effectiveness in facilitating informed decision making and psychological adjustment.

The type of training received by genetic counseling providers is diverse, and thus it is likely that practices vary accordingly (Biesecker and Marteau 1999). In the United Kingdom and Australasia, genetic nurses often work alongside medical geneticists to provide genetic counseling services. In the USA, Canada, South Africa and increasingly, in the UK, genetic counselors receive specialized training at the master's level to provide genetic counseling. In the vast majority of European and South American countries, medical geneticists or social workers provide genetic counseling. Genetic counseling services are not universally available, as underdeveloped nations usually have no specialized genetics health care providers.

1.3 The Principle of Nondirectiveness

Nondirectiveness is often presented as a guiding ethical principle of genetic counseling due to the importance of personal autonomy in reproductive decision-making. Genetic information even outside the prenatal setting often has implications for future childbearing decisions. The principle of nondirectiveness is intended to suggest that within genetic counseling, patients are not persuaded or coerced into specific reproductive outcomes. However, there exists disagreement in the profession about the meaning of nondirectiveness and its importance in practice (Kessler 1997). An international survey of genetic providers revealed that nondirectiveness is a nearly universal guiding ethical principle in the majority of countries that offer prenatal genetic testing (Wertz et al. 1990). An exception is China, where providers are more inclined to advise their pregnant patients to terminate affected pregnancies in the interest of reducing the incidence of children affected with genetic conditions (Mao and Wertz 1997).

2. Genetic Testing

Genetic testing describes any test for inherited factors that may influence one's health or the health of one's relatives. The method of performing a genetic test ranges from DNA sequencing or direct mutation detection, to chromosomal analysis and protein function testing. In addition, the circumstances in which a genetic test may be done vary substantially. Therefore the genetics education and counseling that surround decisions about testing or implications of test results differ in content and emphasis.

2.1 Diagnostic Testing

Genetic tests have most often been used to diagnose genetic conditions. This has been done in three different ways. First, a genetic test may be used when a child or an adult is suspected to be affected with a certain condition based on the clinical features and pattern of inheritance. Second, newborn screening for a subset of rare largely treatable recessive genetic conditions has been conducted in the USA and most other developed countries for several decades. Third, prenatal genetic testing has been available since the early 1970s, used most often to diagnose Down syndrome and other chromosomal trisomies in the developing fetus.

The diagnostic tests used in a pediatric or adult medical genetics clinic are most often considered a part of good medical management when relatives (typically parents) or their health care providers are seeking to make a diagnosis. Genetics education and counseling typically addresses the genetic and medical implications of the diagnosis, as well as the psychological impact on the family of having to live with an affected family member, and the increased risk to other relatives.

Genetic counseling occurs infrequently in conjunction with newborn screening unless a diagnosis is made in an infant. When a genetic diagnosis is made, the parents usually require extensive education about medical management as well as recurrence risks. Although most of the conditions tested for are treatable (unlike the vast majority of single-gene conditions), they require exhaustive efforts by parents to keep their child on a specially restricted diet to ensure his/her health.

Prenatal genetic testing is most often preceded by genetic counseling due to the highly personal nature of reproductive decision making. In most countries where prenatal testing is available, it is offered as an option to pregnant women who are at increased risk of having an affected child. Most commonly, this concerns those over the age of 35 years. Prenatal genetic counseling addresses the personal values of the client or couple, as they are guided in the exploration of the potential consequences of adverse test results. This

includes envisioning both what their lives might be like if they had an affected child, or how they would feel subsequent to terminating a desired pregnancy.

2.2 Predictive Testing

Genetic testing is also used to predict genetic risk. Carrier testing, for example, is used to identify those who carry a gene mutation that does not affect them directly, but may place their children at risk. Relatives of individuals affected with certain genetic conditions and members of certain populations (e.g., Ashkenazi Jews) known to be at increased risk for certain conditions, are frequently offered carrier screening. Most carrier screening programs are accompanied by pretest genetics education, since it is important that those found to be carriers do not misinterpret the test result as indicating they have the disease.

Presymptomatic genetic testing is used to predict certain risk to an individual. Presymptomatic testing for Huntington's disease, a degenerative neurological disorder, is one example. It is now possible for those at increased risk for Huntington's disease to undergo presymptomatic testing prior to the onset of clinical symptoms. Inevitably, those found to carry a gene mutation develop the disease, for which there is no treatment. Due to the dire nature of these circumstances, the counseling that proceeds such testing is often extensive. Before presymptomatic testing was available, the majority of individuals at increased risk of developing Huntington's disease reported that they would choose to undergo testing if it was developed. However, once testing was available, only a small minority of those at increased risk chose to go forward with testing.

The newest type of predictive genetic testing, predisposition or susceptibility testing, results in a risk estimate about one's own future health. The first predisposition tests developed assess inherited susceptibility for cancer. An increased risk for at least two different types of colon cancer and breast and ovarian cancer can now be determined in members of hereditary cancer families. There are also populations of individuals more likely to carry susceptibility mutations due to shared heritage.

Susceptibility tests are being developed for many other common diseases and will be offered to an increasingly large portion of the population of developed nations. As demand for these tests increases, alternatives to in-person genetic counseling for pretest education will need to be developed and evaluated. Computer and Internet-based resources are likely to grow in their importance as sources of genetics information. These technologies allow information to be tailored to the characteristics of the individual user, allowing genetic counselors to focus on counseling and decision making rather than education and information delivery.

Initial studies of cancer susceptibility testing suggest that the majority of people express high levels of interest, but that many members of high-risk families do not utilize testing once it is offered (Croyle and Lerman 1999). The exploration of the psychological and behavioral costs and benefits of this type of testing have only just begun. Although individuals found to be noncarriers of cancer gene mutations report an alleviation of distress after testing, many mutation carriers do not engage in health behaviors that would allow the early detection of disease. These observations suggest that social and behavioral scientists will continue to play a key role in identifying ways to translate the achievements of genetics and biotechnology into improvements in public health.

Genetics and Development

This article describes the major historical misconceptions of the role of genetics in the development of the individual, whether human or nonhuman animal,

and also presents our current understanding of the necessarily co-operative roles of genes and environments in the developmental process.

1. Nature vs. Nurture

Many people believe that behavioral characteristics such as personality or intelligence are determined primarily, if not exclusively, either by heredity or environment. This belief, known as the nature-nurture controversy, has been with us for quite a long period of time and is the cause for much that is sorrowful and tragic in human history (e.g., the notion that some groups are behaviorally inferior or superior to other groups because of hereditary/genetic predispositions). The idea that genes are primarily responsible for some traits and that the environment is primarily responsible for other traits is now known to be scientifically invalid. This has been a hard-won scientific insight that has not yet percolated down to the mass of humanity. It is now known that both genes and environments are involved in *all* traits and that it is not possible to specify their respective weighting or quantitative influence on any trait. These crucial points are documented in the sections that follow.

2. Behavioral Genetics

In a remarkable experiment first conducted by E. C. Tolman (1924) and continued by R. C. Tryon (1942), it was found that it was possible to selectively breed laboratory rats for their ability to learn their way through a maze. Tryon selectively inbred the superior learners among each other and the poor learners among each other. After only seven generations of breeding the brightest rats within each of the brightest litters, and the dullest within each of the dullest litters, the performance of the two groups in learning the specific maze was virtually nonoverlapping, leading Tryon to label the superior line 'maze-bright' and the inferior line 'maze-dull.' It was as if Tryon had been able, by selective breeding, to create two lines of animals which differed greatly in their general learning ability. That turned out not to be the case, however. When Searle (1949) later compared the 'bright' and 'dull' lines on a variety of learning and performance tasks, the dull rats were sometimes superior and often equal to the rats from the bright line. Being bright or dull was not a property of the animals, but, rather, was restricted to the particular learning task that served as the basis for selectively breeding the animals. As it turned out, the specifics of the outcome of the breeding program were even further constrained by the manner in which the rats were reared, as will be described in Sect. 3.

Since the time of Tolman's and Tryon's breeding experiments, the field of behavioral genetics has been able to show that it is possible to selectively breed

Table 1

Examples supporting the notion that it is possible to selectively breed animals for differences in any behavior (more-less, better-poorer, higher-lower)

Species	Behavior
Rats	Maze learning
Mice	Speed in traversing runway
Rats	Spontaneous activity (wheel-running)
Rats	'Emotionality' in an open field
Mice	Sound-induced (audiogenic) seizures
Fruit flies	Orientation toward or away from light source (positive and negative phototaxis)
Rats	Saccharin preference
Chickens	Aggressiveness
Fruit flies	Upward or downward orientation with respect to gravity (negative and positive geotaxis)
Fruit flies	Mating speed
Mice	Alcohol preference
Fruit flies	General activity

The literature sources for these experiments can be found in Gottlieb 1992, p. 150.

animals for differences on any trait, solidifying the idea mentioned earlier that genes are involved in *all* traits. As will be documented below, the results of behavioral genetics breeding experiments are also dependent on the rearing environment being kept constant from generation to generation (recall that the rearing environment is involved in all traits, too). As can be seen in Table 1, both favorable and unfavorable behaviors can be made the subject of selective breeding, not only maze learning but spontaneous activity

(wheel-running), 'emotionality,' sound-induced seizures, saccharin preferences, aggressiveness, mating speed, and so on.

As mentioned above, since all behavioral activities involve both genetic and environmental contributions, it is essential when doing selective breeding experiments to keep the rearing environment the same from generation to generation, otherwise the selective breeding experiments will be a failure. For example, in an experiment by Hood and Cairns (1989), mice were selectively bred for high and low aggressiveness. The standard rearing procedure was to keep the animals in isolation after they were weaned. After the high and low aggressive lines were established, to show the contribution of the isolation rearing procedure to the results of selective breeding Hood and Cairns reared half the animals from each line in social groups rather than in isolation. As can be seen in the right-hand side of Fig. 1, the high aggressive line did not differ from the low aggressive line when the animals were reared in social groups; the high aggressive line was only highly aggressive when reared in isolation (left-hand side of Fig. 1), the rearing condition under which the original selective breeding took place. These results lead into the topic of Sect. 3.

3. Reaction Range vs. Norm of Reaction

Until very recently some biologists and psychologists held the incorrect belief that genes strictly canalize behavioral development, creating a predictable reaction range when rearing environments are changed from the normal or usual (species-typical) to highly

**Figure 1**

Average attack frequency by male mice in two lines selectively bred for either high or low attack frequency. The original selection experiment involved males reared in isolation prior to testing. In this experiment, half of the males were reared in isolation and the others were group-reared, greatly reducing the attacks by the high line. During the test, the mice met in either the home cage, in which the mouse being tested was an intruder, or in a neutral cage (based on data from Hood and Cairns 1989. Figure modified from Gottlieb et al. 1998, p. 249)

Figure 2

Contrasting predictions of reaction range and norm of reaction for maze performance or IQ of three genotypes or individuals, as a consequence of being reared under three developmental conditions. The reaction-range concept predicts a narrow range of variation for each individual over the three rearing conditions, whereas the norm of reaction predicts an indefinitely broader range of outcomes when the rearing conditions are changed from the original condition (usual, normal, species-typical) (modified from Gottlieb 1992, p. 178)

favorable (enriched) or unfavorable (deprived) conditions.

This point of view was expressed by one authority as follows:

Canalization is the genetic limitation of phenotypic development to a few possible phenotypes...The genetic restriction of possible phenotypes is a result of coadapted gene complexes (sets of genes that have evolved together) that buffer the developmental pattern against deviation outside of the normal, species range of variation...The limitation of possible phenotypes to a few rather than many is a fact of genotypes' ranges of reaction (Scarr-Salapatek 1976, p. 63).

The belief in the sheerly genetic canalization of behavioral development leads quite logically to the reaction-range idea. Thus, the basic idea of a reaction range is that genes determine (canalize) the upper and lower limits of psychological development so that, given a knowledge of the outcome of development under one rearing condition, one can make linear predictions of the upper and lower limits of outcomes under other rearing conditions (see as an example Fig. 2).

In contrast to the reaction range, the norm of reaction holds that the outcome of development is an emergent (epigenetic) property that is a nonlinear result of co-actions occurring at all levels of the developmental system (including but not restricted to genes and environments, as elaborated in Sect. 4). Thus, it is not possible to predict outcomes from one rearing circumstance to the next. Unfortunately, it is the reaction range, not the reaction norm, that has

had, until very recently, wide currency in psychology, as evidenced in many textbooks on developmental psychology. These texts reproduced a version of Fig. 2 depicting only the reaction-range concept for learning ability or mean IQ for three hypothesized genotypes reared in very different environments, and not the norm of reaction (far right).

The difference between the predictions of the reaction-range and reaction-norm concepts is testable. As indicated in Fig. 2, the reaction-range idea predicts that the ranking of the different genotypes on IQ or learning ability will remain the same when they are reared in different environments. In the enriched environment, each genotype will show an improvement but the 'brightest' genotype will still rank above the other genotypes. In the deprived rearing environment each genotype's performance will be poorer but the brightest genotype will still rank above the other genotypes. As shown in the far right of Fig. 2, the norm of reaction makes no prediction on relative ranking when the genotypes are reared in environments (enriched or deprived) that differ from the rearing environment in which the selective breeding took place.

There is only one empirical study in the psychological literature that explicitly addresses the reaction-norm concept, a study by Cooper and Zubek (1958). The results very clearly support the reaction-norm concept. It is interesting to note that the study was carried out with the idea of a reaction range in mind, and it is sometimes erroneously cited as supporting the reaction-range concept. Cooper and Zubek reared maze-bright and maze-dull rats in either an enriched

Figure 3

Behavioral reaction range (predicted) and norm of reaction (obtained) for maze-bright and maze-dull rats' performance in a Hebb-Williams maze after rearing in three different environments. Obtained deprived and enriched data points from Cooper and Zubek (1958); obtained usual data points from Hughes and Zubek (1956). Only the obtained usual data points are significantly different from each other (from Gottlieb 1995, p. 137)

BIDIRECTIONAL INFLUENCES

Figure 4

Depiction of the completely bidirectional nature of genetic, neural, behavioral, and environmental influences over the course of individual development (from Gottlieb 1992, p. 186)

or a restricted environment and then tested them in a Hebb-Williams learning maze. Since they had the reaction-range concept in mind in performing the experiment, Cooper and Zubek thought that the learning of both the bright and dull rats would improve relative to each other under the enriched rearing circumstances and would be poorer relative to each other when reared under the restricted (deprived) condition. This prediction is illustrated in the left-hand side of Fig. 3. Instead, as shown on the right-hand side of Fig. 3, they found equality of performance under both of the new rearing conditions. The dull rats made as few errors as the bright rats after enriched

rearing and the bright rats made as many errors as the dull rats after restricted rearing.

When the so-called bright and dull rats were tested in the Hebb-Williams maze after being reared in their usual way (neither enriched nor deprived), a significant difference between the lines appeared (middle points, right-hand side of Fig. 3). The reason is that this developmental situation repeats the rearing condition under which the original selective breeding for superior and inferior performance was carried out (Hughes and Zubek 1956). If the reaction-range idea were correct and the genes coded for upper and lower limits of learning ability, when these lines were reared under

Table 2

Normally occurring environmental and behavioral influences and gene activity

Species	Environmental signal or stimulus	Resulting alteration
Nematodes	Absence or presence of food	Diminished or enhanced neuronal <i>daf-7</i> gene mRNA expression, inhibiting or provoking larval development
Fruit flies	Transient elevated heat stress during larval development	Presence of proteins produced by heat shock and thermotolerance (enhanced thermal regulation)
Fruit flies	Light-dark cycle	Presence of PER and TIM protein expression and circadian rhythms
Various reptiles	Incubation temperature	Sex determination
Songbirds (canaries, zebra finches)	Conspecific song	Increased forebrain mRNA
Hamsters	Light-dark cycle	Increased pituitary hormone mRNA and reproductive behavior
Mice	Acoustic stimulation	Enhanced <i>c-fos</i> expression, neuronal activity, and organization of the auditory system
Mice	Light-dark cycle	<i>c-fos</i> -induced mRNA expression in hypothalamus, circadian locomotor activity
Rats	Tactile stimulation	Enhanced <i>c-fos</i> expression and increased number of somatosensory (sense of touch) cortical neurons
Rats	Learning task involving vestibular (balance) system	Change in nuclear RNA base ratios in vestibular nerve cells
Rats	Visual stimulation	Increased RNA and protein synthesis in visual cortex
Rats	Environmental complexity	Increased brain RNA diversity
Rats	Prenatal nutrition	Increase in cerebral DNA (increased number of brain cells)
Rats	Infantile handling; separation from mother	Increased hypothalamic mRNAs for corticotropin-releasing hormone throughout life
Cats	Visual stimulation	Increased visual cortex RNA complexity (diversity)
Humans	Academic examinations taken by medical students (psychological stress)	Reduced mRNA activity in interleukin 2 receptor (immune system response)

MRNA = messenger RNA; PER and TIM are proteins arising from activity of per (period) and tim (timeless) genes; activity of *c-fos* genes leads to production of C-FOS proteins. Sources documenting the findings can be found in Gottlieb 1998, p. 796

enriched or restricted conditions, the relative differences between them would be preserved. Instead, the experiment shows that the genes are part of a developmental system. The highly specific consequences of rearing under a certain developmental condition were realized by selective breeding under that condition. As called for by the norm-of-reaction concept, selective breeding under one developmental regimen (environment) does not predict outcomes under different rearing conditions. The results of selection depend on the entire developmental manifold, not merely on the genes that are involved.

4. Understanding Development from Genes to Behavior

To provide some insight into what would today constitute a truly developmental behavioral-genetic analysis, Fig. 4 shows a diagram of the four major levels that are involved in moving from genetic activity to environment and back again. This is a fully bidirectional co-actional system, with traditionally trained developmental psychologists working at the Behavior ↔ Environment level, developmental neuro-psychologists and neuroscientists at the Neural

Activity ↔ Behavior ↔ Environment levels, and biologists beginning now to work on the Genetic Activity ↔ Neural Activity levels. Viewed in this way, developmental understanding or explanation is a multilevel affair involving at least culture, society, immediate social and physical environments, anatomy, physiology, hormones, cytoplasm, and genes. Hierarchical, multilevel, or developmental systems' analysis is methodologically not theoretically reductionistic in the sense that psychological understanding or explanation does not come from lower levels (or reside in the lower levels), but that both higher and lower levels of analysis are necessary to explain developmental outcomes. The term co-action is used to emphasize the multilevel systems' nature of developmental analysis.

The notion that genetic activity is necessarily influenced by supragenetic factors (factors above the genetic level) may be unfamiliar, in part because of what has come to be known as the Central Dogma of Molecular Biology. The Central Dogma holds that DNA → RNA → Protein, in which DNA serves as a template for RNA which then serves as a template for the synthesis of a protein. In the Central Dogma there are master genes which contain a blueprint of the organism, so 'information' is said to flow outward from these master genes providing instructions for individual development. The actual story is rather different. Rather than being encapsulated (or 'safely sequestered in the nucleus of the cell,' as some biologists have written), the genes require signals from the internal and external environment to function appropriately. As mentioned above, genes are part of the developmental system of influences; they do not stand outside or apart from the developmental system as the Central Dogma would seem to indicate. Gene expression is influenced by cytoplasmic factors, which provide the immediate environment of the nucleus of the cell. (Structural DNA is found in the nucleus of each cell.) Cytoplasm can be influenced by the external environment of the organism (reviewed by Ho 1984) via the behavior of the organism, which gets the organism into and out of exposure to different environmental influences (physical, social, cultural). Likewise, hormones make their way into the nucleus of the cell and trigger gene expression, and hormones themselves are responsive to the organism's experiences in the external world. In fact, the action of some genes is dependent on sensory stimulation early in development (reviewed by Arenander and Herschman 1993). Finally, different proteins are formed depending on the particular factors influencing gene expression (Davidson 1986). Hence, genes do not stand outside the developmental system acting as independent causes. They are part of the developmental system (for a detailed discussion, see Wahlsten in press). One of the main reasons for the failure of gene therapy as currently conceptualized and practiced (Rosenberg and Schechter 2000) is that the genes do not function

as independent causes; they do not stand outside the developmental system.

Since there are in fact no master genes telling other genes what to do, in order for genes to function appropriately they require signals from the internal and external environment. Table 2 presents a sampling of the normally occurring external environmental and behavioral signals that activate genes during the normal course of development in a variety of species including humans. The findings summarized in Table 2 substantiate the main point of this article: genes and environments necessarily cooperate during the course of individual development.

Genetics and Mate Choice

In a sexually reproducing species, an individual must mate to reproduce. Mates are not chosen at random, but apparently according to sexual preferences. Such preferences may be genetically fixed at birth, or learned—acquired by sexual imprinting, mate-choice copying, etc. To the extent that they are reflected in actual matings, preferences may have immediate consequences for reproductive success and far-reaching effects on genetic evolution.

1. Avoidance of Inbreeding

Consanguinity is an important criterion of mate choice. Throughout the vertebrate, invertebrate, and plant kingdoms, the propensity to inbreed (mate with a blood relative) varies widely (Thornhill 1993). Some species of hermaphroditic plants mate predominantly with themselves—the seed is fertilized by pollen from the same individual. In others, mechanisms such as self-incompatibility have evolved to prevent self-fertilization. Hence, self-fertilization is not the unavoidable consequence of female and male functions occupying the same body. In species where the two sexes are separate, nuclear family incest—matings between father and daughter, mother and son, or full sibs (brother and sister with the same mother and father)—is the most extreme form of inbreeding. For some insects, mother–son and brother–sister matings are routine.

On the other hand, close inbreeding is unusual in birds and mammals. Of special interest are the non-human primates, where nuclear family incest, in particular, is rarely observed. Adult males of the chimpanzee, our closest relative, have seldom been seen mating with their mothers. Most, but not all, females refuse the sexual advances of males in their natal group old enough to be their fathers. The incidence of copulations between inferred maternal (possibly full) sibs is low (Pusey 1980). However, matings between paternal half sibs may not be uncommon in the gorilla.

The claim is often made that behavioral mechanisms have evolved in birds and mammals to prevent close inbreeding. However, avoidance of incest is not necessarily based on recognition of family members. Because of a sex difference in dispersal, sons and daughters may not encounter their opposite-sex sibs or parents as adults. In the black-tailed prairie dog, for example, daughters usually remain in their natal area whereas the sons emigrate. Fathers may also leave or be evicted before their daughters mature. Under these circumstances, incest may be prevented even when matings are indiscriminate. The reason for such a dispersal pattern is unknown, but avoidance of inbreeding is a possible explanation. It is perhaps surprising, then, that the incidence of close inbreeding, mostly between half sibs, does not differ from the number expected if matings were occurring at random in the study area (Hoogland 1992).

Nevertheless, kin recognition has been implicated in some field studies and demonstrated in the laboratory. A likely mechanism is ‘sexual imprinting,’ the phenomenon in which sexual preferences expressed later in life are acquired through exposure at a very young age to other individuals, usually parents or sibs. A prairie dog female, for example, is less likely to come into estrus when her father is still present. Similarly, an older female of the medium ground finch mates with a male who sings a song differing from her father’s. Since song is culturally transmitted from father to son in this species, close kin are apparently recognized and avoided (Grant and Grant 1996). Finally, Japanese quail reared with sibs choose the company of first cousins over that of either sibs, third cousins, or unrelated individuals. Bateson (1982) infers from this experiment that quails learn the characteristics of close kin and subsequently develop a preference for mates differing somewhat from familiar individuals.

It is interesting that cousin marriage, which is a comparatively mild form of inbreeding, is highly popular in some human societies. In particular, in south India and in many Muslim populations, the incidence of first-cousin marriages exceeds 30 percent (Bittles 1994). The reasons for this preference are likely different from those operative in quails.

In contrast to cousin marriage which exhibits much regional variation in incidence, nuclear family incest, marital and nonmarital, has been prohibited and usually avoided in almost all human societies past and present that we know about. A well-known counter example comes from Roman Egypt, where one-sixth of all marriages among commoners were between full sibs (Bagnall and Frier 1994). The evidence comprises over 300 census returns preserved on papyri, from which pedigrees have been reconstructed. Although this example is certainly the exception rather than the rule, it cautions against naive explanations for the existence of incest taboos.

Westermarck (1891) proposed that ‘there is an innate aversion to sexual intercourse between persons

living closely together from early youth.' In particular, full sibs reared together are expected to avoid mating with one another, but not full sibs reared apart. Avoidance is also predicted when unrelated boys and girls are reared together in the same household. Thus, studies on the Chinese custom of *sim-pua* and on marriage patterns among Israelis reared together as children in kibbutzim seem to support the 'Westermarck hypothesis.' For example, the *sim-pua* is a girl who is adopted, often as an infant, into a family with a young boy, to be his future bride ('little daughter-in-law'). After being brought up as sister and brother, they are forced to marry. Compared to other arranged marriages, the fertility of this type of marriage (minor marriage) is low, and the divorce rate is high (Wolf 1995).

This result is usually regarded as reflecting sexual dissatisfaction and supporting the Westermarck hypothesis. Nevertheless, marriages between foster sibs were in fact consummated. Moreover, in the case of institutionalized sib marriage in Roman Egypt, any aversion that may have existed was overridden. Hence, even if negative sexual imprinting occurs, it is apparently not sufficient to prevent an incestuous mate choice when other cultural pressures intervene.

If behavioral mechanisms such as sexual imprinting and sex-biased dispersal have evolved by natural selection to prevent close inbreeding in birds and mammals, there must be a selective disadvantage to mating with close kin. Sexual imprinting and sex-biased dispersal are assumed to be genetically determined capacities—hence innate. An inbred (born of related parents) offspring is known to have lower fitness than an outbred (born of unrelated parents) one. The decrease in fitness, normalized by the fitness of the outbred offspring, is called the inbreeding depression, and is estimated in practice by comparing survival to some arbitrary age. Inbreeding depression is believed to be caused by homozygosity for (having two copies of) deleterious recessive genes. The more closely inbred an individual is, the more severe the inbreeding depression is expected to be.

Estimates of the inbreeding depression associated with nuclear family incest average 33 percent for 38 species of mammals in captivity (Ralls et al. 1988). In humans, one study with good controls obtained an estimate of 29 percent, although this estimate is inflated by the inclusion of morbidity (Adams and Neel 1967).

The conditions under which avoidance of inbreeding will evolve are difficult to compute, but some theory, mostly heuristic, exists for full-sib matings (Maynard Smith 1980). If all males have the same number of mates, then sib mating is selected against, and avoidance will evolve. This would be true of a strictly monogamous species. However, if the inbreeding depression is less than one-third, and a female by being incestuous can give her brother one extra mating, then it will be in her interests to do so.

Another factor that may offset the natural selection against incestuous matings is 'reproductive compensation'—if offspring lost due to inbreeding depression are replaced. Similarly, if ecological or economic conditions are such that sibs can mate earlier than unrelated individuals, then lifetime reproductive success may be comparable—or even greater—for the incestuous pair. Keller and Arcese (1998) argue that this may be the reason why song sparrows do not purposefully avoid close inbreeding. In fact, the incidence of full-sib and parent-offspring matings was as expected if song sparrows were mating indiscriminately.

In modern human societies, age at marriage is lower when the spouses are cousins—and generally when related—than when they are unrelated. Perhaps because of this, or because of reproductive compensation, cousin marriages enjoy a higher fertility (live births) than nonconsanguineous unions (Bittles 1994). When on-going marriages in Roman Egypt are broken down by age, there is a relatively higher incidence of brother-sister and other close-kin marriages among the younger couples. Therefore, it is possible that sibs were marrying earlier than unrelated couples. Moreover, one of the most fertile couples are sibs, with eight surviving children (Bagnall and Frier 1994). If sib mating permitted an early start in reproduction during much of human evolutionary history, then sib mating rather than its avoidance may have been favored by natural selection.

2. Preference for a Mate Differing at the Major Histocompatibility Complex

In (positive) assortative mating, psychologically, behaviorally, or physically similar individuals pair up. Negative assortative, or disassortative, mating occurs as a result of attraction between dissimilar individuals. An example of positive marital assortment is the tendency of deaf persons to marry one another. Another example is the high correlation between the intelligence quotients of spouses. In the latter example, however, it is not known whether someone with an IQ comparable to one's own is actually preferred as a marriage partner. Rather, people who marry one another have often experienced similar environments as children, and since the environment is a major determinant of IQ, spouses may incidentally have similar IQs.

Recently, Wedekind et al. (1995) suggested that humans prefer a mate differing at the major histocompatibility complex (MHC). MHC is an essential part of the vertebrate immune system. It comprises many genes, each of which is highly variable and exists in many alternative forms called alleles. In the human, the genes are called HLA-A, HLA-B, HLA-C, etc. (HLA = human leucocyte antigen.) For illustrative purposes, let us focus on the HLA-A gene and assume

that four alleles are present, which will be called A1, A2, A3, and A4. The pair of alleles in an individual defines the genotype of that individual. The genotypes could be A1A1, A2A2, A3A3, or A4A4, which are called homozygotes, or A1A2, A1A3, A1A4, A2A3, A2A4, or A3A4, which are called heterozygotes.

Mates can share two alleles (as when the genotypes of husband and wife are A1A2 and A1A2), one allele (A1A2 and A2A3, for example), or no alleles (A1A3 and A2A4, say). The hypothesis of disassortative mating asserts that sexual attraction is negatively correlated with the number of alleles shared. Hence, an individual of genotype A1A1, say, given a choice of three different partners whose genotypes are A2A2, A1A2, and A1A1, say, is predicted—all other things being equal—to prefer the first (A1A1 and A2A2 share no alleles) over the second (A1A1 and A1A2 share one allele) over the third (A1A1 and A1A1 share two alleles).

Theoretically speaking, disassortative mating for MHC may make evolutionary sense. Yamazaki et al. (1976) argue as follows. Heterozygotes for MHC genes have a higher fitness than homozygotes, because the presence of two alleles rather than just one would permit an immunological response to a wider range of antigens. Although the genotype that an individual is born with cannot be altered, the genotype of offspring is under some personal control. Namely, by choosing an MHC-dissimilar partner, the chances are improved that offspring will be heterozygotes. A second reason why disassortative mating for MHC might be favored by natural selection is that it leads to avoidance of inbreeding.

A preference for MHC-dissimilar mates is fairly well established in house mice. There is good evidence, at least in mice, that this preference is mediated by body odor, which is influenced by the MHC genes. More precisely, mice imprint on the MHC identities of the individuals by, or with, whom they are raised, who under normal circumstances would be extended family. They subsequently choose a mate differing in MHC from these individuals. Since, close relatives are on average more similar for their MHC than unrelated individuals, the resulting preference would be for MHC-dissimilar mates.

The human evidence is of two kinds. First, in a provocative experiment, male subjects were asked to each wear a T-shirt, and female subjects to rate the odors of these T-shirts for pleasantness (sexiness). The subjects, all of whom were students at a Swiss university, were also typed for their HLA-A, HLA-B, and HLA-DR genes. It turned out that the females preferred the odors of T-shirts worn by MHC-dissimilar males to those worn by MHC-similar males (Wedekind et al. 1995).

Second, a direct test of whether humans mate disassortatively for MHC should be possible by typing married couples. To date, such an analysis has been done on the Hutterites (a North American repro-

ductive isolate of European ancestry), South American Indians from the lower Amazon basin, and the Japanese. Only among the Hutterites has disassortative mating been demonstrated (Ober et al. 1997). In the other two populations, mating is apparently random with regard to MHC.

It is not clear why such contradictory results have emerged. One possibility is that, since the preference for MHC-dissimilar mates is weak, it may sometimes be overwhelmed by other biological or cultural factors. In particular, a preference for cousin marriages will mask any tendency towards disassortative mating. However, there is no evidence of cousin marriages among the couples sampled in the above mentioned studies.

3. Genetically Fixed Preferences vs. Acquired Preferences

In all of the above examples, mating preferences are apparently acquired by sexual imprinting. Despite the title of this article, convincing demonstrations of genetically fixed preferences are hard to find. Even in insects, appropriate social behavior is often contingent on learning to distinguish different categories of individuals—nestmates from intruders, for example.

Nevertheless, a possible example of a genetically fixed preference occurs in ladybird beetles. Ladybirds are polymorphic for color and markings, and females show a preference for melanic males. Majerus et al. (1982) subjected this preference to artificial selection by permitting only those females who mated with melanic males to lay eggs. When the experiment was continued for four generations, a substantial increase in the level of preference was observed.

Cultural transmission of preferences is also difficult to prove. Surprisingly, the best evidence comes not from humans, but rather from small tropical fish—guppies, sailfin mollies, and three-spined sticklebacks—where the phenomenon is known as ‘mate-choice copying’ (Dugatkin 1992). Mate-choice copying is said to occur when a female is more likely to choose a specific male after observing another female doing so. The following three-phase experiment is conducted to demonstrate mate-choice copying.

In phase one, a female (focal female) is given a choice of two males. If the focal female shows a consistent preference for one of these males, then in phase two, a second female (model female) is placed near the nonpreferred male in view of the focal female. Finally, in phase three, the model female is removed, and the focal female is again given a choice of the two males. Mate-choice copying is implied, if the focal female’s preference is reversed as a result of seeing the model female and the nonpreferred male together. (It is not clear how long the reversal of preference is maintained.)

The experiment must control for confounding effects. For example, the focal female might be attracted by the nonpreferred male's activity during or after his interaction with the model female, rather than by the presence of the model female. Or the focal female may simply be exhibiting a tendency to join other females, as is apparently the case with fallow deer. White and Galef (1999), who investigated mate-choice copying in Japanese quail, point out other complications in the interpretation of such experiments.

Given this emphasis on socially learned sexual preferences in fish and birds, it is perhaps ironic that most research on humans—by the evolutionary psychologists—has attempted to identify preferences that are relatively impervious to social influence. For example, it is claimed that men are attracted to women with a low waist-to-hip ratio (WHR)—an hourglass figure. This appears to be true in several Westernized cultures. Moreover, since women with lower WHR are apparently more fecund (physiologically able to give birth) (Zaadstra et al. 1993), Singh (1993) argues that it is adaptive for a man to have such a preference, whence it has evolved to become a panhuman—culturally invariant—male characteristic. The logic is fine, but the prediction has yet to be verified. Recently, Yu and Shepard (1998) studied WHR preferences in an isolated Peruvian population unexposed to Western media. Contrary to prediction, an overweight woman with a high WHR was most attractive and desirable as a spouse for the men of this population.

Genetics and the Media

Genetics is in the news as the scientific frontier, the cutting edge of current research. Every new discovery is reported in the media with optimistic expectations as a 'breakthrough'—even when the significance of a particular finding is in question. A survey of the coverage of genetics in the American press from 1970 to 1996 found that reports were overwhelmingly positive as journalists equated research with economic potential and medical progress (Lewenstein et al. 1998). Beyond the news, the gene has also become a prevalent media metaphor appearing in fictional narratives, popular magazines, visual images, and the cultural detritus of sound bites, slogans, and snippets: it's all in the genes. These media attribute extra-

ordinary powers to the gene, conveying a concept of 'genetic essentialism' (Nelkin and Lindee 1995). DNA in media narratives is an essentialist entity—the cause of disease, the definition of personhood, the location of the true self.

DNA is data without dimension, text without context, so that the equation of DNA with personhood requires a profound leap of faith. Yet, the gene as a solid source of identity holds media appeal. So too does the belief that the physical and behavioral traits of individuals, and the social and economic differences among groups are caused by inborn distinctions.

Genetic language has become a code in the media, readily applied and broadly understood. What is genetic is powerful, predictable, and permanent; 'hard-wired' in the human constitution. Underlying the notion of genetic destiny is the old idea of biological determinism: people are the way they are because they are born that way. This article reviews several themes conveyed by media gene talk:

- (a) Genetic technologies provide the means to predict health and disease.
- (b) Genes determine behavior and personality traits.
- (c) Genetic research holds the promises of therapeutic solutions.
- (d) But there are also potentials for abuse.

Following a brief description of these media themes, this article offers some reasons for the appeal of genetic stories. It suggests how the media coverage of genetics conforms to popular stereotypes and prevailing ideologies, and reflects the rhetorical skills of scientists who are eager to promote their work in the public arena. The article concludes by suggesting some of the problems with the media message that health, behavior, personhood—indeed, life itself—can be defined in genetic terms.

1. Media Themes

1.1 Predicting Genetic Destiny

Genetics is a science of prediction. Scientists emphasize the predictive possibilities of genetics as they seek to convey the importance of their science as a way to identify predispositions. Using media-appealing terms, geneticists call the gene a 'Delphic Oracle,' a 'time machine,' a 'trip into the future,' a 'medical crystal ball.' James Watson, the first director of the Human Genome Project, has announced in frequent media interviews that 'our fate is in our genes.'

Such metaphors convey several messages: a definition of the gene as the basis of human destiny, an expectation that genetic research will enable the prediction of future disease, and a promise of therapeutic solutions. These messages are disseminated by a receptive press.

The media, for example, cheered the discovery in the mid-1990s of the *BRCA1* and *BRCA2* genes that

helped to explain many cases of familial breast cancer particularly among Jewish women of Ashkenazi descent. News headlines announced that scientists had found the gene causing breast cancer, some referring to the 'breast cancer gene.' They suggested that heredity is the major cause of breast cancer and that those found to have the gene were certain to get the disease. In fact, genetic factors contribute to only about 5 percent of all breast cancer cases, and even among those with a *BRCA* gene, modifying factors, including diet and genetic variables, may limit the predictive power of the genetic diagnosis. But widespread publicity, according to former Director of the National Institutes of Health, Bernadine Healy, created an ambience of 'medical bookmaking and fortune telling' that was devastating for women who believe they are at risk (Healy 1997).

Joseph Alper describes the media coverage of genetics as OGD (One Gene One Disease) reporting (Alper 1996). When journalists report on the discovery of disease genes, they tend to minimize the complex, multicausal, and poorly understood sources of the genetic mutations that lead to disease. They are responding to the public desire for simple causal explanations. But Steven Rose (1995) describes genetic predictions as faulty reductionism based on 'reification, arbitrary agglomeration, improper quantification, misplaced causality, and dichotomous partition between genetic and environmental causes.' Similarly, Philip Kitcher (1997) describes how journalists tend to leap from an association of genes with particular conditions or traits to the attribution of genetic causation. Correlations turn into causes in the press.

Gene discoveries are newsworthy, but qualifications and disconfirmations are ignored. Studying the media reports about the causes of mental illness, Peter Conrad (1999) finds only limited coverage of inconsistent and contradictory information. The media message is rather that genes are destiny and the gene for mental illnesses will eventually be found. Science, however, is provisional and scientists routinely disconfirm their claims. These disconfirmations, like failed experiments, are important to the methods of science, but they are not regarded as news.

1.2 Genes Determine Behavior

Encouraged by the enthusiastic media response to research in medical genetics, behavioral psychologists in the 1990s began to extend the notion of genetic determinism to the inheritance not just of diseases, but of complex behavioral conditions and personality traits.

Such complex attributes as shyness, obesity, directional ability, aggressive personality, caring tendencies, exhibitionism, homosexuality, dyslexia, job success, arson, traditionalism, preferred styles of dressing, tendencies to tease, political leanings, re-

ligiosity, criminality, intelligence social potency, and zest for life have all appeared in media accounts as if they are simple Mendelian disorders, directly inherited like brown hair or blue eyes. Behavioral characteristics, once viewed in psychological or sociological terms, are now framed through genetic lenses (Alper and Beckwith 1993).

Seeking provocative and controversial copy, journalists have focused attention on claims attributing antisocial behavior to biological predisposition (Conrad 1997). There is violence, homelessness, alcoholism because people have genes that predispose them to aggression, depression, or alcoholism. Journalists refer to 'bad seeds,' criminal genes,' and 'alcohol genes.' To a *New York Times* writer, 'evil is embedded in the coils of chromosomes that our parents pass to us at conception' (Franklin 1989).

Journalists are also attracted to controversial theories about genetics and intelligence. In the 1970s, the dispute over Arthur Jensen's claims about the relationship between race and IQ attracted considerable media attention. Two decades later, the similar claims by Richard Herrnstein and Charles Murray in *The Bell Curve* again attracted an attentive press. Media interpretations of these studies, however, were more guarded than most reports on genetics.

Snyderman and Rothman (1988) saw the media as strongly biased against genetic explanations of intelligence, favoring arguments based on nurture or nature. Yet the coverage of the genetics and IQ debates has been extensive and the repeated articles about books like *The Bell Curve* disseminated their ideas very widely and ultimately served to amplify their importance.

In the 1990s, the media disseminated the claims about the genetic basis of behavior that were generated by studies of identical twins reared apart. These were controversial studies that often appeared in the media well before they were published in peer-reviewed journals. Offering a simple explanation of complex behavior and a reinforcement of prevailing stereotypes, this research attributed an extraordinary range of behaviors to 'the genes.' *US News and World Report* (April 13, 1987) published an authoritative-looking table providing precise percentages of how much personality traits were determined by heredity rather than culture: extroversion 61 percent, conformity 60 percent, worry 55 percent, creativity 55 percent, optimism 54 percent, and so on.

In the same issue, *US News* published an article called 'How Genes Shape Personality,' claiming that 'solid evidence demonstrates that our very character is molded by heredity.' It suggested that the future of Baby M, the child in a controversial surrogacy dispute, may not rest on which family got her, but in her genes. In 1992, *Time* was still offering the time-worn explanation of sex differences: 'nature is more important than nurture' and it is just a matter of time until scientists will prove it (January 20, 1992).

Media references to genetic influences draw on research in molecular and behavioral genetics, but they minimize the complexities of genetic and environmental interactions. They offer a distorting lens by ignoring the distance between the molecular level of genetic systems and actual behavior (Wilkins 1993). Beyond the curious notion that every quality has a gene, these media often convey a fatalistic and almost resigned attitude, for genetic predispositions appear to be immutable (Alper and Beckwith 1993).

One quantitative evaluation of magazine articles on genetics from 1919 to 1995 found a decreasing emphasis on genetic determinism over time (Condit et al. 1998). However, the way genetics is reported in the media of the 1990s suggests a retreat from the myth of 'can do' optimism that once led to the notion that every child could be president. The old story about those who make it despite difficult social circumstances is no longer a mystery. Genetic predisposition implies genetic destiny.

1.3 Biological Solutions

Good news, magic bullets, solutions, and cures appeal to public hopes and expectations. Journalists are strikingly optimistic as they cover the promise of 'medical breakthroughs' and 'wonder therapies.' Genetics claimed a journalist is 'the medical story of the century which will dramatically cure cancer, heart disease, aging and much more' (Rosenfeld 1992).

The media have welcomed every new claim about gene therapy with extravagant headlines and promotional hype as reporters convey—often uncritically—a wild array of futuristic scenarios presented by enthusiastic scientists. In the future, said a geneticist to *Discover*, 'present methods of treating depression will seem as crude as former pneumonia treatments seem now' (Wingerson 1982). In the future, said geneticist French Anderson to a *Time* reporter, 'Physicians will simply treat patients by injecting a snippet of DNA and send them home cured' (*Time* January 17, 1994). News headlines have promised: 'Genetic research leaves Doctors hopeful for Cures,' 'New Hope for Victims of Disease.' In a story called 'the Age of Genes,' *US News* reported that 'advances bring closer the day when parents can endow children not only with health but also with genes for height, good balance, or lofty intelligence' (Brownlee and Silberner 1991).

The development of pharmaceutical products and the proliferation of clinical trials on new therapeutic procedures have encouraged genetic optimism. The first official gene therapy experiment in 1990—the injection of cells containing ADA genes in a child with an immune system malfunction—became a major news event, touted as the arrival of 'the long awaited era of genetic therapy' (Culver 1991). The isolation of

the colon cancer gene in 1993 prompted an enthusiastic scientist to tell a *New York Times* reporter of its implications: 'deaths are entirely preventable' (*New York Times* December 3, 1993). The media reports implied that gene therapy would allow doctors to 'do something' about devastating disease. But in fact, diagnostic capabilities have far outreached the possibilities of solutions.

The gap between the promise and the reality of gene therapy has led to increased ambivalence in media reports of genetics. While few questions are raised about the ultimate benefit of research or the credibility of scientific claims, reporters are expressing concerns about the growing availability of genetic information and its potential abuse.

1.4 The Potential for Abuse

Stories extol the benefits of research, but then decry the risk of gathering genetic information. We are told of the dawn of a new genetic era but then cautioned about an impending eugenic nightmare.

Ambivalence is especially apparent in the coverage of genetic manipulation. Jon Turney (1998) notes the continuous use of Frankenstein metaphors in the media. An illustration for a *New York Times* article (September 16, 1990) on gene therapy and the potential of genetic engineering featured a drawing imitative of the famous Edvard Munch painting, 'The Scream.' A figure stands, horrified, mouth ajar, eyes wide open, its hair a mass of coiled DNA. Media reports have often associated experiments in gene therapy with genetic engineering or 'tampering' with genes. 'Lurking behind every genetic dream come true is a possible Brave New World nightmare' says a *Time* reporter. 'To unlock the secrets hidden in the chromosomes is to open up the question of who should play God with man's genes.' An accompanying image portrayed scientists balancing on a tightrope of coiled DNA (Dewitt 1989).

An important feature of these ambivalent media reports on genetics is their concern about the social and economic context in which this field is developing. The ties between the science of genetics and its commercial applications invite cynicism. Reporters call attention to the nonscientific interests—the investments and profits in this intensely competitive field. Science journalists, many of whom were once scientists themselves, have maintained an image of science as a pure and unsullied profession, a neutral source of authority, and an objective judge of truth. They are skeptical of corporate driven science. These days, according to some disillusioned journalists, biology has 'lost its virginity.' Scientists working in genetics are 'greedy entrepreneurs,' 'gene merchants,' or 'molecular millionaires' driven by economic interests that threaten their objectivity and override concerns about abuse (Nelkin 1995). Political cartoons portray genet-

icists in less than flattering terms as bumbling, naive, and unaware of the social implications of their discoveries. News reports and editorials repeatedly call attention to troubling aspects of the growing links between science and industry, the conflicts of interest that are inevitable when profits and ethics collide (Krimsky 1991). While the media have retained their history of genetic optimism, they are also expressing concern that expanding commercial interests will override important social considerations.

2. The Media Appeal of Genetic Explanations?

The Human Genome Initiative has replaced the space program as a new frontier, the cutting edge of high technology exploration, and, just as in the heyday of NASA, journalists are receptive to the enthusiasm of their scientific sources.

The stories of the 'gene of the week' meet the immediate pragmatic needs of the press for sound bites, newspegs, and events that will attract readers. The notions of genetic determinism offer relatively simple causal explanations of complex behavior—a welcome change from messy and uncertain social and environmental speculations. Genetic explanations conform to prominent cultural biases, intersecting with important American social values. Locating social problems within the individual, they support the ideology of individual responsibility. They are consistent with faith in scientific and technological progress. The status of the gene as a deterministic agent, a blueprint for life, offers certainty, predictability, and control. By promoting genetic explanations of behavior, however, the media are using the imprimatur of science to support a particular world view. They do so with little attention to the substance of science and the limits of theories purporting simple explanation of complex human conditions.

The appeal of genetics to the media largely reflects the promotional efforts of scientists themselves, for journalists rely on scientific sources for information. Scientists seek media coverage as a form of public relations, regarding public visibility as a means to attract funds for their research and support for their priorities (Shinn and Whitley 1985). They have become skilled in rhetorical strategies designed to attract media attention. Using media-ready metaphors, they have described the genes as 'master molecules': we are but 'readouts' of our genes. They describe the body in deterministic terms—as a set of instructions, a blueprint, a map, or a program that is transmitted from one generation to another. They suggest that by deciphering the text, classifying the markers on the map, and reading the instructions, they will unlock the key to human ailments and human nature, revealing the secrets of human life. Geneticist Walter Gilbert, introduces his public lectures on gene sequencing by pulling a compact disk from his pocket and announc-

ing to his audience: 'this is you.' Scientists, he claims, will 'provide ultimate answers to the commandment, know thyself' (Gilbert 1990).

The biotechnology industry has further encouraged media hype about gene therapy. The industry has made a major financial commitment to gene therapy, expecting this will be the basis of future medicine. Over 60 percent of gene therapy studies are directly financed by industry in anticipation of a profitable market in the near future. Corporate advertisements announce 'a great leap in the treatment of disease,' and promise 'a healthy future one gene at a time.' Corporate and university press releases are inclined to turn tentative experimental findings into magic bullets. An advertisement appearing in sports magazines said it all: 'Bad Genetics? Use Opti-genetics—The first genetic optimizer.'

When they report on complex scientific issues, journalists do not create science news; they mainly amplify and disseminate the messages provided by scientists themselves. They are seldom critical, responding with untempered enthusiasm to promotional hype especially when packaged in accessible media-friendly terms. However, the surfacing of hereditarian beliefs, their media appeal must be examined critically, for such beliefs have practical implications for both individual choices and social policies.

3. The Growing Power of the Gene

Tracing the history of popular images of genetics, Van Dijk (1998) has documented the changing metaphors that correspond to various stages in the development of this scientific field from the new biology of the 1970s to the rise of the biotechnology business and the Human Genome Project in the 1990s. At each stage, she says, 'performers'—scientists, journalists, and public relations people shape the media discourse (Van Dijk 1998).

Nelkin (1995) found considerable media skepticism in the 1970s when journalists wrote about the 'runaway science of genetic engineering.' But by the 1980s, gene splicing became a 'race toward better human health.' Today, genetics is the 'technological frontier.' Journalists describe geneticists as pioneers, 'unlocking the basic laws of nature,' discovering the 'secrets of life,' solving the problems of devastating disease. Genomic researchers are 'riding the DNA trail.' Geneticists are 'relentless hunters of genes,' involved in a 'race' to find the markers for disease. Media accounts in the 1990s have been reverent—almost religious: a 1994 cover of *Time* depicts a figure on a pedestal, his arms extended in a Christlike pose, his torso inscribed with a double helix. The caption reads: 'Genetics—The Future is Now.' The image, of course, is the Ascension. Though simply a biological entity, the gene in the media has assumed cultural significance extending far beyond its scientific meaning.

The media are mainly promotional, yet they are increasingly conveying mixed messages about the costs and benefits of biotechnology. Journalists seem to welcome the notion of biological determinism—simple, seemingly certain, and easy to convey—yet many writers remind their readers of the history of eugenics and place current research in this threatening historical context. While journalists report with enthusiasm and wonder the promises of gene therapy, they also warn about potential abuses of genetic manipulation.

Why should we be concerned about media images? Common and recurring media images provide insight into beliefs that are deeply embedded in society—beliefs that shape the questions of concern to scientists and the public appropriation of scientific findings. The media portrayal of the powers of the genes can have a powerful influence. For science has long served as a cultural resource appropriated and interpreted to support social beliefs and to legitimate social policies (Nelkin 1999). The language of determinism not only reveals but also creates social attitudes. The sound bites and headlines (gay genes, obesity genes, aggressive genes) attract readers, but they also endorse certain modes of thought and explanations.

Media coverage of science and technology provides a useful window on public attitudes, but also has an important influence on public perceptions. The way people perceive research in human genetics—the way they interpret their costs and benefits—may be influenced less by the details of scientific evidence than by the repeated messages conveyed in the popular press. These media messages help to create the beliefs and assumptions that underlie personal decisions, social policies, and institutional practices.

Genetics in Anthropology

Anthropologists of biological orientation began to undertake the study of genetics as soon as it became apparent about 1900 that biological inheritance was indeed particulate, and that the supposed essence of inheritance, genotype, could be inferred from phenotype. Within 'the science of man' theories were soon developed which applied these insights to the solution of problems that had long been central to anthropology, many of which were deeply entangled with political and religious controversies concerning 'race' and evolution. These problems especially included: (a) the extent and significance of human variation, (b) the phylogenetic relationships among humans and other primate species, (c) the migration and adaptation of human populations to different continents and geographical regions since the earliest times, and (d) the relationships between biological variation and other kinds of human variation, especially in language and culture. Despite some episodes of resistance to this new source of information, by the end of the twentieth

century it was clear that genetics had become central to the science of anthropology, not only for helping to illuminate these problems, but for discovering new problems and creating new fields of study within the discipline (Crawford 2000).

1. Human Variation

When laboratory techniques for studying Mendelian traits first became available, international anthropology had just emerged from a serious controversy over racial typology during which Franz Boas, recognized by many as the founding father of American anthropology, had repudiated to the satisfaction of most anthropologists the racial theories of Gobineau and his intellectual heirs. Originally trained as a physicist, Boas presented data and arguments between 1910 and 1913 showing that 'race,' 'language,' and 'culture' were three independent phenomena which, he asserted, should all be studied by anthropologists, but using different kinds of theories and techniques. On the heels of this observation, the Hirtzfelds, building on the work of Landsteiner and others, showed in 1919 that while the ABO blood system was universal among human populations, the phenotypes and hence the alleles, the alternative forms of a gene, were in different proportions, thereby supporting Boas' contention that the differences among 'racial' populations were not qualitative but quantitative (Weiss 1998). The ability to taste PTC (phenylthiocarbamide), a simple Mendelian trait, also seemed to occur in many different human populations, likewise in different frequencies. But other apparently Mendelian traits examined early in the century—eye color, skin color, and ear lobe shape—turned out to embody genetic relationships with a much more complex genetic architecture (McKusick's current list of over 30,000 Mendelian traits can be found at World Wide Web URL: <http://www3.ncbi.nlm.nih.gov/Omim/>).

Data on human phenotypes assembled for military purposes in World War I continued to encourage anthropological geneticists in the decades following the war. In addition to complex and composite anthropometric traits such as height and weight, the military was especially interested in those factors that affected the compatibility of blood and blood components used in transfusion. The collection of such data was continued through World War II, when most European and American soldiers and sailors were typed for ABO and Rh factors during initial processing, and this body of data became generally available to scientists after 1945 (Harrison et al. 1964).

For anthropologists, the major theoretical model which emerged to describe human genetic variation in this period was the notion of cline, the gradual geographic change in the frequency of an allele, which also served to undermine further the idea of racial typology. As regularities began to emerge, especially

in the European data, it was found that the alleles of a gene, and also phenotypic traits such as red hair, seemed to vary across the landscape in a regular manner. These were mapped using arrows to show the direction of increasing frequency of one of the component alleles of a gene, or by isographs which identified geographical areas where allele frequencies were within a particular range. Traits mapped in this manner included blood system alleles, phenotypic traits, and also diseases which were suspected of having a simple genetic basis, such as albinism, color blindness, and some types of cancer (Harrison et al. 1964, pp. 234–76).

Some patterns which emerged from the analysis of clines conformed to more general biological principles pertaining to other animals. It was found, for example, that Gloger's, Bergmann's and Allen's Rules for variation within a mammalian species (pertaining to pigmentation, mass, and limb length, respectively) were also valid for the human species, reflecting adaptation to the different latitudes, climates, and environments inhabited by local human populations. Since these traits were so clearly adaptive, it was suspected that other patterned traits, with definite clines, likewise reflected genetic adaptation to local conditions.

2. Adaptation

The most forceful new example of human genetic adaptation was presented by Livingstone in 1958 with his study of sickle cell disease, especially as it existed in Africa. In addition to presenting convincing evidence of several types to prove that sickled blood cells were a response to the presence of malaria, Livingstone's work illustrated several other lessons in anthropological genetics. First of all, it was the heterozygote of hemoglobin S (HbS) which had the adaptive advantage, not the HbS homozygote, who often sickened and died. The second lesson was that an apparent 'disease,' sickle cell anemia, was on closer inspection actually a successful adaptive mechanism, a proposition which is still better understood by anthropologists and population geneticists than by their colleagues in clinical medicine (Weiss 1993).

Another highly visible connection between genetic variability, culture, and environment concerns the ability of human adults to digest milk and milk products from dairy animals, an ability that seems to be under genetic control. When mapped geographically, the alleles responsible for adult lactose tolerance in human populations seem to be correlated, in the Old World, with the locations of pastoral peoples. Significantly, populations where lactose tolerance is high include pastoral societies all the way from Scandinavia to southern Africa, producing east–west clines which cut across the north–south clines describing the distributions of all sorts of other phenotypic

characteristics, including those related to latitude and climate (Durham 1991).

There are indications that the frequencies of many other diseases, such as cancer and diabetes, correlate with blood types and also with alleles involved in the digestion of food. People of A phenotype, for example (in the ABO system), may carry an increased risk of death from cancers of the esophagus, pancreas, and the stomach, but whether these diseases are in any sense 'caused' by type A blood, as the sickling trait can cause anemia, or whether both disease and blood type are derived from an independently variable genetic or environmental condition, is very problematic to clarify. Northern Scandinavia, for example, has a high frequency of type A individuals and a high incidence of stomach cancer. But their diet is different from other Europeans, and their climatic environment is different as well, so it is difficult to separate the variables which might cause stomach cancer (Molnar 1998, pp. 100–7).

Perhaps the most useful way of looking at the various genetic and environmental factors correlating with disease frequencies is to say that each 'contributes' to the likelihood that an individual will exhibit the disease (Terwilliger and Göring 2000). Many anthropologists argue that from the standpoint of adaptation, no gene of itself is a 'bad' gene. Like HbS, any allele manifested in the phenotype might be beneficial in certain circumstances. Among anthropologists, it is increasingly recognized that the relationship of gene to environment, like the relation of gene to gene, is very complex. Also, the distinction between 'genetic disease' and 'infectious disease' begins to break down when we consider that smallpox, for example, takes a more virulent course in people of blood type A or AB, as opposed to O or B (Stein and Rowe 2000, pp. 427–30).

The study of adaptation to cold climate and high altitude has provided an opportunity to differentiate between the effects of genetic differences among human populations and phenotypical differences engendered by growth and development—more simply, the difference between nature and nurture. Most recently, Beall has shown that Tibetan and Peruvian populations have a different genetic basis for their respective adaptations to thin air (hypoxia), but many other aspects of human adaptation to climatic extremes remain to be examined (Jones et al. 1992, pp. 46–51). These studies require the comparison of highland to lowland Peruvian Indians, and the examination of such characteristics as body type, especially lung capacity, and oxygen saturation rates among migrants and colonists in both locations.

3. Population Genetics

With increased funding for science in the United States after World War II, and increased access to field sites,

anthropologists began to investigate isolated, small-scale human populations with renewed vigor, often including a biological anthropologist in the research team. The most visible of these joint enterprises was probably the comprehensive study of the Yanomamö, who live in the upper drainage of the Orinoco River in Venezuela and Brazil. In the 1960s, James Neel of the University of Michigan organized a comprehensive multidisciplinary series of field expeditions which investigated the environment, ecology, biology, culture, and social organization of these then little-known people. After a series of books and articles was published over the next two decades, the Yanomamö became not the least known but one of the best known tribal societies in the world.

For the genetics part of the research, Neel and Ward examined six blood systems relatively well known at the time (MNS, Rh, Kidd, Duffy, Diego, and haptoglobin) among seven villages of Yanomamö, seven villages of nearby Makiritare, and 12 other tribes of Central and South America (Neel and Ward 1970). After comparing the different groups, the authors concluded that human evolution might have been proceeding at a pace '100 times more rapid' than previously thought, if these small-scale societies could be taken as analogues of earlier Pleistocene or Paleolithic human peoples.

In the same period, Friedlaender and Harpending were proceeding with similar investigations in Oceania and Africa, respectively. Working in the Solomon Islands from 1966 to 1973, sometimes alone and sometimes as part of a multidisciplinary team, Friedlaender simultaneously undertook studies of demography, anthropometry, genetics, and social structure, seeking to integrate his results into some general conclusions that cut across these traditional fields of research. Like Neel and Ward, he emphasized the genetics of blood systems, in this case ABO, MNS, Rh, Kell, and Duffy. In these years, blood system alleles were not sequenced directly, but determined from immunological reactions to blood proteins, usually through the intermediary use of rabbit antibodies (Jones et al. 1992, p. 304). From this kind of data, Friedlaender calculated phenotype frequency and then allele frequency by techniques described in his major ethnographic work, *Patterns of Human Variation* (Friedlaender 1975). His most general conclusion, combining results from anthropometry, dermatoglyphics, genetics, and demography, was simply that Bougainville communities tended to exhibit high biological variability within the group, but low variability among the groups, and that some traits, such as skin color, eye color, and hair form, were 'monotonous' on the island, while dermatoglyphic characteristics and some blood system alleles were discontinuous from village to village. Those expecting that these early studies would provide fundamental insights into the mechanisms of human evolution were soon disappointed. Summariz-

ing a widely shared consensus of opinion in 1974, Harpending concluded (1974, p. 229):

... studies of the genetic structure of small populations have made particular and incidental contributions to formal genetics, to regional history and prehistory, to epidemiology, and to several other fields to which they are peripheral, but ... they have not advanced our understanding of human evolution in a global sense. The sample sizes available have been too small to allow reliable inferences about natural selection; the extensive occurrence of what is presumably local random genetic drift has little or no consequence for evolution over long time periods over large areas; and the presumed selective agents in the various environments of these peoples differ greatly so that few of the generalizations which have been put forward hold for many groups.

4. *Evolution of Primates*

Although anthropologists, even before the publication of Darwin's *Descent of Man* had recognized that humans and apes were closely related, the significance of the differences between them had been both exaggerated and misunderstood. Based on the fossil record, the split of humans from the ape line had been put far back in time, about nine million years, and it was assumed that all the ape species were closely related to each other and quite distinct from humans. Therefore the allegation of Sarich and Wilson, published in 1967 and based primarily on immunological data, that humans and apes had diverged as recently as five million years ago (mya), created a serious confrontation between 'the bone people' (paleontologists) and 'the lab people,' human geneticists such as Sarich and Wilson. The former accused the latter of inaccuracies in their assumptions about the speed of 'evolution,' in this case the evolution of blood albumin, while the latter accused the former of manipulating primate taxa to preserve the supposed profound differences between ape and human. In fact the fossil *Ramapithecus*, with an antiquity of about 14mya, soon fell out of the human lineage on osteological grounds, so that even the fossil evidence seemed to point to a more recent divergence between human and apes.

Beginning in the 1970s, Morris Goodman and his associates have become prominent in the reconciliation of fossil and biological evidence which, taken together, provide the best description of the evolution of apes and humans. In 1974 Goodman proposed that humans, chimpanzees, and gorillas should join humans as hominines, a subfamily of the family Hominidae, perhaps leaving the more distantly related gibbons and orangutans as separate families or subfamilies. Goodman's conclusions, like those of Sarich and Wilson, were based on molecular data, in this case amino acid sequences from blood proteins.

Goodman's current synthesis (1999) includes data from many kinds of direct sequencing of DNA from

humans and other primates, especially the β -globin gene cluster, and from the analysis of morphological features, especially certain diagnostic skeletal features on living and fossil primates. His current picture of relationships among living humans and apes shows a split between the Tribe Hominini and the lesser apes about 18mya, between orangutans and the Subtribe Hominina about 14mya, and among gorillas, humans, and chimpanzees within the last seven million years. The timing and significance of the chimpanzee–bonobo separation has not yet been firmly established, since they have only recently been recognized as distinct species, and basic comparative genetic studies of both groups are now underway.

5. Methods

Although thousands of laboratory procedures have been developed over the last half-century, especially by medical researchers, to elucidate the structure of the human genome and show how it reproduces itself, certain techniques and certain targets have been more interesting to anthropologists because of their particular research agenda. Ideally, anthropologists interested in adaptation would like to know the locations of all human genes on the chromosomes, the number of alleles for each gene, and the locations of all loci involved in constructing a protein, but in practice researchers have had to settle for much less. Early in the twentieth century, the identity of alleles had to be teased out of complex immunological procedures in the laboratory. Later, proteins could be examined directly, but without much knowledge of the DNA structures, the precise sequence of nucleotides which had produced the protein. But with the development of slow though reliable DNA sequencing procedures in the 1970s, anthropologists became much more selective about which portions of the chromosomes they wanted to study, and for what purposes.

Surprisingly, with the inception of direct sequencing, it was discovered that perhaps 93–97 percent of the mass and length of human chromosomes consisted of apparently inactive regions variously called introns, satellites, tandem repeats, noncoding regions, or even ‘junk.’ Almost immediately these regions began to attract the attention of anthropologists even though they did not contain genes. It was the presumed inactivity of these regions which was interesting, since accumulated mutations on these regions were apparently selectively neutral, that is neither favored nor disfavored by natural selection. Therefore, it was reasoned, they might in a more accurate, clock-like manner reflect not only the relationships among primate species, but also the migrations and gene flow of ancient human populations. That is, satellite DNA was considered to constitute a ‘passive’ record of evolutionary events, rather than comprising active agents under selective pressure.

5.1 Stains

As soon as chromosomes could be observed directly through microscopes, attempts were made to stain them chemically so that bands would appear which might show differences in structure. Initially, the purpose was to discriminate among the different chromosomes of the human karyotype, or suite of chromosomes (22 autosomes, 1X and 1Y), so they could be counted and numbered. During the course of this research, it also became apparent that patterns of stains on a particular chromosome might vary from one individual to another within a population. In addition, when it was noted that certain patterns of staining were characteristic of particular species, yet another method became available for evaluating the phylogenetic relationships among apes and humans. At first the functional significance of the patterns was unknown, but this is changing rapidly as new techniques allow the identification of gene-rich regions identified by stains.

5.2 Restriction Enzymes

In 1973 it was discovered that certain enzymes, mostly recovered from bacteria, could sever a strand of DNA selectively at locations defined by a known base pair sequence. For example, the enzyme *AluI* recognizes the sequence AGCT and cleaves DNA at that location to produce fragments which are on average 300 base pairs in length in humans. The resulting distribution of segments of different length serves to define the structure of a chromosome, even without knowing the entire succession of base pair sequences on each segment. An appropriate enzyme, or several enzymes applied in series, can be selected to produce a small or a large number of segments, long or short, depending on the purposes of the research. By comparing the phenotypes of individuals contributing DNA samples and examining their pedigrees, ‘linkages’ could then be discovered between particular alleles included in the same segment.

Electrophoresis, which had previously been used to separate blood proteins obtained from serum, can be used to separate DNA segments according to size and net electric charge, with the segments sometimes enhanced or differentiated visually by using a large number of new stains developed in the last two decades of the twentieth century, some of which are fluorescent. In the 1980s, the PCR (polymerase chain reaction) ‘revolution’ occurred, which allowed researchers to clone or amplify small pieces of DNA indefinitely. PCR procedures make it possible to amplify a tiny bit of DNA clipped from an electrophoresis gel, or even a single sequence from a single cell, to obtain sufficient material for analysis (Hillis et al. 1996). All of these became useful tools for describing genetic variation in a population within a species, or to compare and contrast variations between and among species.

5.3 Chromosome Mapping

A major objective of human genetics research is to locate all genes on their respective chromosomes as well as to identify all the other functional regions of DNA, including some formerly dismissed as 'junk.' One technique for gene mapping involves the use of genetic markers, like the restriction enzyme sites described earlier, or other DNA sequence variants discovered by various means at hundreds of other chromosome locations. Because many of these are relevant to human disease, high levels of funding were made available to the Human Genome Project to identify the location of these variable sequences or 'polymorphisms.' This support has led to the development of very fast computer and molecular technology and machinery, and much of the resultant data appears in easily searched form on the worldwide web.

5.4 Mitochondrial DNA (mtDNA)

Most human genes reside in the nucleus of the cell and occur in two copies, one each inherited from the mother and the father. However, the body or cytoplasm of each cell also contains structures known as mitochondria, which are involved in the production of energy for the cell and contain their own DNA. This DNA is special in many ways. At fertilization, the mitochondria of the ovum are transmitted to the offspring, but the mitochondria of the sperm are not. Thus mtDNA is inherited in a strictly maternal manner, a biological phenomenon which parallels several important sociological phenomena of special interest to anthropologists, such as matrilineal clan membership.

Since mtDNA is haploid rather than diploid in form (a single rather than double strand), it does not recombine during replication, and over time, as sequence variations accumulate through mutation, it produces distinct, diverging, lineages of mtDNA sequences. This variation can be used to reconstruct the mtDNA structure of the common, apical ancestor (the coalescent sequence) from a sample of mtDNAs collected from individuals alive today. Because the mitochondria are so numerous in the cell, mtDNA can be recovered much more easily than DNA from the nucleus.

The mtDNA chromosome takes the form of a relatively small ring of 16,500 base pairs (16.5kB), which was entirely sequenced by 1981. By 1987, 147 human individuals had contributed additional sequences and the structure of the converged mtDNA lineage was announced, which 'coalesced' on a woman who was promptly dubbed 'mitochondrial Eve,' alleged to have lived in Africa about 200,000 years ago, and whose 'modern human' progeny had emigrated from Africa and repopulated the world, which was at

that time allegedly occupied entirely by earlier forms of human, such as Neanderthals and *Homo erectus* (Cann et al. 1987).

5.5 Y Chromosomes

There is one DNA molecule that is uniquely inherited in the paternal line, a kind of mirror image of mtDNA. When it was discovered that certain regions of the Y chromosome were very stable and apparently did not recombine during meiosis, it was hoped that the Y chromosome would become the analytic reciprocal of mtDNA. That is, Y chromosome lineages should parallel patrilineal social practices in the same way that mtDNA lineages paralleled matrilineal social practices. A dramatic confirmation of the utility of Y chromosome analysis has been provided by Thomas et al. (1998) who showed how Y chromosome lineages confirmed the patrilineal inheritance of the Jewish priesthood among widely dispersed Jewish populations. Seielstad and others have opened another promising line of research by comparing the geographical distributions of mtDNA and Y chromosome lineages in attempts to reconstruct the marriage practices of prehistoric peoples (see *Y-chromosomes and Evolution*; Stoneking 1998).

5.6 Satellites

Although the picture is constantly changing, researchers at this point recognize three general categories of tandemly repeated sequences, which are classified by length. They are satellites, the longest sequences, minisatellites, defined as sequences which are 500–40,000 base pairs in length, usually consisting of five or fewer repeated nucleotides, and microsatellites, which tend to be short and simple in motif, even consisting of repeats of a single base pair, or a triad or tetrad of nucleotides (for example, CACACA or CAGCAG) (Jackson et al. 1996, pp. 171–210).

These short, apparently neutral sequences are useful to anthropologists because their rate of mutational change is much higher than the single nucleotide mutation of DNA, so that minisatellites and microsatellites, like mtDNA, provide a finer control of historical relationships among individuals and the populations they represent. While the mutation rate for single nucleotides is about 10^{-7} , the rate for microsatellites is about 10^{-3} per generation.

6. Grand Synthesis

Before the entry of genetics into anthropology, the recent history of our species, over the last 6,000 years, was determined largely from written accounts or, in

the case of preliterate societies, from oral narratives. To reconstruct events farther back, in the late prehistoric period, archaeologists examined architecture and technology, with architecture becoming less important farther back in time and technology, especially stone tools, becoming more important, especially before the Neolithic period began about 10,000 years ago. In all periods, compared to cultural remains, biological evidence in the form of graves and fossil humans has been rare, and the interpretations have been controversial.

In some ways, the present evolutionary debate among anthropological geneticists can be seen as a continuation of an historic dispute in paleontology between 'lumpers' and 'splitters.' Lumpers have historically emphasized the general evolution of the whole species, while splitters have tended to group human fossils into named regional and temporal categories, which were considered to evolve somewhat separately and independent of other regional populations. Splitters tended to assign new names to new fossil finds, while lumpers were reluctant to inaugurate new taxa, emphasizing instead the ongoing wide diversity within the human species.

The nature of genetic evidence lends itself to the continuation of this kind of debate. To a considerable extent, all modern human populations share similar alleles, and can be distinguished in this respect only by their different frequencies. An array of allele frequencies from a population can in principle be analyzed as a combination of two or more previous arrays, identified by name and allegedly specific to some region. This is a splitter's approach. On the other hand, genetic 'lumpers' can maintain that the human species has always been diverse, and is no more heterogeneous now than it was hundreds of thousands of years ago.

The debate can also be characterized as between cladistic theorists who see local or regional human populations as largely maintaining their social and biological integrity, increasing in size, dividing into daughter groups, and then migrating to replace less successful populations. By contrast, ethnogenetic theorists postulate that gene flow by reciprocal marriages or matings among small adjacent populations might be as significant as long distance migration in changing regional allele frequencies, and that while language and culture might change rapidly within a region, biological characteristics change more slowly.

Luca Cavalli-Sforza and his colleagues have been prominent in this debate, and viewed by many as leaders of the cladistic school of thought. In the final decades of the twentieth century, they have produced several important theoretical books, followed by a huge compendium of maps, tables, and texts showing known global genetic variation (Cavalli-Sforza et al. 1994). In this school of thought, current human genetic variation is explained as the result of historic and prehistoric migrations of named ethnic groups from

region to region and continent to continent, especially including the 'African Replacement' by Eve and her progeny.

If these works have not entirely convinced all of their academic readers, they at least have served as a convenient target for 'lumpers' and advocates of ethnogenetic theory. Prominent among these critics has been Milford Wolpoff, who argues, primarily on the basis of osteological evidence, that global human evolution has been mostly *in situ*, since modern populations, in the Far East for example, tend to reflect unique or unusual osteological features exhibited by pre-Eve residents of the region. The other main line of criticism has been from linguists and social anthropologists, who argue that Cavalli-Sforza and his co-workers have got the languages and ethnography wrong, and that their hypothesized migrations and other social and linguistic processes cannot be confirmed independently (MacEachern 2000, Terrell 2000). Such critics argue that human groups, especially the small-scale hunting-collecting societies which existed in Paleolithic times, were more fluid and less bounded than required by the migration hypotheses.

Accumulating genetic evidence seems to support the migration hypotheses. Concerning Eve, other genetic lineages besides mtDNA also seem to coalesce at about 120–200,000 years ago, supporting the Out of Africa hypothesis. However, rates of evolution of sequences on the autosomal chromosomes are difficult to judge, and the particular histories of gene families and other segments of chromosomes, especially their evolutionary odysseys of travel among the chromosomes over the last millions of years, are just beginning to unfold.

The analysis of ancient DNA from human fossils has the potential for resolving many problems of human prehistory and evolution, provided that appropriate and usable DNA can be retrieved from scarce and damaged human bones, of great antiquity. Already the examination of mtDNA sequences from a few Neanderthal specimens has shown deep rather than shallow genealogical relationships to modern human sequences, as if indicating that modern Europeans replaced them, rather than being descended from them. A human of lesser age, the so-called and well-publicized Tyrolean Ice Man, has an estimated antiquity of about 5,000 years, according to carbon-14 dating, and could have been ancestral to modern Central Europeans (Herrmann and Hummel 1994, Kolman and Tuross 2000).

The most formidable but most satisfying task facing anthropological geneticists in the near future is to continue the confirmation and criticism of the fit, or lack thereof, among genetic, linguistic, and archaeological evidence for human migrations. No technique has yet been found for differentiating allele distributions resulting from gene flow from those resulting from a sudden migration after several generations

have passed. Inter-marriage and recombination tends to blur the distinction, so that anthropologists for the next several decades will no doubt continue to debate the accumulating evidence for global, continental, and regional migration and gene flow.

7. Problems

The greatest barrier to using variation in DNA sequences—polymorphisms—to trace the antiquity of relationships among human individuals and populations is the unreliability of the molecular clock. While mtDNA sequences, DNA lineages constituting gene families, and specific microsatellite sequences can be arranged into evolutionary trees, no one knows for sure the time between each generation or branch of the tree. It is clear that the frequencies of base pair deletions and other forms of mutation are not the same in different chromosomal regions, and similarly the amount and dynamics of variation seem to vary greatly among regions on the same chromosome, and among the autosomes, the Y chromosome, and mtDNA. There also seem to be ‘hot spots’ where mutations or recombinations are more frequent, near telomeres and centromeres, for example. An additional concern in calibrating the molecular clock is that the ‘proofreading,’ repair, and editing functions of genetic reproduction seem to be uneven for different genes and loci (especially, mtDNA seems to have weaker repair systems), so that some sequences are actually much older than they appear, because they have been systematically repaired (Kumar and Hedges 1998). What all of this means is that each gene has its own history, and only by aggregating information from many such histories do some aspects of the picture of human history begin to emerge.

Genetics of Complex Traits Through the Life Cycle

The purpose of this article is to present a schema for conceptualizing the sources of individual differences in lifespan developmental processes. The two broad domains of genetic and environmental factors are presented as co-acting in their influence on complex traits, with the relative influence differing from trait to trait. Furthermore, intricate interactions are possible among genes and between genes and environments. The system is dynamic, with the possibility that the relative contributions of genetic and environmental sources can change over time. Newly available

methods assure finer-grained descriptions of the inter-relationships of genes and environment in the 'architecture' of complex systems in the near future.

1. Mendelian Genetics

Prior to the research of Mendel, the general conceptualization of the hereditary material was of an amorphous, miscible substance, in which the contributions of the parents were blended and influences from the environment altered the mix. Mendel's ingenious contribution was to postulate the existence of discrete elements (later termed 'genes'). Further postulations, in abridged form, were that an organism possesses many such genes, and each occurs as a pair, with an organism receiving one element from each parent. There are different forms of the genes (later to be named 'alleles'). Just as an individual received one allele for each gene from each parent, it transmits only one of each pair to its offspring. The alleles do not blend and are not modified during the association with their partner alleles or with the alleles of other genes, but are transmitted from the organism in the same functional condition in which they were contributed to the organism. Likewise, environmental factors do not alter the nature of the elements.

A critical distinction in Mendelian genetics is made between the phenotype, the measured attribute, and the relevant genes, or genotype, and the crux of the theory was the set of rules determining the relationships that could obtain between genotype and phenotype.

Mendelian genetics deals with categories. In the ideal case, all individuals are assignable unequivocally to one of two or three categories. A particular reason that the genotype/phenotype distinction is important is that the relationship between the two is not always additive. Knowing the phenotype is not always unambiguously informative about genotypes. For example, in one classical Mendelian situation, those individuals possessing two copies of a particular allele of the gene belong to category A, those possessing two copies of another allele of the same gene belong to category B, and those possessing one copy of each also belong to category B. That is to say, one copy of the allele 'for' category B is as effective as two. This relationship is described as dominance; the allele for which one copy is as effective as two is the dominant allele, and the other is termed the recessive allele. The two genotypes with identical alleles are called homozygotes, and the genotype with one each is called a heterozygote. Other relationships are possible: In some situations, the relationship between allelic 'dose' and phenotype is strictly additive, and intermediate degrees of dominance are found for other phenotypes.

Even when dominance is present, there is, of course, an additive component to the relationship. Thus, the phenotypic variability can be regarded as due to an

Figure 1

Depiction of a Mendelian partial dominant situation with environmental influences responsible for within-genotype phenotypic variation. Phenotypic values of all genotypes are projected onto a single distribution on the right Y axis

additive component and to dominance deviations. Another major reason that the distinction between genotype and phenotype is critical is that genes may not be the sole determinants of the phenotypic outcome. The basic principle of multiple influences underlying quantitative genetics is illustrated in Fig. 1. Phenotypic values are shown for a number of individuals of each genotype for a single gene with a partially dominant functional relationship to the phenotype. The within-genotype variability is assumed to be due to environmental circumstances that have uniquely affected each individual. A projection of these phenotypic values onto the right Y-axis reveals a distribution, the variability of which is attributable both to genetic differences (with some of this genetic influence due to the additive effect of allelic 'substitution' (represented by the dashed regression line), and some due to dominance (the deviations of the X's marking the means of each group from the regression line) and also with a portion of the variance due to environmental differences among the individuals. The consequence when more than one gene can affect the phenotype will be discussed below.

The source of genotypic diversity is, of course, the existence of different alleles. These alternative forms of the gene arise through mutational events, and their ultimate fate in a population depends upon their influence on the reproductive 'fitness' of their possessors, among other matters (see Falconer and Mackay 1996, Hartl and Clark 1997). In any population, the relative frequencies of the alternative alleles (there may be many more than two, but this discussion will be restricted to the simple case of two) will ordinarily be far from equal. Thus, the different genotypes will also not be equally frequent. If p represents the

frequency of the most abundant allele (say A1) and q represents the least frequent one (A2), and if mating is at random, then the relative frequencies of the genotypes $A1A1$, $A1A2$, and $A2A2$ will be p^2 , $2pq$, and q^2 , respectively. Different values of p and q will thus obviously lead to different genotype frequencies, and thus to different means and to different variances.

2. Polygenic Inheritance

For many phenotypes, it is not possible to assign individuals to categories; instead, they are arrayed along a continuous distribution. Although for a time there was a conjecture that different genetic systems were engaged in the categorical and continuous, a model (Fisher 1918) that postulated the existence of many loci, each performing according to Mendelian rules, but each having only a small influence on the same phenotype, resolved the issue. The collective effect of these multiple genes (polygenes) yields statistical expectations of resemblance of relatives of different degrees of biological relationship. For example, our understanding of the mechanism of gene transmission informs us that a parent shares half of his or her alleles with a child; grandparents share one quarter of their alleles with their grandchildren; siblings share half of their alleles on average; fraternal twins are just like siblings in this regard, and identical twins share all of their alleles. Comparison of the degree of similarity of phenotypes to the fraction of shared alleles permits the estimation of the proportions of phenotypic variance that can be attributed to genetic sources and to environmental sources. Each of these broad categories can be further divided. The overall genetic component can be described in terms of an additive component and a non-additive one. The non-additive component itself can be subdivided into effects arising from dominance, which can be regarded as the interaction of alleles at a locus, and from epistasis, which is the interaction of genotypes at different loci. This latter effect will be discussed in more detail later.

In the quantitative genetic model, environment is usually defined by exclusion—it is all of the influences that are non-genetic; i.e., not arising in a causal sense from the coded material of the DNA. Thus the scope and range of environment in this conceptualization is enormous, including in its compass factors from cellular biochemistry to peer group dynamics. This environmental contribution to phenotypic variance can also be partitioned in a number of ways, depending on the purpose of the research and on the data available. Long-term environmental effects may be distinguished from short term ones, for example, for developmental studies. One common distinction is that between environmental effects that are shared by family members and non-shared environmental influences that are experienced uniquely by individuals.

A simple, broad-stroke conceptual model represents the phenotype as the additive outcome of genetic and of environmental influences. Algebraically, this can be stated as

$$P = G + E$$

In a system such as this, the variances can be described as

$$V_P = V_G + V_E + 2\text{Cov}_{GE}$$

As noted previously, these terms are further divisible. Thus, as noted, V_G includes both an additive component (V_A) and a nonadditive (V_{NA}) component, and V_E is similarly subdivisible. These components yield an estimate of the relative influence of the two general domains. (There are also formulations that include a component of stochastic or of nonlinear dynamic influences [see Molenaar et al. 1993, Finch and Kirkwood 2000].) Measurement error is usually found in the environmental term, and as will be discussed below, there are also interaction terms that can be of great importance. The most commonly encountered index is that of heritability, which is the proportion of total phenotypic variance that is due to genetic differences among individuals. In the narrow sense, heritability is V_A/V_P , and in the broad sense, it is V_G/V_P . These two values are differentially useful for different descriptive and predictive purposes (see, for example, Falconer and Mackay 1996). The same information can be captured by an index of environmentality ($1 - h^2$), of course, but this term is infrequently encountered. It is very important to recognize that heritability and environmentality are descriptive statistics describing the state of affairs of a specific population under specific environmental circumstances. Different gene pools, or different environmental forces, might yield quite different estimates. Note also that high heritability does not mean that there is no conceivable environmental influence that can affect the phenotype. It means that in the population that was studied, there was either no sufficiently powerful environmental influence, or that if one existed, it impinged on so few of the population that it had little effect on the overall variability. Thus high heritability for a condition such as Attention Deficit Hyperactivity Disorder should not inhibit the search for environmental interventions. The classical single locus exemplar of this point is that of phenylketonuria, in which the homozygous recessive condition for a particular allele at the phenylalanine hydroxylase locus results in devastating mental retardation in ordinary environmental circumstances. However, the understanding of the metabolic process in which phenylalanine hydroxylase is involved led to the development of a rational intervention—a diet without phenylalanine, which cannot be metabolized normally by the homozygous recessive individuals.

Note that a gene is an unobserved hypothetical element both in a Mendelian system and in a polygenic system. The basic sequence involved in identifying a Mendelian inheritance pattern is to observe a categorical distribution of some phenotype, then to determine if the transmission pattern within families accords to Mendelian rules. In a polygenic, multifactor system, the issue is whether the pattern of resemblance among relatives conforms to expectations of the quantitative model. It is not required to know anything concrete about the gene or genes involved in either of these situations. But in fact, historically, while the range of application of Mendelian rules was being explored and the elaboration of the quantitative genetic model was proceeding, much was also being learned about the physical reality of genes. The key observation was that small bodies in the nucleus of cells behave according to rules similar to those of Mendel's elements. The hypothesis that these small bodies, the chromosomes, were the vehicles of the genes was quickly confirmed, and the field of cytogenetics emerged. Examination of the fine structure of chromosomes revealed distinctive banding patterns that permitted specification of chromosomal location, and subsequent research showed that the Mendelian elements resided in fixed positions on the chromosomes. The position of a gene came to be called its locus, for obvious reasons. The term, locus, was a terminological advance, making it possible to distinguish easily between the concept of gene, which everyone has, and the alleles, which different individuals can have in different combinations.

Throughout the first half of the twentieth century, a major biological mystery concerned the mechanism through which genes exert their influence. In mid-century occurred the revolution of molecular biology that discovered the chemical nature of genes and revealed the processes through which the genetic information in DNA is transcribed into RNA and translated into protein. This work connected the genetics of hypothetical genes to anatomy, physiology, immunology, endocrinology, biochemistry, neurobiology—to all of the disciplines that have explored the biological functioning of the organism. The question of the mechanism of gene action is thus answered in broad principle (although the details of specific cases may be unknown). Genes have no special route of influence to the phenotype; they operate through the complex systems comprising the familiar structures and functions of the body.

Complex systems such as this have some properties of great importance for the developmental sciences. A fundamental feature is the existence of feedback relationships of the sort involved in regulated processes, such as the familiar negative feedback in homeostatic systems. Another related feature is the typical presence of redundant pathways leading to the phenotype. With such properties, deficiencies in a particular element of a pathway might be compensated by up-

regulation of other elements in that pathway, or by enhanced activity in the parallel pathway. Kacser and Burns (1979) have emphasized that in biochemical pathways with feedback loops, it becomes impossible to specify the impact of any element without specifying the other elements in the system. In general, the simple notions of linear, unidirectional causation must yield to circular or network causal concepts (Sattler 1986). Specific to interpretation of genetic influences, we are cautioned that the effect of genotypic differences at a particular locus may be greatly influenced by other loci in the system, or by the environment in which the organism exists. The magnitude and complexity of these interactions will be illustrated later.

3. New Tools

Recent developments in molecular genetics have provided some remarkable new methods with which to approach the issues identified in this review. Some of the most relevant are the following.

3.1 Quantitative Trait Loci

Although the original quantitative genetic model postulated an indefinitely large number of loci with equal small effects, it has long been suspected that within a polygenic set there may exist a distribution of effect sizes. Prior to the genome projects that have provided chromosomal markers throughout the genomes of human beings and several model species, attempts to locate such loci have been fraught with difficulties. With the availability of the new markers, it has become possible to identify segments of the chromosomes in which are located genes that have a detectable influence on the variability of a phenotype. This is obviously a critical step on the way to further characterization of the locus at the molecular level. These individuated polygenes are termed quantitative trait loci (QTLs).

3.2 Transgenic Procedures

Among other enticing possibilities, there are now procedures that bring about changes in the DNA molecule constituting a gene so as to prevent its expression (knockout preparations), to alter its regulatory system in order to cause overexpression, or to insert a new gene. These preparations, permitting the examination of the downstream results of altering single loci, provide new avenues of approach to the causal nexus between gene and phenotype.

3.3 Arrays

Wedding of the technological advances of microchips with molecular biology has provided chips on which

are arrayed hundreds or thousands of gene segments. When exposed to preparations containing DNA from particular organs or tissues, the chips can identify, through the hybridization of the tissue DNA to the segments on the chips, those genes that are being expressed in the tissue being investigated. Both the bright promise and the methodological issues of this new technology have been well presented by Claverie (1999) and by Lockhart and Barlow (2001).

Although these procedures and techniques are new on the scene, they are already providing powerful complements to the accumulated data on interactions and developmental changes in the architecture of complex phenotypes.

4. Epistasis

The phenomenon of interaction among genes has been known since the early days of the last century. An epistatic variance component can be incorporated in the quantitative genetic model, as well, but the detection of interaction effects in polygenic systems is challenging. There are numerous examples of the dependence of single locus effects on a polygenic background, however. A now-classic result can illustrate. Coleman and Hummel (1975) investigated the phenotypic consequences of homozygosity for a particular allele (*db*) at the diabetes locus in inbred mice. Inbred strains approximate the condition of being homozygous at all loci (see McClearn and Hofer 1999); animals within a strain are identical, and different inbred strains differ from each other at some unknown number of loci. It was possible to arrange the *db/db* genotype on the background of two different (but related) inbred strains—C57BL/6 and C57BL/Ks. The phenotypic outcome differed dramatically, in respect to body weight, glucose level, pathophysiology (atrophy of the Islet cells in one strain, and hypertrophy in the other), and in effects on lifespan.

The advent of QTL methods has greatly facilitated the study of epistasis. It has become possible to examine the interaction of these as yet unidentified (but approximately located) loci. In mice, to illustrate the point, QTL interactions have been described affecting blood pressure (Rapp et al. 1998), diabetes (Galli et al. 1999), epileptic seizure frequency (Frankel et al. 1995), and lung cancer (Fijneman et al. 1996).

In human research, an epistatic interaction concerning risk for dementia has been reported. The $\epsilon 4$ allele of the *ApoE* locus has been implicated by many studies as a risk factor for the development of Alzheimer's disease. Overall, an allelic dose-response relationship has been observed, with a significant risk in heterozygous condition and an even greater risk in homozygous condition. Kamboh et al. (1995) describe an interaction of this locus and the *ACT* locus, alleles of which are labeled *A* and *T*. If an individual is homozygous *TT*, the risk associated with two $\epsilon 4$ alleles is not greater than with one. The $\epsilon 4$ -associated risk is

elevated if individuals are also *AA*, and individuals homozygous both for $\epsilon 4$ and for *A* are especially vulnerable.

These few examples represent the scope for the influence of genetic context on the effect of allelic differences at specific loci (i.e., the effect of allelic substitution, or the allelic dose-response effect). Characterization of a gene as 'the' gene for some phenotype must be understood to involve acknowledging the potential of this contextual influence.

5. Gene-Environment Interaction

Under the rubric of gene-environment interaction are those phenomena in which the relation of genotype to phenotype is altered as a function of environment, or, conversely, in which the impact of an environmental agency or condition is dependent upon the genotype of the individual exposed to the environment.

This theme can be illustrated by the results of Fosmire et al. (1993), who, in the context of risk factors in Alzheimer's disease, explored the effects of exposure to high levels of dietary aluminum on brain aluminum levels in five strains of mice. Three strains showed no elevation as a consequence of the exposure, one showed a moderate effect, and one showed a threefold increase.

Logically parallel to evidence such as this on genetic influence on risks of deleterious outcomes engendered by environmental factors is evidence of genetic influence on responsiveness to intended therapeutic interventions. Yaffe et al. (2000), for example, investigated the effects of estrogen used by women 65 years of age and older on risk of cognitive impairment, and found an interaction with *ApoE* genotype. Risk was not affected in women who possessed at least one $\epsilon 4$ allele, but was reduced in those who were $\epsilon 4$ -negative.

A final example illustrating the potential scope and complexities of gene-environment interactions may be taken from the work of Vieira and colleagues (2000). Seventeen QTLs were identified affecting lifespan in *Drosophila* reared in one of five different environments: three levels of rearing temperature, one involving a brief high temperature exposure, and one involving starvation stress. The results revealed an astounding level of interactions of the QTLs with sex and with environment. Some QTLs were effective only in one or a few environments and not in others; some were effective only in one sex; some were effective in both sexes, but only in one environment; and so on. In a summary statement, the authors reported that *all* of the genetic variance in this system was involved in some type of interaction!

6. Temporal Considerations

Dynamic change in the network of genetic and environmental factors over time is a key concept for developmental genetics. A fundamentally important

principle to emerge from investigations of the mechanisms of gene action is that genes may be turned on and off, or may have their level of expression up-regulated or down-regulated. There were temporal aspects to many of the previously cited studies; in a number of researches, the temporal dimension is the major focus. A particularly apposite example is the work of Rogina and Helfand (1995), who measured the expression of a gene in the antennae of *Drosophila melanogaster*. At hatching, there is little or no activity of this gene, but expression rises systematically to a peak in mid-life, with a subsequent gradual decline to near-zero levels at the end of life. When lifespan was shortened under conditions of an elevated rearing temperature or through the introduction of a different gene that shortens lifespan, the expression of the gene followed the same pattern, but in an accelerated manner, scaling to the proportion of the lifespan rather than to chronological time.

The existence of a program that 'knows' what proportion of a lifespan has already passed (and what remains) is an intriguing prospect. But for our present purposes, the important point is that this unambiguous demonstration of lifespan-scaled change in expression of this single gene informs us of the sort of changes that can be taking place in a polygenic system.

An example of dramatic developmental change in a mammalian system is provided by Cheverud et al. (1996) who studied mouse growth. Two sets of QTLs were identified: one affecting early growth but with diminishing influence by 6 weeks of age, and the other coming into play in the interval from 3 to 6 weeks of age.

It remains unclear how many or what proportion of loci can be expected to undergo systematic changes during the lifespan. The new chip technology is poised to generate a flood of data that will illuminate this issue, among many others. As a promissory illustration, Lee and colleagues (1999) have described differences between 5-month and 30-month old mice in respect to gene expression in skeletal muscle. Of 6,347 genes examined, 58 showed a more-than-twofold increase in expression levels and 55 showed a decrease of that magnitude. Although these numbers indicate that only a small percentage of genes are changing expression of this magnitude in this tissue over this time span, the impact of these changes in complex aging systems could be substantial. Information from other tissues is urgently needed, and will undoubtedly be reported soon.

Life stage has also been shown to be critical to the genetics of development in human beings. In a single locus example, Ferrari et al. (1998) showed that the major locus for the vitamin D receptor has an appreciable effect on the bone mass of pre-pubertal girls, but does not have any such influence during post-pubertal adolescence.

Concerning late life, there is a widely shared expectation that with advancing age the cumulative

Figure 2

(a) Percent of variance of various biomedical phenotypes attributable to genetic sources. Data from the Swedish Adoption/Twin Study of Aging. Estimates are shown for a younger group of twin pairs (aged less than 65 years) and an older group (65 years of age and older). (b) Percent of variance of various biomedical phenotypes attributable to non-shared environmental sources. Data from the Swedish Adoption/Twin Study of Aging. (c) Percent of variance of various biomedical phenotypes attributable to shared environmental sources. Data from the Swedish Adoption/Twin Study of Aging.

effects of uniquely experienced environmental factors will lead to reduced proportional contribution of genetic factors to that variance. Evidence on shifting variance components in aging has been provided by twin studies on the elderly; the classic expectation is fulfilled in the case of some phenotypes, but not all. Fig. 2 gives results from some biomedical variables included in the Swedish Adoption/Twin Study of Aging (SATSA) (Heller et al. 1993, Hong et al. 1994, McClearn et al. 1994). Estimates were derived from structural equation modeling of genetic, shared environmental, and non-shared environmental components of variance.

Participants in the study were Swedish identical and fraternal twins, some of whom were reared together and some of whom were separated in early life and reared separately. Estimates were derived separately for a younger group (less than 65 years of age) and an older group (65 years of age and older). Figure 2a gives the estimates of heritability. The difference between the older and younger cohort clearly conforms to the classical expectation of reduced heritability for measures of cholesterol, triglycerides, systolic blood pressure, and vital capacity. Heritability of diastolic blood pressure is, however, modest and essentially the same in both cohorts, and, with respect to forced expiratory volume (FEV), heritability is very substantial in the younger cohort, and even higher in the older cohort.

Fig. 2b gives the estimates for the influence of non-shared environment for these phenotypes. Most of these phenotypes (FEV being the exception) do display the classically expected result of greater non-shared environmental influence in the older group. Shared environmental influences, shown in Fig. 2c, are generally smaller than the nonshared environmental components. An interesting result is the hint that the effects of early shared rearing environment on cholesterol, systolic blood pressure, and vital capacity may be more manifest in the older cohort than in the younger one.

In addition to the fluctuation of genetic influence over the lifespan, there is growing evidence of shorter-term temporal variability. In rats, for example, the liver mRNA concentration of aldolase B, an enzyme of the glycolytic system, declines during fasting, and increases four- to eightfold upon re-feeding of a carbohydrate-rich diet (Munnich et al. 1985). Investigating the mechanisms involved revealed that regulation of the expression of the relevant gene is accomplished very differently in liver, kidney, and small intestine.

Another example of environmentally mediated alteration of gene expression is provided by the work of McMahon and colleagues (1992), who studied the effects of immobilization stress in rats. Among other results, it was found that a single stress resulted in elevation of levels of tyrosine hydroxylase mRNAs in the adrenal glands.

Thus, the responsiveness of the genetic system to the environmental stimulus can occur quickly. From the point of view of behavioral science, an especially pertinent observation is that the expression of a gene in a particular brain region can be classically conditioned (Smith et al. 1992).

7. Summary

The studies reviewed here are but a few, selected, examples from a vast literature pertaining to an enormously broad array of phenotypes observed on species representing the phyletic range from prokaryotes to eukaryotes. Obviously, a brief review such as this can provide only the sketchiest outline. But, hopefully, it provides a hint as to the possibilities of dynamic interaction of genes with genes and of genes with environment and of the changes of this whole complex system over time. It may also serve as a preventive against simplistic interpretations of the old nature vs. nurture variety in issues of lifespan development. The current data are impressive; the anticipated flood of new data from new methodologies will provide us both with sharpened reductionist understanding, and, in the context of the quantitative model, an integrated view appropriate to the complex systems with which the developmental sciences are concerned.

Genocide: Anthropological Aspects

Genocide is a crime in international law. It was established as such by the United Nations Genocide Convention of December 9, 1948 which committed 'contracting' states to 'prevent and to punish ... acts committed with the intent to destroy, in whole or in part, a national, ethnical, racial or religious group.' This legal definition was reached following political compromises between the major powers at the UN, and a more precise, academic definition is adopted here, according to which genocide is 'a series of purposeful actions by a perpetrator(s) to destroy a collectivity through mass or selective murders of group members and suppressing the biological and social reproduction of the collectivity' (Fein 1990, pp. 28–9). After many years of academic avoidance of the topic, there has been a recent surge of interest across disciplines from psychology through political science to anthropology, the best of which work has been interdisciplinary in perspective. Sociological and anthropological investigation of genocide covers four main areas: the definition of genocide and the characterization of particular instances of mass slaughter; the sociology of genocides themselves; the sociology of representations of genocide (from 'survivor testimony' through memorialization and forms of material culture such as architecture to studies of war crimes tribunals); and the sociology of the after effects of genocide. These will be treated in turn.

1. Problems of Definition

The term genocide is a neologism, coined in 1944 by Raphael Lemkin, a legal scholar and Polish Jewish

émigré to the USA. Lemkin took over ancient Greek roots for 'tribe' and 'killing' to create a word that would adequately convey the enormity of Nazi and Axis crimes in Central and Eastern Europe during World War II. This definition inspired a UN General Assembly resolution of 1946 but when, two years later, the same body established a binding Genocide Convention, the range of reference was narrowed in two important ways. First, cases where a culture is destroyed without the extermination of people—now commonly referred to as *ethnocide*—were excluded. Secondly, and much more critically, in order to accommodate concerns of the USSR, which might have faced indictment for mass killing of 'class' enemies (as in the deliberately created famine in the Ukraine in 1932–3, or the then still undiscovered 'gulag'), the 1948 UN definition excluded the extermination of 'political and other groups' such as social classes.

These questions of legal definition are important because the Convention commits states which subscribe to it 'to prevent and to punish' the crime of genocide by pursuing perpetrators 'whether they are constitutionally responsible rulers, public officials or private individuals.' Moreover, since the Convention explicitly denies that genocide can be a 'political' crime, perpetrators are subject to the laws of extradition.

Perhaps precisely because of its ambitious promise, the Convention has been invoked remarkably little since 1948. Both the desire of member states to preserve inviolate their claims to sovereignty and of others not to have to commit resources to humanitarian interventions have played a role. Leaving aside UN silence during the slaughter of half a million Indonesian communists in 1965 and the death of 1.5 million Cambodians in 1975–9 (since it could be argued that the 1948 Convention excluded such cases) it is a matter of record that US officials at the UN were instructed in 1992 to avoid using the term 'genocide' with respect to Bosnia so as not to trigger obligations under the Convention. In fact, the only major development since 1948 has been the establishment, in 1994, of the *ad hoc* International Criminal Tribunals for former Yugoslavia and Rwanda, though under the peace enforcement provisions of the UN Charter (Chapter VII), not the Genocide Convention, and refused permanent status due to Chinese objections.

While considerable academic energy has been expended in attempting to classify particular mass murders as genocide or otherwise (the destruction of the Albigensian Cathar heretics in France in the thirteenth century, the removal of up to 50 million persons from Africa during the slave trade, the slaughter of the Hereros of South West Africa by German forces in 1904–7, the massacres of the Armenians in 1915, the persecution of political enemies under Stalin in the USSR, the elimination of various indigenous peoples such as the Ache of

Paraguay, to name but a few) perhaps the most broadly attended and resonant debates have concerned the uniqueness or otherwise of the Nazi genocide of the Jews. On the one hand, some scholars argue that the Jewish Holocaust is the only case in history of the attempted destruction of an entire people because they were that people. Other genocides were committed as a by-product of the course of war (Hereros) or political struggles (Democratic Kampuchea), or aimed to destroy a culture or way of life by eliminating some of its bearers (Gypsies in World War II), or occurred indirectly as a consequence of actions not *per se* intended to destroy a people (the slave trade). The Nazi persecution of the Jews differed from all these in intent, extent and 'success' (Bauer 1984).

Other scholars, however, resist the implication of the 'exceptionalist' position that the Holocaust occurred in some sense 'outside of normal history' and thus had neither precedent in the past nor lessons for the future. Unsurprisingly, this debate leads on to conflict over the interpretative framework for understanding the causes and the motivations of the Holocaust and its perpetrators. For their part, most anthropologists would favor retaining a comparative, sociological framework and resist the suggestion that any sociological phenomenon can be unique in the strong sense argued by exceptionalist scholars, or require recourse to abstract notions of 'evil' (Conte and Essner 1995, Clendinnen 1999).

This debate has implications beyond German historiography. An anthropologist working in former Yugoslavia has recently argued that the public understanding of what constitutes genocide, which derives from images of the Nazi Holocaust, prevented observers from recognizing an actually existing genocide as it developed before the world's eyes (Sorabji 1994). Indeed, one of the puzzles of the sociology of genocide is why outside observers tend in general to be so unwilling to face the facts until it is too late, and why even after the event such effort is put into obfuscation and evasion of the brute historical record.

2. *The Sociology of Genocidal Mass Murder*

Though anthropologists aim to study the sources of human social and cultural variation, surprisingly little effort has been contributed by this discipline to the study of genocidal mass murder. This gap in the literature is all the more surprising in that many of the acknowledged genocides of the last century and a half have taken place in parts of the world where anthropologists work. Naturally, part of the explanation lies in the way anthropologists carry out their research. Participant observation in the life of a community is not a methodology that is easily adapted to the study of murderous gangs manning roadblocks or units of

the local military on active service. Beyond methodological considerations, there may also be a sense, shared with those who work for Amnesty International, that to explain is in some sense to forgive, and that the task of observers is merely to record, lest we forget.

Recently, however, anthropological avoidance of this topic—an evasion that was characteristic of most social science, with some noteworthy exceptions like Leo Kuper (1982)—has been coming to an end. Inspired in part by a wave of ethnographic writing about political violence, especially in South Asia (Spencer 1990), a new generation of anthropologists have written on particular genocides (Bosnia, Rwanda, and Cambodia most notably, but also Nazi Germany). In this work, the anthropologists attempt, with more or less success, to bring to bear a sense that violence is rarely simply pragmatic and is often patterned in ways specific to a particular time and place and always interpreted in local, cultural terms.

As in the other social sciences and humanities which deal with cases of mass murder, anthropological analyses aim above all to answer the question, 'how could this happen?' Under what conditions did one group of humans attempt to wipe out another? Responses can be divided along a familiar line into two camps: those who stress cultural factors and those who stress social, political, and economic factors. Taking the former first, for authors in this school the goal is to provide a specifically 'anthropological contribution,' to prove that an ethnographer's interest in 'cultural variation' adds an otherwise missing ingredient to analyses of genocide.

Much of this 'culturalist' work (notably writing on Rwanda and Cambodia) takes a cue, wittingly or not, from an essay by the historian Natalie Zemon Davis (1973) on differential patterns of violence in the religious wars in France in the seventeenth century. Davis showed that the forms of Protestant on Catholic violence were not the same as those perpetrated by Catholics on Protestants. Each religious tradition had its own construction of the nature of demonic power in the other and adherents of the two faiths acted to cleanse the world accordingly. Because of their interest in demonstrating a 'cultural logic,' the anthropological writing on Rwanda and Cambodia does not advance theoretically on Davis's original insight (Taylor 1999, Hinton 1998). Evidence is presented that shows how in some instances cultural patterns seem to have given form to and shaped people's violent behavior, but little or no attempt is made to explain how particular segments of the population or groups of individuals came to participate in the genocide at a particular time and place.

Curiously, this kind of explanation of 'how it happened' has several features in common with the approach adopted by Daniel Goldhagen (1996) in *Hitler's Willing Executioners*, a book which enjoyed runaway popular success across the USA, Europe,

and particularly Germany in the mid-1990s (while being almost universally condemned by the historians with period expertise). Goldhagen's answer to the question 'how could it happen' was that it was Germans who killed Jews in World War II (it was not just they, in fact) and they did so because of the activation of a tradition which he dubbed 'eliminationist antisemitism' which had long characterized German culture (while in reality antisemitism had actually been a vote-loser for the Nazis prior to 1933).

For authors working in this tradition, genocide is derived or emerges out of a 'cultural model.' What tends to be missing from such explanations is any attempt to detail political manipulation by those who planned the genocides, to analyze the institutional apparatus which prepared and carried through the genocides, and to establish the sociological and even biographical profile of identified killers. In the case of Rwanda one has to turn away from the anthropologists, to the work of the political scientist Rene Lemarchand to discover, for instance, that the genocide was planned by a core of one extended family and advisors, promulgated through 300–500 middle level, rural cadres, set off by a presidential guard of around 6,000 persons who massacred all opponents of the genocide (Hutu and Tutsi alike) and finally continued by militias who may have made up 1–2 percent of the population, each member of which may have killed 200–300 people (Lemarchand 1997).

Work that searches for the cultural models which underpin and apparently feed directly in to genocide bears a close affinity with the first efforts by anthropologists to deal with issues of genocide during and shortly after World War II. Then adherents of the culture and personality school provided textbook/manual type explanations of the personality of the enemy in an effort to explain the success of totalitarian regimes in Japan and Germany and as a prelude to reconstruction and democratization. At the beginning of the twenty-first century, with decades of detailed analysis of the paradigmatic Nazi case behind us, there really is little excuse for allowing this kind of cultural reductionism to pass for 'anthropological explanation.'

An alternative approach within anthropology is to be found in work on Bosnia. Here the research was carried out by a British-trained *social* rather than US-trained *cultural* anthropologist (Sorabji 1994). This work owes much to the tradition of historical and sociological investigation of the Holocaust represented by such scholars as those around Herbert (2000), as well as the kind of political science of Bosnia pursued by Bougarel (1997). It puts stress less on 'culture' than 'local knowledge,' and tries to provide a fuller sense of 'what happened' before answering the more difficult question, 'why?'. Anthropological expertise is combined with a journalist's sense of political manipulation, a sociological interest in institutions, and a historian's concern with events of the recent and

remembered past. Not only is the Bosnian genocide not represented as being rooted in 'cultural traditions,' but it is shown how this very representation is part of the armory of the perpetrators, used, with great success in this case, to keep outsiders from interfering. As long as US Secretary of State Warren Christopher, or British Prime Minister John Major was advised that 'ethnic cleansing' was not 'genocide' and that deep-rooted cultural patterns on all sides were to blame, they felt justified in evading calls for intervention. Indeed, the very 'disorganized' quality of the genocide (compared with the Nazi model case) came to be taken as evidence of its nonexistence. In reality, however, institutional patterns were at work: Violent criminals were being released from Belgrade jails and sent to join militias. These operated formally independently but under the cover of the official military. Intellectuals were among their first targets, often identified on pre-prepared lists; local schools and other sites of intercommunal, neighborly interaction were chosen as locales for internment and torture; neighbors were deliberately sent to kill neighbors. The 'sites of memory' of Bosnian social life were being systematically and consciously destroyed by the instigators of a genocidal violence that was presented as medieval but was, in reality, wholly modern.

This kind of work points to a need to think more broadly about the psychological and mental underpinnings of the violent behavior of individuals and collectivities and to relate these findings to work elsewhere within anthropology. It is striking that the language of genocide in Bosnia, as in some other cases, was one of sacrifice, an invitation, one might think, to introduce anthropological work on the relation between religious representations of transcendence and political violence (e.g., Bloch 1992).

3. *The Sociology of the Representation of Genocide and Memorialization*

It is possible to argue that much of what has recently passed for analysis of the cultural soil of genocide in anthropology is in reality merely the re-presentation of local, folk explanations of genocidal behavior. This data, which is often part of the discourse around the genocide and ought to be part of the material analyzed and explained by a sophisticated social science, is instead relied upon, more or less uncritically, as if descriptively neutral.

In analyzing perpetrator discourse anthropologists have pointed out how genocide, like political violence more generally, tends to be presented by the perpetrators as a just defense against others who are about to attack, or are already attacking, the perpetrators. But a less sceptical attitude has been adopted, for instance, over accounts which focus on the rural, resentful character of supposed killers (Hinton 1998). Going

further into the psychological roots of genocidal violence, the fundamental challenge, as everyone knows who has ever investigated these issues, is that no one ever admits to having personally been a genocidal killer. No researcher has yet overcome this obstacle.

A more fruitful domain has been analysis of survivor testimony and of the reconstructions of generations who have come after (a field which overlaps with broader interests in memory, narrative, and representations of the past). Discussion of the relationship between trauma, personal memory, and reconstruction of the 'self' is still at an early stage in all the disciplines which touch on this area. One feature that is commonly pointed to in victim testimony is a flat, matter-of-fact tone adopted, a technique of distancing and dissociation. In innovative work in transcultural psychiatry, Laurence Kirmayer has developed a notion of *landscapes of memory* to characterize some of the differences in narratives of trauma between child abuse and holocaust victims: 'while holocaust stories involve bearing witness to what is widely ... recognized as a human catastrophe, personal stories of abuse are revelatory, shameful and damaging' (Kirmayer 1996, p.188). In this context memorialization may be a key feature of legitimating the experience of suffering. Work is, however, only just beginning on situations where memorialization does not take place (as for instance with most Gypsies in Eastern Europe).

One important new area of investigation is the social and political understandings and implications of particular ways of representing genocides. Early work in material culture on the activity of memory in holocaust memorials has shown how the meanings of memorials are contingent on social and political realities (Young 1993). At a literary level, work by Inga Clendinnen (1999) has opened up one path for a generation who no longer have access to direct testimony from survivors; more challengingly, Peter Novick's (1999) iconoclastic study of the Holocaust in US public life argues that some representations of genocide may act to inoculate a society against its own history and current world duties.

Apart from academic analysis, anthropologists have, at times, become centrally involved in acts of memorialization. In 1989, Polish Prime Minister Mazowiecki convened a commission to reconstruct the Auschwitz-Birkenau museum and monument for a postcommunist world. At the behest of the Polish Ministry of Culture, Jonathon Webber, an anthropologist with field research in Poland, and head of Oxford University's Centre for Hebrew Studies, invited an international body of experts to discuss 'the future of Auschwitz.' Alongside determining major issues of factual history—that 1.6 million had died there, and not four million as previously claimed, that 90 percent of those killed were Jews and not Polish and so on—the commission also addressed such tricky questions as to whether and how one should preserve

the ruins: reconstruction of the gas chambers was out of the question, but what sort of renovation should be permitted?

4. Postgenocide Societies?

Work on the representation of genocide is intimately connected with an interest in the afterlife of such massive social trauma. Many have suggested an association between German and Japanese urban terror in the 1960s with the phenomena of the 'second generation' but the link has never been established systematically. Now, however, a body of clinical work on individual responses to massive trauma is emerging. Imaginative work here often comes at the interface of disciplines, as in Lynne Jones's (2000) ethnographic-psychological examinations of how subjective understandings and political context mediate the impact of political violence on adolescent mental health in Bosnia. Jones, who is based at Cambridge University's Centre for Family Research, has, among other things, investigated children who had watched others being cleansed from their own town. In this case the 'therapeutic remedy' of 'the search for meaning' exposed children to uncomfortable truths about their community and appeared to lead to psychological discomfort, depression, and anxiety. Those children who avoided examining such events had better psychological health, but at the cost of leaving their elders' discourse unchallenged for a second generation.

For many victims of direct attack, the search for meaning, to name the unnameable is unavoidable. Here too, it is to be hoped, ethnographic work will emerge examining the impact of the International Criminal Tribunals. The president of the Yugoslav tribunal has sought to bring as many witnesses as possible to the Hague, so they can see their stories heard and entered in the register. But what effect has this had, and how will the expanding work of the Tribunal change the 'landscapes of memory' in Bosnia? It has been argued that significant use was made in 1990–2 of representations of experiences of World War II in cultivating an environment in which violence came to be seen as a serious option (Hayden 1994). Investigation of how societies deal with these kind of events is thus not merely of academic interest.

At an even broader level of analysis, anthropology would have much to contribute to the study of the experience of societies like Israel—for long unwilling to incorporate the genocide into its collective memory and now, having made it central to the nation, finding it hard to create a unified identity with Arab Jews who did not suffer. In the case of the perpetrator states the issue is almost invariably one of the social consequences of denial. Racist attitudes to Gypsies in Eastern Europe are likely related to denial and ignorance of Gypsy persecution in 1940–5. In this regard the German case is unique—a perpetrator state

that has accepted historic responsibility. German foreign policy will be constrained by the Nazi past for the foreseeable future and perhaps as long as there is a German political entity, but it is also clear that for the time being this is a society which cannot shrug off its past. Daniel Goldhagen's work struck a profound chord in Germany perhaps because it offered a new generation a fresh chance to stare at an unadulterated image of the heart of some of their ancestors' 'darkness.' At that very moment there was also anguish over the Berlin Holocaust memorial. One particularly radical proposal was to construct a bus station in central Berlin with timetabled buses taking visitors and pilgrims to and from the death and concentration camps—a reminder of just how close so many of these camps lay to the capital of the Reich and lie to the new capital of a reunified Germany. It was rejected for 'lack of taste' and necessary 'monumentality.' Such phenomena can provide sociologists and anthropologists with rich seams of cultural and social significance.

Genocide: Historical Aspects

Genocide is any intentional act to physically eliminate a non-combatant group in whole or in part by direct assault, or by inflicting deadly life conditions including measures to prevent biological, economic and cultural reproduction.

This article will outline the development of genocide research as well as the tasks of this young academic discipline (Sect. 1). It will, in Sect. 2, deal with the problem of applying the twentieth-century term genocide to a wide variety of mega-killings which have happened throughout history. The term genocide has generated a tendency not only to rewrite, but also to morally judge anew, historical events to settle recent political accounts. Groups whose ancestors have suffered massacres at a period in which neither they themselves nor their victorious opponents had drawn up or adhered to international legal standards outlawing such atrocities may yet label their past fate as genocide to attract attention to contemporary plights. The entry will try to circumvent this extra-scholarly or ideological use of the term genocide by implicitly or explicitly using a caveat of the sort that an event called genocide 'today' was not seen as such then. It has to be stressed that all figures used in this entry are estimates. There is no such thing as an undisputed figure for even the best researched genocides.

1. The Term Genocide and the Development of Genocide Research

Genocide is not only a historical concept but also an international crime defined by the 1948 United Nations *Convention on the Prevention and Punishment of the Crime of Genocide*. In its Article II

genocide means any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such: (a) killing members of the group; (b) causing serious bodily or mental harm to members of the group; (c) deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part; (d) imposing measures intended to prevent births within the group; (e) forcibly transferring children of the group to another group.

The crimes mentioned in paragraphs (a) to (e) of Article II of the Convention are generalizations of practices employed by Nazi Germany after September 1, 1939 (beginning of World War II) against Slavs and/or Jews, and gypsies. The UN Convention was mostly written by a Polish lawyer and Holocaust refugee, Raphael Lemkin (1900–59), who had first in 1933 proposed a similar measure to the 'League of Nations.' In 1943, he had termed the crime in Polish as *ludobójstwo* (*lud* = people; *zabójstwo* = murder). A year later, he translated it into English as *genocide* (from Greek *genos* = people, and Latin *caedere* = kill, see Lemkin 1944, p. 79).

Since the UN Convention—today signed by some 140 nations—excluded 'politicide'—the murder of any person or people because of their politics or for political purposes—as well as 'ideological genocide'—the murder of any person or people because of their ideology, theory or knowledge—scholars have broadened the concept. Rudy Rummel's term 'democide' may be considered as the most comprehensive one. It is the murder of any person or people including genocide in the international legal sense, politicide as well as ideological mass murder (Rummel 1996, p. 39).

Besides the narrower term genocide and the more inclusive term democide the term 'crimes against humanity' is still in wide use. It was coined on May 24, 1915 by France, Great Britain, Russia, and the USA on behalf of the slaughtered Ottoman Armenians as 'new crimes of Turkey against humanity and civilization.' The term 'crimes against mankind' created, on October 12, 1942, in London (*Declaration of St. James*) to denounce the Nazi Holocaust of European Jewry is also still in use. Less known though quite appropriate is Gracchus Babeuf's French term 'populicide,' a shorthand for his 'système de dépopulation' executed—during the French Revolution—in the Vendée (1793/94) by killing its entire royalist peasantry of some 120,000 (Babeuf 1795).

The discipline of comparative genocide research draws on the entire corpus of historical research of the

last three millennia. Mega-killings have always attracted the attention of laymen and scholars alike. Yet, a first world history approach to genocide was tried by Lemkin who had drafted three volumes on the *History of Genocide* by 1959 (Jacobs 1999). Several publishing houses had turned him down. The manuscripts are only now being prepared for publication by Steven L. Jacobs.

The 1967–1970 massacres of half a million Ibos in Biafra/Nigeria triggered a new interest in the subject. In 1970, Yvan van Garse published *A Bibliography of Genocide Crimes against Humanity and War Crimes* (Garse 1970). The genocide, in 1971, of some 1.5 million citizens of East-Pakistan (today's Bangladesh) also has drawn a steady albeit not widespread attention to the subject. Both killings had world wide television coverage. Only a year later, in 1972, *The Twentieth Century Book of the Dead* by Gil Elliot became the first major published monograph devoted to comparative genocide research (Eliot 1972). In 1975, sociology entered the field with Dadrian (1975). Irving Louis Horowitz's *Genocide: State Power and Mass Murder* followed in 1976 (Horowitz 1997). In 1981, Leo Kuper reached a major academic publisher, Yale University Press, with *Genocide: Its Political Use in the Twentieth Century* (Kuper 1982). More systematically and historically minded works followed in 1990 with Fein's (1990) *Genocide: A Sociological Perspective* as well as Chalk's and Jonassohn (1990) *The History and Sociology of Genocide*.

The first—one person—institute devoted to the subject: 'Institute on the Holocaust and Genocide,' was founded in 1979 by Israel W. Charny in Jerusalem. Helen Fein followed in 1982 with the 'Institute for the Study of Genocide,' in New York. Next were Frank Chalk and Kurt Jonassohn with the Canadian 'Institute for Genocide and Human Rights Studies' (Montreal, Concordia University). Australia with the 'Centre for Comparative Genocide Studies' (Macquarie University), and Europe with the 'Raphael-Lemkin-Institut für Xenophobie- und Genozidforschung' (University of Bremen, Germany) followed in 1993. An international 'Association of Genocide Scholars' was established in 1995 with some 150 members by mid-2000. The first encyclopedia of genocide was published in Germany (Heinsohn 1999). A similar endeavor in English followed shortly afterwards (Charny 1999). Both works, with a combined volume of some 1,200 pages, cover most of the contents of this entry.

Historical, sociological, and sociopsychological studies of genocide aim at the assessment of genocidal potential as well as the formulation of means to prevent the crime. Interventions against ongoing genocides are rather dealt with in studies of warfare than in comparative genocide research. The prevention of genocide requires an early warning system. Historically, roughly 25 percent of high risk nations have transformed their perpetrator potential into

actual genocide (the rate is higher for democide). Since every genocide needs certain steps of preparation which are difficult to conceal, like, e.g., registering the victims and training the killers, all nations with perpetrator potential (today close to 100) may one day be scanned for these red alert signals indicating the imminence of a genocide.

2. History of Genocide

Because of its modern provenance it is difficult to employ the term genocide to the common periodization of history. Homer's *Iliad* (VI: 55–62), e.g., paints, as perfectly legitimate, an intention that today would be considered as genocidal in its full legal sense:

"My good Menelaos" [king of Sparta], said he [Agamemnon, king of Mycene], "this is no time for giving quarter. Has, then, your house fared so well at the hands of the Trojans? Let us not spare a single one of them—not even the child unborn in its mother's womb; let not a man of them be left alive, but let all in Ilios [Troy] perish, unheeded and forgotten." Thus he did speak and his brother was persuaded by him, for his words were just.

Moreover, a practice of killing considered the expectable as well as acceptable outcome of conflict in an early period of history may continue to this very day. As an example in question one may look at the Yanomami Indians of Southern Venezuela and Northern Brazil. They must—since 1980—be considered a possible victim of genocide by modern settlers and—at the very same time—were successful in nearly wiping out a neighboring tribe (Keegan 1993, p. 97).

2.1 Tribal Societies

Genocidal acts in the modern sense were hardly distinguishable from acts of war in tribal societies—covering the longest stretch of human history—because there was no separation of noncombatant civilians and warriors. Warfare was "ecological" in motivation' and led to the redistribution of hunting and fishing grounds or arable land 'from the weak to the strong' (Keegan 1993, p.101). Means of these wars were 'battles of annihilation' or, if space allowed, 'displacement of the weaker' (Keegan 1993, pp. 29, 387). Genocidal tribal raids continued well into the second half of the twentieth century in territories of the Amazon, New Guinea, the Philippines and elsewhere: 'Typically the goal in such raids is to destroy an entire village or settlement, the common intention being to kill everyone, perhaps excepting a few of the younger women and children who are carried off for incorporation into the home group' (Glick 1994, p. 45).

2.2 Early Antiquity

Early stages of civilization (Early and Middle Bronze Age with priest-kingship feudalism) saw tribal practices of annihilation on a larger scale: 'I slew them without sparing them, they sprawled before my horses, and lay slain in heaps in their blood,' Egypt's Pharaoh Ramses II (conventionally dated 1279 to 1212) boasted after a campaign against the Hittites whose leader, then, begged him for mercy: 'Look, you spent yesterday killing a hundred thousand and today you came back and left no heirs. Be not hard in your dealings victorious king' (Lichtheim 1976, pp. 70 f.). Other powers of the Ancient Near and Far East behaved very much in the same way, as did Bronze Age, i.e., Mycenaean Greece.

2.3 Antiquity/City States

The annihilation practices of time immemorial were cast into a principle by Athenians. When, in the Peloponnesian War (431 to 404 BC), Athens had decided to wipe out Sparta's ally Melos, the admirals in charge tried to formulate an eternal law underlying their action:

Our knowledge of men leads us to conclude that it is a general and necessary law of nature to rule wherever one can. This is not a law that we made ourselves, nor were we the first to act upon it when it was made. We found it already in existence, and we shall leave it to exist for ever among those who come after us. [...] We know that you or anybody else with the same power as ours would be acting in precisely the same way. [...] The Melians [in 415 BC] surrendered unconditionally to the Athenians, who put to death all the men of military age whom they took, and sold the women and children as slaves (Thucydides, *The Peloponnesian War*, (1954 trans) V: 85 ff.).

As a first step away from mutually slaughtering their males, the Greeks developed the practice of exchanging prisoners of war.

Within the Roman Empire—a private ownership based society on a much larger scale—the practice of destroying enemies who had caused problems in the past was continued. The elimination of Corinth (metropolis of mainland Greeks) and Carthage (metropolis of Phoenicians) in 146 BC, of Numantia (capital of Spanish Celtiberians) in 134 BC, and the elimination of the Etruscans (92 BC) and the Samnites (82 BC) as major opponents in Italy proper provide typical examples with 50,000 to 150,000 dead in each case. Of course, the opponents acted in the same manner as, e.g., in the slaughter of the inhabitants of the Greek cities Selinus and Himera (Sicily) in 409 BC by the Phoenicians of Carthage. In 88 BC all Romans and Italians, including women and children, living in Greek Asia Minor were put to the sword by orders of Mithradates VI. The Romans of Britannia met a similar fate in 61 BC. Within the Roman Empire a *ius gentium* was developed for strangers who did not hold

citizenship with, sometimes, more protection for these minorities than for full citizens.

Parallel to practices of the Greek City States and the Roman Empire, movements against blood sacrifice emerged around 600 BC. Well known are Buddhism in India and the Pythagoreans of Classical Greece. It was, however, monotheistic Judaism whose moral code—albeit slowly—came to influence international ethics most deeply. To overcome expectations of salvation tied to the slaughter rituals of blood sacrifice, Hebrew prophets found a new moral vision: 'I desired mercy, not sacrifice; and the knowledge of God more than burnt offerings' (*Hosea* 6:6). The sanctity of life became the highest principle: 'Thou shalt not kill' (*Exodus* 20:13 and *Deuteronomy* 5:17) including—in its universal character—the strict outlawing of infanticide.

The Torah—rather a moral compilation than a historical record—emphasizes the sanctity of life as the core of the law and as a value identical with goodness ('the good law'): 'See, I have set before thee this day life and good. [...] I call heaven and earth to record this day against you, that I have set before you life and death, blessing and cursing: therefore choose life, that both thou and thy seed may live' (*Deuteronomy* 30:15, 19). From the principle of life's sacredness derived other commandments like 'Thou shalt love thy neighbor as thyself' (*Leviticus* 19:18). Anti-xenophobic teaching followed suit: 'And if a stranger sojourn with thee in your land, you shall not vex him. But the stranger that dwelleth with you shall be unto you as one born among you, and thou shalt love him as thyself' (*Leviticus* 19:33–34). 'Are ye not as children of the Ethiopians unto me, O children of Israel? Saith the Lord. Have not I brought up Israel out of the land of Egypt, and the Philistines from Caphtor, and the Syrians from Kir' (*Amos* 9:7).

Against Judaism, the first recorded order (of Haman) for an ideological, though abortive, genocide (also called religiocide) was issued in the Akhaemenid Empire of fourth century BC: 'And the letters were sent by posts into all the king's provinces, to destroy, to kill, and to cause to perish all Jews, both young and old, little children and women, in one day' (*Esther* 3:8/13). Christians who had adopted the Jewish rejection of blood sacrifice to planetary deities actually suffered the first well recorded religiocides. The edict of Emperor Decius of AD 250 forced them to eat sacrificial meat or suffer death. Four more edicts by Diocletian from AD 303/304 repeated the order upon pain of death. The massacres ended in AD 312 when Constantine the Great converted to the new faith.

2.4 Middle Ages

The Middle Ages saw attempts at a *Pax Romana*, directed by the Papal See. Its concept of a *Pax Dei* (peace of God)—developed since AD 975 and extended over all Christian lands at the Synod of Clermont

(AD 1095)—outlawed war from Wednesday night to Monday morning as well as on Christian holidays. Excommunications and interdicts were the only means of enforcement. It was the beginning of international law based on the Judeo-Christian code of ethics. Yet, the transgressions were severe and, in modern terminology, definitely genocidal.

The crusades—starting in AD 1096—not only brought massacres of thousands of Jews in Germany and tens of thousands of Jews and Muslims in Jerusalem (AD 1099), but also of fellow Christians. Against Pope Innocent III's interdict, Dalmatia's port Zadar, arch rival of Venice, was bathed in the blood of all its inhabitants in November 1202 during the fourth Crusade by French and Italian troops transported on Venetian ships. The same men butchered 2,000 inhabitants of Greek Constantinople on April 13, 1205 before they went on a three-day-rampage of indiscriminate slaughter, not sparing women and children.

Since 1167, the Cathars (from Greek *katharoi* = pure), called Albigensians after the French city of Albi, suffered a series of religiocides by Catholic forces, because they rejected any spilling of blood and did not believe in the resurrection of Christ, and the Holy Communion as the residue of blood sacrifice within Christianity. By 1234 the Cathars were wiped out with the massacre of Béziers as the largest slaughter of this crusade in which all 15,000 inhabitants were killed.

A few years later, in AD 1211, Gengis Khan's Mongols (Morgan 1986)—with no authority to arouse their consciousness by threats of excommunication or invoking the image of all men as protected children of the one God—began their terrifying campaigns from the Japanese to the Baltic Sea. To turn their fertile areas into horse pastures the Mongols have, up to AD 1290, eliminated some 25 million Chinese. Another 5 million perished in Persian, Arab, and Christian territories where the Steppe warriors revived the memory of Attila's fifth century Huns. Behind their lines, the Mongols used to kill everyone perceived as a future threat, i.e., all males not suitable to join their ranks. Defeated armies were allowed a brief lease to life by serving as shields or trail blazers for advancing Mongol troops. Tamerlane, a pious Muslim, supposedly had, in a single day of 1398, some 100,000 Hindus strangled in sight of the walls of Delhi which had rejected surrender. In 1402, he dealt a mortal blow to Arab civilization by killing 90,000 inhabitants of Baghdad.

2.5 Modern Period

A sovereign's right to war (*ius ad bellum*) dominated the period of sixteenth to nineteenth century in which Europe came to dominate the world. What happened within a war was more or less up to the sovereign. Laws of warfare or the definition of crimes of war (*ius in bello*) had to wait for the turn of the nine-

teenth/twentieth century. In Europe as well as overseas, the results were genocidal. To give only two examples, Tenochtitlan, the Aztec capital in the valley of Mexico with its 100,000 inhabitants, was totally annihilated by Cortes' Spaniards in 1521. All 30,000 inhabitants of German Magdeburg, the richest city of Protestantism, were slaughtered on May 10, 1631 by Catholic troops under General Tilly in the Thirty Years' War.

The European Population Explosion—beginning at the end of the fifteenth century, and still not fully understood—bestowed this small continent with 25 percent of world population by 1900. During the same period, some 60 million young Europeans, with the superior military technology of their ownership-based economies but no attractive positions in an overcrowded continent, conquered their settlement space in the Americas, Australia, Africa, and Northern Asia. In the wake of this 'emigration,' a population of 55 to 85 million native Americans estimated for 1492 (Spanish conquest) was reduced by 85 to 95 percent around 1650. Between 250,000 and 500,000 native Australians estimated for 1788 (British conquest) were reduced to 60,000 by 1921. All means of killing were employed from outright genocide to infections—including intentional ones. Africa, between 1500 and 1870, lost up to 20 million inhabitants into American slavery with 2 million dying on transport. The slave trade within Africa may have cost, for the same period, the lives of 4 million. On the slave routes to—mostly Islamic—Asia another 11 million may have perished in these gigantic democides (Rummel 1996, p. 48).

Though not an invention of modern times, politicide became one of the most heinous activities of this period. It does not necessarily include the killing of the families of the victims. However, in a so-called 'Vespers' in which politicide is turned against a foreign elite, it usually grows into a full blown genocide. It took its name from the Easter massacre in Palermo on March 29, 1282, at the hour of evening prayer (Vespers) when the French in control of the Kingdom of Sicily were killed with their families ('Sicilia Vespers'). It had been preceded, in 1268, by the butchering of some 5000 members of the Hohenstaufen elite of Sicily by the hands of the French conquerors. The best remembered example of politicide was the annihilation, after eight inconclusive civil wars, of the Protestant leadership of France (ca. 100,000 victims), starting on Saint Bartholomew's Day (August 24, 1572) when the Huguenots—easily recognizable by their black clothing—were guests at the royal marriage of Henri of Navarra and Marguerite of Valois. The politicide, in February 1579, against Novgorod, Russia's richest city, by Ivan IV (the Terrible) was peculiar insofar as the Tsar had put together special killing units—the 'Oprichniki'—because the army was not trusted to act ruthlessly enough. In the 'Ulster, Massacre' (October 23, 1641), as the last 'Vespers' of

Table 1

Rough estimates of numbers of victims by genocides, politicides and ideological mass murder of a wide variety of regimes usually lumped together under the term Communism (Rummel 1996).

Soviet Union, 1917–87	40–60,000,000
Red China plus Maoists before 1949	40–60,000,000
Khmer Rouge in Cambodia, 1975–79	2,000,000
North Korea, 1945 onwards	1,700,000
Yugoslavia of Tito, 1941–87	1,100,000
North Vietnam, 1945–87	1,700,000
Poland (deportations of Germans), 1945ff.	1,400,000
Czechoslovakia (deportations of Germans), 1945ff.	240,000
Ethiopia, 1974–91	4,000,000
Albania, 1944–90	100,000
Communist Germany 1945–52	96,000

Western Europe, Irish rebels killed most of the Protestant British settlers and administrators on their island. The Creoles of Haiti delivered their French masters a ‘Vespers’ in 1791/1805 as did, in 1857/58, albeit with no lasting success, the sepoy to the British masters of India.

2.6 Twentieth Century

The Hague Conventions of 1899 and 1907 with *The Regulations Respecting the Law and Customs of War on Land* prohibited, in Articles 22–8, the murder, ill-treatment, or deportation of enemy civilians and prisoners of war. The use of poison and special ammunitions was banned. However, a nation’s harm to its own civilians was not taken into consideration. This had to wait for the ‘Istanbul Trials,’ installed in January 1919 to inflict punishment on those responsible for the Armenian massacres. On April 10, 1919, Mehmet Kemal Bey, procurator of the province Bogazliyan, became the first person executed for genocide, then called crime against humanity. In the Nuremberg Trials of Nazi-Germany’s leadership (1945/46) as well as in the Tokyo Trials of Imperial Japan’s leaders (1946–48), ‘International Military Tribunals’ further developed the legal tools to punish perpetrators of crimes against humanity. Special United Nations courts explicitly devoted to the crime of genocide started, in 1993, to prosecute the perpetrators in Yugoslavia (‘ethnic cleansings,’ since 1991) and, a year later, in Rwanda (genocide of Tutsis in spring 1994). The statute for a permanent ‘International Criminal Court’ was passed in Rome on July 17, 1998.

The entire twentieth century is on record for close to 180 million victims of democide according to Rummel’s statistics. The extermination of the Ottoman Armenians (1894–96, 1909, 1915/16, 1919, 1923)

combined strategic, racial, and ideological intentions (Dadrian 1995). A shrinking empire was to be consolidated by a homogenous pan-Turkic population within an undivided settlement space under Islam as the only religion. That’s why not only more than 1 million Armenians suffered genocide but also other Christian minorities like Maronites (1860), Assyro-Chaldaeans (1915), and Greeks (1915–23) with a combined death toll of some 440,000.

Since 1917, single party totalitarian regimes with agendas may have killed up to 110 million people (Rummel 1996, Courtois 1997). After World War II, ‘one-party communist states are 4.5 times more likely to have used genocide than are authoritarian states’ (Fein 1933b, p. 79)

The figures given in Table 1 are all estimates. Totalitarian regimes are not only known for most of the killings of the twentieth century, but also present the most difficult problems for research because archives were destroyed and many deeds never recorded. Thus, totalitarian regimes have to live with possibly exaggerated figures of their atrocities.

Extreme anti-capitalism slowed economic development though superior prosperity was promised. The shortcomings were frequently blamed on sabotage and/or party comrades still infested with the reactionary spirit of ownership. This view was used to justify massive party purges like the ‘Great Terror’ in the Soviet Union (1934, 1936–38) with more than 7 million or the ‘Cultural Revolution’ in China (1964–75) with nearly 8 million dead.

Annihilation through forced labor in camps was initiated by Trotzki on June 26, 1918. By 1922, 23 Soviet camps were at work, forming the nucleus of Stalin’s Gulag fully emerging in 1928, and eventually running some 8000 camps. Working people to death became, in the long run, the most devastating killing tool of history. It allowed the elimination of opponents by simultaneously using them for the creation of big projects—like canals, railroads, subways, etc.—to prove by ‘miracles’ the promised productive superiority of communism that otherwise was wanting.

The traditional siege tool of man-made famines had to wait for the twentieth century to be welded into the most efficient fast-killing techniques ever. To crush national ambitions of the Ukraine, for example, a famine was turned into the mass death of some 7 million in the single winter (4 months) of 1932/33. Ethiopia’s Derg managed to kill up to 4 million peasants between 1982 and 1986 by the same means, often intentionally aggravating natural disasters.

The mega-killings by left totalitarian regimes came as a combination of politicides (elimination of like minded rivals for power), genocides (elimination of minority nations, mostly in the Soviet Union and the Peoples Republic of China), and ideological genocides (foremost the elimination of proprietors or property-infested citizens). The latter category probably became the largest victim group in history with some 50

million dead (55 percent in China, 40 percent in the Soviet Union, 5 percent in the other communist regimes).

Of all twentieth-century totalitarian regimes, Nazi Germany was the most genocidal. Following September 1, 1939, deformed newborn and mentally-handicapped Germans—as well as some German soldiers severely wounded in the military campaign against Poland—were killed by injections or in gas chambers. Close to 130,000 handicapped eventually ended in this so-called euthanasia operation. Later exterminations struck Gypsies, stigmatized as socially inferior, as well as non-reproductive homosexuals etc. A bigger target, however (outlined in the ‘*Generalplan Ost*’ (Masterplan East)) were 100 million Slavs (Czechs, Poles, White-Russians, Ukrainians, and Russians) living between Germany’s Eastern border and the Ural Mountains, a territory marked to become Germany’s ‘*Lebensraum*.’ Of the Polish elite, 75,000 members, most of them holders of academic degrees, were killed in autumn 1939. The second Eastern campaign, against the Soviet Union (June 22, 1941), was aimed at the immediate killing of 30 million Slavs. Another 30 million were destined to be worked to death to lay the infrastructure for German settlements. The remaining 40 million were to be driven into Siberia with a calculated death toll of another 10 million. With 13 million Slavic civilians and prisoners of war killed by 1945 (Kumanev 1990, Vitvitsky 1990), Nazi Germany had fallen short of its 70 million goal but still had committed the largest twentieth-century genocide explicitly directed against a particular ethnic group. Nazi Germany’s Eastern campaigns, thus, were not only massive wars but also militarily enforced genocides (Hillgruber 1993).

In connection with the Eastern wars, 5 to 6 million Jews were killed. Though a ‘theory of the Holocaust is lacking’ (Herbert 1998, p. 66), Hitler’s practice of ‘strengthening’ Germany by killing its handicapped and of gaining settlement space through genocide of its Slavic inhabitants put him inevitably against the Torah. To him the sanctity of life was a Jewish ‘invention,’ a weakening ideology that could be cleansed from the German sphere of influence by exterminating its ‘carriers.’ The Holocaust, in this perspective, was a ‘genocide for the purpose of reinstalling the right to genocide’ (Heinstohn 2000, p. 424).

Since 1944/45, some 100 acts, fulfilling the definition of the UN Genocide Convention have taken place. In the two decades from 1980 to 2000, some 80 distinct ethnic and religious groups—mostly in Africa, Asia, and Latin America—were victimized with 12 of them going through full blown genocide: Bosnian Muslims, Kurds, Tibetans, Dinka (Sudan), Nuba (Sudan), Shilluk (Sudan), Isaaq (Somalia), Tutsi (Rwanda), Mayans (Guatemala), Albanians (Serbian Kosovo), and Timorese of Indonesia (Harff and Gur 1996, updated by the author).

2.7 The Future

Ecologically and ideologically motivated genocides most probably will have a future in the twenty-first century. Politicides may also occur wherever solidly established democratic structures are missing. Democracies usually do not go to war against each other. The same cannot be said for democide like nuclear and carpet bombing against totalitarian powers with, e.g., a death toll of 1.5 million in Germany (600,000) and Japan (900,000) during World War II.

The prevention of genocide by spreading democracy remains the preeminent goal for the future. Meanwhile, some experience with intervention has been made, in 1999, in Kosovo and Timor. To preempt the cruelties unavoidable in an intervention by force, genocide early-warning stations are now seriously considered. They may be in place within a few years.

G. Heinsohn

Genotype and Phenotype

The fundamental distinction between genotype and phenotype was first introduced into biology by Wilhelm Johannsen in 1911 to make explicit a distinction that was implicit in Mendel's explanation of heredity, and which marked it off from previous theories of inheritance. Mendel found that when he crossed two pure-breeding varieties of garden pea, the first generation of hybrid offspring were indistinguishable from one of the two parental strains, but if these hybrids were crossed with each other, both of the original types appeared in the offspring of these hybrids. So, for example, a pure bred red-flowered crossed with a pure bred white-flowered form produced all red-flowered plants, but these, when

interbred with each other produced both red- and white-flowered plants.

In order to explain this extraordinary result, Mendel postulated the existence of internal, unseen 'factors' contributed by each parent to the offspring, factors that were causal determinants of the outward appearance of the plants, but whose nature was unaffected by their passage from one generation to the next. So, pure bred white-flowered plants had two white 'factors' one contributed by the pollen and one by the egg of their male and female parents, while pure bred red-flowered plants had received two red 'factors' from their two parents. The hybrids of red-flowered and white flowered forms would then contain one red and one white 'factor,' yet these plants were indistinguishable in appearance from a parent that had two red 'factors.' There was then a fundamental distinction between the state of the internal causal 'factors' and the outward state of the plant that carried them. Moreover, to explain the reappearance in the next generation of some white-flowered plants, Mendel had to suppose that the temporary coexistence of red and white 'factors' in the hybrids had no effect on their nature, but that they could be passed on uncontaminated to the offspring of the hybrids. An offspring of the hybrids that happened to contain two white 'factors' was then white like its white grandparent.

This scheme of explanation makes a radical separation between the internal factors that behave according to one set of physical relations in their passage between generations, the laws of *heredity*, and the external appearance of the organism that results from a different set of physiological relations which determine the consequences to the organism of carrying those factors, the laws of *development*. This distinction between the phenomenon of heredity and the phenomenon of development which we usually associate with August Weissman's separation of the germplasm from the somatoplasm had already been made by Mendel twenty years earlier. Earlier theories of heredity had not made such a separation of inner factors from outward manifestation and had been posed as the problem of the inheritance of the organism's characters themselves. It was Mendel's realization that characters are not inherited, they develop. In Johannsen's terminology the description of an organism's internal factors that were passed on to it in the gametes from its parents is a specification of the organism's *genotype*, while the description of the total physical and behavioral state of the organism is a specification of its *phenotype*.

1. Description of Genotypes and Phenotypes

As a result of the discoveries in molecular and cellular biology since Johannsen's time genotypic and phenotypic descriptions have become more concrete, more detailed and greatly amplified in their scope. Originally genotypes had no independent physical descriptors

but were distinguished from each other entirely on the basis of the external phenotypic manifestations and the patterns of similarity in phenotypes of related individuals. 'Genes' were simply abstract placeholders of unknown physical composition, inferred entities that could be characterized only by their phenotypic effects.

The modern identification of DNA as the physical material that behaves in heredity in the manner inferred for Mendel's mysterious 'factors' has allowed a precise physical description of the genotype of an organism. It is the complete spatially-ordered sequence of the four alternative nucleotide bases, adenine, cytosine, guanine and thymine contained in the DNA of the organism's cells. In its most complete form this genotypic description includes not only the DNA in the nucleus of the cell but in certain cellular organelles such as mitochondria or chloroplasts that carry the DNA that is related to their physiological function and that is passed across generational lines. Phenotypic description has also been greatly amplified beyond the external characteristics of individuals. It now includes the gross structure of the various cells of the organism, the physico-chemical description of the various molecules within cells, including their shape and intra-cellular localization, and the network of biochemical reactions in which these molecules participate.

The concepts of phenotype and genotype require a distinction between *types* and *tokens*. Phenotype and genotype are, as the words indicate, types, sets of which individual organisms are members, sets delineated by the complete descriptors of those organisms. Any individual member of these type sets is a token of the type. In addition it is necessary to distinguish the descriptors of organisms from the physical object or behavior that is being described. The concepts phenotype and genotype refer to the descriptors. The physical objects that are being described are the *phenome* and *genome* of an organism, the actual physical material or behavior of some particular individual and its actual DNA molecules. If we take the definitions literally, then no two organisms belong to the same phenotype because there is always some physical difference in morphology, physiology and behavior between any two organisms, even between identical twins, cloned individuals, or cells that result from asexual reproduction. Moreover, except for the results of twinning, cloning or vegetative reproduction, no two individuals belong to the same genotype, as the process of mutation guarantees some variation in their DNA between any two individuals.

The rate of mutation per nucleotide per cell division is of the order of one in a billion, so for mammals, with over a billion nucleotides of DNA making up their genes, even identical twins are likely to have some small difference in total genotype. There is, in addition, an ambiguity in the assignment of an individual to a genotype because mutations occur during the millions

of cell divisions that occur in development, so that all cells in the body do not have identical DNA.

In practice phenotypic and genotypic descriptions are not total but partial, referring to some aspect of the genome and phenome that are of particular interest, while ignoring the rest. The partial phenotypic and genotypic descriptions are partial in two senses. First, only some aspect of the morphology or function of the organism is characterized; say the rate of enzymatic splitting of alcohol, a phenotype, and the DNA sequences that code for the enzyme proteins involved in the reaction, a genotype. Second, a decision must be made about the collection of actual partial phenotypes and genotypes that will be regarded as indistinguishable. At the phenotypic level, given the actual variation in enzymatic rates from individual to individual and from time to time, what range of rates will be regarded as belonging to the same phenotypic class? For any phenotypic variable that is continuous, some boundaries of distinguishable phenotypic classes must be laid down in order to make a mapping between phenotype and genotype because genotypes, by their nature, are discrete classes.

The problem of aggregation exists at the genotypic level as well. The relation of DNA differences to differences in the amino acid sequence of a protein is not one-to-one. Because the DNA triplet code is redundant, substitutions of nucleotides in the third position of the triplet often do not change the amino acid that is specified, so for some purposes many different alternative DNA sequences of a gene count as the same genotype. On the other hand, nucleotide substitutions that do not affect the amino acid sequence of a protein may affect the rate of synthesis of that protein and so may, for some questions, be counted as belonging to different genotypes.

The decision about which aspects of total phenotype and genotype are relevant in creating genotypic and phenotypic classes is a deep question of biology that is largely ignored because everything cannot be considered at once. Sometimes biologists act as if the rest of the organism really were constant, sometimes they recognize the variation but claim that it is causally irrelevant to the phenomenon of interest and sometimes they admit its causal relevance but claim that the variation can be treated as background experimental noise that can be averaged out by repeated observations on a large class of individuals. These decisions are usually made either for the sake of observational convenience without a coherent rationale or from a commitment to a reductionist view of the organism that asserts that an understanding of the whole system can be obtained by breaking it down into 'obvious' small components to be studied in isolation.

2. Relationship Between Genotype and Phenotype

It is clearly true that organisms do indeed consist of a collection of quasi-independent genotypic and pheno-

typic subsystems, within which there are strong interactions and between which there are very weak interactions. But the boundaries of these genetic and phenotypic subsystems can only be found by actual experiment and differ from function to function. The hand and eye are, as far as is known, developmentally independent systems for which different gene combinations are relevant during embryogenesis, but hand-eye coordination is essential for reaching out and picking up observed objects and so cannot be regarded as phenotypically or genotypically independent in considering this elementary behavior.

The problem for genetics and development is how the genotypic and phenotypic spaces map into each other. It is now certain that Weissman was correct in claiming that the genotype-phenotype mapping is causally asymmetrical. Genotypic differences may cause phenotypic differences during the process of development, but there is no material pathway by which changes in the phenome can result in related changes in the genome. There is no biological inheritance of acquired characters. This causal asymmetry sets the program for developmental, physiological and behavioral genetics which is to discover the mechanisms by which the reading of DNA by the cell machinery is causally efficacious in influencing the phenotypic state of the organism. This is the problem of making the forward mapping of genotype on to phenotype.

There remains, then, the problem of the backward mapping, how the causal knowledge of epigenetic processes can be used to infer the genotype, given the phenotype. Even if a knowledge of the genotype gave perfect information about the phenotype, the inverse would not be true, as discovered by Mendel. The phenomenon of dominance alone makes it impossible to distinguish between heterozygotes and homozygotes from phenotypic information at an arbitrary level. In addition, the same phenotype may appear as a result of changes at different locations in the DNA. There are, for example, more than 200 different nucleotide substitutions known in the genes coding for blood-clotting proteins, any one of which leads to hemophilia. The major difficulty of mapping between genotypes and phenotypes is, however, in the forward direction. The complete DNA sequence of an organism does not contain the information necessary to specify that organism.

3. Genotype, Phenotype, and Environment

First, the outcome of development and the ongoing functioning of an individual is the consequence of a unique interaction between the molecules contained in the fertilized egg, including the DNA, and the sequence of environments in which development occurs. Figure 1 shows the result of a cloning experiment in a plant, *Achillea*, grown at three different elevations in the

Figure 1

The growth of cloned plants of *Achillea* at three different elevations. The ordinate shows final the plant height and the abscissa the elevation. Each connected line is the pattern of growth for a different cloned genotype. Data of J. D. Clausen, D. Keck and W. W. Hiesey, 1958

Sierra Nevada. Immature plants were sampled from nature, each plant was cut into three pieces, and one piece was replanted at each of the three elevations. The figure shows the height to which the pieces grew in the different environments, each line connecting the three genotypically identical pieces in the three environments. A line, giving the phenotype of a given genotype as a function of different environments is a *norm of reaction*. The norms of reaction in this case show that there is no genotype with unconditionally better growth and, in fact, there is no way to predict the order of growth of the different genotypes in one environment from their order of growth in another environment. Thus, the phenotype is not only contingent on the environment but in an unpredictable and irregular way.

Such irregular and particularistic relations between genotype and phenotype in different environments is characteristic of norms of reaction whenever they have been measured for morphological and behavioral characteristics in experimentally accessible organisms. There are, of course, extreme exceptions; genotypes that result in the same phenotype in any environment and environments that are in no way contingent on genotypes for their effect. Eye color variation among humans is entirely a consequence of genotypic differences, uninfluenced by environment, while regional and social class differences in the phonemic structure of speech have no influence of genetic differences. Moreover, major differences between species are a consequence of genetic differences that are manifest in

all environments. There is no environment in which a gorilla could learn to write this article. Within species, however, the vast majority of phenotypic variations in morphology, physiology, and behavior are a consequence of particular contingent relations between genotype and phenotype.

4. Developmental Noise

Second, even a complete specification of the genotype and the environment is insufficient to specify the organism. All cells contain a very small number of copies of biologically active molecules, spatially segregated within the cell, so that the number of various reactions per unit time vary greatly from cell to cell and time to time. Moreover, when cells divide they do not distribute the molecules exactly evenly, except for DNA which has a special machinery for guaranteeing its equal distribution. The consequence of these small molecular numbers is that there is random variation from cell to cell in time to the next cell division, in cell size, in cell shape and in the movements of cells during development. These random events, random at the level of thermal and quantum chemical molecular states, can have considerable effect on the formation and behavior of the whole organism. (Goss and Pecoud 1998)

So-called 'bilateral symmetries' are not, in fact, symmetrical but vary between sides in an irregular way from individual to individual. The fingerprints on the left hand are not identical, although similar to, those on the right. Such *random developmental noise* is a nontrivial source of variation in phenotype. During the development of the central nervous system of a multicellular organism, superimposed on the major regular patterns of neuronal connection are random variations in the growth and connections of specific neuronal pathways, even in organisms like the roundworm *Caenorhabditis* with a very simple central nervous system. It has yet to be determined how much of the behavioral variation among individuals is a consequence of such random variation in the development of the central nervous system, variation that is inborn, but not genetic.

The environmental and chance contingency of the mapping between genotype and phenotype arises from the nature of organisms as physical objects. They are intermediate in size between particles and planets and they are internally functionally heterogeneous. As a result, unlike simple physical systems like the movement of planets around the sun, their functions are not the consequence of a few strong causal forces whose parameters govern the outcome. Organisms are the nexus of a very large number of individually weakly determining forces subject to noise at all levels. The consequence for the understanding of the physical properties of organisms, including their individual and social behavior, is that we cannot expect any simple

and universal generalizations like Newton's Laws. That is certainly true for the relation between genotype and phenotype.

Geoarchaeology

Research that uses the techniques, methods, and concepts of the earth sciences to address archaeological problems is called geoarchaeology. In the important early exposition, *Archaeology as Human Ecology: Method and Theory for a Contextual Approach* (1982), Karl Butzer described geoarchaeology as a collection of techniques for contributing substantive data critical to understanding prehistorical and historical human ecosystems (Butzer 1982, p. xi).

There are at least seven major concerns of geoarchaeology that must be integrated into research programs at the design, excavation and analytical stages and include: (a) site survey techniques that use geochemical, electromagnetic and other remote sensing procedures to locate sites or features within a known site; (b) documentation of site-formation processes and the regional context of a site; (c) using a wide array of approaches to differentiate cultural from natural (nonhuman) sediments and features, including disturbance processes by biological, pedological, and geological processes; (d) the development and correlation of intra- and extrasite temporal contexts by relative and/or absolute dating; (e) integration of ancient landforms and biological information for the reconstruction of palaeolandscapes (after Gladfelter 1981, p. 347); (f) reconstructing palaeoenvironments by the identification of pollen, wood charcoal, leaves, and seeds; and (g) the geochemical analysis of artifacts to document interaction between social groups. Exam-

ined here are a few techniques of geoarchaeology that are geared towards: discovering archaeological sites and documenting their internal structure; surveying site formation and disturbance processes; the analysis of soils and sediments; palaeoenvironmental reconstruction and the impact of humans on the landscape; and the physical analysis of archaeological materials.

1. Site Discovery and Definition

Traditionally, locating archaeological sites was accomplished by asking local residents in conjunction with a pedestrian survey; that is, simply walking over the landscape and looking for artifacts and food remains or larger features such as stone house foundations, terraces, or earthworks. In the 1960s with the advent of public archaeology programs—also known as ‘contract’ archaeology or heritage management studies formulated in response to development projects—archaeological surveys became more systematic, utilizing sophisticated sampling procedures, predictive modeling, and techniques of remote sensing, or archaeological prospecting as it is called in Europe.

1.1 Remote Sensing or Archaeological Prospecting

Archaeological prospecting ‘is considered as an exercise in the deliberate planned measurement and evaluation of physical properties which lead to the detection and mapping of archaeological sites’ (Scollar et al. 1990, p. 27). Since all surface indications of many archaeological sites have been obliterated by modern urban encroachment or been buried under soils, excavation has been the technique of choice for locating subsurface cultural deposits. Remote sensing techniques are nondestructive and include aerial photography, and resistivity, magnetic, electromagnetic, and thermal prospecting (see Scollar et al. 1990 for a detailed explanation of these techniques).

1.2 Aerial Photography

The oldest form of remote sensing, aerial photography is used in archaeology primarily for discovering field monuments, whether earthen or stone constructions. A huge corpus of aerial photographs exist some of which were taken during various wars for reconnaissance purposes, others for urban planning, to record changing shorelines, and to document vegetation patterns. However, aerial photos made exclusively for archaeological site discovery are the most useful since they are taken at the appropriate scale, angle, and time of day for enhancing surface features. Prehistoric agricultural field systems in areas such as Mexico and the Pacific Islands, consist of low terraces and earthen

mounds and embankments which are readily mapped from aerial photographs, saving countless hours of field survey and mapping.

1.3 Other Techniques of Remote Sensing

Once archaeological sites are located, identifying internal structures (intrasite variability) can be accomplished with other techniques of remote sensing including resistivity prospecting, where subsurface anomalies (such as burial pits, compacted ancient floors, or buried house foundations) are mapped by identifying the variation in an electric charge as it passes through the ground (Scollar et al. 1990, pp. 307–421). Magnetic prospecting can locate the shape, size and depth of subsurface anomalies that can then be mapped. Thermal prospecting uses variations in surface temperatures as an indication of subsurface (often cultural) structures.

1.4 Coring Archaeological Sites

Identifying subsurface archaeological site boundaries, internal features, and differential distributions of artifacts and faunal material can be accomplished by coring (Stein 1986), especially in conjunction with the analysis of sediment chemistry. Small cores or bucket augers (about 10cm in diameter) are used to collect sediment samples for the analysis of cultural content and to differentiate cultural from noncultural layers. Since organic matter, carbonates (e.g., marine shells), and phosphates (deposited in the form of urine, excrement and organic refuse) can increase relative to the intensity of human occupation, these residues are good indicators of past site use (Sjöberg 1976) and their distribution is used to identify subsurface cultural deposits with a minimum of site disturbance.

2. Site Formation Processes

The archaeological record is not static, but changes in response to a number of processes—both cultural and environmental (or noncultural). Once deposited in, or on, the surface of an archaeological site, cultural material (artifacts and food remains) and noncultural matter, such as pollen grains and terrestrial sediments, can shift their position or, in some cases, be removed completely. Since archaeological interpretations gain their strength from identifying and analyzing the vertical and horizontal distributions of material within and between sites, it is vital to understand how the positions of these materials may have changed since they were originally deposited—this is the challenge of site formation research defined as the processes, both natural and cultural, that build, disturb, redeposit, and destroy archaeological sites (Schiffer 1987).

2.1 Nonhuman Disturbance Processes

Since the soils and sediments that make up an archaeological site are part of a dynamic open system, archaeological sites are best viewed in a regional context. It is at this level that soil development is best understood because it is influenced by such large-scale processes as precipitation and temperature and erosional agents—including wind and surface water (e.g., rivers, marine shore waves, and sheet wash). Wood and Johnson (1978) have outlined a number of disturbance processes that affect archaeological deposits. Some of the more important processes include faunalurbation, or the mixing of deposits by animals, especially the burrowing kind (rodents, crabs, insects, earthworms, and birds). Digging burrows not only brings buried material to the surface, but open holes are traps for surface material to accumulate beneath the ground. The mixing of deposits by plants that occurs during root growth and decay is known as floralurbation. Uprooted trees can also bring material to the surface, often from a meter or more below the ground.

Discrete layers within archaeological sites can be homogenized by alternating freezing and thawing episodes which sort sediments by size. This is a problem with sites in the higher latitudes that consist of clay soils that swell and contract in response to precipitation and temperature. Gravity can cause mixing and movement of soil and rock debris downslope, as well as settling or subsidence of relatively large areas. Aeroturbation occurs when wind winnows fine sediments from deposits leaving a 'pavement' of artifacts. This is a significant problem in areas with active sand dune systems. Despite the range of disturbance processes that operate on a regional and site-specific basis, most cultural deposits maintain some order of integrity and, after the site formation processes are understood, valid interpretations are possible.

2.2 Human Disturbance Processes

In addition to natural or environmental site formation processes, people intentionally contribute to the formation of archaeological deposits by bringing to a site raw materials such as fine-grained rock to fashion into tools, finished artifacts of bone, shell, wood and stone, cooking fuel, building materials, and food. Many of these items are discarded on site as waste. Even sand grains adhering to feet, after countless thousands of trips to a site, can add significantly to the cultural matrix. Digging pits for earth ovens and trash disposal, small holes excavated for wall or fence posts, or trenches dug for building foundations can displace subsurface cultural deposits during later periods of occupation. Accurate interpretations of the archaeological record can only be made after understand-

ing both noncultural and cultural site formation processes.

3. Definition of Soils and Sediments

Soils and sediments figure prominently in discussions of site formation processes, so it is essential to know how these terms differ. Soils develop *in situ* at or near the ground surface through the various processes of weathering in conjunction with plant growth and decay, other biological elements, time, climate (temperature and moisture), and local topography. Sediments are particulate matter that has been transported from one location to another by one or more processes such as wind, water, or people.

3.1 Principles of Sedimentation

All particles, including artifacts and food remains, found in archaeological deposits can be viewed as sediments (Stein 1987, p. 339) and, because of this, the four principles of sedimentation (Shackley 1975) apply equally to natural and cultural sediments. First, the source of sediments found at an archaeological site can be unconsolidated particles of bedrock as well as humanly-transported stone tools, shells, bones or building stones, to name but a few examples. Second, the transport history of sediments is usually determined by textural and compositional analysis in that biological agents (people, plants, and animals), wind, and water move sediments according to certain physical constraints. For example, wind normally transports evenly-sorted sand-sized sediments, while water—in the form of rivers, sea waves, and glaciers—can move anything from clay particles suspended in its volume to huge boulders that are pushed under enormous power. Third, the environment of deposition, in this example, is the archaeological site, but offsite examples can include sedimentary basins, aggrading shorelines, sand dunes, and till and erratic boulders deposited from melting glaciers. And last, postdepositional alterations, discussed above, are caused by people, other animals, plants, and geologic erosional processes.

3.2 Sampling Soils and Sediments

Soils and sediment samples are usually taken from a profile in an erosional exposure or from the sidewall of an excavation unit or trench. Beginning from the bottom up, samples are taken from separate stratigraphic layers or in a continuous column. The sample volume varies according to the kinds of analyses undertaken and the size of sediments. For example, small samples of about 20 grams are needed to analyze the texture of clays and silts, while several kilograms are necessary for analyzing cultural content or, if

sediments are gravel, to cobble size. The key is to collect a representative sample of the sediment.

3.3 Analytical Techniques

Among other things, particle size analysis permits the detection of the agent of deposition (e.g., wind, river, sea) and the environment of deposition such as beach, flood plain, and dune (Shackley 1975, p. 87). As mentioned above, well-sorted sand is often wind-deposited and certain agents of deposition have particular sediment signatures. Mineral identification of individual grains can suggest a likely source of the sediments, especially if the regional geology is well known. Grain shape (roundness and flatness) can indicate the transport agent, depositional environment, and history. Grains can be, for example, platy or flat; angular, or granular. Roundness refers to the general grain surface curvature and is more a function of mineral composition (certain minerals are harder or softer than others and respond to friction differently), depositional history, and final depositional environment (Shackley 1975, p. 46). Grain surface textures, examined under high-power magnification, can be: unworn and angular, suggesting a fresh or minimally-transported history; rounded and glossy, the result of transport by running water; or matt-surfaced grains, the result of wind transport. A good review of the analytical methods of sediment analysis can be found in Shackley (1975).

4. Palaeoenvironmental Reconstruction and Human Impact

The relationship of people to the landscape (and here I use 'landscape' to mean the physical and biotic environment) is of worldwide interest, not only to archaeologists, but to biologists and politicians alike, to name just a few. How humans have historically managed their resources—whether successfully or with tragic consequences—is of utmost importance to contemporary society—especially as the world becomes increasingly one 'global village.' Archaeology is better positioned than any other discipline to understand the historical details of human-landscape relationships over tens of thousands of years and across an enormously varied set of environmental conditions that posed opportunities and problems for our ancestors.

To document and understand the variation in human-landscape interactions, the analysis of soils and sediments is especially useful when used in conjunction with the differing distribution of floral remains (see Hastorf and Popper 1988 for a review of analytical methods). The analysis of faunal material is also of importance here and is addressed in *Zooarchaeology*. Whether of carbonized wood fragments, pollen, opal phytoliths (minute silica bodies formed in

the cells of living plants that can be diagnostic of certain species), or leaves, plant remains are often indicative of vegetation on or near an archaeological site and, in the case of wind-dispersed pollen, can reveal regional floral patterns. Recovered from dated stratigraphic contexts, vegetation history can be charted over time—before, during, and after human settlement. In essence, archaeological sites hold an historical record of local and regional palaeo-environmental change, often in response to human modifications to the landscape.

5. Physical Analysis of Archaeological Materials

A growing area of interest in geoarchaeology is the elemental analysis of artifacts such as ceramics and stone tools so links can be drawn from the geological source or, in rare occasions, the site of production, to the place of deposition or archaeological site. The emphasis is on establishing lines of interaction or communication between or within social groups. The distribution of exotic artifacts across space and through time (that is, artifacts recovered from dated contexts or layers) is thought to reflect changing aspects of social organization—a topic of great interest to archaeologists.

5.1 Physical Analysis of Ceramics and Stone Tools

Ceramics are manufactured from clay, water, and nonplastic inclusions (temper). Pots were often decorated with an exterior clay slip, incised or stamped with various intricate patterns. Of interest to interaction or 'sourcing' studies is the elemental composition of the clay and temper. If the latter consists of crushed rock or terrigenous (land-based) sands, then chemical analysis of the temper may isolate its source. Stone tools, manufactured from obsidian, basalt, chert, or other fine-grained rocks, also can be geochemically analyzed to determine the artifact's geological source. Economically-important rock sources were generally well known in prehistory and had a limited distribution, thus facilitating sourcing studies.

There are many useful techniques for determining the elemental composition of ceramics and stone tools. (See Parkes 1986 for a description of various techniques.) These include, for example, x-ray fluorescence (XRF) and lead isotope analysis at the newer and more sophisticated end of the techniques (Weisler 1997), to thin-section petrography which has been used in geologic investigations for over a century.

5.2 X-ray Fluorescence Analysis

Simply stated, XRF analysis consists of bombarding a specimen with primary x-rays. The sample emits fluorescent x-rays that are indicative of the kind and

frequency of its elemental composition (oxides, such as iron or silica, are measured in weight percent, while elements are counted in parts-per-million or ppm). Dedicated computers are used for data analysis, while statistical clustering programs can aid in grouping artifacts with possible sources. Once sources are adequately characterized in terms of their geochemical variability, then unknowns or artifacts can be more confidently assigned to a specific source.

5.3 Thin-section Petrography

Thin-section petrography is used extensively today in ceramic sourcing studies when the mineral identification of temper is desired. Samples measuring up to 25 mm by 40 mm are cut from ceramic sherds and ground thin enough to pass light through them. Placed under magnification, minerals (such as olivine and feldspar) are identified and texture measured. Within a geologically well-known region, temper composition can be assigned to a particular river drainage (in the example of placer sands), a marine beach, or a larger region such as a group of hills or a mountain range.

Geoarchaeology uses the techniques, methods, and concepts of the physical sciences to address archaeological questions. In this short article, I have only touched on a few of the techniques and methods applied to research domains that are of worldwide interest. This subdiscipline of archaeology is continually expanding the range of techniques and their applications to innovative questions. The successful melding of interdisciplinary research typical of geoarchaeological pursuits continues to have a bright future.

Geodemographics

1. Introduction

A geodemographic database is a collection of spatially referenced data about individuals or groups, and geodemographics describes a rapidly growing segment of the marketing industry that collects massive amounts of data on consumer characteristics and behavior, constructs statistical models of consumer identity, and maps and analyzes distributions of market-related activity. It is used primarily to identify, or ‘target,’ potential customers, or ‘prospects,’ and in business applications such as retail site evaluation, trade area analysis, market share analysis, sales territory management and micromarketing. It can also, however, be used by nonprofit institutions to enhance fundraising, by governments for administrative purposes, such as school districting, and by political campaigns to identify voters susceptible to customized political messages. The sophisticated techniques of geodemographics depend on two simple assumptions: that ‘you are what you buy’ and ‘you are where you live.’

2. The Development of Geodemographics

The collection of customer information and target marketing have been around since the late nineteenth century, and customer segmentation and micromarketing were introduced in the 1950s. It was not until the 1970s, however, that theoretical, technological and institutional innovations made possible the maintenance of electronic databases on consumer behavior, the statistical analysis of consumer identity, and precise geographical location of consumers upon which geodemographics depends. Its invention is attributed to Jonathan Robbin, a sociologist who, in the early 1970s, saw entrepreneurial potential in the

recently introduced Zone Improvement Plan (ZIP) of the US Postal Service. First, he aggregated demographic data for the 240,000 block groups of the Bureau of the Census into the 36,000 postal delivery areas. Then he performed multivariate analyses of this data to produce 40 lifestyle categories describing consumer potential—hence he called the system PRIZM (Potential Rating Index for ZIP Markets). This innovation allowed marketers to target potential customers through heavily discounted bulk direct mail campaigns.

Today, publicly produced census data are still a vital component of geodemographics, and vendors still adopt clever acronyms like ACORN (A Classification of Residential Neighborhoods developed by CACI Marketing Systems, UK) and PSYTE (from CompuSearch, Canada) to describe proprietary segmentation systems. However, the US Bureau of the Census itself provides ZIP level data as a result of lobbying and financial assistance from the geodemographic industry, and its computerized spatial database called TIGER (for Topologically Integrated Geographic Encoding and Referencing) is the basis of the geography of most geodemographic systems. In Canada and the UK, there is also close cooperation between industry and government—in the UK, for example, Pinpoint Ltd. and the General Post Office have digitized every address that receives mail. In these countries, geodemographic databases incorporate diverse sources of data from official records, reported consumer behavior, lifestyle preferences and even psychological profiling ('psychographics'). Elsewhere, the industry has been slower to develop, largely owing to limitations in quantity and quality of public and private data, but it is truly international, with business marketing publications and software solutions available for many individual countries and most regions of the world. A cross-cultural clustering of consumers is already available for Europe.

While a host of specialist corporations and consultants offer individual services, a series of licensing agreements, acquisitions and mergers have resulted in national, and in some cases, transnational 'information conglomerates' (Curry 1993, p. 27) that purvey complex, integrated geodemographic systems. Such systems typically include three principal components: electronic databases composed of public and private, individual and aggregate information; segmentation routines that identify consumer types through cluster analyses of behavioral and psychographic data; and a geographic information system that provides the means for spatial analysis and mapping.

3. *Electronic Consumer Databases*

The geodemographics industry accumulates data from numerous sources to create its Marketing Customer Information Files: purchasing proprietary informa-

tion on customers from corporations, such as point of purchase surveys, warranty registration questionnaires, customer-preference cards and satisfaction surveys, and from government agencies; purchasing customized data from syndicated national consumer panel surveys, media surveys, opinion polls and credit bureaus; obtaining public transaction records of institutions such as banks, insurance companies and health services, which are kept in compliance with government regulations; and 'mining' public records on births, deaths, marriages, property transactions, crime, and mailing address changes. The scale is enormous, encompassing the vast majority of all of US households, and what were once databases are now 'data warehouses' with more than one trillion entries. Specialist firms and software programs provide means to sift and sort data to eliminate redundancies and match entries, particularly in terms of street addresses, and consumer information is now updated instantly and can be downloaded on line from most of the geodemographic vendors.

Such data are often collected and sold with only the implicit consent of consumers, who are unaware of the further uses to which data gathered in one transactional context might later be put. As a result of informational campaigns and legal actions, consumers are becoming increasingly wary of invasions of privacy and suspicious of 'consumer espionage' (Larson 1992, p. 5), and the industry has adopted voluntary controls. Even individuals who explicitly opt out when presented the option, however, are likely represented in official databases, and their consumer 'profile' can be inferred accordingly. Privacy is a notoriously tricky issue, and surveillance may be a necessary quid pro quo of participation in capitalist society (Robbin, cited in Larson 1992, p. 55). Perhaps public concern should be not so much about specific instruments of surveillance technology nor their applications to particular individuals, but the manner in which social subjects are constituted and represented in the discourses of social and spatial sciences (Foucault 1979). Thus, geodemographics is replete with 'strategic' metaphors of military operations, sexual conquest, and psychological manipulation, based upon reduction of identity and social difference to consumer profiles and residential location through its segmentation schemes and 'market mapping' (Goss 1994).

4. *Consumer Profiling*

Contemporary segmentation schemes go well beyond the abstract demographic variables of the census to offer 'Character: not just characteristics,' and this system, called Focus, for example, offers 'multidimensional portraits of real people,' revealing 'lifestyle and mindset' and promising marketers will 'see how customers view themselves,' and 'meet their customers on a first name basis' (National Demographics and Lifestyles 1993, p. 2). Segmentation schemes draw

upon information on brand preferences, media habits, credit rating, lifestyle and values, to divide neighborhoods in the US, typically into 30–40 categories such as ‘Pools and Patios,’ ‘Shotguns and Pickups,’ ‘Fur and Station Wagons,’ and ‘Hard Scrabble’ (PRIZM) or ‘Cautious Young Couples,’ ‘Sustaining Ethnic Families,’ and ‘Young Accumulators’ (MicroVision). Marketers ‘get acquainted’ with these potential customers through visual scenarios representing consumers engaged in a typical activities in front of their home and/or detailed imaginary vignettes describing their typical names and everyday lives—particularly their consumption practices. Although analysts argue their schemes imply no social judgments, the rankings, weightings and premiums charged for names of affluent consumers, and description of segments give them away: to the marketing industry, social identity and value is lifestyle, and ‘you are what you buy’ (Piirto 1991, p. 23).

5. *Geographic Information Systems*

The ‘geo’ of geodemographics is essential for several reasons: first, because the map transforms complex data into simple ‘actionable’ visual images—red typically represents a ‘hot’ market—ideal for busy executive officers; second, because addresses of households provide a convenient way to match database records; third, because addresses are means by which consumers are reached with marketing messages or products, whether delivered by mail, conventional media or retail outlet; fourth, because a range of analyses and transformations can be applied to spatial data to create ‘custom’ geographies such as retail trade areas, sales territories and media footprints; and finally because marketers infer characteristics of individual consumers from aggregate data and substitute missing values in their databases based on residential location. This last function is important because in some forms of data (census and vehicle licensing, for example) individual records are not available for confidentiality reasons, and where records are missing, the costs of collecting such data are generally prohibitive.

The importance of the geographical basis of marketing information is attested by the lengths to which the industry goes to infer residential location even for users of the World Wide Web, constructing user profiles from ‘search engine queries; online shopping patterns; requests for localized information, such as movies, concerts, lectures and stores; and interested in regional websites such as *yourcity.com*’ (Melville 1999, p. 34). Inference from ‘neighboring’ records is based on the assumption, according to Jonathan Robbin, that ‘humans group themselves into natural areas ... They create or choose established neighborhoods that conform to their life-style of the moment’ (cited in Burnham 1983, p. 92). Not surprisingly, Claritas’ promotional material similarly claims that it

is ‘based on the fundamental sociological truism that “birds of a feather flock together”’ (Claritas/National Planning Data Corporation (NPDC) 1992). The geographical basis of consumer profiling is also a result of the so-called neighborhood effect, such that, for example, ‘when one moves into a suburban neighborhood in which everyone has a gas barbecue there is a strong motivation to buy one’ (Lea and Heumann 1999, p. 26). There is, of course, an undeniable spatiality to everyday life, but to infer individual characteristics from those of an area is to fall for the ecological fallacy (to assume that individual characteristics can be inferred from group characteristics, which is only true if the population is homogeneous) and the question is how much such an effect is natural or intrinsically motivated, and how much it is the product of the marketing enterprise itself.

6. *Conclusion*

Geodemographics is particularly hype-ridden and the success of its applications limited, for example, to very modest ‘lifts’ in customer response by 5–10 percent in direct mail campaigns, even if this represents considerable savings in a large-scale operation. It is, nevertheless, the fastest growing segment of the information industry, presumably because of its promise of intimate and actionable knowledge about consumers. Geodemographics first reduces the subjectivity of individuals to objective and quantifiable characteristics, then reconstructs composite ‘soap opera’ identities (Goss 1995, p. 187), perhaps more consistent with marketers prejudices than social reality—hence one geodemographic system promises that ‘as you get to know [our cohorts], you’ll discover these are all people you know: your friends, neighbors, relatives, and—most importantly—your customers’ (National Demographics and Lifestyles 1993, p. 2). There is a second, more sinister, self-fulfilling promise, however, in that the definition and targeting of consumers based on residential location may effect redlining of consumption, such that marketing campaigns and retail services are provided only to addresses—with known names, inferred names, or merely ‘Current Resident’—with the ‘right’ statistical and behavioral profiles. This is not to argue that there are not cleavages in consumption based on class and residential location, but if, for example, magazine issues are differentiated in terms of advertising content for subscribers in different ZIP codes, as some already are in the US, consumption of these goods and services in turn will reproduce, and perhaps actually produce, further segmentation and segregation of society. Such is the instrumental reason behind the hype of geodemographics.

Geographic Education

Despite the commonly used name, 'geographic' education is more appropriately thought of as 'geography' education. The distinction is significant. The use of 'geographic' as a modifier might suggest a special type of educational theory or practice. For example, it could imply distinctive and particular pedagogical procedures and therefore unique methods of training for teachers of geography. While the interaction between content and pedagogy in any domain of knowledge requires discipline-specific understandings and skills, there is nothing inherent in the nature of geography that warrants a special type of education, fundamentally different in nature from that practiced in disciplines such as physics, psychology, and history. Geography education is about the teaching and learning of geography (Bednarz et al. in press).

Both geography education and geographic education must be distinguished from the geography of education. As a major sector of the modern economy, the education system employs significant numbers of people and involves substantial capital investments in terms of school buildings, university and college campuses, buses, computers, textbooks, etc. The geography of education is concerned with understanding the spatial organization of the education

system. It encompasses, for example, the relationships between patterns of tax revenues and levels of education expenditures, the diffusion of colleges and universities, the optimal design of bus routes to link students with schools, and the equity and efficiency of the provision of education to different socioeconomic and/or racial and ethnic groups. The focus is on understanding the spatial manifestation of the K-22 education system as part of the infrastructure of society.

Although an understanding of the educational infrastructure is not part of geography education as such, the state does have a major impact on the nature of geography education. In the USA, for example, the fundamental belief is that education is best controlled at a local, sub-state level. In Britain, and in France to an even greater degree, education control is more strongly vested in the national government. The ideological and structural differences between decentralized and centralized systems affect the nature of the curriculum, the training of teachers, the selection of educational materials, and the relative emphases on geography education.

1. The Nature and Process of Geography Education

Geography education is concerned with fostering an understanding of the domain of geographic knowledge (its subject matter content, skills, and perspectives). The intent is not necessarily to produce geographers as such but to provide the essential geographic knowledge and skills for an educated person.

1.1 The Nature of Geography

As the science of space and place on the earth's surface, geography seeks to describe and explain the distribution, pattern, and nature of places and regions as seen at scales ranging from the local through to the global. The understanding of places and regions is set in multiple contexts: spatial, environmental, and temporal. The character of places and regions is seen as shaped by the interrelationships between physical phenomena, such as climate, terrain, the hydrologic cycle, biosystems, etc., and human phenomena, such as demographic characteristics, economic functioning, culture, politics, urbanization, etc. The shaping process is understood in a variety of ways, in terms of:

(a) the coalescence of physical and human phenomena to create the particular character of a place (e.g., local topography, microclimates, level of urbanization, ethnic composition, etc.);

(b) the impacts of global environmental and economic changes on local places (e.g., economic restructuring in labor-intensive industries, with the loss of local employment to cheaper 'offshore' production facilities); and

(c) the interdependencies between places on local, regional, and global scales (e.g., chemicals in runoff from farms in upstream areas polluting regional water tables and watersheds).

Therefore, the focus of modern geography is on understanding the evolving character and organization of places and regions on the earth's surface. Geography's approach is distinguished by (a) a sensitivity to context, (b) an appreciation of interconnections between spatial patterns and processes, (c) an emphasis on understanding systemic interrelationships at different spatial scales, and (d) an awareness of the reciprocal relations between physical and human systems.

The skills necessary for geographic understanding are of three types. There are general problem-solving or critical thinking skills which ask and answer geographic questions by means of acquiring, organizing, and analyzing geographic information. There is the use of broadly applicable methods such as spatial analysis (quantitative and qualitative), geographic information systems (GIS), field methods, and cartography. Finally, there is the application of discipline-specific technologies such as satellite image interpretation, computer-based geographic visualization, and global positioning systems (GPS). Perspectives in geography start with the essential spatial and ecological perspectives and have been extended to include, for example, feminist, historical, economic, social and critical theoretic, and humanist perspectives.

1.2 The Process of Geography Education

The process of geography education involves the teaching and learning of geography in formal (e.g., preschool, school, college) and informal (e.g., familial, societal, workplace) contexts. Ideally, the process is lifelong in the context of an individual person—preschool, K-12, and perhaps beyond into higher education (13–16 or even 17–22) and the workplace—and continuous in the context of developments in the discipline of geography. In practice, however, there have been significant historical changes in:

(a) the ages at which geography education has been offered;

(b) its links to other components of the formal education system (e.g., geography as a standalone or as an infused subject);

(c) the role of the state vs. informal organizations in developing materials, training teachers, and setting the educational agenda; and

(d) geography's role in facilitating societal imperatives (e.g., support for exploration and imperialism, mass education, and the development of workforce skills). The field of geography itself has also changed its emphasis on and approaches to geographic education.

2. Approaching the History of Geography Education

Livingstone (1992) characterized the history of geography as a 'contested enterprise.' His strategy for 'telling geography's story' was to focus on the 'intellectual and social context within which geographical knowledge was produced' (Livingstone 1992, p. 23). If we affix 're' to 'produced,' then we can also tell the story of geography education.

While the production and reproduction of knowledge are necessarily linked, they do not move in some elegant *pas de deux*. The field of geography—the social organizations by which domain knowledge is generated, preserved, and transmitted—is complex. As a discipline, geography has an existence as an academic and as a popular subject, the latter exemplified by the activities of the National Geographic Society, which at first were confined to the USA but now have an increasingly international reach. The two parts of the discipline are characterized by approaches, agendas, and audiences that are more often competitive rather than complementary. Moreover, internal, disciplinary views and external, societal views of the purpose and value of geography are different and sometimes at odds with one another. Superimposed on these differences are the valuations placed by professional geographers on the roles for geography education.

3. Geography Education as a Contested Enterprise

The history of geography education is also a contested enterprise. It has been shaped by complex interactions among a variety of factors:

(a) individual and societal valuations of geographic knowledge;

(b) the current state and past history of geography as a discipline (in terms of dominant approaches, concepts, models, and theories);

(c) the state of the formal education system (in terms of societal goals, physical infrastructure, resources, teacher training, textbooks, etc.); and

(d) the state of pedagogical theory and practice in education in general, and geography in particular.

While all of these factors vary across time and space, they coalesce into changing national approaches to geography education.

4. The Rationales for Geography Education

As with many disciplines, the rationale for the importance of geographic knowledge has been intertwined with the definition of an educated person. That definition has been subject to changes in the nature of

geographic understanding, and to the shifting emphases of the larger projects of society.

While it is impossible to unearth the roots of geography education, we can trace the emergence of some of the rationales for expecting people to understand geography. In late-Medieval Europe, for example, one grounding of formal education was in the teaching and learning of the seven sciences of the *artes liberales*: the *quadrivium* or advanced division (arithmetic, geometry, music, and astronomy) and the *trivium* or lower division (grammar, logic, and rhetoric).

5. Two Geographic Themes

Geography, as in knowledge of the location and character of places and the creation and use of maps, fell partially within the rubrics of geometry and astronomy. Place knowledge was an expected and necessary part of the knowledge base of an educated person and map use was a valuable practical skill in travel, navigation, surveying, business, warfare, and diplomacy. As both foundational knowledge and applied skill, geography therefore had elements of what we would today recognize as a liberal arts subject and as a science discipline, thus accounting for the discipline's varied placement within the college and faculty structures of universities in North America.

The two themes of foundational knowledge and applied skill are interwoven throughout the history of geography education in all countries. On the one hand, geography education is seen as essential to the project of creating an educated person, whether that project is couched in terms of (a) a broad liberal education, (b) citizenship education (in local, patriotic and national, or world contexts as expressed in the slogan 'think globally, act locally'), or (c) geographic literacy (e.g., reading and understanding the contents of a newspaper). Participation in local community affairs, voting, and support for national and increasingly international policies all depend upon a level of geographic literacy. On the other hand, geography education is seen as providing essential skills for operating in society in general (e.g., map-reading skills) and for participating in the workforce in particular (e.g., using geographic information systems). Careers in planning, business, and government agencies all depend upon significant levels of geographic skill.

5.1 Geography as Foundational Knowledge

The foundational knowledge approach to geography education has many variants. Geographic knowledge is seen as a way of counteracting and overcoming the natural and/or socially induced human tendencies towards egocentrism, parochialism, and ethnocentrism. Knowledge of the diversity of patterns of

human occupancy of the earth's surface reduces the chances of privileging one's own place in the world and increases the appreciation of cultural diversity and human creativity. Similarly, geographic knowledge underpins an understanding of physical environments, especially important as those environments are under threat from human-induced changes at local and global level. It can reinforce an understanding of the interdependency between human and physical systems. Geographic knowledge is seen as important for the teaching of other subjects, especially history, sociology, anthropology, economics, business, and political science. Without an appreciation of the intersections between space and place and between environment and society, the subject matter of those other disciplines cannot be appropriately grounded and understood. And finally, geographic knowledge need not be seen as exclusively instrumental or utilitarian: '(t)he power and beauty of geography lie in seeing, understanding, and appreciating the web of relationships among people, places, and environments' (Geography Education Standards Project 1994, p. 3).

5.2 Geography as an Applied Skill

The grounding of geography education in skills also has multiple bases. The science, art, and craft of cartography has been fundamental to many social projects, including surveying, documenting land ownership systems, exploration and navigation, colonization and military conquest, regional and local planning, and environmental science. As technologies for data gathering (e.g., satellite remote sensing), ensuring data accuracy (e.g., global positioning systems), data processing (e.g., GIS), and displaying geospatial data (e.g., geo-visualization tools) have become pervasive, so too have been the needs for geographically educated people to produce and interpret an increasing range of graphic displays. Those technologies and their products are central to the daily operations of government (local and national), the military, business and logistics, international politics, and so on. For example, knowledge of the spatial structure of national and world economies, together with the tools of spatial analysis, are seen as essential for individual participation in, and national success in, the business of the increasingly interdependent global economy.

Geography education has, therefore, been based on an intermixing of four principal rationales:

- (a) the existential value of understanding one's place in the world;
- (b) the ethical imperative of appreciating the fragile human and physical systems upon which we depend;
- (c) the intellectual power of understanding the interplay between two pairs of ideas—space and place, and environment and society—in shaping the patterns of the earth's surface; and

(d) the utilitarian motivation of using geography to solve individual and societal problems. These rationales have motivated the process of geography education and have been differentially emphasized during the history of geography education (Douglass 1998).

6. Geography Education: a History

While there had been a strong classical tradition of geography in the eastern Mediterranean as far back as 2000 BC, the efflorescence of geography was contemporaneous with the so-called Age of Exploration and the origins of the Scientific Revolution beginning in fifteenth-century Europe. Built on the maps and texts surviving from the Greek, Egyptian, Roman, and Arab cultures, geography was both a statement about the world and a way of recording the new information about diverse places. Maps were both tools for navigation and means of recording the results of travels. Texts captured descriptions of the location and properties of places encountered.

6.1 Varenius and the Two Geographies

These two roles of maps and texts are a convenient starting point in an account of the history of geography education. In 1649, Bernhardus Varenius (Bernhard Varens), a German doctor living in the Netherlands, published *Descriptio Regni Japoniae et Siam*, followed in 1650 by his *Geographia Generalis*. In the latter work Varenius systematized an understanding of the logic of geography, distinguishing between general and special geography. Although the terms were not original to Varenius, his statement of the distinction was crucial to the development of geography as a discipline in general and to the history of geography education in particular.

General (or universal) geography was explanatory in nature, seeking to understand the patterns and processes of the world via general (or natural) laws. Echoing the links of geography to geometry and astronomy in the *quadrivium*, general geography was linked to the 'mixed' (or applied) mathematics. Its focus on the terrestrial globe was paralleled by astronomy's focus on the celestial globe. General geography sought to understand global patterns of climate, topography, hydrography, etc., by means of forces and mechanisms (the laws of motion, heat, erosion, etc.). It moved from global explanations to accounts of regional variations, emphasized physical over human phenomena, and incorporated both geodesy and cartography.

Special geography was descriptive in nature, seeking to depict the characteristics of particular places. Although Varenius did not offer a detailed description of special geography in *Geographia Generalis*, his

outline description matched the contents of his earlier *Descriptio Regni Japoniae et Siam*. While the basis for general geography was demonstration from general laws, special geography derived from experience, systematized in terms of the terrestrial (physical) and human properties of places.

While there is a necessary link between special and general geography, there is also a recognition that general geography is more challenging, more intellectually demanding, and therefore in a sense, more advanced than special geography. General geography seats the discipline squarely within the tradition of natural philosophy and eventually the mathematical and empirical sciences. Varenius' work was influential throughout Europe for over two centuries (used by Newton in England and Kant in Germany, for example) and in the USA (Warntz 1964, 1982).

For geography education, Varenius' distinction between general and special geography establishes the two tracks along which geographic teaching and learning developed. It also helps to account for the trajectory of success, failure, and eventual re-emergence of geography instruction in educational systems. The book itself is important for two additional reasons. First, Varenius was concerned with restoring what he felt was a needed balance between general and special geography, the balance being decidedly in favor of special geography. To Varenius the imbalance meant that students were ignorant of the foundations of their discipline and this lack of attention to general geography placed into question the status of geography as a science. Second, the book was written as a textbook for advanced students, not for scholars. The changing balance between special and general geography, the relative intellectual status of the discipline, and the role of textbooks are themes that recur through the history of geography education.

From the sixteenth to the early nineteenth centuries, geography was part of both the school and college education systems in Europe and North America. In the USA, for example, admission to the colonial colleges was based in part upon knowledge of geography. It was expected that school and college students would know about the world in general and their national worlds in particular, and that they would have some minimal understanding of the maps and globes which were instruments for conveying and using knowledge about the world. Geography instruction incorporated both general and special elements, although there was a preponderance of the latter in schools and the former in college. Geography was a standalone subject in the curriculum of schools and the faculty of colleges and universities. It was supported by a rich infrastructure of textbooks, atlases, wall maps, and globes. Geography instruction led, for example, to new tools. In England in the 1760s, John Spilsbury, a London mapmaker, created 'dissected maps' as a way of teaching geography. In an interesting twist, dissected maps became jigsaw puz-

zles, a major source of entertainment named after the tool used for their construction, and they lost their meaning as a tool of geographic instruction.

During the late-eighteenth and early-nineteenth centuries, geography instruction responded to larger societal projects. In European countries, the twin forces of nationalism and imperialism reshaped territorial relationships throughout the continent and the world. Geography became a way of inculcating an understanding of national identity and international aspirations. Thus there are numerous literary allusions to children being forced to learn maps of the British Empire in which imperial possessions were boldly portrayed in vast expanses of red. Children were subjected to a world being carved into places that were named and owned, demarcated by sharp lines and differentiated by rich physical and human detail. This detail was the cumulative result of several centuries of exploration, conquest, colonization, and settlement. There was also an ideology for structuring this world understanding. Places were ordered as being populated by savages, barbarians, half-civilized, and civilized and enlightened people. Progression along this typology was allegedly a response to the civilizing influences of European society. This ideology was the basis for many eighteenth and nineteenth century textbooks and atlases.

In the USA, two interlocking forces shaped the nature of geography education and led to its gradual demise as a school subject during the first half of the twentieth century. The first force was universal or mass education, a force which applied equally to European societies. The second force was the expansion and integration of the national territory. As the nation grew in size and complexity, there were increasing demands that students should understand the geography of the emerging nation. Universal education brought with it pressures towards access for all students and the fostering of a spirit of national identity. Political independence meant also independence in terms of what was taught and the material on which teaching was based. All of these imperatives lead to an increasing focus on special geography, with the USA being the focal point of the world view and with a sense that understanding one's own country was essential, easy, and accessible to all (Bruckner 1999).

Beginning in 1784, Jedidiah Morse wrote a series of textbooks that shaped American school geography. An 1814 edition was entitled *Geography Made Easy* and it was developed 'for the use of schools and academies in the United States of America.' These books spawned a series of progenitors throughout the nineteenth and twentieth centuries. The texts made all places, but especially the nation and the student's state of residence, seem special and perhaps unique. Children learned by rote, working from the ubiquitous trio of the globe, the textbook, and the wall map of the world. As geography, particularly special geography,

literally became easy, it lost respect in the eyes of many in the academy. While the knowledge gained was useful and even essential, it did not challenge children's minds, except in the most trivial sense of factual learning.

From the middle of the nineteenth century to the beginning of the twentieth century, major geographic scholars were centrally involved in the process of geography education at all levels, K-12 included. For example, William Morris Davis in the USA and Halford MacKinder in the UK exemplified a seamless approach to the development of geography as an academic discipline and as a school subject. In both countries, there were organizations, the National Council for Geographic Education and the Geographical Association, whose primary function was the fostering of geography education in society. The National Geographic Society pursued its goal of increasing and diffusing geographic knowledge for mass audiences in as many countries as possible. Geography remained a popular subject, as exemplified by two bestselling books. V. M. Hillyer's (1929) *A Child's Geography of the World* and Hendrik van Loon's (1932) *Van Loon's Geography* remained in print for over 20 years and both were translated into many languages. There was a popular interest in geographic knowledge and therefore modest levels of support for K-12 geography instruction.

7. Geography Education in the Modern Era

During the middle to late twentieth century, geography education played different roles in different countries. In the UK, it remained a standalone subject that was part of the curriculum at all school levels and it was available as one of the Ordinary and Advanced level exit exams in high school. In this context, geography was traditionally grouped with the arts rather than the sciences. In both France and Germany, geography also played a comparably steady but modest role in the school curriculum. In the USA, geography languished at all school levels. The integrity of the discipline as a whole was destroyed as a consequence of being split apart as a subject. Human geography was subsumed within the social studies and physical geography within the earth sciences. These curricular emphases were mirrored in the structure of the education training system, with preservice teachers being explicitly trained as specialists in geography in many countries but not in the USA. In all cases, geography was taught as a cross between knowledge of the fundamental properties of places and regions in the world and, to some limited extent, a set of practical skills (e.g., map and atlas use, survey methods, fieldwork, etc.)

There are three principal frameworks underpinning the scope and sequence of geography in the K-12 curriculum. Curricula were place, scale, or concept-

based. The place-based curriculum structure is the oldest structure, dating back to the eighteenth century focus on special geography. Various known as the 'capes and bays' or the 'principal products of Peru' approach, it employed a simple classificatory framework to capture the characteristics of places around the world. Students learned about the location, boundaries, physical geography, and human geography of places, often in a rote fashion and using simple maps and atlases. In effect, younger children learned less, as in fewer and simpler things, and older children learned more, as in more detail, about the world. Geography education became an A to Z world tour, organized around continents, countries, and regions.

The scale-based structure is also known as the expanding environments or expanding communities approach. It begins in the early grades with a focus on the familiar and on the local world of the child, progressing to increasingly distant places with increasing age of the students. The local-to-global progression is premised on teaching about what is readily accessible to the understanding of children at different ages and levels of cognitive understanding. The third approach is concept-based, developing a systematic understanding of sets of concepts that can be applied to a range of spatial contexts at different scales. Geography is seen as a way of asking and answering questions about what is where in the world, and about why and how it got there.

These three curricular structures fall loosely into a historical sequence, if not progression, and reflect significant changes in the view of the discipline of geography. The essential transition is from seeing geography as a property of the world (the geography of a place) to seeing geography as a perspective on the world, as a way of understanding patterns and processes on the earth's surface. In the place-based approach, there are lists of things to be known about the world; in the concept-based approach, there are alternative ways of knowing about the world. Beginning with the scale-based approach, there is a sense of active involvement with the world, an involvement based on field trips, on maps as tools for recording and investigating places and environments, and students as explorers and creators of their own understanding.

Underpinning these three approaches are, therefore, approaches to child development. Many of the great educational theorists (Pestalozzi, Montessori, Piaget, etc.) treat issues that are central to the child's understanding of the world, although they do not necessarily do so within the formal domain of geography. Thus, for example, Piaget discusses the development of spatial understanding, the sense of nation, the understanding of basic physical phenomena (e.g., clouds, rain, etc.) and he makes use of maps and spatial models in his research designs. Geography education, while not necessarily basing its approaches explicitly on such theorists, is of necessity informed by their ideas.

In the early to middle 1980s, there was a resurgence of interest in many countries in the success—and often failure—of education systems in generating knowledgeable and competent students. The context for this interest was the intersection among several factors, including the effects of globalization on national economies, the desire to remain competitive in a rapidly changing world, and the increasing demands for technical skills in the workforce. As typified in the seminal US report *A Nation At Risk* (National Commission on Excellence in Education 1983), there were significant concerns about the structure of education in terms of teacher training, teacher support, curricula, textbooks, assessment, accountability, etc.

In the case of geography, the focus, especially in the USA, was on unacceptably low levels of geographic literacy among recent high school graduates. International comparisons showed relatively low levels of geographic literacy in a range of countries, but the performance of American students was particularly disappointing. As a consequence of the renewed national interest in education, geography education became the focus of attention from national and private organizations in many countries.

That attention paralleled national concerns about the knowledge and skills of school graduates and it led to a normative focus on what students should know and be able to do. The focus gave rise to national documents specifying the content of the curriculum at various grades and/or ages. Often these documents specified learning outcomes that were expected of students and therefore the documents became the basis for the assessment of student learning. In the case of geography, both the UK and the USA produced national guidelines (or standards).

8. *The Current State of Geography Education*

Geography education remains a contested enterprise. As K-12 educational systems place an increasing emphasis on immediately relevant skills—mathematics, writing, and to some extent science—other subjects are of necessity given less attention in terms of time in the classroom, teacher training, material support, and access to computing resources. Where geography education is infused in the curriculum, this lack of attention is a serious problem and results in geography being squeezed out or at best subsumed within another subject such as history. While there is public support for a level of geographic knowledge, that support is often in terms of place location knowledge, a necessary but insufficient base for geography education.

Geography education is changing in ways that move it away from the negative image associated with 'old-fashioned' rote learning of geographic facts. Several

transitions are underway. The first is a recognition that the process of geography education can be set within a novice–expert framework. This entails understanding the different types of knowledge that underpin increasing expertise: (a) declarative or propositional (e.g., factual and conceptual understanding), (b) procedural (e.g., how to perform some operation), and (c) metacognitive (when, where, and why to link facts, concepts, and operations to answer geographic questions). It involves understanding the organization of the mental models that children develop (e.g., Earth–Sun relations, the water cycle, urban growth), the ways in which different skills are available at different ages (or cognitive developmental levels), and the role of peers and teachers in supporting the student's developing understanding (Downs 1994).

A second transition is a switch from rote learning to active, inquiry-based learning. Geography becomes a way of finding out about the world rather than simply a set of things to be known about the world. Computers and geographic databases allow students to ask and answer geographic questions for themselves. A third transition is from tests to authentic assessments. Assessment is built into the structure of the ongoing learning process and is focused on problems and situations that are likely to be encountered in real-world contexts. Students can demonstrate their developing skills by building portfolios of their work.

9. The Future of Geography Education

All of these changes in geography education mirror changes that are occurring in the nature of education in general. The short-term future of geography education lies in the successful linking of the case for geography education with the increasing capacity to do geography. In the same way that geography was fundamental to past societal projects (e.g., exploration and imperialism), it is also fundamental to the current development of an information society. Much of the data that is available can be assigned geospatial coordinates and therefore it can be handled efficiently and effectively via geographic information systems. The larger parent field of geographic information science requires an understanding of maps and graphics, of space and place, of the interactions between environment and society. Those understandings, while not exclusive to geography, are central to the subject and can be taught through geography education. Given the growing importance of information science and technology to all aspects of modern society and economy, there is a potential to re-establish an essential role for geography education in the contest for space—and time—in the educational system (Rediscovering Geography Committee 1997).

Geographic Information Systems

A geographic information system (GIS) is best defined as a software system designed to provide services related to geographic data. Such services include storage, analysis, transformation, maintenance, editing, visualization, modeling, and many more. That somewhat dry definition masks a record of rapid growth and widespread applications, beginning some 30 years ago. GIS is now the focus of a substantial software industry and boasts a user community that probably numbers in the hundreds of thousands or

even millions worldwide. While many of those applications lie in areas of social and behavioral science, they also extend across the full range of sciences, industries, and government agencies that deal in one way or another with information about the surface of the earth, the subsurface, and the atmosphere.

1. Overview

GISs are one of several geographic information technologies that have appeared or evolved rapidly in recent years. Geographic information is also handled in image processing systems, in the form of aerial photographs or images from space satellites, and many GISs include image-processing capabilities. The Global Positioning System (Kennedy 1996) and its Russian equivalent use satellites to allow users to measure their positions on the earth's surface, with accuracies that range from millimeters to tens of meters depending on the complexity of the measuring device. Earth-observing satellites (Jensen 1996) capture images of the surface and are now widely used to map, detect change, discover and inventory resources, forecast weather, and measure variables of importance to earth science. The Internet and the World Wide Web (WWW) are widely used to distribute geographic data from data archives and digital libraries, and to provide GIS services to remote users.

Today, the potential user of GIS might take advantage of any of a number of hardware and software configurations. The examples that follow relate to systems available in the year 2000 and are ordered by increasing cost and power.

(a) A simple WWW browser, running on a laptop or office machine, and used to access WWW sites that offer a range of GIS services. Such services include generation of standard map products, and simple analysis and mapping of data.

(b) A desktop system, such as a PC or Macintosh, running a relatively simple GIS such as ArcView (Environmental Systems Research Institute (ESRI), www.esri.com) or MapInfo (MapInfo Corporation, www.mapinf.com). Data would be resident on the system's hard drive, and might have been created locally or obtained from a data supplier. The operating system would likely be a Microsoft or Apple product.

(c) A networked workstation, linked to other workstations and servers in a local area network, perhaps under the Windows NT or Unix operating system. The software would be more complex than in the first option, perhaps ESRI's ArcInfo or Spatial Database Engine.

A social scientist 'doing GIS' might use any one of these configurations, depending on personal skills and needs. The system would provide services that include preparation of simple maps, manipulation of data to overcome issues of map projections, running of statistical tests, and fitting of complex models to data.

Courses in the use of GIS and in methods of spatial analysis and modeling are now offered in almost all universities and colleges, and in many high schools. A wide range of educational materials are available in the form of textbooks (e.g., DeMers 1997; Clarke 1997; Heywood et al. 1998; Burrough and McDonnell 1998), WWW sites (e.g., www.esri.com and www.geoplace.com), and WWW-based courses (e.g., www.unigis.com). GIS software vendors maintain WWW sites with much useful information, and trade magazines (*GeoWorld* and *GeoInfo Systems*) carry information about new products and initiatives.

The history of GIS (Foresman 1998) originated in the 1960s, with the development of the Canada Geographic Information System (CGIS). Analysis of paper maps is notoriously difficult, because of the awkwardness and unreliability of techniques for measuring simple properties such as length or area, and because of the difficulties associated with overlaying different maps of the same area. Computer technology was applied in the late 1960s and early 1970s to the editing of maps by producing agencies such as the US Geological Survey, and to the automation of various functions associated with taking the census. But early efforts were crude and expensive, and GIS became widely available to government agencies and corporations only in the early 1980s. Today, the general public is increasingly aware of GIS through WWW sites such as www.mapquest.com, which generates several million maps a day for users who need driving directions, and through simple mapping packages such as Microsoft's MapPoint 2000.

2. GIS Essentials

General computer packages to support analysis of data began to appear in the 1960s, led by BMD, SAS, and SPSS. The table is a powerful model for organizing data, by arraying cases in the rows and devoting each column to some property of each case, and early packages took advantage of this commonality by organizing housekeeping and analytic functions around it. Thus, means and variances could be computed by column; regression could be readily applied to two columns; and data could be aggregated by computing the mean value of a column for every unique value of some other, categorical column. In essence, these packages exploited an economy of scale in software production: once the housekeeping functions for a simple data model like a table had been built, it became very cost-effective to add new functions based on the same data model.

GIS similarly exploits economies of scale, but in this case by supporting not one but several data models, all of them effective ways of representing the information content of a map or image. The real geographic world is enormously complex, and there are many different ways of capturing its contents in digital form, all of

Figure 1

The concept of layers. Geographic reality is represented by a set (five in this case) of co-registered rasters, each representing the spatial pattern of one variable. Example layers might include soil type, vegetation cover type, ownership, mean annual temperature, or elevation

them involving some form of approximation. Remotely sensed images use a raster model, capturing the earth's reflectance in each of an array of square cells. Because of its simplicity, the raster model has been used as the basis for many GISs, each of them representing data as a series of layers of co-registered raster cells (Fig. 1), with each layer capturing some distinct variable, such as land elevation, county name, average income, population, or class of land use.

In the vector model the world is viewed as occupied by collections of points, lines, and areas. Points are located by coordinates, often latitude and longitude or some universal coordinate system such as the Universal Transverse Mercator (UTM). Lines are represented as polylines by connecting an ordered sequence of points with straight lines. Areas are similarly represented as polygons or figures with point vertices connected by straight edges. Each point, line, or area

object in the vector model is associated with one or more attributes which capture the object's significant characteristics. A set of objects of the same type is associated with an attribute table by assigning one row of the table to each object, and one column to each characteristic.

Figure 2 shows a simple example of raster and vector data. The same set of census tracts is shown in Fig. 2(a) in the form of a raster, and in Fig. 2(b) in vector form. Most GISs include support for both models, and for transformations between them. They also support various kinds of map projections, allowing the user to switch readily between latitude and longitude, UTM, and other coordinate systems, and to display any part of the earth's surface in the form of a flat paper map.

One of the most compelling arguments for GIS relies on the ability to integrate information around a common geographic location. A project might involve many different kinds of information about different themes or variables for a geographic area. Every point, line, area, or raster cell in a GIS database has an associated location, so it is possible to determine the distance between two locations or to place locations correctly on a map. But more significantly, it is also possible to identify all of the information available about a location, or to link together two data sets through common location. GISs include functions to determine how much overlap exists between two areas, or whether a given point lies inside a given area, and functions to select all of the points lying within a given distance of a line. To return to a point made earlier, the economics of software production provide great advantages to GIS designers once a basic structure has been laid down, because new functions that work on the same structure can be added very easily.

Certain key GIS functions are particularly relevant to social and behavioral science applications.

(a) Geocoding, or the ability to convert street addresses to geographic coordinates, and vice versa.

Figure 2

Representation of three adjacent census tracts using raster cells (a) and vector polygons (b). In the raster case, cell size determines the accuracy of boundary positions. In the vector case, each tract is located by specifying the coordinates of its vertices in order

This function might be used to associate coordinates with surveyed households, allowing locations to be mapped, integrated with other data, or subjected to various kinds of analysis.

(b) The point-in-polygon function, or the ability to compare a set of points to a set of polygons, to identify the polygon containing each point, and to combine the characteristics of the containing polygon with those of the point. For example, this function might be used to associate census tract properties with those of the individuals who live there.

(c) The polygon overlay function, or the ability to combine two sets of polygons, creating a new polygon for every unique area of overlap, and associating it with the attributes of the two polygons that overlap to create the area. By overlaying a map of county boundaries on a map of school districts, it would be possible to estimate the number of children living in each school district based on knowledge of the population density of each county (subject to the assumption that population densities are uniform within each county).

(d) The buffer function, which identifies the area lying within a specified distance of a given point, line, or area, and gives it the attributes of this object. By combining this with the geocoding and point-in-polygon functions, it would be possible, for example, to determine the addresses of households within a certain distance of a shopping center.

3. GIS as Research Infrastructure

GIS software first became widely affordable in the late 1980s, when personal computers powerful enough to manipulate geographic data became available for a few thousand dollars. Social and behavioral scientists began to invest in its capabilities, particularly in those disciplines that had traditionally adopted a spatial perspective. Archaeologists and anthropologists, for example, began to use GIS software to map and store artifacts at the scale of the dig, to build digital maps of reconstructed landscapes, and to make use of spatial analysis to understand how early societies operated in space (Aldenderfer and Maschner 1996). Criminologists use GIS to map crime, correlate crime rates with social variables, and examine detailed spatio-temporal patterns of criminal behavior. Political scientists use GIS to evaluate districting schemes, and to explore the spatial diffusion of political movements (Eagles 1995). Market researchers and location analysts use GIS to map market potential, model the spatial behavior and choices of consumers, and search for optimal locational strategies (Martin 1996).

Of all the social and behavioral disciplines, geographers have long claimed a special interest in space, and much of the early work on GIS design and application was strongly associated with the discipline.

Geography is often the home department of GIS, though many other arrangements exist, especially at institutions lacking a geography department. GIS courses are frequently offered by geography departments, and geography is often the sponsor of campus GIS infrastructure, in the form of laboratories, software licenses, and data repositories.

In recent years efforts have been made to develop wider linkages. In the USA the University Consortium for Geographic Information Science (www.ucgis.org) now links over 60 member institutions in an organization dedicated to advancing GIS and its applications through research and education. In Europe, the Association of Geographic Information Laboratories in Europe (AGILE) has a similar mission, and the European Science Foundation has sponsored a major study of GIS in the social sciences through its GISDATA program. National centers have been funded in several countries to pursue GIS research: in the USA, the National Center for Geographic Information and Analysis (www.ncgia.org) was founded by the National Science Foundation in 1988, while in Canada the GEOIDE network was founded by the three national research councils in 1998 (GEOIDE, *La géomatique pour des interventions et des décisions éclairées*; see www.geoide.ulaval.ca).

Several journals are devoted to advances in GIS, including the *International Journal of Geographical Information Science*, *Cartography*, and *Geographic Information Systems*; *Geoinformatica*, the *Journal of Geographical Systems*; and *Transactions in GIS*. Descriptions of research using GIS can be found in major journals in many application disciplines.

Comparisons have often been drawn between GIS and statistics, since both can be seen as generic tools and concepts used widely across the sciences (e.g., Goodchild 1987). It is argued that GIS provides the implementation of methods of spatial data analysis in easy-to-use computer tools, just as the statistical packages implement methods of statistical analysis. In this context spatial data analysis can be defined as a set of analytic methods whose results are not invariant under changes in the locations of the objects of analysis—in other words, location matters. This serves to distinguish these techniques from more familiar numerical and statistical analyses, such as the calculation of a mean, or the preparation of a scatterplot, that do not normally include location or respond to it. Spatial analysis predates GIS, and major texts include those by Berry and Marble (1968), Haining (1990), and Bailey and Gatrell (1995). However, the advent of GIS has greatly improved access to these methods and, moreover, it has come at a time when there is increasing interest in visual, intuitive, and exploratory techniques, all characteristics that are readily compatible with GIS. For discussions of the impact of GIS on spatial analysis see, for example, Fotheringham and Rogerson (1994), Goodchild and Longley (1999), and Fischer et al. (1996).

4. Sources of Data

Maps are highly compressed representations of large amounts of information, and extremely tedious to convert to digital form. Two methods are available, with both advantages and disadvantages:

(a) Digitizing, a process in which a human operator traces information from a map, capturing the locations of features and their attributes using a pointing device and a keyboard. The process is very expensive, since it is difficult to capture complex geographic features rapidly and accurately.

(b) Scanning, in which an automated device captures the information from a map. Extensive editing and error correction is necessary, especially if the map is of low quality, such that scanning is typically as expensive as digitizing.

In the social and behavioral sciences, data are often highly specific to applications and must be rendered into digital form using one of these methods. Thus an archaeologist may have to digitize the locations of sites or artifacts from manuscript maps or drawings. In other cases, however, the process of database creation will take advantage of the widespread availability of framework data, or geographic data sets of generic use that already exist in digital form. These include:

(a) Topographic maps, in both raster and vector form (produced in the USA by the US Geological Survey and known as digital raster graphics, or DRGs, and digital line graphs, or DLGs. Various mapping scales are commonly available (in the USA the most detailed scale is, 1:24,000).

(b) Elevation data in raster form (produced in the USA by the US Geological Survey and known as digital elevation models, or DEMs). These data sets vary according to the spacing of the grid: for the entire earth the best spacing available is several kilometers, but 30m spacing is available for much of the USA.

(c) Street centerline data in vector form. These data sets record the locations, names, address ranges, and other information on streets. The TIGER (Topologically Integrated Geographic Encoding and Referencing) database created and maintained by the US Bureau of the Census covers all of the USA, and includes boundaries of statistical reporting zones. These data sets represent streets by single lines and have positional accuracies of tens of meters.

(d) Imagery from aerial photography. The Digital Orthophoto Quad (DOQ) is typical of these data sets, with a 1m ground resolution and a 6m positional accuracy, and available from the US Geological Survey for much of the USA.

(e) Imagery from satellites. These sources include images collected by the Landsat and SPOT satellites, with cell sizes down to 10m.

(f) Municipal databases created by local government agencies, often in collaboration with utility companies. These are in vector form and often include

property boundaries, locations of buildings, and streets represented by double lines. In some countries, notably the UK, they are produced by government for the entire land area. In the USA, coverage is patchy. Positional accuracies are typically in the meter range.

(g) Gazetteers, the digital versions of the indexes found in atlases, linking placenames to geographic coordinates. These indexes make it possible to translate information recorded by placename to map form, for analysis and display.

Many of these data sets are created and maintained by longstanding programs of national mapping agencies. Recently, many countries have attempted to place them within broader policy frameworks that emphasize sharing of data, avoidance of duplication, and the setting of standards. In the USA, the National Spatial Data Infrastructure (National Research Council [NRC] 1993) is a leading example.

These data sets provide the framework on which social and behavioral scientists can often hang their own features and attributes. For example, a criminologist might use a municipal database, adding records of crime locations; a sociologist might use reporting zone boundaries from the TIGER database to create maps and analyze data at the census tract level; and a planner might use imagery to monitor urban growth. By using data that are already in digital form the cost and tedium of database creation are greatly reduced.

Unfortunately, the conditions under which such framework data sets are accessible vary widely. In the USA, policy requires that geographic data produced by the federal government be distributed to anyone at no greater cost than that of dissemination. It is often argued that this policy has stimulated growth in the use of GIS and in the geographic information industry generally. But while US courts have held that geographic data are facts and therefore not subject to copyright, in other countries national governments have adopted cost-recovery policies, protected by copyright. Academic scientists in such countries have found various ways of accessing geographic data at lower cost, through bulk purchase agreements. Lower levels of government in the USA are also not subject to the cost-of-dissemination policy, and have made efforts at cost recovery under trademark protection. For more discussion of these issues, see *Spatial Data Infrastructure*.

While the public sector has traditionally supplied many of the geographic data used by the scientific community, a growing private sector may have substantial impact in the coming years. Very large geographic databases are being created for internal purposes by insurance, retail, banking, and other corporate sectors. Point-of-sale systems now routinely capture data on grocery purchases, and direct-mail and delivery companies make use of detailed geographic data for scheduling and targeting. These activities have raised privacy concerns, and it is clear

that the levels of detail now available to corporations, together with the ability to integrate and merge data based on geographic location, have very significant privacy implications. Much of this activity remains largely outside any regulatory framework.

5. Networks

The Internet and WWW have had major impact on GIS. They have made it much easier to share data and to access data remotely. Data can be published and disseminated easily, as can the more sophisticated results of analysis. Indeed, the entire process of scholarly communication and publication is being radically restructured by networking technologies.

It is useful to distinguish two forms of processing of geographic information. The term 'geographic information system' suggests a combination of hardware and software that may or may not be connected to a larger network. It is probably controlled directly by a single user, and provides capabilities and functions directly related to the user's needs. On the other hand the term 'geographic information services' is used to describe WWW sites that offer specific GIS functions in response to user requests. Instead of sending the data to a GISystem, a GIService retains its data, sending only the results of analysis. The Mapquest site (www.mapquest.com), for example, provides a range of services from the generation of maps at user request to the geocoding of addresses supplied by the user.

GIServices are growing rapidly, and are expected to grow much further in the coming years. In addition to avoiding lengthy transmission of data, they allow the custodian of a sophisticated analysis tool to retain control, and to upgrade the tool, rather than undertake a complex process of distribution to user sites. Pricing based on services is very different, and perhaps simpler, than pricing based on data (Guenther and Mueller 1999). GIServices also assume a level of adherence to standards, and encourage the development of interoperable tools using common formats and protocols (the Open GIS Consortium, www.opengis.org, is a major influence toward greater interoperability in GIS).

Several major initiatives are making geographic data more easily found and accessed via the WWW. In the USA, the Federal Geographic Data Committee sponsors the National Geospatial Data Clearinghouse (www.fgdc.gov), a catalog of sites offering geospatial data, linked together using the Z39.50 protocol. The Alexandria Digital Library (alexandria.ucsb.edu) offers the services of a map library, including search and retrieval of data, over the WWW. Other sites offer more specialized data, for example, a site at the Massachusetts Institute of Technology (ortho.mit.edu) offers DOQs for the Boston area. The term 'geolibrary' has been coined to describe WWW sites that allow search for data based on geographic location, including search for information that is associated with

a geographic area, but which is not a map or an image, such as a planning report. The implications of geolibraries are discussed in a recent report of the US National Research Council (NRC 1999).

6. Space and Scientific Explanation

Ultimately, the value of GIS and related technologies in the social and behavioral sciences will be intimately tied to the role of space in scientific explanation and understanding. Before expanding on that point, however, it is useful to distinguish between normative and explanatory applications. Many applications of GIS may be scientific in their objectivity and rigor, but nevertheless aimed at supporting decisions, developing policy, or solving day-to-day problems. Such normative efforts often apply the principles and knowledge of social and behavioral science. Moreover, many do so in a spatial context, by combining principles about behavior and society with the specific conditions existing in a geographic area. Thus, there are abundant normative applications of GIS.

In this section, however, the focus is on those applications that advance scientific knowledge about the world, through observation, experiment, hypothesis-testing, and deduction, because such explanatory efforts lie at the heart of the social and behavioral sciences. To what extent can GIS be used as a tool to advance scientific knowledge?

Ideally, scientific knowledge advances through controlled experiment, by varying the conditions under which society operates and observing the response. But although such experiments are common in areas such as agriculture, and GIS is often used as a tool to manage experimental plots, they are unlikely to be possible in the case of social and behavioral processes operating at geographic scales. Instead, science must advance through inference, either inductively by inferring the nature of a process from its geographic or temporal expression, or deductively by comparing the predictions of theory with reality.

GIS is most strongly associated with cross-sectional approaches to observation and inference. A phenomenon is compared across a geographic area, and its spatial variation is compared with the variation in relevant conditions. Inferences are drawn about process, but since the process is not observed directly it is impossible for inference to be definitive. Alternatively, patterns may be used to provide confirmation of hypothesized processes, though again confirmation is never definite. The tradition of using maps as a basis for inference has a very long history, one of the most compelling historic examples being the map made by Dr. John Snow of a cholera outbreak in the Soho district of London in the 1850s, which provided evidence of the role of drinking water as the disease vector.

It is often argued that longitudinal observation and inference based on change through time is more

definitive than cross-sectional inference. But cross-sectional data are widely available from sources such as the census, and powerful technologies like GIS increasingly make it possible to examine data from both cross-sectional and longitudinal perspectives.

Geographers draw a distinction between the properties of a site, and the site's situation in spatial context. Many social processes respond both to the conditions at a place, and to the conditions in the place's surrounding area. For example, choice of residential location is affected both by the properties of the available sites, and by their surrounding communities and neighborhoods. GIS makes it possible to observe and analyze a site's situation, in the form of maps and images, and also to link one property of a site to other properties through their common geographic location. Further discussions of the spatial dimension of explanation, and of the role of GIS, are available in many sources (e.g., Abler et al. 1992, NRC 1997a).

7. GIS in the Future

There is every indication that the use of computers to handle geographic information will continue to increase dramatically in the future, and that the user base will continue to broaden. But trends in the software industry, and in society more generally, suggest that the nature of GIS will continue to evolve.

In 1997 the US National Research Council sponsored a workshop on the Future of Spatial Data and Society (NRC 1997b). It found strong support for continued increases in technical power, in the form of computer speed, network bandwidth, and storage capacity, at constant or diminishing cost. But it also identified a large number of societal trends that are likely to affect GIS, and also fundamental trends in the nature of software.

The report found a discernible trend in recent years towards the solution of problems at the local level. It is reflected, for example, in the popularity of place-based decision making in the US Environmental Protection Agency, a policy that encourages the solution of problems locally, by local stakeholders. It is also reflected in efforts to devolve power to lower levels in the administrative hierarchy.

In the 1960s, the so-called quantitative revolution in geography emphasized the nomothetic search for general laws affecting spatial phenomena, and saw traditional geography's approach as idiographic, with its stress on cataloging the unique properties of places. Today, there is much interest in quantitative techniques that accommodate spatial variation in parameters, and emphasize the role of spatial analysis in exploring local variation. Fotheringham, for example, has identified this as one of the most important themes in contemporary spatial analysis (Fotheringham 1997). GIS provides an ideal platform for such methods, since it makes it easy to analyze spatial data, and to display spatial variation.

At the same time, there is increasing interest in several disciplines in the incorporation of spatial effects directly into theory, on the grounds that a system that is spatially distributed, and forced to communicate over distance, is fundamentally different from one that is infinitely connected. Spatial economics and spatial ecology are now significant areas within the theoretical wings of those disciplines, while geography has a long tradition of explicit theorizing about space. Again, GIS provides an ideal platform for subjecting such spatially explicit theory to empirical test.

Finally, the spatially explicit nature of GIS provides an ideal environment for linking normative and explanatory science. The implications of theories for real geographic areas are readily evaluated, and models that incorporate social and behavioral processes can be combined with geographic boundary conditions to provide readily visualized predictions. Thus, GIS offers an ideal environment for bridging the gap between theory and practice, and a significant clue in the eternal search for relevance.

Geographic Information Systems: Critical Approaches

Geographic information systems are computerized information systems, computer hardware and software, used to store, manipulate and map geo-referenced databases of information about the physical and human world. Growing rapidly since their development in the 1970s, GIS are now used in a wide variety of private and public organizations, and increasingly by individuals and grassroots organizations, for analysis, decision-making, and the display of geographical information. In response to this growing influence, critical assessments of GIS have emerged. These have analyzed their positivist bias, their potential to reinforce social inequality, their capacity for surveillance and ethical and legal implications, and have sought to examine these issues and to pursue alternative approaches to contemporary GIS. Critical approaches refer to analyses of GIS that are based in critical theory, i.e., that assess GIS in terms of their relationship to power hierarchies and wealth inequalities in society (Habermas 1984). This article:

- traces the origins of such critiques of GIS;
- discusses the engagement between critical theorists and GIS researchers that resulted in development of a GIS and society research agenda;
- examines critical assessments of the impact of society on GIS, and of GIS on society; and
- summarizes attempts to seek alternatives to GIS that may reduce some of the problems identified through these critical approaches.

1. Early Critiques

Broad-based claims were made about GIS as the key to a new integrated scientific geography at the end of the first wave of GIS research. This was the point in time when the technology had stabilized around a layer-based GIS architecture, and when the US National Science Foundation had recognized the importance of GIS through establishment of the National Center for Geographic Information and Analysis (cf. Dobson 1983). Written at a time when human geographers were moving away from positivist and critical rationalist approaches to research, such statements catalyzed a series of critical responses (Pickles 1999).

These criticisms focused on both epistemological and practical implications of the spread of GIS. Epistemologically, GIS was argued to be a Trojan horse for the reassertion of broadly positivist approaches within geography, because of its quantitative and empirical nature. Critics argued that geography was too complex and varied a discipline to be analyzed with this approach alone, criticized the claims that positivist science is foolproof, universal and objective, and claimed that the use of GIS would marginalize critical theoretic and hermeneutic approaches to geography, thereby limiting its ability to make sense of the world. They also argued that this kind of scientific approach would not promote human emancipation, and would not leave space for investigation of other possible worlds than those observed and experienced. The benefits for geography of using GIS to enhance its status as a science were seen to be outweighed by the costs associated with a consequent narrowing of geographic inquiry.

It was also argued that embedded within GIS are certain conceptions of space (particularly a geometric and relative space) and certain forms of reasoning (particularly Boolean logic) that are unable adequately to represent non-European conceptions of space and communicative rationality (Habermas 1984, Rundstrom 1995, and Sheppard 1995). Practically, it was argued that increased use of GIS in society would enhance current social and geographical inequalities. It was noted that social actors have differential access to GIS; wealth, gender, race, and geographic location are all strongly correlated with access to the necessary equipment, access to training, and comfort in working

with GIS. Consequently, GIS was seen as facilitating practices of surveillance, social engineering, opinion formation, and warfare by those with access to the technology. These arguments closely parallel more general analyses of the digital divide. These critical attacks provoked equally sharp responses by GIS specialists.

These specialists saw the critiques as simplistic, unduly pessimistic, and even paranoid, and as reflecting a lack of understanding of and experience with GIS and/or a lack of patience or aptitude for the rigors of science. They also resented the implication that GIS specialists are unconcerned with the social issues raised, and/or unaware of the social implications of science. At the same time, they saw such criticisms as a minor irritation that could be ignored given the growing interest in GIS among both students and practitioners. As a consequence, after some initial high profile exchanges, from 1983 to 1993 there was little communication between the two 'cultures of indifference': those critical of and those specializing in GIS (Pickles 1999).

2. Engagement: GIS and Society

This intellectual divide was challenged in 1993, when the National Center for Geographic Information and Analysis sponsored a conference organized by both GIS specialists and social theorists who sought a more constructive engagement. This and a subsequent conference in 1995 brought together prominent researchers (Poiker and Sheppard 1995 and Harris and Weiner 1996). Notwithstanding some early tensions, caricatures broke down as participants gained a greater appreciation for the breadth of skills and interests of those coming from the other side. A common desire among those present to learn from one another stimulated development of a GIS and society research agenda composed of the following themes:

- the social history of GIS as a technology;
- the relevance of GIS for community and grassroots perspectives and lifeworlds;
- issues of privacy, access to spatial data, and ethics;
- the gendering of GIS;
- GIS, environmental justice and political ecology;
- GIS and the human dimensions of global change;
- and
- alternative approaches to GIS.

Formal collaboration continued, as collective research catalyzed by these meetings, in jointly organized sessions at GIS and geography conferences, and within the 'Geographies of the Information Society' research initiative workshops between 1997 and 1999 (Sheppard et al. 1999). In addition, critical theorists were asked to participate in key GIS events, and GIS theorists were given voices in critical theory projects (cf. Pickles 1995). By the end of the 1990s, the constructive engagement between GIS specialists and

their critics had substituted overlapping cultures of respect for separate cultures of indifference, notwithstanding the continuing reluctance of many critical geographers or GIS specialists to engage with one another.

Tensions between different perspectives remain. For example, the renaming of GIS as Geographic Information Science revived concerns about attempts to reassert an agenda of normal, positivist science with all its trappings (Pickles 1997). Yet the tone of debate had shifted to a search for common ground; much to the relief of graduate students who had been uncomfortable about having to choose between GIS and critical geography (Sheppard et al. 1999). With the shift towards more constructive engagement has come a shift from critique, in which possibilities were suggested and individual cases cited to bolster their plausibility, to analysis of the GIS and society nexus, which attempts to trace the complex ways in which each influences the other in specific contexts. While the GIS and society research agenda consistently has pointed to the dialectical relationship between the two, more research effort has been put into the impact of GIS on society than vice versa.

3. From Society to GIS

The starting point of this research has been the proposition that, as for technological change in general, the evolution of GIS has followed only a restricted number of the many paths that could have developed (cf. Arthur 1994). On the one hand, research has investigated the evolution of the software and hardware itself, the rise to dominance, for example, of a layer-based GIS over object-oriented GIS. This research has closely examined processes of technological development at key sites and moments when paths of future development were set, and has speculated on the 'paths not taken'; the alternative designs that never got off the ground or never became popular. The roles of key individuals, technical barriers, disciplinary tradition, and broader social forces in shaping paths of development have been analyzed (Chrisman 1988 and Curry 1998). Critical research has also stressed that the practice of GIS includes not just the technology itself, but the whole set of practices through which it is utilized, adapted, and connected with other related activities on a daily basis in the particular places where it is used. Drawing on insights from actor network theory and science studies, this approach has focused on how users, as well as inventors, go beyond learning-by-doing to shape the technology (Harvey and Chrisman 1998).

4. From GIS to Society

Critical approaches to examining the societal implications of GIS have focused on case studies examining

how some of the hypothesized implications are realized in particular contexts. A number of the implications raised in critiques of GIS have been examined:

- limits to GIS representations of the world;
- limits in access to and in the appropriateness of GIS technologies;
- legal and ethical implications of GIS use; and
- the applicability of GIS for redressing social and geographical inequalities.

Those examining the limits of GIS representations of the world have taken seriously the criticism that GIS, as we know it, undergoes a process of representational stabilization, foregrounding representations which prioritize a Cartesian view of the world, reify geometric spatial objects, and rely on institutional databases for their information. More generally, such criticisms contrast the instrumental rationality of GIS with the communicative rationality of lifeworlds, and conclude that GIS has difficulty capturing the latter. Rundstrom (1995), for example, argues that American Indian conceptions of space are inconsistent with those used in GIS, concluding that it is inappropriate for representing Indian lifeworlds. Harris et al. (1995) experiment with incorporating into conventional GIS sketch maps made by local peasant farmers in South Africa, in order to determine whether the capabilities of GIS can be extended to incorporate lifeworld-based information. The sketch maps represent African farmers' views of the landscape and their roots in local narratives about land alienation under apartheid. Goss (1995) examines GIS-based representations used in geo-demographic marketing, and how these may shape lifeworlds and the places in which they are pursued.

Those examining limits in access to and in the appropriateness of GIS have often begun with the observation that GIS was developed initially for large organizations, universities, corporations, state agencies, and the military, raising questions about its appropriateness for other (more marginal) social actors. Public participation GIS (PPGIS) research has been examining whether GIS, as we know it, is accessible to grassroots organizations; whether it is appropriate to the goals of such organizations, and thus to their empowerment; and whether it enhances or undermines the participatory decision-making processes characteristic of such organizations (Obermeyer 1998). Barriers to the use of GIS by grassroots organizations have been identified, and strategies to overcome these have been suggested. Studies of the impact of GIS use on the empowerment of, and on democracy within such organizations are beginning. Research into legal issues has focused on undesirable social implications of the spreading use of GIS and geo-referenced databases, for which legal remedies may be desirable. It has also focused on how the laws governing information policy and intellectual property shape the social implications of GIS use. Prominent social implications include:

violations of privacy resulting from the capability to map individual actors and events (such as AIDS cases);

the consequences of inappropriate GIS use, and the question of who bears legal responsibility; and

reduced public access to publicly funded spatial databases, as a consequence of intellectual property laws and the cost recovery strategies of local government agencies (cf. Curry 1998 and Sheppard et al. 1999).

Legal questions frequently revolve around ethical issues, but ethical implications of GIS are far broader than this. Curry (1998) suggests not only that there are significant ethical issues revolving around GIS use, but indeed that a close examination of GIS reveals that conventional models of ethical behavior are themselves problematic. The use of GIS to redress social inequalities has been dominated to date by GIS-based analyses of environmental equity (Nyerges and McMaster 1997). Much of this research employs GIS, as we know it, in fairly conventional ways to gather empirical information about the significance, pervasiveness, and correlation of social and geographical inequities in the potential exposure to toxic hazards. Considerable complexities in the relationship between exposure, social characteristics, and location have been revealed, and measures for determining their significance explored. Research into the historical processes behind such patterns has helped unravel the roles of social actors, and of race and class in creating such patterns (Pulido 2000). Some research is beginning to go beyond this, exploring ways to make information about exposure available to communities, and examining the utility of GIS as a tool for neighborhoods to carry out environmental inventories and develop sustainability indicators.

5. Prospects

Critical approaches to GIS are an even newer field of endeavor than GIS themselves, although they draw their inspiration from longer standing traditions of critical social theory and critical geography. The growth of the information society, and the central role of GIS and GIS-related information technologies (such as navigation systems, geo-referenced cellular phones, geographical positioning systems, and on-line real time mapping systems) in shaping the geography of the information society, mean that the questions raised in this research will remain important. Yet, the novelty of this field and its considerable potential for growth make it hard to predict major areas for future research. In addition to further elaboration of current research, however, two topics are likely to become increasingly important. First, the path-dependent nature of how GIS developed, and concerns about its limitations, suggest that an important issue, raised in the early 1990s but as yet little examined, is the potential for using digital technologies to convey

geographic knowledge in ways that are very different from those instantiated in GIS as we know it (Harris and Weiner 1996). Possibilities of alternative GISs have been broached, based perhaps on forms of rationality and information and opinion exchange that have more in common with the communicative logic of the Internet than with the instrumental logic of current GIS (Harris and Weiner 1996). Little research has been done, however, examining how such systems might be developed, and whether their social implications are likely to be more emancipatory than current GIS designs.

Second, we know little about reasons for inequalities in access to and use of GIS as yet. While the great majority of GIS researchers and users are white males, there has been little research into why this is the case as yet, and how it might be mitigated. Research taking a critical perspective on GIS has matured from postulating significant potential problems and limitations, to some selected case studies examining actual interrelationships between GIS and society in individual concrete cases. Such case studies are a vital step forward, and much more of this research is necessary. Yet a fuller understanding of these interrelationships will require comparative case study analysis, to tease out which kinds of contextual conditions affect which kinds of outcomes. Research designs should compare both case studies of similar organizational contexts in different places, *inter alia*, and case studies of different organizational contexts in similar places.

Geographic Learning in Children

1. Early Childhood Development and Geographic Learning

Most research on early childhood geographic learning has been concerned with the ability of the developing child to understand space, and in particular, to comprehend spatial location. Children begin to be capable of spatial perception—the perception of small-scale spaces they can see at once—shortly after birth. Not long thereafter, they begin to crawl around, and slightly later to toddle through rooms filled with obstacles that impede perception. It is at these slightly later ages that geographic learning really begins, when a child goes from merely perceiving to actively searching the environment. Between 12 and 18 months

of age, children can find objects once seen and now hidden (by a screen, for example) from view. Children between 18 months and two years of age can also deal with 'invisible displacements,' in which a toy, for example, is not just concealed but 'invisibly' transported to another hiding place. Two- and three-year olds can carry out much more complicated searches. However, at these age levels most research has been limited to the scale of an ordinary room, or slightly larger (Matthews 1992).

There is now strong evidence that children acquire basic map-reading skills and the ability to engage in certain aspects of map-reading somewhere between the ages of three and five (see Blades and Spencer 1990, DeLoache 1989, Newcombe and Huttenlocher 1992). Studies have focused on two general levels of spatial ability: (a) micro- or meso-spatial contexts—i.e., table-scale or room-scale representations (e.g., Cohen 1985), and (b) macro- or geographical-scale environments. Micro-spatial cognition involves understanding spatial relationships among objects that can, for the most part, be directly perceived as themselves and at their own scale. For example, micro-spatial cognition is required to put together a jigsaw puzzle. Macro-spatial cognition, on the other hand, involves representations at a perceptual scale of objects and object arrays that occupy much larger spaces in the 'real world,' objects that, together, would not ordinarily be perceived at once on the ground, for example, reading a map to navigate through a city.

The most interesting aspects of spatial development and geographic learning concern the ability of children to understand macro-spatial environments, which are large in extent, and their representation in the form of maps (Blades and Spencer 1990). Almost all research in this area has involved miniature representations of such environments in the form of aerial photos, maps, and modeled landscapes. At issue is how to ascertain very young children's understanding of the connection between these miniature representations and full-scale geographic reality. Children younger than five have limited vocabularies, and efforts to use verbal responses as indices of this understanding have not been very successful.

However, ethnographic studies done in several cultures have begun to document the universality of the use of toys or natural objects to model large-scale environments (Blaut 1999, Stea et al. 1996). It has been noted that some three-and-a-half-year-old children are able to build model landscapes and to solve navigation problems on these landscapes. Such navigation problems involve getting from one place to another on the map in a 'realistic' manner, that is, by a route on the representation that would be reasonable in the 'real world'. However, a series of studies have found that while some spatial skills (micro-spatial puzzle and block-building ability; macro-spatial navigation ability) are present as young as age three-and-a-half, they do not necessarily appear and develop at

the same rate. This indicates that while spatial skills are related, they likely reflect different dimensions of cognitive development. Beyond age four-and-a-half, a majority of children studied appear capable of the above tasks, including navigation.

Studies done with children in a number of cultures have concluded that five-year-olds can verbally identify objects in an aerial photograph at scales of from 1:1000 to 1:3000 with minimal errors (although attempts to identify landscape objects at scales larger than 1:10,000 do result in some errors of scale). Further, such children can trace 'maps' from these photos, and can use these maps to solve simple navigation problems.

Slightly older children, in kindergarten through second grade, are capable of drawing quite complex maps. While these maps are plan views, overall, children typically draw the elements of such maps in elevation rather than in plan (e.g. house facades instead of house roofs), leading to the conclusion on the part of some psychologists that these children are unable to 'coordinate perspectives'. However, when seven-year-olds are asked to tell why they have drawn their maps in that way, they show full recognition that theirs is not a literal representation of an 'airplane view' of the world. On the contrary, they say that they are purposely trying to show what's most interesting about each object: a house facade is obviously more interesting than the view of the same house from above. That this is not simply a failure to coordinate perspectives is further indicated by the fact that many maps drawn by adults in the Middle Ages had the same characteristics.

2. Theoretical Controversies Concerning Spatial Aspects of Geographical Learning

In determining when children are ready for the introduction of geographic concepts in school, geographic education has been more concerned with the sequence of children's development than with their learning, in a psychological sense. The dominant theoretical paradigm in geographic education is that provided by the noted theorist and researcher in child development, Jean Piaget. In Piaget's view, all cognitive development, including spatial cognition, goes from lower to higher levels of conceptual and symbolic functioning, part of a more general set of competencies acquired in a stagewise, lock-step fashion (see Piaget and Inhelder 1956). Thus, such development is said to progress stepwise through four stages, which he termed sensorimotor, pre-operational, concrete operational, and formal operational, loosely associated with certain age ranges. Children at the sensorimotor and preoperational stages view the environment in relation to themselves and their own actions. Thus, according to this developmental view, children begin to be capable of true geographic learning only upon

reaching the concrete operational stage of development (Liben and Downs 1989). While Piaget stressed that his developmental sequence is to be measured in 'stages, not ages,' some influential educators, more comfortable with ages, have proposed that map concepts cannot be understood by children younger than seven.

An alternative theoretical perspective is termed 'universal mapping' (Stea et al. 1996). Universal mapping, while not directly challenging the general concept of developmental stages, suggests that the kinds of spatial skills that eventually result in the production and use of geographical maps transcend cultural differences and begin to appear very early in the life of the child. Universal mapping states that, throughout the development of the human species, people have had a need to construct mental representations of the environment at a geographical scale. Comprehension of maps requires perspective taking ability, in particular, moving from a three-dimensional real-world perspective to a two-dimensional, micro-level perspective. Thus, the theory proposes that young children have a 'natural' ability to represent the world in symbolic form at a reduced scale, rotated to the overhead perspective. Some proponents of universal mapping theory in its strongest form suggest that children may have an inborn mapping acquisition device analogous to the language acquisition device proposed by the linguistic theorist Noam Chomsky.

There is still some question as to whether and in what way mapping skills and spatial development are related. Piagetian theory has been interpreted by many educators to imply that children are incapable of engaging in the form of geographic learning called mapping at school-entering age. Universal mapping suggests, to the contrary, that some geographic abilities are so fundamental that their mastery by pre-school children can form a base for the teaching of other subjects in school.

Deciding between these two theoretical positions has been made more difficult by marked differences in methodologies used by their respective proponents. Studies have differed in dependence on verbal or nonverbal responses by children, interpretations of errors made in verbal responding, degree of generalization from results obtained in meso-scale (room-level) environments to macro-scale (geographical) environments, and widely divergent scales of material used in aerial photos studies, to name but a few. At present, it seems that while cognitive development certainly takes place, and probably in stages, this staged sequence is neither quite as stepwise nor as irreversible as originally proposed. It may be that transition between stages occurs earlier in the development of spatial abilities at the geographic scale than in other cognitive realms, indicating its importance to both human development in general and geographic learning in particular.

3. *Geographic Learning, Geographic Education, and Future Directions*

As children begin to master perspective taking and part-whole relations, they should become more adept at attending to elements that will aid in their learning map information. However, while learning about space at the geographical scale is one important aspect of geographical learning, learning about other characteristics of geographical environment, including its flora, fauna, landscapes, and geology, is also important. Thus, learning to map, while in many ways the keystone of geographic learning, is not all of it. With increased demand in US school systems to develop a systematic program of geography instruction, there is a need for standardized, cost-effective methods for delivering this information. Instruction via electronic media (e.g., videotapes, computer programs) can be both appealing and educational to young viewers. The success of such television shows as *Where in the World is Carmen San Diego?* provides one demonstration that programs can be produced which capture children's attention and at the same time stretch the boundaries of their geographic knowledge.

Geography instruction at the primary school level usually involves, at least in part, the comprehension of pictographic information, in particular, learning the spatial locations and boundaries of continents and geo-political regions such as countries and states. Because of its inherent visual and spatial content, geography lends itself well to instruction via electronic media. In fact, the types of visual and spatial content that are included in televised instruction can determine how readily that information is encoded and later retrieved from memory. For example, the addition of unique visual images can serve as a mnemonic aid for learning geographic shapes. Recent studies have demonstrated that visual icons, such as the Blue Ridge Mountains in the shape of Virginia, provided strong recall cues for state shapes (see Piñon 1999). Similar studies have shown the facilitative effects of icons and imagery in recalling map content (see Webb et al. 1994).

Geographic Thought, History of

1. General Conditions

1.1 Vernacular, Corporate, and Scientific Geographies

As a scientific discipline, geography has a long history. Its practice goes back to the time of Herodotus (484–425 BC) in the 5th century BC. The term itself was used in *De Mundo* attributed to Aristotle in the 4th century BC. Geography deals with orientation, the location of places, the surface of the Earth, the features which characterize it, and the way people conceive and experience places, the Earth, and the Cosmos. It means that geography existed as a practice of daily life before the development of scientific thought. People had to find places, evaluate the value of soils and the best way to plant them, detect and exploit mineral ores, etc. Many of these vernacular practices and knowledge coexisted simultaneously with the formal development of the discipline.

Since geography gives information on distant places, the ways to reach them, their economy, population, and culture, it is important for rulers. Governments rely either on empirical knowledge accumulated by local persons or on objective evidence gathered by their cartographic, statistical, and ethnographic services for the management of a territory. In the first case, the local agents of the sovereign know

the country they are in charge of so well that they can develop policies of their own. Hence, there is a tendency for all governments to develop centralized forms of control, for which they need special forms of geographic knowledge. Modern enterprises also have to develop geographic skills. They have to locate resources, exploit them, and distribute goods. A part of modern geography is linked with their activity.

The history of scientific geographic thought has always been situated in this context, with an eye to the type of practices used by ordinary people as well as to the skills developed by administrative services in gathering and interpreting spatial data. The discipline was institutionalized for several reasons:

(a) the will to provide the state (or other power institutions) with valuable knowledge for domestic control or overseas expansion;

(b) a curiosity for the low culture forms of geographic lore and their preservation; and

(c) the will to provide the citizens of modern nation states with an image of their country and the rest of the world in order to build or strengthen their national identity and explain how the contemporary world is working.

1.2 Geographic Narratives and the History of Geographic Thought

Geographic thought was expressed through standardized forms of narratives. The history of the discipline is partly that of the transformation of geographic discursive fields. What were the publics aimed at, the rhetoric used to attract or convince them, and the type of knowledge judged convenient for them? In Greek and Roman times for instance, according to one of the established geographic genres, geography was often presented as the account of a journey by Icarus.

From the Renaissance onwards, geography developed, as narratives on the newly discovered lands and the strangeness of their inhabitants, universal geographies, i.e., pictures of all the places and countries of the Earth, or quantitative assessments of the population, activities, wealth, and military assets of the provinces of kingdoms in order to facilitate their control. During the nineteenth and twentieth centuries, geographers developed other types of narratives: the description of exotic places for tourists and the analysis of national territories for the civic instruction of young people.

Geography is a complex discipline. Its changes are partly explained by the ways it was institutionalized and partly by the evolution of the discursive fields geographers developed in order to gain a large readership. However, its transformation mainly reflects the dynamics of its scientific purposes. It is convenient to distinguish five different scientific programs that were transformed into traditions later.

2. *The Five Approaches in Geography*

2.1 *Geography as a Science of Terrestrial Locations. Cartography*

The first program was linked with the problems of orientation. In order to build a reliable system of place locations, Greek geographers discovered that the best solution was to rely on an abstract grid of reference (Jacob 1991). The idea appeared with the first forms of mapmaking. For the Ionian mapmakers in the late sixth and early fifth centuries BC, all territories had geometric shapes. The idea of spherical coordinates, which appeared in the third century BC, was conducive to the first scientific cartography. At the same time, it provided a coherent grid of reference for locating places. As expressed by Ptolemy (AD 98–168), geography became ‘the sublime science which reads in the sky the image of the Earth.’

The Earth is a sphere and terrestrial positions, i.e., longitudes and latitudes, can be measured through the observation of the Sun and stars. Eratosthenes (273–192 BC) was the first to develop this line of research. Hipparchus (second century BC) proposed the idea of geographic coordinates. In the second century AD, Ptolemy synthesized the accumulated data in this field. His contribution was preserved and improved by Arabic geographers during the Middle Ages. The rediscovery of his texts in the fifteenth century marked a new start in the history of geographic thought. In the seventeenth century, Bernhardus Varenius (1622–1650) modernized the cosmographic approach through the introduction of the Copernician view of a Sun-centered Universe.

The major problem for this conception of geography came from the impossibility of keeping time, so that astronomical observations were unable to give a measure of longitude—a weakness which subsisted from Antiquity to the discovery of the marine chronometer by John Harrison (1693–1776) in 1735. Until the mid-eighteenth century, one of the main tasks of geographers was to compile data relative to distances in travel accounts. From the mid-eighteenth century, mapmaking became the task of specialized engineers and scientists. They provided geographers with the topographical maps they needed.

Geographers ceased to be responsible for the basic cartography, but the problems of location and mapmaking remained important for them. Their role changed; they learnt in the nineteenth century to use statistical sources to produce thematic maps. During the twentieth century, remote sensing facilitated the gathering of data on land use, vegetation, temperatures, atmosphere, etc. Thanks to computing facilities, the building of geographical information systems has recently become easy; one of the most prized skills of contemporary geographers is to provide administrations or firms with this new cartographic aid to decision-making.

Thanks to cartography, geographers were the first able to describe the Earth as seen from the sky—the Icarus’ viewpoint, according to Greek geographers. It was essential for getting an objective description of the face of the Earth and its regional divisions.

2.2 *Geography as Description. The Regional Approach*

The second agenda developed by geographers was the description of the Earth’s surface and its regional differentiation. During Antiquity, it was illustrated by Herodotus, Marinus of Tyre (first or second century AD) and Strabo (64 BC–AD 20). Arab geographers improved much of the knowledge of the Middle East, India, the Far East, and Africa south of the Sahara. With the great discoveries, the program became really worldwide.

The main problem was: What to describe and how to describe it? Thanks to the map and the vertical perspective it offered, geographic description was different from the travelers’; it was not structured along itineraries, but on the apprehension of regional units as seen from above. Such a perspective allowed for the contraction of much information, but it destroyed the link between direct observation and description, hence the dryness of many descriptions until the eighteenth century.

Because there was no standardized vocabulary to speak about the details of topography, rocks, plants, animals, and human activities, geographers were unable to grasp the real world in their narratives. Sometimes, they preferred to provide their readers with information on local mythology (in the Greek and Roman times), the history of Christianity (during the Middle Ages), and the local coats of arms and heraldry (in feudal Europe). In a way, the travel accounts of the Middle Ages and Renaissance are generally more interesting for today’s geographers than the geographical publications of the time.

Everything changed in the eighteenth century, with the development of natural history and a new curiosity for human activity. The work of Linné in botany and zoology, a few geologists for rocks, and the first agronomists for rural life, created the technical terms geographers needed in order to write precise descriptions of the world. Thanks to Jean-Jacques Rousseau (1712–1778) and Johann-Heinrich Pestalozzi (1746–1827), geographers began to offer descriptions on two scales: one was based on both fieldwork and direct observation, and the other on the synthetic vision of the map-reader. Carl Ritter (1779–1859), one of the pioneers of modern geography, has been trained in a Pestalozzian school, just as Elisée Reclus (1830–1905). Alexander von Humboldt (1779–1859) discovered the value of first-hand contact with landscapes through his training as a natural scientist and his contacts with

Georg Forster (1754–1794), who was on Cook's second voyage around the world.

The quality of geographic description kept increasing with the development of new scientific fields: pedology, meteorology, and climatology on the natural side of the discipline, and agronomy, demography, and social and cultural anthropology on the human one. Many of these research fields were initially explored by geographers and then turned independent.

Because of the improvement of geographical descriptions, geographers conceived their discipline in a different way: they began to consider that one of its major advantages was to deal with the real world. The idea that geography was a science of concreteness appeared. Geographers did not consider themselves only as scientists; description was an art, so that they had to display a literary bent.

During all of the nineteenth century and a good part of the twentieth, when writing descriptions, geographers felt to provide impartial views of the world since their work was based on objective observations. They considered that the descriptions and modes of regionalization developed by laymen were subjective and as such, not reliable. They preferred to ignore them.

2.3 Geography as Explanation: The Perspective of Natural Philosophies and Natural Sciences

As soon as description progressed in the eighteenth century, a third task appeared for geographers: they had to explain the distributions they observed. A precise description was necessarily conducive to questions about the causes responsible for the patterns read on the maps or the features discovered through fieldwork. Geographers had to give an explanatory dimension to their analyses.

During the first half of the nineteenth century, the main interrogation was about the interaction of natural features, their mutual conditioning, and their influence on the destiny of human groups. In the seventeenth century, Varenus had opened the way through his analysis of position. In order to explain terrestrial distributions, he stressed the role of latitude and of the major topographic accidents. He opposed inland and coastal locations. In the first half of the nineteenth century, this approach was transformed into a coherent paradigm: the analysis of position, well exemplified by Alexander von Humboldt and systematized by Carl Ritter. The major factors in the shaping of the Earth and the explanation of regional distributions were latitude, altitude, continental versus coastal locations, and the patterns of mountain ranges and coastlines. This kind of analysis had to be developed at different scales.

Geographers used these tools to explain the distribution of particular natural features: the altitudinal patterns of vegetation in tropical mountains for Alexander von Humboldt. Ritter wished to explain

how the destiny of peoples was shaped by the countries they inhabited. Behind these projects, the influence of early nineteenth century philosophies was obvious. Humboldt stressed the harmony between the different levels of the geographic reality according to the natural philosophies of his time. Ritter followed Herder (1744–1803) when exploring the influence of environment on cultures.

This first type of explanation, linked with the German philosophies of late eighteenth and early nineteenth centuries, was displaced by a natural science perspective when Charles Darwin (1809–1882) stressed the role of the environment in the transformation of life. Geographers of the late nineteenth century, Friedrich Ratzel (1844–1904) in Germany and Paul Vidal de la Blache (1845–1918) in France, built human geography on this evolutionist, either Darwinist or neo-Lamarckian basis. Their ambition was to explain human distributions through the analysis of the mainly 'vertical' (or local) relations people had with their milieu. In fact, they combined the analysis of position inherited from Ritter with an ecological approach. They stressed both the significance of local environments (the ecological approach) and of circulation (the analysis of position). The risk with the ecological approach was to accept a deterministic interpretation of human beings/nature relationships. Circulation offered a way to escape this danger.

Vidal de la Blache used the idea of *genre de vie* as the main concept of the new approach. In order to exploit an environment, people developed sets of techniques and practices that were soon transformed into a way of life because of the force of habits. The main interest of the *genre de vie* notion was to give a social dimension (the force of habits) to human geography and to stress the role of techniques in the mediation between human groups and the environment.

Even if Ratzel and Vidal de la Blache were conscious of the significance of circulation, their human geography tried mainly to explain the influence of physical geography on human distributions and the way people took advantage of natural endowments. The role of social relations and of distance as an obstacle to interaction was practically ignored. Human geography was at its best when it used the *genre de vie* paradigm to explain regional structures through the interaction between physical forces and social groups. Unfortunately, this approach could not work in urbanized and industrialized societies, where *genre de vie* became too complex to be a useful means of investigation.

Because human geography was unable to explain satisfactorily the distribution of social groups and artifacts on the surface of the Earth, some geographers, specially in Germany, preferred to define geography as the science of landscape, which avoided splitting the discipline between natural and social parts.

The analysis of position played a central role in the first efforts to investigate political geography. Alfred T. Mahan (1840–1914) and Halford Mackinder (1861–1947) stressed the opposition between inland locations and coastal ones. This theme became central to geopolitical studies in the first half of the twentieth century.

Thanks to the natural sciences, an explanatory dimension had been introduced in geography. Geographers succeeded in organizing efficiently physical systematic disciplines: geomorphology, climatology, biogeography, pedology, hydrology, oceanography, etc. On the human side of the discipline, the results were less impressive. Geographers capitalized more on the analysis of position than on the ecological paradigm. Even cultural geographers like Carl Sauer (1890–1975) did not try to explore systematically the role of techniques in the distribution of human groups. By the mid-twentieth century, a feeling of dissatisfaction had developed in human geography.

2.4 *Geography as Explanation: The Social Science Approach*

Many geographers tried to give a new start to their discipline. The most successful was Edward Ullman (1912–1976). His diagnosis was clear. Human geography failed because it was conceived as a natural science. Overemphasis had been given to the study of human beings/milieu relationships. Circulation, the other face of human geography as defined at the end of the nineteenth century, had been neglected. In order to build a modern geography, emphasis had to be given to social interaction (Ullman 1980).

Geographers discovered that economists had developed an interest for spatial economics since the beginning of the nineteenth century. They had explored the influence of distance upon the location of farming, industrial activities, and services. Geographers decided to take advantage of the results of spatial economics to give a more systematic dimension to human geography. It was the basis of the new geography of the late 1950s and 1960s.

In a way, this new geography translated Ritter's position into social terms. Instead of focusing on the opposition between inland and coastal locations, for instance, it focused on the dialectics between center and periphery. The center was defined in terms of social physics as the point or the area that enjoyed the highest accessibility to the totality of a social group. Procedures were invented to measure centrality and to map it. The idea of population or income potential changed the traditional vision. Instead of the center as a point, it presented the center as an area. In the United States, a central core, the manufacturing or industrial belt, appeared as the main feature of the territorial structure.

Geographers relied on spatial economics to develop their new understanding of human geography, but they went far ahead of economists in their analysis of spatial organization. The regional geography of the first half of the twentieth century fell short of a systematic formulation. Thanks to the works of Edward Ullman, Torsten Hägerstrand (born 1916) and a few other geographers, the way space was organized—through specialization, the development of networks, the dynamics of scale and external economies, and the opposition between center and periphery—became clear.

During the 1970s and 1980s, a few geographers, for instance, Paul Claval (born 1932), tried to extend the analysis of spatial interaction to non-economic aspects of social life, either social relations or political structures. Instead of focusing on transport costs, they analyzed communication, the structuring influence of commutation costs, the role of medias, and the significance of symbolism. In this way, they provided a new understanding of the dynamics of globalization, so evident from the 1960s.

The emphasis on social interaction had positive effects on geography in many respects, but it reduced the interest in the ecological approach at a time when ecology came really of age and pollution became a major problem at the local, regional, and global levels.

2.5 *Geography and Postmodernity: The Cultural Approach and the Experience of Nature, Place, and Society*

From the early 1970s, a strong critical movement developed in geography. Young colleagues struggled against the conception of their discipline as a natural science and the interpretation that was given to its social dimension. The positivist approach considered social relations as natural facts. It ignored their historical dimensions and their creation through human agency. As a result, neo-positivist geographers did not criticize the hierarchical structures and spatial organizations of the groups they observed and explained, even if they were conducive to exploitation and oppression.

From the eighteenth century, a different conception of geography had developed. In his *Géographie politique*, Turgot (1727–1781) wished to promote new geographies much more than to explain the existing one (Turgot 1808–1811). It was one of the main features of the geographic projects of the Enlightenment. The critical tradition was represented during the nineteenth century by anarchists like Elisée Reclus and Peter Kropotkin (1842–1921), who made it illustrious, but the prevailing option for a natural science approach restricted their influence.

At the beginning of the 1970s, David Harvey (born 1935) played a decisive role in the development of a new interest for social justice (Harvey 1973). However,

the break with the neo-positivist positions of the 1950s and 1960s had other correlates. If social realities are the product of human agency, it is urgent to study the ways people experience places and conceive nature and society, the dreams they have about their future, and the significance they give to their lives. Geographers can no more ignore the ways people organize their existence. The rigid division between vernacular or corporate geographies on the one side, and scientific ones on the other, fades out. Scientific geographers have to explore the geographies of lay people in order to understand the landscape they shape and the institutions they create. Ethnogeography becomes a new field of investigation.

There was an old but limited interest in people's conceptions of place thanks to the analysis of choronyms. The development of new attitudes among geographers had not been possible without the influence of Heidegger (1889–1979). Eric Dardel (1902–1968), in France, was well aware of the significance of his philosophy, as Yi-Fu Tuan (born 1930) or Edward Relph (born 1944) a generation later.

When societies are conceived as a product of human activity, i.e., in an historical perspective, it becomes important to understand the practices, attitudes, knowledge, and beliefs shared by social groups, the techniques they master in the fields of material activity and social life, and the significance they give to their lives. The cultural approach, which had been mainly developed by Carl Sauer in the first half of the twentieth century and had experienced a crisis in the 1960s and early 1970s, benefited from a new popularity thanks to Denis Cosgrove (born 1948), James S. Duncan (born 1945), Joël Bonnemaison (1940–1997), and Augustin Berque (born 1942). It was one of the main frontiers in human geography from 1980 onwards. Culture ceased to be considered as a collective heritage. It was analyzed as a continuous process of communication, adaptation, evaluation, and refurbishing.

The criticism of the neo-positivist conceptions of social sciences was by no means restricted to geography. The transformations of the discipline were parallel with new orientations in sociology, anthropology, and history. Geographers discovered the interest of the Clifford Geertz's type of thick description as a tool to explore ethnogeographies and enter the complexities of cultures.

Under the aegis of French deconstructionist philosophers, Jacques Derrida (born 1930) and Michel Foucault (1926–1984) for instance, social knowledge was increasingly analyzed as a tool to legitimize the Establishment and gain support for governmental policies, whatever their content. Geographers began to scrutinize geographical narratives and look for their hidden significance. They got increasingly aware of the role of geography as an instrument to build efficient forms of social control. Thanks to Derek Gregory (born 1951), the study of geographical imaginations

and of their role in social life and power situations became popular (Gregory 1994).

The new epistemologies are increasingly critical of the great narratives of the past. Geographers are reluctant to rely on macro-theories or philosophies—historical materialism for instance. They develop a growing interest in the local and privileged micro- or meso-theories. They explore realms that had been previously neglected: gender geography, the geography of young and aged people, the varied forms of segregation, and exclusion or sexual differences that most societies build.

Men and women do not live in a standardized, sterilized, and acclimatized space. They inhabit specific places, develop territorial identities, and use landscape markers as symbols of what unite them and provide them with a sense of shared community. Consequently, geographers are increasingly concerned with the religions, philosophies, or ideologies people create in order to give significance to their lives. They explore the moves the human mind performs in order to discover perspectives of society, nature, and collective destiny, and build values. Transcendence and immanence are wrongly considered as purely philosophical concepts. They have a spatial dimension; geographers have to explore them.

Men and women are part of nature; they live in nature, with nature (Harvey 1996). The ecological perspective has been completely recovered. Geographers are increasingly involved in the study of the energy and material relations which develop between human beings and their environment, and in the analysis of the attitudes towards nature, the significance given to natural landscape, and the management of the planet Earth.

Contemporary geography goes much deeper into the analysis of social and psychological processes than was the case in the 1970s. At the same time, it has become a more critical and modest discipline. For many of the young radicals, scholars have to refrain from building mega-narratives, as in the past. It is better to concentrate on limited problems.

3. The Coexistence of Perspectives Instead of the Displacement of Paradigms

Kuhn's interpretation of scientific revolutions was very popular among geographers in the 1970s. They interpreted the new geography of the 1960s as a new paradigm. In fact, the history of geographic thought does not fit well into the Kuhnian model. We have distinguished five traditions, but when a new one appeared, it did not displace the older ones. The interest in location and map making is less central today than in Antiquity or modern times, but it is still fundamental to the discipline. Description as an intellectual venture worth pursuing for its own sake has long ceased to be fashionable, but progress in the

analytical instruments offered by other natural or social sciences allows for new readings of landscapes and maps, and the discovery of new patterns. It makes geographers aware of new problems.

Geography as a natural science and geography as a positivist social sciences are still alive. They provided geographers with many of the tools they use, the analysis of position both relative to physical factors along Ritter's views, or social distributions according to Ullman's conceptions, and the ecological approach to human beings/milieu relationships. Many colleagues try to develop more performing models of economic or social distributions. The emphasis on communication is a new development of an old curiosity.

When building a periodization of the history of geographic thought, the development, fading out, and renewal of geographical traditions constitute only one component of the whole picture.

Greek geography was born out a Kuhnian revolution, the invention of the grid of meridians and parallels, but its successes came partly from its role as a repository of Greek culture. With the development of empires, first in Alexandria and then in Rome, it became a useful tool for the new bureaucracies because of the maps it produced and the descriptions it provided.

The decline of the Classical tradition in the Middle Ages reflected the disappearance of imperial polities in Western Europe and their displacement by feudal structures, which did not involve explicit corporate geographies. Maps were used as symbols of the monarch's power, not as a tool for his or her action. Because of the development of trade from the eleventh century, new cartographic and geographic instruments were needed—hence the invention of Portolano charts. In the Arab world where imperial polities played an important role, the fate of medieval geography was far better.

The new phase of development of geography which started from the Renaissance was linked with the rediscovery of Ptolemy and the cartographic perspective, the voyages of discovery, the rise of the modern state with its proto-bureaucracies, and new forms of corporate economic activities. For two centuries, geography remained based on the two perspectives of cartography and regional description.

The eighteenth century was as a major turning point. The cartographic limitations disappeared thanks to an easier measure of longitudes. Because of the progress of natural sciences and the birth of social sciences, geographic description improved much and ceased to be problematical. This kind of description necessarily led to an interest in explanation. The transition from pre-modern to modern forms of geography was a difficult one and lasted for about a century, since it meant a change in the institutionalization of the discipline: from state cartographic services to universities.

The naturalist orientation that was born at the beginning of the nineteenth century, prevailed until the mid-twentieth. From that time, geography became first a neo-positivist social science, and then a discipline, partly scientific, partly humanistic, or philosophical, based on human experience and the significance of the human presence on Earth. Institutionalization began once again to change. Geography is increasingly dependant on research institutions and private funding.

Geography offers the intellectual tools that are needed to understand the contemporary acceleration of globalization. It explains why technical uniformity is conducive to new forms of regional organization and does not entail the destruction of all spatial differentiation.

What will be the future of the discipline? As in the past, a part of the specialty fields it nurtured will develop as fully-fledged sciences of their own. The technicalities of contemporary physical geographies will deepen the gap between them and human geography. The future of geography as a unitary discipline is perhaps more on the reflective side than on the analytical side of human knowledge.

Geography

The practice of geography—literally ‘earth writing,’ from the Greek *geo* and *graphein*—goes back at least 2000 years, but it has a much shorter history as an academic discipline, with little formal presence in universities before the twentieth century. There have been many attempts to define it: one widely accepted in the mid-twentieth century saw it ‘concerned to provide accurate, orderly, and rational description and interpretation of the variable character of the Earth surface’ (Hartshorne 1939, p. 21). Its focus remains areal differentiation, but it has moved beyond cataloging and description to *analyzing and providing explanatory accounts for the nature and implications of the material character of the earth’s surface and its use by people and societies*. Its key concepts are space, place, and environment, each studied at a variety of scales.

Although most definitions and university departments of geography embrace both physical and human worlds, studies of the two are now substantially separate components of the discipline. This article focuses on human geography, that part normally affiliated to the social and behavioral sciences.

1. Intellectual Origins

As a source of information about the earth, geography has been important to all societies. It was part of the curriculum at Cambridge and Oxford Universities by the late sixteenth century, for example, taught for its practical value with two main themes. The provision of locational information involved cartography, on which a wealth of early material in many cultures has been identified. Alongside was chorology, the description of physical environments and their inhabitants. Geographers portrayed the different parts of the world, meeting the needs of traders, diplomats, and the military and also whetting the curiosity of the ‘educated classes.’

Although geographical material was widely disseminated and used, there was no formal discipline with institutional status in universities. This was countered in the nineteenth century by societies founded to promote the dissemination of geographical knowledge (Livingstone 1992): many were closely linked to imperialist projects and actively promoted exploration of extra-European *terrae incognitae*. The

first university chairs and departments were established by royal decree in Germany in the 1870s; they were to prepare school teachers, as part of the creation of an educated citizenry, and to sustain colonial and military enterprises. Similar successful campaigns elsewhere included the Netherlands, where the first established chair was in ‘colonial geography,’ and in England, where the Royal Geographical Society provided financial assistance to establish departments at Oxford and Cambridge, although the first honours degrees in geography were awarded at Liverpool, in 1917. The departments were small but provided the foundation for substantial expansion after World War II, when there was a geography department in nearly every British university and a graduate school in 27 United States’ universities.

2. The Creation of a Discipline

The subject matter taught in these new departments focused on the inter-relations among peoples and environments, as conceived by several important German and French geographers (such as von Humboldt, Ritter, Ratzel, and de la Blache: Livingstone 1992). Geographers sought a unique intellectual rationale within the academic division of labor, increasingly so as universities adopted the German tradition of marrying teaching with research. Of the six trends that Freeman (1961) identified up to c.1950 (encyclopedic, educational, colonial, generalizing, political, and specialization), the generalizing trend became increasingly important, with individual specialization as a necessary consequence.

The emerging practice of geography was strongly influenced by its milieu (Livingstone 1992). Debates in the first half of the twentieth century crystallized around the concept of the region. Hartshorne (1939, p. 462) presented geography as:

... a science that interprets the realities of areal differentiation of the world as they are found, not only in terms of the differences in certain things from place to place, but also in terms of the total combination of phenomena in each place, different from those at every other place.

Regions possess unique characteristics based on their inter-related physical and human environments, and regional geography aimed (Wooldridge 1956, p. 53):

... to gather up the disparate strands of the systematic studies, the geographical aspects of other disciplines, into a coherent and focused unity, to see nature and nurture, physique and personality as closely related and interdependent elements in specific regions.

This identifies two long-recognized strands in geographical practice: the systematic, focusing on particular subject matter, and the regional, concentrating on specific areas.

There were common elements to geographical practice in those countries where it was established early:

Hartshorne's 1939 essay exemplified the strong German influence on American geography, for example, and much regional geography was based on classic French work. The links between the different language realms weakened after World War II, however (Johnston and Claval 1984): the remainder of this article focuses on the English-speaking world.

2.1 A 'New' Geography

Systematic specialization increasingly dominated the expanding discipline in the mid-twentieth century, with two significant intradisciplinary divides: a split between physical and human geography; and the creation of separate specialisms within each. Regional geography declined in importance as a research field, but remained important in the discipline's teaching. The early systematic strengths were in historical geography, particularly strong in the UK (led by Darby and his major work on the Domesday Book: Darby 1977), and cultural geography in the USA, led by Sauer (1952) and with strong links to anthropology. Economic, political, and social geography were small enterprises until the second half of the twentieth century.

Two strongly linked developments in the 1950s/1960s—termed 'quantitative and theoretical revolutions'—generated an explosion of interest in both physical and human geography. Quantitative methods were adopted to handle spatial data, but the 'revolutionary' component within human geography involved explicit consideration of theory, notably location theories whose key element was a geographical variable—space, usually represented as the cost involved in moving people, goods, and information. Classic works on the location of agricultural land uses industry and retail establishments (notably Christaller's central place theory) were appropriated and formed the basis for a 'new geography,' a spatial science whose goal was identifying and accounting for spatial order. This was largely North American in provenance, initially focused on a few departments (Johnston 1997), but the approach soon infiltrated other parts of the discipline, assisted by two seminal British anthologies (Chorley and Haggett 1965, 1967). Further spatial theories were added—on the diffusion of innovations and the widely-applied gravity model for studying flow patterns—and the entire corpus was synthesized in influential text books, notably Haggett (1965) and Abler et al. (1971).

The expansion was accompanied by increased specialization. Economic geography spawned subdivisions of industrial, agricultural, transport, and development geography, for example; urban geography grew a substantial subsector in urban social geography and was paralleled by interest in rural geography; social geography begat population and medical geography; and political geography was both

revived and spawned electoral geography. The shared goal was the discovery of spatial order—in both individual behavior patterns and their outcomes in the built environment.

Although diverging systematic interests reduced links between physical and human geographers, they explored common ground in techniques of spatial analysis and approaches to knowledge. The switch from an ideographic focus on unique characteristics of places to a nomothetic search for spatial order largely occurred in a philosophical vacuum, but some geographers promoted the positivist approach to knowledge production (Bunge 1966, Harvey 1969).

These shifts occurred when the discipline was expanding rapidly within universities. Their promoters achieved major intradisciplinary changes by portraying spatial science as meeting contemporary needs among the burgeoning, increasingly quantitative and theoretical, social sciences. They presented the regional approach as outdated: the concepts of areal differentiation and region were retained—though employed in different ways.

2.2 '-Isms,' Schisms, and 'Turns'

Although some promoted this 'new geography' as surpassing its predecessor, there was no complete revolution to a new hegemonic paradigm in the Kuhnian sense. Not all geographers were won over, and some continued to teach and research in their established ways—sustaining the traditions of historical, cultural, and regional geography which were foundations for later responses to the 'shock of the new.' Those responses criticized spatial science on two main grounds. The first attacked location theories for narrow economism, for privileging profit-maximizing (translated geographically as transport-cost-minimizing) as a determinant of decision-making and so denigrating the wide range of cultural and other influences on behavior. Spatial science, it was claimed, removed free will by assuming that humans react to stimuli in predetermined ways while its elevation of space as the predominant influence on locational decisions led to a derogation of place. Some critics explored alternatives to positivism—such as phenomenology, idealism and existentialism—in work categorized as humanistic geography.

The second set of criticisms concerned spatial science's approach to explanation. Location theories, it was argued, could not account for the major contours of the geography of development and underdevelopment at various spatial scales, of inequality and injustice, wealth, power, and discrimination. Explanation required understanding how economic systems, especially capitalism, work and involved more than adding the costs of transport and communications to neoclassical economic models: such explanation could be achieved through Karl Marx's writings. Harvey's (1973) collection of essays initiated

a series incorporating space to Marxian thought (notably Harvey 1982) and stimulated others during a period of social tensions over civil rights and the Vietnam War. Their work became known as radical geography.

Although both critiques attracted adherents, many were as dissatisfied with each as they were with spatial science. As Gregory (1978) demonstrated, whereas some spatial scientists strayed very close to naive economic determinism, much humanistic geography approached another extreme of voluntarism, tearing the individual out of context, while some radical geography offered little more than an alternative economic determinism. Much effort was spent in the late twentieth century integrating aspects of humanistic and radical geography.

3. *The Contemporary Discipline*

Sheppard (1995) divided human geographers into two main groups—spatial scientists and social theorists; strands of contemporary geographical scholarship that operate somewhat independently (Johnston 1997). Some recent textbooks in the ‘social theory mold’ dismiss spatial science as part of a discredited past (as in Peet 1998), whereas a volume promoting geography within the US scientific community concentrated on it (plus physical geography; NRC 1997). Attempts at comprehensive overviews include anthologies which lack integration (e.g. Gaile and Willmott 1989, 2001) while the editors of a volume on the ‘pervasive themes’ and ‘common elements within a discipline whose practitioners are in danger of forgetting their shared heritage and ideals’ concluded that not only had they failed to bridge the human–physical divide but they also feared a similar divide was opening within human geography (Abler et al. 1992).

3.1 *Spatial Science*

Spatial science remains a substantial component of contemporary human geography. It is strongly quantitative, but the formal (geometrical) location theories based on a single causal variable (space) have largely been abandoned: the search for spatial order neither anticipates the discovery of regular structures nor seeks universal laws of spatial behavior. Sayer (1984) drew an important distinction between extensive and intensive research: the former seeks empirical regularities whereas the latter explores the causal chains responsible for particular outcomes. Much spatial science is extensive research, a necessary precursor to many detailed investigations; by not eschewing empirical generalisations, it identifies significant features and trends in the mass of numerical data which characterize modern societies.

In the 1950s–1970s geographers assumed that standard statistical procedures could be applied unprob-

lematically to analyses of point, line, flow, and area patterns. This was challenged by work on spatial autocorrelation, which identified a range of problems and proposed new methods of spatial data analysis (e.g. Haining 1990). Other issues identified included the modifiable areal unit problem. Some geographical analyses study the characteristics of populations aggregated by areas (such as census administrative units), but there is an extremely large number of ways in which such places can be defined, involving both scale (how large are the areas?) and aggregation (how many different ways can areas of the same size be created?) effects. Openshaw (1985) showed that different aggregations can produce divergent statistical results, creating problems in deciding which to employ. There are also related geographical examples of ecological fallacies—assumptions that results for a particular dataset can be generalized to others at different scales and/or aggregations (including individuals). Various procedures for attacking these problems and providing robust solutions are exemplified by essays in Longley and Batty (1996), many significantly assisted by developments in computing power (including applications of artificial intelligence) and stimulating the conception of geocomputation to describe such work in both physical and human geography (Longley et al. 1998).

The most significant technological developments have been in geographical information systems (GIS: Longley et al. 1999), combined hardware and software for the organization, integration, analysis, and display of spatially-referenced data, with the powerful display media underpinning the growth of visualization strategies. These systems have revolutionized spatial analysis and led to the identification of a geographical information science: traditional studies can be undertaken much more readily and quickly; exploratory studies are increasingly feasible, and large-scale modeling strategies integrating datasets collected on different spatial templates made possible.

Much contemporary spatial science, including GIS, is applied in a wide range of public and private sector contexts—as in spatially-targeted niche marketing strategies based on small-area classifications (geodemographics). This has partly been in response to changes in the economic context for universities: the pressure to increase nonstate income has stimulated ‘applied research’ and has seen the development of such skills as a major selling point in the attraction of students to read for geography degrees (see NRC 1997).

3.2 *Social Theory*

Although spatial science remains a substantial component of the discipline, to many human geographers approaches involving social theory form the disciplinary mainstream (as in Massey et al. 1999). Humanistic and radical geography have metamorphosed

into new forms, although some maintain allegiance to the latter—notably Harvey (1989) and his continued reworking of Marxian approaches for understanding the contemporary world.

Work within this umbrella category focuses on understanding difference. Place now takes precedence over space among the main geographical concepts (on the tension between the two, see Taylor 1999): places provide contexts within which differences are produced and reproduced. But places are not fixed containers; like spaces, they are produced and continually reproduced by human action so that whereas in spatial science space is an exogenous independent variable (though modifiable, as in transport network developments), in social theory it is both independent and dependent variable (as stressed in Martin's 1999 critique of the 'new geographical economics' which relates more to the spatial science of the 1970s than to either strand of contemporary human geography). The interactions between people and places/spaces continually transform both, introducing a geographical component to the structure-agency dialectic for which Giddens (1977) sought a resolution in his structuration theory, very influential in human geography in the 1980s. People make their own histories, but within constraining/enabling spatial contexts—locales, or settings for interaction. (Giddens 1984 was one of the few social theorists who not only used spatial metaphors in his writings but was also influenced by geographical work, notably time-geography—e.g. Hägerstrand 1982—which draws attention to the geographical constraints on how individuals pursue personal and collective projects.)

A very important stimulus to recognition of the role of context/locale in the production and reproduction of difference came from feminist geography. Initially launched to highlight the discrimination against women within a male-dominated discipline and the consequential many silences in what geographers studied, this expanded into a much wider critique of 'single-factor' approaches (such as Marxist's concentration on class and the economic infrastructure) that ignored important other societal cleavages (Women and Geography Study Group 1984, Rose 1993). People viewing society from different positions create separate identities of self and other, which are potential foundations for identity politics. The class struggle is not the only one within capitalist society, and others (based on sexual orientation, race and religion, for example, as well as gender) cannot be folded within it.

Other stimuli came from postmodernism, which also emphasized difference and rejected the search for grand theories. Dear (1988) and introduced it to geographers as a way of addressing the contemporary condition, exemplified in the argued transition from a Fordist regime of accumulation, characterized by mass production of uniform commodities for mass consumption, to post-Fordism, characterized by small

niche markets and consumption for status as well as use (sometimes called flexible accumulation). Harvey (1989) countered by arguing that this shift, involving the production of new spaces and places, is but the latest response to a crisis of capitalism.

More important has been the impact of the various strands of poststructuralist thought derived from the humanities and social sciences. Poststructuralists argue that human subjectivity is not given but rather produced in contexts. So much of that production process is spatially and temporally contingent that truth and knowledge are contingent too, varying through time and over space in a range of situated and local knowledges that form the resource foundations for structuration dialectics and identity politics. Representation of these contingencies is crucial to social conduct, and poststructuralists stress the importance of language not only as the communication medium involved in creating human subjectivity but also as a social construction itself, with variations that are fundamental to the creation and understanding of difference (i.e. in the relationship between the signified and the signifier and in its interpersonal transmission—the hermeneutic process). Language is just one means of communicating understandings, however, and as well as interpreting written texts geographers have focused on other images (works of art, films, landscapes) implicated in the creation of situated knowledges—as in Harley's (1989) seminal work on deconstructing maps.

Said's (1978) book on the Western creation of a 'mythical East' was an important stimulus to geographers' studies of the roles of images of places and spaces in the creation and transmission of meanings and identities. They have embraced the postcolonial movement which challenges not only the political and economic components of colonialism and imperialism but also their roles in creating imaginative geographies at variance from those of the peoples who experienced that external power and are creating alternative geographies, knowledges, and identities through their own writings.

Many of these arguments were introduced through cultural geography but not confined to it and have been instrumental in reducing some of geography's fragmentation. Several parts of the discipline have experienced a 'cultural turn': the perceived interdependence of cultural and economic processes, for example, has stimulated broader studies of production, exchange, and consumption (Lee and Wills 1998); critical geopolitics emphasizes the ways images of the world are created, transmitted, and underpin geographies of power and conflict (O'Tuathail 1996); and writing on nonrepresentational theory focuses on the transitory, the 'billions of happy or unhappy encounters' (performances) which characterize the daily interactions among people, places, environments, and 'things' but are never recorded/represented in the traditional source materials for geographical schol-

arship (Thrift 1996). At an extreme of spatial scale heretofore ignored, geographers are also exploring the body as a site of identity-formation, as the most intimate of 'personal spaces' or 'the geography closest in' (Pile 1996).

Research within this area is both catholic and eclectic in its substantive interests. Space and place are being theorized in a wide range of contexts and scales. There are increasing links with other social science and humanities disciplines experiencing a 'spatial turn,' both in their use of spatial metaphors and in their appreciation of the roles of space and place in the structuration of people and societies.

Such work is very far from most spatial science and there is little methodological or philosophical common ground: one area of interaction, however, has emerged from critiques of the representations of the world created within GIS (Pickles 1995) and, more broadly, in cyberspace (Kitchin 1998). Social theory also lacks an 'applied' element as generally appreciated by those promoting geography as a 'relevant' or 'saleable' discipline (hence the absence of much on social theory in NRC 1997). Critical human geography is increasingly used to categorize work committed to emancipation, however, clarifying ways in which space and place are manipulated in the creation and maintenance of power relationships. This has a strong moral/ethical component, concerned not only with how geographical research and teaching are conducted but also with evaluating what is right and wrong, good and bad (Smith 1994, Sack 1997).

One area of traditional geographical interest revived by social theorists is the study of people-environment interactions, on which there has been a continuing stream of studies on various aspects of environmentalism, human impacts on the environment (Turner et al. 1990), environmental policy, and political economy approaches to environmental problems and issues. Poststructuralists argue that nature is a social construction—work on nature-culture interrelationships must take account of the cultural constructions of nature even the binary nature: culture categorization sets up an unreal opposition since each is part of the other. Writing on society-nature interrelationships has thus been substantially broadened, expanding from the technical issues involved in the production of 'environmental problems' and the political ones in their 'solution/resolution' to raise fundamental questions regarding the role of humans in nature. Some argue that studies of the environment can integrate physical and human geography (Simmons 1997) and present a major opportunity for geographers to undertake relevant research.

4. Conclusions

Human geography is a large, expanding, and vibrant discipline, characterized like most others by fragments and tensions: its extent and the nature of the expansion

can be appreciated by comparing the four editions of *The Dictionary of Human Geography* (Johnston et al. 2000). It has an established niche without the academic division of labor; its core concerns remain those crystallized over a century ago; and its basic concepts remain place, space, and environment. Within those general characterizations, however, the discipline has changed markedly in recent decades, not only in what it studies but also in how and why. Buttimer (1993) has suggested that throughout their discipline's history geographers have regularly shifted among four foundational metaphors (mosaic, machine, organism, and arena)—without the academic revolutions that are central to Kuhn's (1970) paradigm model of scientific progress. Contemporary spatial science employs the mosaic metaphor with its emphasis on spatial order (without the earlier determinist overtones when the machine metaphor was employed to 'explain' those mosaics), whereas social theory concentrates on organism and, especially, arena—the spatial contexts, or places, which are involved in the production of human-ness while being produced and reproduced by humans.

Geopolitics

The idea of geopolitics evokes mixed reaction. It is understood variously as: a set of geographically determined 'laws' governing a state's strategic destinies; the geographical underpinnings of *Realpolitik*; and a scholarly analysis of the geographical factors underlying international relations and guiding political interactions. Widely embraced by policy makers, geopolitics has encountered scholarly criticism for its sometimes deterministic doctrines and lack of moral considerations.

1. Definitions

Geopolitics is a product of its times, and its definitions have evolved accordingly. Johan Rudolph Kjellén, who coined the term in 1899, described geopolitics as 'the theory of the state as a geographical organism

or phenomenon in space' (Kjellén 1916). For Karl Haushofer, the father of German Geopolitik, 'Geopolitics is the science of the conditioning of political processes by the earth ... of political space organisms and their structure ... [and] aims to be equipment for political action' (Haushofer et al. 1928). In 1939, Derwent Whittlesey, the American political geographer, dismissed geopolitics as 'a dogma ... the faith that the state is inherently entitled to its "place in the sun".' In contrast, Edmund Walsh espoused an American geopolitics based upon international justice, and 'a combined study of human geography and applied political science ... dating back to Aristotle, Montesquieu and Kant' (1944).

Saul Cohen defined geopolitics as a mode of analysis, relating diversity in content and scale of geographical settings to exercise of political power and identifying spatial frameworks through which power flows (Cohen 1973). Recently, Gearoid O'Tuathail argued that 'geopolitics does not have a singular, all-encompassing meaning or identity ... it is discourse, a culturally and politically varied way of describing, representing and writing about geography and international politics' (1998).

Because geopolitics straddles two disciplines—geography and politics—its approaches vary according to frameworks of analysis common to each. While most early theories and concepts in geopolitics grew out of geographical thought, historians and political scientists often failed to adapt their later theories to the dynamic, complex nature of geographical settings.

2. Stage One—The Race for Imperial Hegemony

Geopolitical thinking can be traced back to Aristotle, Strabo, Bodin, Montesquieu, Kant, and Hegel. Nineteenth century precursors include von Humboldt, Guyot, Buckle, and Ritter. Modern geopolitics has developed through four stages—the race for imperial hegemony, German Geopolitik, the Cold War era, and the post-Cold War years. The theories of its founders, Ratzel, Mackinder, Kjellén, and Mahan, reflected their era of intense nationalism, state expansionism, and overseas empire-building. Their principles and 'laws' reflected national perspectives and experiences, as well as the influence of social Darwinism.

2.1 Ratzel

Friedrich Ratzel (1844–1904), German natural scientist and 'father' of political geography, was the first to treat space and location systematically in his comparative studies of states (1897). He provided successor geopoliticians with a 'scientific' basis for state expansionist doctrines that reflected Germany's nineteenth century experiences and ambitions for the future. During the last half of the century, Germany emerged as continental Europe's chief economic and military

power. Unified under Bismarck's leadership and victorious in its wars with Austria and France, Germany had enlarged its territory, expanded its heavy industries, and enacted social reform. With the aid of a new powerful naval fleet, Germany posed a serious threat to Britain and France as it acquired an overseas empire in Africa and the Western Pacific, and commercial footholds in East Asia.

Ratzel based his system upon principles of evolution and science (1882/1891). He viewed the state as an organism fixed in the soil, whose spirit derived from mankind's ties to the land. His geographical 'laws' focused on space (*Raum*) and location (*Lage*), the former dependent upon and contributing to the political character of groups living in the space, the latter providing space with its uniqueness. He introduced *Lebensraum* (living space) as the law driving states to expand. Ratzel's 'organic' theories of state growth fitted Germany's view of its future as a youthful, aggressive, capitalist 'Giant State.'

2.2 Mackinder

Halford Mackinder (1861–1947), who established geography as a university discipline in Britain, was concerned with safeguarding the British Empire's political, commercial, and industrial primacy, in an era when command of the seas no longer guaranteed world supremacy owing to the wider reach and speed of rail. For Mackinder, geographical realities lay in the advantages of centrality of place and efficient movement of ideas, goods, and people. He theorized that the inner area of Eurasia, characterized by interior or Arctic drainage and impenetrable by sea power, was the 'pivot area' of world politics (1904). He warned that rule of the heart of the world's greatest landmass could lead to world domination. A Eurasian land-power (be it Russia, Germany, or even China, and especially an alliance of the first two) that gained control of the pivot area would outflank the Maritime world. Eleven years later, the English geographer James Fairgrieve (1915), who coined the term 'Heartland' opined that China was in an excellent position to dominate Eurasia.

In *Democratic Ideals and Realities* (1919) Mackinder, now using the term 'Heartland,' and taking into account advances in land transportation, population increases, and industrialization, enlarged his map to include Eastern Europe from the Baltic through the Black Sea as Inner Eurasia's strategic annex. This became the basis for his dictum, 'Who rules East Europe commands the Heartland; who rules the Heartland commands World-Island; who rules World-Island commands the world.' The warning to Western statesmen was clear—the key to world domination lay in the middle tier of German and Slavic states, or Mitteleuropa. Mackinder's world-view guided Lord Curzon's imperial strategies in South Asia and South Russia (Blouet 1987), German Geopolitik between

World War One and Two, and for Western containment strategies of the post-World War Two era. Foreseeing Britain's decline as the world's leading power (Mackinder 1924), he advocated that Western Europe and North America constitute a single community of nations—a forerunner of the North Atlantic community concept.

Whereas Ratzel's theories of the large state were based on concepts of self-sufficiency, closed space, and totalitarian controls, Mackinder was strongly committed to cooperation among states, democratization of the Empire into a Commonwealth of Nations, and preservation of small states. He bridged the academy and politics, serving as a Conservative and Unionist member of Parliament (1910–1922), and as British High Commissioner for South Russia (1919–1920). Initially a Liberal Imperialist and proponent of free trade, he eventually became committed to a preferential tariff system to protect British imperial unity.

During World War Two, Mackinder presented a global strategy based upon two equal power units—Heartland and Midland Ocean (the North Atlantic)—separated from two other regions (Monsoonal Asia and South Atlantic lands) by a mantle of empty deserts and mountains. He felt that, ultimately, Monsoonal Asia (India and China) would emerge to challenge a combined Heartland/Midland Ocean (1943).

2.3 Kjellén

Johan Rudolph Kjellén (1864–1922), the political scientist who, in 1899, coined the term 'geopolitics' was influenced by both his Swedish background and Germany's growth into a giant state. He viewed the impending breakdown of the Concert of Europe and the drift towards war and chaos as the death-knell for small states like Sweden (Parker 1998). Adopting Ratzel's organic state concept, he considered Germany's emergence as a great power inevitable and desirable. Sweden's needs would be fulfilled within the framework of a new Mitteleuropean bloc from Scandinavia and the Baltic, through Eastern Europe and the Balkans, dominated by ascendant Germany.

A Conservative member of the Swedish parliament, Kjellén viewed geopolitics as the 'science of the state,' whereby the state's natural environment provided the framework for a power unit's pursuit of 'inexorable laws of progress.' The dynamic organic approach led Kjellén to espouse the doctrine that political processes were spatially determined (1916). Moreover, since giant states in Europe could be created only by war, he viewed geopolitics as primarily a science of war (Gyorgy 1944).

2.4 Mahan

The global perspective of Admiral Alfred Thayer Mahan (1849–1914) was also Eurasian-centered

(1900). For Mahan, the northern land hemisphere, connected by Panama and Suez, was the key to world power; within that hemisphere, Eurasia was the most important component. Mahan recognized Russia as the dominant Asian landpower whose location made it unassailable. However, he felt that its landlocked position put it at a disadvantage, because, contrary to Mackinder's opinion, sea-movement was superior to land-movement (1890).

Mahan argued that world dominance could be held by an Anglo-American alliance from key bases surrounding Eurasia. The critical zone of conflict lay between the thirtieth and fortieth parallels in Asia where Russian landpower and British seapower met. He viewed the USA as an outpost of European power and civilization, its Pacific shoreland and islands extensions of the Atlantic-European realm. Indeed, he predicted that an alliance of the USA, Britain, Germany, and Japan would one day hold common cause against Russia and China.

3. Stage Two—German Geopolitik

German Geopolitik emerged in reaction to Germany's devastating defeat in World War One. Humbled by the Treaty of Versailles, Germany was stripped of its overseas empire and important parts of its national territory, and the social cohesion forged by Bismarck's policies was shattered. The Socialist Weimar Republic was beleaguered by class warfare and attempts to overthrow it by Communists on the Left and racist militant nationalists and aristocratic conservatives on the Right. Unemployment was rampant and inflation raged. Within this setting, Haushofer and his colleagues established the *Zeitschrift für Geopolitik* (1924–1939) and the Institute for Geopolitics at the University of Munich. Undoing Versailles by restoring the lost territories and rebuilding Germany as a world power undergirded the pseudo-scientific 'laws' and principles of Geopolitik that served Nazi Germany.

3.1 Haushofer

Karl Haushofer (1869–1946), the general who became a political geographer, was not an original thinker. The Geopolitik of the German geopoliticians whom he led (Otto Maull, Erich Obst, Ewald Banse, Richard Hennig, Colin Ross, Albrecht Haushofer) was based essentially upon the writings of Kjellén, Ratzel, and MacKinder. Mahan, Fairgrieve and the American geographical determinist Ellen Churchill Semple were also influential. The organismic-Hegelian philosophy of Geopolitik came from Ratzel directly or via Kjellén.

Lebensraum and autarchy became slogans for doctrines whose consequences were conflict and total war. Three geographical settings permeated the literature

of Geopolitik: Ratzel's large states, Mackinder's World-Island, and Pan-Regions. The organic growth of Germany to its west and east was regarded as 'inevitable.' To gain mastery over World-Island, it was necessary to dominate the USSR and destroy British seapower. The geopoliticians posited that German control over Pan-Europe (including Eastern Europe) would force the Soviet Union, regarded as an Asian power, to come to terms.

During most of the 1920s and 1930s, Haushofer espoused continental pan-regionalism based upon complementarity of resources and peoples: Pan-America, Pan-Eurafrica, and Pan-Asia, with the USA, Germany, and Japan as respective cores. His position on the USSR was ambiguous. He proposed variously a German-Russian alliance, a Pan-Russia-South Asia, and a Japan-China-Russia bloc. His call for Germany, the USSR, and Japan to form a Eurasian pan-region that would dominate World-Island, influenced the German-Soviet pact of 1939, made moot by Hitler's subsequent invasion of the Soviet Union. The principles of Geopolitik were designed to fulfill German national and imperial aims, without concern for contradictions.

Haushofer's extraordinary influence derived from his close ties to Rudolph Hess, his aide-de-camp in World War One and subsequent student at the University of Munich. Through Hess, he gained access to Hitler from 1923 to 1938. Doctrines such as *Blut und Boden* (blood and soil), *Rasse und Raum* (race and space), and *Lebensraum* were incorporated into *Mein Kampf* and became ideological tenets of the murderous Nazi regime. He also advised Hitler at Munich 1938. With Hess's flight to England in 1941, the influence of the Geopoliticians upon Hitler ended. Haushofer was imprisoned briefly at Dachau (ironically, he had a Jewish wife), and his son Albrecht, also a geographer with links to aristocrat military circles, was killed by the SS for involvement in the 1944 Generals' Plot to assassinate Hitler. Haushofer and his wife committed suicide in 1946.

4. Stage Three—The Cold War: State-centered vs. Universalistic Approaches

Onset of the Cold War re-awakened Western interest in geopolitics by historians, political scientists, and statesmen. Geographers distanced themselves from geopolitics because of the taint of German Geopolitik.

4.1 State-centered 'Political' Geopolitics

American Cold Warriors embraced geopolitics as a basis for national policy aimed at confronting the

Soviet Union and International Communism. Building on early geographically derived geopolitical theories, and holding static interpretations of global and regional spatial patterns, they introduced into the lexicon of Cold War geopolitics such political-strategic doctrines as containment, domino theory, balancing linkages, and linchpin state.

Germany and Japan emerged as the key military bases for the USA and its allies in the struggle to contain Soviet and Chinese continental power, thrusting the Allies' World War Two enemies into the strategic forefront. Military alliances forged as part of containment produced mixed results. NATO, established in 1949, has proved an enduring strategic instrument. However, SEATO, formed in 1954 to oppose the spread of Communism in Southeast Asia after France's withdrawal from Indochina, collapsed with the US defeat in Vietnam, and was disbanded in 1977.

In the Middle East, the Baghdad Pact (later called the Central Treaty Organization) was even shorter-lived (1955–1959). Its members included Turkey, Iraq, Iran, Pakistan, and Britain. Iraq's subsequent withdrawal to pursue a non-alignment policy left the pact with no Arab representation and therefore limited capacities to counter Soviet influence in Egypt, Syria, and South Yemen.

Western foreign policy was not long confined to containing the Eurasian continental power along Heartland's borders, but adopted a strategy of checking the spread of Communism throughout the Third World. The idealistic vision that had prompted the USA to support freedom and democratization among colonial peoples quickly gave way to expedient realpolitik—propping up right-wing dictatorships in order to stop the threat of Communism.

Another popular geopolitical doctrine, 'domino theory,' was first proposed by William Bullitt (1947), who feared that Soviet Communist power would spread, via China, into Southeast Asia. It was adopted by both the Kennedy and Nixon administrations, rationalizing American intervention in Vietnam to 'save' the rest of Southeast Asia (O'Sullivan 1982).

Domino theory was an important argument for extending Western containment policy well beyond the Southeast Asian and Middle Eastern shatterbelts into the Horn of Africa and Sub-Saharan Africa, Central America and Cuba, South America, and South Asia. These regions became battlefields for both superpowers, each supporting local surrogates militarily, politically, and economically. The goal was to protect or gain sources of raw materials and markets, while denying the enemy overseas military bases.

The imagery of 'dominos' persists. Threat of the spread of Kosovar Albanian irredentism to Macedonia, Bulgaria, and Greece precipitated NATO's air war against Yugoslavia. Ironically, the result has been Serbian ethnic cleansing of the Kosovars, further destabilizing the region.

A third doctrine, 'linkage,' introduced into geopolitics by Henry Kissinger in 1969, was based upon the theory of a network that connected all parts of the world's trouble spots to the Soviet Union, and that US involvement in any single conflict would have an impact upon overall superpower balance (Kissinger 1979). Linkage rationalized continued US fighting in Vietnam long after the war had been lost.

Linkage was applied to detente with the Soviet Union and accommodation with China. To maintain the balance of power, the Nixon administration sought Moscow's agreement on strategic arms limitations and mutual nuclear deterrence, and tried to play China off against the USSR. The logical consequence of this policy was non-intervention in the 1968 Czech uprising, acquiescing to the Brezhnev Doctrine, which held that military force was justified to keep the socialist countries of Eastern and Central Europe within the Soviet camp. The threat of credibility loss also served as a driving force in NATO's war against Yugoslavia.

Zbigniew Brzezinski's geopolitical world-view was based on the struggle between Eurasian landpower and seapower. For him, the key to preventing Soviet world dominance lay in US control of 'linchpin' states (1986). These were defined by their geographical locations which enabled them to exert strategic military and/or economic influence. The designated linchpins were Germany, Poland, Iran or Pakistan-Afghanistan, South Korea, and the Philippines. Their dominance by the USA would effectively contain the Russian 'Imperial' power, protecting Europe and Japan and, in the case of South Korea and the Philippines, preventing encirclement by China.

For Brzezinski the US-Soviet conflict was an endless game, and linchpin control was a necessary part of US geostrategic game plan. In this there is little consideration of the geopolitical complexity of the global system and of the multiplicity of forces beyond superpower reach that had become active agents in the system.

4.2 Universalistic Geographical Geopolitics

When geographers re-engaged in geopolitics in the 1960s and 1970s, they developed theories based upon universalistic/holistic views of the world and the dynamic nature of geographical space. Three approaches predominated: a polycentric, international power system; a unitary, economically based world system; and an environmental and socially ordered geopolitics. These fresh geographical theories which challenged bi-polar Cold War geopolitics had little appeal to the Cold Warriors and failed to make their way into 'political' geopolitics.

The polycentric or multinodal/multilevel power approach rejected the Heartland theory of world domination, as had Halford Mackinder in his later

writings. His reinterpretation became a take-off point for those geographers who developed theories of geopolitical polycentrism. In the USA, Saul Cohen proposed a flexible hierarchy of two geostrategic realms, geopolitical regions, shatterbelts, national states, and subnational units within a system that evolved through dynamic equilibrium forces (Cohen 1973). The USA, European Union, and Japan are the cores of the Maritime realm, and Russia and China of the Continental. This developmental theory posited that the structural components of the global system had evolved from a stage of undifferentiation with relatively few parts, to specialization/integration with many parts at different geo-territorial levels (Cohen 1982). Equilibrium is maintained by moving from one stage to another through responses to short-term disturbances.

In England, Chrone presented a geopolitical system of 10 regional groupings that were also hierarchically ordered, and had a historical and cultural basis (Chrone 1969). In Chrone's view, the world power balance was shifting from Europe and the West towards Asia and the Pacific. He predicted that the Pacific Ocean would become the future arena of confrontation for the USSR, the USA, and China.

Peter Taylor, the English geographer, broke away from the 'realistic' school of power-centered geopolitics in applying a world-systems approach based upon global economics (1989). He drew upon the work of Immanuel Wallerstein (1983), who argued that the world economy means a single global society, not competing national economies. Taylor integrated the Wallerstein model with George Modelski's cycles of world power (1978), and presented power and politics within the context of a cyclical world economy in which nation states and localities are fitted.

Taylor, as Wallerstein, viewed global conflict in North/South terms (rich nations vs. poor nations), arguing that capitalist core areas aggrandize themselves at the expense of the periphery. This offered a geopolitical frame for the North-South dichotomy that the 1980 Brandt Report highlighted in its study of Third World issues.

An environmentally and socially oriented geopolitics was promoted by Yves LaCoste in France with the establishment of the *Journal Hérodote*. In moving towards a 'new géopolitique,' he sought to overcome the national chauvinism of the 'old' geopolitics by focusing on the land, not on the state. Hérodote linked geopolitics to ecology and broader environmental issues, as well as such matters as world poverty and resource exhaustion. Much of LaCoste's work was inspired by the French human geographer and political anarchist, Elisée Reclus, who believed it essential to reshape the world's political structure by abolishing states and establishing a cooperative global system. While this French geopolitics did not produce systematic geopolitical theory, it did put the spotlight on applying geopolitics to significant global problems.

5. *Stage Four—The Post-Cold War Era: Competition or Accommodation?*

The end of the Cold War has generated a number of new approaches to geopolitics, in addition to those that continue from the earlier era. For some, it heralds a 'new world order' and the geopolitics of US global hegemony. President George Bush, addressing Congress in 1990 defined the policy behind the war against Iraq as envisaging a new world order led by the USA, 'freer from the threat of terror, stronger in the pursuit of justice, and more secure in the quest for peace ... a world in which nations recognize the shared responsibility for freedom and justice' (Bush 1991).

In contrast, Robert Kaplan's geopolitics of anarchy is based on a world divided into the rich North and the poor South. He concludes that the South, especially Africa, is doomed to anarchy and chaos. His map of the future, dubbed the 'last map' is an 'ever mutating representation of chaos' (1994).

Neither of these predictions has come to pass. In most cases, the overthrow of Communist regimes has not led to stable, free-market economies. The restraints upon the unilateral application of US military, economic, and political power are evident from the failures to gain US objectives in Iraq, Somalia, and Haiti. In southeastern Europe, Russia and China have been called upon to help mediate the NATO–Yugoslav conflict.

Chaos theory gives inadequate attention to the regional and global systemic forces that contain turbulence and absorb its positive aspects into the system. Indochina has been stabilized under the leadership of Vietnam. Nigeria has led the community of West African states in attempts to restore order in countries plagued by civil war. The West cannot ignore instability in the South despite regarding it as 'quarter-sphere of strategic marginality.' This is necessitated by humanitarian considerations, as well as fear of the spread of nuclear weaponry and massive out-migrations.

The main thrust of post-Cold War geopolitics continues to follow the two streams of the previous era—the nation-centered/political and the universalistic/geographical. Political geopoliticians advocate projection of Western power into Central and Eastern Europe to weaken Russia's Heartland position at its western edge. They also advance strategies for penetrating the Caucasus and Central Asia, and for playing China off against Russia.

Brzezinski's prescription for maintaining US global hegemony is to achieve primacy in three parts of the 'Eurasian Chessboard': the West—Europe; the South—Middle East and Central Asia; and the East—China and Japan. He advocates pulling Ukraine and the Black Sea into the Western orbit, strong engagement in Central Asia and the Caucasus, and support of Chinese regional dominance in peninsular southeast Asia and Pakistan. China would be limited

to regional power status by the globally framed US–Japan strategic alliance. On the assumption that Russia's weakness is a permanent condition, this strategy seeks to prevent Russia from reasserting strategic control over 'near abroad' states, or from joining with China and Iran in a Eurasian anti-US coalition (Brzezinski 1997).

Advancing a geopolitics of 'the West against the Rest,' Samuel Huntington argues that world primacy can be maintained by dividing and playing off the other civilizations (1993). His thesis is that the fundamental sources of conflict will not be ideological, but cultural, and the fault lines between civilizations will be the battle lines. In dividing the world into Western, Confucian, Japanese, Islamic, Hindu, Slavic-Orthodox, Latin American, and possibly African civilizations, he makes little allowance for religious, ethnic, economic, or strategic divisions. He also assumes the permanence of the fault lines, despite the massive changes that are brought about by demography, migrations, and modernization.

Geographical geopolitical theory continues to reflect the universalistic approaches advanced during the Cold War. Building on the works of Taylor and LaCoste, 'critical' geopolitics applies social scientific critical thinking to ask how power works and might be challenged. This school views the following as central to geopolitical studies: analysis of discourse—rhetoric, metaphors, symbolism (O'Tuathail and Agnew 1992); feminist approaches to the subject of national security; and the geographies of social movements, particularly in relation to newly radicalized and participative democracy (Painter 1995).

In contrast, reality-based, polycentric geographical geopolitics emphasizes the continuous proliferation and inter-connectedness of the various parts and levels of the world. The current number of 200 national states could increase to 250–275 within the next quarter of a century. As the pace of devolution quickens, some of these new geo-territorial entities will be highly autonomous 'quasi-states.' Regional geopolitical restructuring is also a continuing process. Just as Southeast Asia has disappeared as a shatterbelt, so may the Middle East. The effort to detach Eastern Europe from the Russian Heartland is underway. However, with Russia's revival, the region could serve as a gateway between Europe and Russia.

In addition, the network of global cities—centers of capital flows and financial services, linked ever more closely by cyberspace, tourism and immigrant communities—will emerge as a major new geopolitical level, promoting policies sometimes contradictory to national interests. International social movements, such as environmentalism, are also influential in shaping national and regional policies, including military ones.

Whatever the course of geopolitical restructuring, we are entering an era of power-sharing among a wide variety of states of different sizes and functions.

Geopolitical theory will continue to be a valuable tool for understanding, predicting, and formulating the structure and direction of the world system.

Geriatric Psychiatry

1. The Field of Geriatric Psychiatry

Geriatric psychiatry deals with disturbances of mental health in older persons. Its practitioners are physicians who have trained first in medicine and general psychiatry, then specialized in the treatment of psychiatric disorders affecting people in later life—usually taken to be from the seventies on. Geriatric psychiatry deals with the following: the diagnosis and accurate assessment of individual patients; the development and use of treatments that are the best available; and the administration of health services for older people, involving family physicians, community health workers, and carers.

The importance of geriatric psychiatry expanded greatly in the latter decades of the twentieth century, mainly because of the unprecedented change in the world's population: many more people are living into old age, and even more are becoming very old. For example, according to predictions published by the United Nations (1998), by 2050, the world's population aged 60 and over will be 74 percent larger than the number of people under 15 years of age. The population aged 80 years and older will rise from 61 million in 1995 to 1,055 million in 2150, a 17-fold increase. And it is in less developed countries where the most dramatic increases will occur. The social, economic, and public health consequences for many countries are profound. This is because the very elderly tend to have poor physical health, a greatly increased risk of dementia, and a degree of personal disablement that makes them dependent on others. The prevention and effective treatment of age-related disease has become a compelling need.

The agenda of geriatric psychiatry falls into three categories: how it is practiced; the main disorders treated; and the research questions or gaps in knowl-

edge that are currently the most important. Jeste et al. (1999) have set out the response that is needed to this forthcoming crisis. It is generally acknowledged that, to be effective, the practice of geriatric psychiatry requires close collaboration with other professionals, particularly nurses, social workers, clinical psychologists, family physicians, and specialists. This is because of the nature of the disorders being encountered, the behavior of the elderly person in poor health, and the simultaneous presence of both medical and psychiatric problems that so commonly occurs. Much of the practice of geriatric psychiatry is in the community and in primary care, not in specialist settings or hospitals.

2. Mental Disorders in Later Life

2.1 The Dementias

The most common group of disorders in geriatric psychiatry is the dementias. In these, changes have taken place in the structure and function of the brain, particularly areas concerned with memory, information processing, and social behavior. 'Dementia' originally meant 'out of one's mind,' from the Latin *de* (out of) and *mens* (the mind). Early in the nineteenth century, Esquirol (1845) gave a succinct definition of dementia as 'a cerebral affection ... characterised by a weakening of the sensibility, understanding, and will' (cited by Caine et al. 1995). In describing with such words how the condition can be recognized, Esquirol drew attention not only to the cognitive features of the disorder, with impairment of memory and thinking in day-to-day life, but also to its other manifestations such as apathy, deterioration in social behavior, occasional aggressiveness, delusional ideas, and hallucinations. These show how widespread the changes are in the brain. Following extensive consultations with experts in some 40 countries, the World Health Organization ([WHO] 1992) has described dementia as:

a syndrome due to disease of the brain, usually of a chronic or progressive nature, in which there is disturbance of multiple higher cortical functions, including memory, thinking, orientation, comprehension, calculation, learning capacity, language and judgement. Consciousness is not clouded. Impairments of cognitive function are commonly accompanied, and occasionally preceded, by deterioration in emotional control, social behaviour, or motivation. This syndrome occurs in Alzheimer's disease, in cerebrovascular disease, and in other conditions primarily or secondarily affecting the brain.

In Alzheimer's disease, an abnormal protein called β -amyloid accumulates in the brain, particularly in the hippocampus. In vascular dementia, areas of the brain become damaged by having their blood supply in-

terrupted, as happens in stroke. Other causes of dementia are Lewy body disease, Pick's disease, Huntington's disease, Creutzfeldt-Jakob disease, and AIDS.

2.1.1 Prevalence. There are published reports on the prevalence of dementia in diverse areas of the world including North America, Europe, Scandinavia, Russia, Japan, China, Singapore, India, Africa, and Australasia. An integrative analysis of 47 surveys across 17 countries has suggested approximate rates under one percent for dementia from any cause in persons aged 60 to 69 years, rising to about 39 percent in persons 90 to 95 years old (Jorm et al. 1987). The prevalence doubles with every five years of age within that range. Throughout the world, many more people than in the past are living to an age when the prevalence of dementia greatly increases, so that the absolute number of persons with dementia is now expanding rapidly. In some countries, the proportion with a dementia is increasing *much faster than the growth of the elderly population*. This is because of the greater increase in the very old, in whom the prevalence of dementia is highest.

2.1.2 Secular change. It is often asked if there is more dementia now than some decades ago. Because there are larger numbers of the elderly now, and more of the very elderly in particular, there has inevitably been a large increase in the number of persons suffering from a dementia. Furthermore, having developed a dementia, an elderly person is now likely to survive longer. This is at least partly attributable to the 'failure of success.' Even with no change in incidence, longer duration of illness leads to an increased prevalence. Studies in Sweden and across Western Europe have found no change in the age-specific incidence of Alzheimer's disease, but it is intuitively plausible that vascular dementia may be decreasing in many countries in parallel with a general decrease in vascular disease.

2.1.3 Age-related cognitive decline. There is no doubt that nearly all people undergo a deterioration in memory and a slowing of mental processes in very late life; and some experience these changes earlier than others for reasons that are not yet well understood. Various terms have emerged to describe such states. The term 'benign senescent forgetfulness' was introduced by Kral to describe one group of such states. Although it was not well defined by him, the term has persisted because it fulfills a need and has no sinister connotations. Other concepts have since

been introduced. A useful review of this important issue has been provided by Ritchie and Touchon (2000).

2.1.4 Risk factors for Alzheimer's disease. As reviewed by Jorm (2000) and Henderson and Jorm (2000), four risk factors can now be regarded as confirmed for Alzheimer's disease: age, a family history of dementia; having the Apolipoprotein E ϵ 4 genotype; and having Down's syndrome. There are then a number of risk factors where the evidence is at present not fully established: a first-degree relative with Down's syndrome, advanced maternal age, a head injury earlier in life, a previous depressive episode, hypothyroidism, and a long-standing history of physical inactivity. Aluminum has been considered, whether ingested in drinking water or the diet, or absorbed from antiperspirants. From all the evidence available, it remains unproven that aluminum from drinking water or any other source plays a role in causing Alzheimer's disease (Doll 1993).

2.1.5 Possible protective factors. Some factors may confer protection against dementia, or even specifically against Alzheimer's disease. For the latter, four have so far been proposed, each having been identified through epidemiological research: education, anti-inflammatory drugs, estrogen replacement therapy, and statins. Each of these points the way to the possibility of prevention. It is well established in medicine that prevention can precede an understanding of etiology.

2.1.6 Education. A recurrent finding in field surveys is that rates for dementia and cognitive impairment are higher in elderly persons who have had little education. One interpretation is that education may delay the point at which a developing dementia becomes clinically manifest. A recent longitudinal study of American nuns (Snowdon et al. 1996) suggests that intelligence or education, which are inextricably linked, may actually protect against the neuropathological processes in Alzheimer's disease. If such a protective effect does apply, the implications for public health could be appreciable because education has become much more widely available to young persons during the twentieth century.

2.1.7 Geographic and ethnic comparisons. Alzheimer's disease and vascular dementia may occur at different rates in different parts of the world and in different ethnic groups. But it is not easy to be cer-

tain what factors are responsible. There may be different patterns of mortality for dementia cases under different living conditions, different genetic vulnerabilities, or different environmental exposures. A finding of potential significance comes from a comparison of prevalence rates for dementia and specifically for Alzheimer's disease in elderly Nigerian Africans and African Americans in Indianapolis by Hendrie et al. (1995). The two groups have much of their heredity in common, but very different lifestyles. The prevalence was only 2.3 percent and 1.4 percent for dementia and Alzheimer's disease respectively in the Nigerians, but 8.2 percent and 6.2 percent in the combined community and nursing home sample of African Americans in Indianapolis. This demonstration of significant differences in rates in two different communities having similar ethnic origins again points to the possibility that some unknown environmental factors promote the neuropathological processes in Alzheimer's disease. The Cree Indians in Canada have also been found to have a lower prevalence of Alzheimer's disease than White Canadians (Hendrie et al. 1993).

In India, Ganguli et al. (1996) and Chandra et al. (1998) undertook a methodologically sophisticated survey of 5,126 individuals aged 55 years and over in Ballabgarh, Northern India. Using the same criteria to define a case, they found a prevalence of only 1.1 percent in persons aged 65 and over for Alzheimer's disease, much lower than in industrialized countries. Neither gender nor literacy were associated with prevalence, but this rose with age for both Alzheimer's disease and all dementias. Their conclusion was that the low prevalence compared to Western estimates could be due to shorter survival of cases, but it is also possible that the incidence is lower, speculatively attributable to differences in the underlying distribution of risk and protective factors.

2.1.8 Anti-inflammatory drugs. An inverse association was noticed between rheumatoid arthritis and Alzheimer's disease, suggesting that persons who have taken aspirin, steroids, or nonsteroidal anti-inflammatory drugs (NSAIDs) over long periods may have a lower risk of dementia, or have slower cognitive decline in late life. The most recent information is that anti-inflammatory drugs probably do prevent or attenuate the symptoms of Alzheimer's disease (Breitner 1996). But it is premature for physicians to prescribe anti-inflammatory drugs for Alzheimer's disease until the size of their effect is established in a randomized controlled trial and the findings are balanced with their risks.

2.1.9 Estrogen replacement therapy. Case-control studies have provided pointers to the possible

protection against Alzheimer's disease afforded to women who take estrogen. But since they also tend to be better educated and to differ in other life-style factors, this finding could be misleading. Again, only randomized controlled trials will establish whether a protective effect exists.

2.1.10 Risk factors for vascular dementia. The assumption is that risk factors are similar to those for stroke. These are age, male gender, a family history of stroke or dementia, hypertension, diabetes mellitus, transient ischemic attacks, elevated cholesterol or lipids, cigarette smoking, heavy alcohol use, oral contraceptives, physical inactivity, obesity, and ethnicity.

2.1.11 Treatment of dementia. The treatment of dementia presently consists of minimizing the deleterious effects of other conditions and of optimizing the person's day-to-day social environment. For Alzheimer's disease, medications have been developed that attempt to correct the deficiency in the neurotransmitter acetylcholine, but none has yet been found to bring about unequivocal and lasting benefit. Intense research is being conducted to find other drugs that enhance cognition. The possibility is emerging that people could be immunized against Alzheimer's disease in earlier adulthood to prevent the deposition of the harmful β -amyloid protein in the brain (St George-Hyslop and Westaway 1999). Meanwhile, remarkable progress has been made by clinical psychologists in developing nonpharmacological methods for treating dementia, including the reduction of severely difficult behavior such as wandering, incontinence, and screaming (Bird in press).

2.2 Delirium

Delirium, a term introduced by Celsus 2,000 years ago, is derived from the Latin *de* (from, away) and *lira* (a track or furrow). It is characterized by incoherence of thought and speech, together with perplexity, in a setting of clouded consciousness that fluctuates in severity. Despite its long-established place in nosology, delirium must number among the most underdiagnosed conditions in medicine. Delirium occurs most commonly at the extremes of life. Its highest incidence is in the elderly, in whom it may indicate the presence of systemic or cerebral disease, or drug toxicity.

2.3 Depression

The elderly might be expected to have higher rates of depressive disorders than younger adults because of

their personal and social circumstances. But here a puzzle emerges. Although a high prevalence is usually found in nursing homes, the consistent finding is that the elderly in the community have *on average* less depression than younger adults (Henderson 1994; Henderson et al. 1998). Some think these findings may be attributable to an error in ascertainment. This could be through inappropriately discounting symptoms that may also be due to physical illness or to age itself, such as tiredness, feeling slowed up, or sleep difficulties. Alternatively, a cohort effect has been proposed, in which people who are now elderly may have been protected against depression; or younger adults may have higher rates through being exposed to factors that older adults have been spared.

There is then a further intriguing possibility that is at first counterintuitive: that aging actually protects against depression, and indeed against a range of other mental disorders. It has been suggested that exposure to adverse experience over a lifetime may induce an increased resistance to depression and anxiety through psychological immunization.

2.3.1 Causes of depression in the elderly. When elderly persons have a depressive disorder, one may reasonably ask if it is a recurrence or if it has developed for the first time. Several studies have noted that severe life events precede the onset of depression in at least half of all patients; conversely, depressive disorder may emerge in elderly persons with relatively untrammelled lives. Risk factors for depression in late life are a past history of such a disorder, physical illness or chronic pain, recent adverse experiences, and the absence of a confiding relationship. Contrary to expectation, elderly persons who live alone have not been found to be at risk for depressive disorder. A consistent finding in community surveys is that the complaint of loneliness is associated more with depression than with actual social isolation.

Where depression develops in elderly persons for the first time in their lives, a recent finding is that the brain often shows selective atrophy on neuroimaging.

2.3.2 Treatment. Depression in older persons is highly responsive to psychotherapy and antidepressant medication that is highly effective, non-addictive, and usually well-tolerated. Often, the main problem lies in having the depression recognized in the first place, instead of its being ascribed by patient, family, and doctor to the inevitable experience of old age.

2.4 Suicide

In most countries, elderly men consistently have higher rates for suicide than other age-groups. Factors

associated with death by suicide in the elderly include depressive disorder, disabling physical illness, chronic pain, and social isolation.

2.5 Anxiety Disorders

Anxiety disorders in late life have been overlooked even more than depression as a significant cause of morbidity. In an integrative review of eight community-based surveys of persons aged 60 years and over, anxiety disorders were found to have a lower prevalence than in younger adults. The explanation is unknown. Co-occurrence of depression with generalized anxiety disorder or phobias was a frequent pattern, the depression usually being inappropriately treated with a benzodiazepine. Anxiety symptoms may also occur in the early stages of dementia and in association with depressive disorders. There is little information on the prevalence of post-traumatic stress disorder in the elderly, risk factors for it or its natural history.

2.6 Schizophrenia

It is recognized that schizophrenia can begin in later life. The term *paraphrenia* has been used for this condition. A number of distinguishing features may be present, as reviewed by Henderson and Kay (1997): a higher ratio of women, a better occupational history, and a higher frequency of marriage than in younger patients, with the occurrence of sensory loss being more common in those with onset at a more advanced age. Psychotic symptoms are appreciably more common than formal diagnostic categories. Impaired hearing and vision have both been found to be associated with psychotic symptoms. Social isolation is a further associated factor, but it is unknown if this is a premorbid characteristic, a causal factor, or a consequence. There is consistent evidence that paranoid or delusional symptoms are more frequent in persons who also have cognitive impairment.

3. Services for the Elderly

The extent to which the elderly with mental disorders receive services is itself an issue amenable to systematic examination. The notion of filters proposed by Goldberg and Huxley (1992) is very useful. The first filter determines which persons with mental disorders reach a physician, whether they initiate the consultation themselves or whether it is initiated by their families or the physician. The second filter determines whether the physician recognizes that significant mental disturbance is present. This may happen in only about half the consultations. The third filter determines referral to specialist services. Although family

physicians recognize early dementia quite efficiently, they may often need further training in the diagnosis of depressive disorders in elderly persons. This is because symptoms of tiredness, poor appetite, insomnia, and apathy may be mistakenly ascribed to old age. The benefits of correct diagnosis for both the patient and the community are self-evident.

4. Disability

From a public health perspective, information about the elderly and the services they require has to include an assessment of disability. This is because it is impairment of functioning in daily life rather than symptoms or diagnoses that brings about the need for services. Dementia is second only to arthritis as a cause of disability in the elderly. Less is known about the impairment of functioning caused by depressive disorders and depressive symptoms but, since they often occur with physical disease, their interactive effect is considerable. One community-based study conducted by an experienced geriatrician found that neuropsychiatric disorders of cognition, behavior, and mood, together with Parkinson-related disorders of gait, are major predictors of disability in late life.

5. Research in Geriatric Psychiatry

There has been an enormous expansion of research activity in recent decades. Much of it is directed at the following questions:

- (a) What determines the course of cognitive decline in old age?
- (b) Are there factors in the environment that contribute to dementia?
- (c) Can dementia be prevented?
- (d) Can drug treatments for dementia be found?
- (e) What are the applications of the new neuro-imaging techniques to diagnosis and treatment?
- (f) What improvements are needed in primary health care for older persons; and how can these be brought about?
- (g) What interventions will promote quality of life in the elderly?

The needs of tomorrow's communities, together with the rapid advances taking place in neuroscience, will ensure an exciting future for geriatric psychiatry. Its practitioners will need, as never before, to be highly trained but interpersonally skilled physicians.

Gerontological Clinical Psychology

Clinical geropsychology is the field that specifically focuses on developing empirically supported skills for the psychological assessment and treatment of older adults. Adults who might merit such attention include those with psychopathology or whose quality of life is negatively influenced by psychosocial factors. Given the increasing population of older adults and the complex life experiences and changing demographics of the population, it is important for mental health professionals to be prepared to assess and treat older clients.

1. Proficiency in Clinical Geropsychology

Until recently, outpatient mental health care services have been underutilized by older adults, despite 1975 legislation mandating specialized services for mentally ill older adults within community mental health centers. The majority of the elderly who receive mental health services are seen as inpatients during hospitalization in a psychiatric hospital or a nursing home. Possible explanations for this phenomenon include the idea that there is stigma attached to receiving mental health services within this cohort, but this concern has not been supported in limited research (Rokke and Scogin 1995). Alternatively, mental health professionals have historically displayed 'professional ageism' dating back to Freud, who was pessimistic about psychological change or the benefits of therapy in later life. Finally, Medicare reimbursement for psychological services in the United States is very limited. The majority of the money spent goes toward psychopharmacology as opposed to psychotherapy, reducing the availability of psychological services.

However, patterns of usage of psychological services by the elderly are changing. Successive cohorts of older persons have higher levels of education and a greater acceptance of psychology. Rokke and Scogin (1995), for example, showed that older adults considered cognitive therapy to be more credible and acceptable than drug therapy for depression (see

Cognitive Therapy). It is likely that psychologists could be much more active in reaching out to older adults to provide services, and that they can expect an increasingly positive welcome.

As more older adults seek or accept psychological services, psychologists must be prepared to meet this need. To address issues of responsibility and competency in providing such care, the American Psychological Association (APA) has approved Clinical Geropsychology as an area of special proficiency. Guidelines addressing the needed competencies for proficiency in clinical geropsychology have been drafted and widely promulgated (APA Interdivisional Task Force 1999). In this document, 13 areas of knowledge and skills that define proficiency knowledge in Clinical Geropsychology are specified, as listed below and then reviewed in more detail:

- (a) Research and theory in aging
- (b) Cognitive psychology and change
- (c) Social/psychological aspects of aging
- (d) Biological aspects of aging
- (e) Psychopathology
- (f) Problems in daily living
- (g) Sociocultural and socioeconomic factors
- (h) Assessment
- (i) Treatment
- (j) Prevention and crisis intervention services
- (k) Consultation
- (l) Interface with other disciplines
- (m) Special ethical issues in providing services to the aged.

1.1 Research and Theory in Aging

It is important for psychologists to understand aging in a broad context, as a psychological, biological, and social process. Further, some research methodology issues are especially relevant to aging, in particular understanding the impact of cohort or group differences by age.

1.2 Cognitive Psychology and Change

Changes in cognitive and behavioral function are common with aging; most such changes are relatively minor, such as increased difficulty with short-term memory or recall memory. However, the prevalence rate of more severe cognitive changes, indicating dementia, also increases with age. At age 65 only 1 percent of the population have dementia, compared to 30–35 percent by age 85 and 50 percent by age 90. The concept of dementia has evolved from the nonspecific ‘organic brain syndrome’ to a more precise picture of a complex disorder encompassing several distinctive disease entities, each with its own specific set of treatment implications (see *Dementia: Psychiatric Aspects*). More detail is provided on cognitive changes

with age under proficiencies Sect. 1.5, Psychopathology, Sect. 1.8, Assessment, and Sect. 1.9, Treatment.

1.3 Social/Psychological Aspects of Aging

Aging is a personal process and a social process that occurs in a context of familial, cultural, and political elements. As reviewed above, the demographics of aging reflect a changing social context of aging. This changing context also affects intergenerational relationships, the nature of relationships in later life (e.g., since more adults are living to old age, larger peer networks of older adults exist than in prior generations), and perceptions of aging.

1.4 Biological Aspects of Aging

Important biological aspects of aging include normal biological aging changes, abnormal changes and disease, lifestyle and behavioral factors in health, chronic and terminal illness, and pharmacological issues. Chronic health problems (e.g., arthritis, hypertension, hearing impairment, heart conditions) are often experienced by older adults. Many of these physical conditions are associated with chronic pain, and psychologists can employ strategies to help with pain management. Because of health concerns, many older adults are given medications, often without good explanation of the importance of taking the medication routinely, resulting in erratic usage. Psychologists can work with older adults to encourage consistent use of prescribed medication, to help them understand its importance, and to help identify the health-related belief system of older adults and incorporate those beliefs into the medical regimen. Insomnia, particularly sleep-maintenance insomnia, is an age-related and debilitating condition. Behavioral procedures for treating insomnia in older adults are more effective than relaxation training or imagery training. In addition, they offer the ability to avoid or discontinue sleep-inducing medications that can cause iatrogenic problems (Morin et al. 1999).

1.5 Psychopathology and Aging

The best estimate of the rate of psychopathology in the older population in the United States is approximately 22 percent (Gatz and Smyer 1992), but there are huge differences among different groups of older adults and across different types of psychopathology. Specifying the prevalence and incidence of psychopathology in older adults is complicated by problems with methodology and design. Most studies on older adults do not take racial and or cultural distinctions into account in the manifestation of disease. Finally, studies do not

always agree on diagnostic criteria and terminology, thus yielding imprecise estimates. For all disorders, the accepted criteria for older adults are exactly the same as those for younger adults using the *Diagnostic and Statistical Manual-IV (DSM-IV)* diagnostic system. However, interpreting some of the criteria for each disorder may be complicated by other aspects of the aging process. In the following subsections, some of the most common mental disorders will be examined and, when appropriate, issues that make diagnosis more complex in older adults will be addressed.

Older adults have a lower rate of major depressive disorder than middle-aged adults; however, there is a higher prevalence of subclinical symptoms in older adults (Gatz et al. 1996). Data from a number of studies indicate that across the adult life span, the highest depression scores are found among younger adults and persons 75 years and older. As with younger adults, women show higher rates of depression than men, although studies suggest that by age 80, men and women have an equal rate of depressive symptomatology. A subset of depressed older adults that warrant particular concern is white men aged 60–85, particularly those with medical illness or living alone; this group has the overall highest rate of suicide.

Life events, such as deaths of loved ones and change in residence, have shown an inconsistent relationship with depression. Although these negative life events occur more commonly in older adults, some scholars argue that older adults have experienced a number of stressors earlier in life, and/or that older adults are better able to cope and regulate emotion more effectively (e.g., Carstensen and Charles 1998), causing the relationship between negative life events and depression to be less strong among older adults. Physical illness, although a statistically major risk factor for depression, probably is not the causal variable in this relationship. Instead, loss of physical function, such that one cannot take care of basic needs (e.g., dressing, bathing) or must give up valued activities, is the significant vulnerability factor (Zeiss et al. 1996; see also *Depression, Clinical Psychology of*).

Anxiety disorders in older adults occur more often than depression, with estimates of approximately 5.5 percent prevalence (e.g., Beck and Stanley 1997). However, in comparing younger and older adults, the rate of anxiety is lower in older adults than in any other age group. Older women are more likely to be diagnosed with anxiety than older men. Although more prevalent than depression, anxiety disorders have been less studied in older adults. Panic disorders, phobias, generalized anxiety disorder, and post-traumatic stress disorder in older veterans have received the greatest attention.

Dementia is characterized by loss of cognitive function sufficient to impair performance of daily activities. Most dementias are due to irreversible changes in the brain; the most common are Alzheimer's disease and vascular dementias. Revers-

ible causes occur in 10–20 percent of dementia patients, as a response to a medication or physical illness, such as thyroid dysfunction, vitamin B12 deficiency, or a treatable brain lesion. Usually, when reversible causes of dementia are treated, good recovery ensues with return to prior level of cognitive functioning. Since most forms of dementia are progressive, it is important to identify the disease early. However, assessment of dementia in older adults is difficult; in particular, patients differentiating depression and dementing illness can be difficult to differentiate (Kasznik and Scogin 1995). Alzheimer's disease affects not only the person with the disease, but also the family (Thompson and Gallagher-Thompson 1996). Family members experience a range of emotions that can include guilt, anger, and depression. There are also positive components of providing care for a person with Alzheimer's, and many family members report caregiving as a rewarding experience.

1.6 Problems in Daily Living

Clinical geropsychologists need to be aware of many problems that can interfere with the ability to carry out normal daily activities for older adults. These include deficits in social and daily living skills, decision-making capacity, and elder abuse and neglect. Of these issues, elder abuse is one of the most difficult to handle; law in all states mandates reporting of elder abuse; the primary goal of reporting is to stop the abuse.

1.7 Sociocultural and Socioeconomic Factors

A variety of sociocultural issues are important in understanding the experience of aging, including losses from a variety of sources (deaths, end of employment, limitations in functioning, financial problems, environmental restrictions); cross-cultural and minority aging issues (e.g., interacting with older minorities to convey respect); the role of religion and spirituality; and the roles of intergenerational acquaintances, lifelong friendships, intimate relationships, and other social relations.

1.8 Special Issues in the Assessment of Older Adults

Clinical geropsychologists are asked to evaluate older adults with regard to presence or absence of psychopathology, cognitive capacity, competency to make decisions, substance abuse, etc. As with younger adults, the techniques used in psychological assessments include clinical interviewing, life history record and data review, cognitive and neuropsychological evaluations, behavioral assessments, and situational observations; however, with older adults, psycholo-

gists need to use different norms for tests and to include cognitive testing more frequently. With patients who exhibit disruptive and/or potentially harmful behavior (e.g., wandering, shouting, assaultiveness), behavioral assessment is helpful in determining what type of techniques would be useful for working with the patient (see Lichtenberg 1999 for thorough overview).

1.9 Treatment of Older Adults

Psychotherapy with older adults is as effective as therapy with younger adults. Most research on psychotherapy with older adults has used cognitive-behavioral approaches, and these have been shown to be effective for a wide variety of problems (Scogin and McElreath 1994). There also is a small amount of literature supporting the use of other approaches, such as Interpersonal Therapy and Brief Time-limited Psychodynamic Therapy, especially with depression in older adults (see Zarit and Knight 1996).

There are few major content differences in therapy with older compared to younger adults. Older adults have more health problems resulting in functional impairment, and psychological status is often related to their functional status. In addition, older adults may face obstacles in terms of resources for supporting adequate quality of life, such as limited financial resources or transportation, or the experience of loss of friends or family. The largest content difference is the need to deal more frequently with older adults with therapy issues related to death and dying. Many older adults accept death as part of the life course and engage in active adaptations to death, for example, by making wills, leaving instructions, negotiating interpersonal conflicts, and reintegrating life experiences in a meaningful way, but others have greater emotional difficulty in facing death or dealing with losses of loved ones. Clinical geropsychologists must be sensitive to factors that influence the experience of death and dying, including gender, class, economic variables, and cultural considerations. Recent studies have shown that bereavement practices, once highly structured and culturally determined, are becoming diverse; as a consequence, what practices will be therapeutic is becoming more individualized rather than shared within a common culture (Riley 1992).

With regard to therapy process, chronological age is not a good marker for what adaptation of therapeutic strategies originally developed with younger adults may be needed. Therapy adaptations to enhance utility with older adults might be helpful or even necessary, but assessment of each client determines which adaptations are appropriate (see Zarit and Knight 1996 for a thorough summary of suggestions regarding therapy adaptations). Primary areas of adaptation include changes to compensate for memory and information processing deficits with older adults. As a result of cognitive changes, the pace of therapy may be slower

than with younger adults. More repetition of material may be necessary, and processing of new ideas may be slower. Memory aids, such as audiotapes of therapy sessions or written summaries of each session, may be helpful. It may help to present material in multiple ways, both because of potential sensory loss and because repetitions provide multiple routes to memory storage. A key phrase for therapists working with older adults is 'Say it, Show it, Do it': state it clearly, write it down, and help the client use the idea in a specific way.

On the positive side, some changes in therapy process reflect relative strengths of older adults. One such strength can be thought of as wisdom (Baltes and Staudinger 1993), which is an age-related, but not inevitable, consequence of life experience. Older adults have faced many difficult life experiences, and most can abstract helpful information from those experiences and describe personal skills that have helped them handle adversity. Showing respect for the client's accumulated experience can enhance therapy.

1.10 Prevention and Crisis Intervention Services with Older Adults

Outreach, referral, and early intervention are important for making assessment and therapy available to older adults. The organization of many health care systems presents significant obstacles to good care for older adults who may need care provided in their homes, need short, easy drives to reach services, need care for the patient and the caregiving system, etc. In addition, providing health promotion resources to older adults is useful yet often neglected. For example, exercise is effective in improving physical and mental health for older adults, but may not be recommended or supported by health care providers to the extent it is with younger adults.

1.11 Consultation

Since most health care providers are not well trained in providing services to older adults, yet the demand is great and growing, clinical geropsychologists frequently need to provide consultation. Consultation to other professionals is a major component of this work and includes providing specialized information to health care institutions, agencies, and community organizations; providing staff training; and consulting on program development. In addition, consultation to families, lay caregivers, and self-help and support groups is needed.

1.12 Interface with Other Disciplines

Since typical problems older adults face are multimodal, a comprehensive interprofessional approach

to assessment and treatment that encompasses diverse health care providers (e.g., geriatricians, nurses, social workers) as well as psychologists is usually needed. The *biopsychosocial* model combines clinical and scientific approaches to treatment by defining problems in relation to the interactions among biological, social, and psychological systems. This model captures the complexity inherent in addressing the problems of older adults and highlights the need for an inter-professional approach (Zeiss and Steffen 1998).

1.13 Special Ethical Issues in Providing Services to Older Adults

Special ethical issues with older adults include obtaining informed consent for treatment with cognitively impaired elders, balancing patient autonomy and self-determination with apparent needs for care, balancing competing interests between older adults and family members, role conflicts in nursing homes, and confidentiality issues in working with families and teams.

2. Summary and Future Directions

Older adults are a heterogeneous population in terms of values, motives, social and psychological status, and behavior, as well as a quickly growing one. The need for clinical psychologists to be more informed about work with this diverse population of older adults have been summarized in the definition of proficiency in clinical geropsychology. That definition emphasizes broad-based knowledge of aging and adaptations of assessment and treatment for older adults. It also emphasizes the need for psychologists to work as part of interprofessional teams to meet the broad biological, social, and psychological needs of older adults.

However, as helpful as this summary is, much of what we currently know is based on research with the current cohort of older adults, particularly those who are Caucasian Americans. That research does not fully represent the heterogeneity within older adults now and will be less representative of future generations of older adults. In particular, there is considerable speculation that the large number of children born after World War II (now nearing older adult status) may age differently; two competing issues have been raised. First, it is often suggested that this cohort of elders may be more open to psychological interventions, escalating needs for research on assessment and therapy with older adults and for enhanced training of all clinical psychologists regarding work with older adults. On the other hand, coming generations of older adults may be healthier and more functional (Waidmann and Liu 2000), reducing depression and other psychological sequelae of disability, thus reducing the need for psychological

interventions. The increasing proportion of minority elders also will create challenges; as current generations of minority Americans age they will carry with them salient features such as a continuing imbalanced sex ratio, segregated distribution, and proportion in poverty. Clearly, researchers and clinicians in clinical geropsychology need to be guided by research to date but open to dramatic shifts in the field.

Gesture in Linguistics

When we communicate, we not only produce a string of words, but also orchestrate various potentially interpretable body movements such as gesture, gaze shift, holding of a certain posture, interpersonal spacing, self-touch, and bodily symptoms of emotional and physiological states. From the totality of these activities in the communicative situation, this article takes up gesture and examines its relationship to language. In the first section of the article the definition of gesture is discussed and the following sections review its role in conversation, their relation to linguistic semantics and pragmatics, and mental processes underlying speech production.

1. What is Gesture?

Though there is controversy as to how to classify nonverbal behaviors (Efron 1941, Ekman and Friesen 1969, McNeill 1992), the central cases of nonverbal behaviors that have been designated by the term 'gesture' can be captured by the following definition. Gesture is nonpractical, nonlinguistic discrete body movement that arises from the intention to express something, and that encodes some aspects of what is intended to be expressed and/or how the accompanying speech should be interpreted.

Gestures are discrete spurts of body movement, which occur in the background of a period of nongesturing. This is similar to verbal utterances occurring in the background of silence. The sporadic nature of gestures contrasts with the inherently continuous nature of other nonverbal semiotic codes such as posture, interpersonal spacing, and gaze.

Gesture is nonpractical in the sense that gestural body movement is not involved in achieving non-expressive practical goals. For example, the way one holds a cigarette may be used intentionally to express a certain attitude or social affiliation, but it is not considered to be gesture because the body movement serves a practical purpose for smoking.

Gestures arise from the intention to express something. Gesture can be the intended code for transmission of the information. Raising a hand when taking a vote in a meeting is such a case. However, gesture can arise in the situation where gesture seems not to be the code intended for the recipient. For example, it is not uncommon to produce direction-

indicating gestures as one gives directions on the telephone. In such cases, the gestural body movement is still caused by the intention to express the instruction for how to get to the destination.

In this respect, gesture contrasts with self-touch, such as rubbing the chin or fiddling with clothing, in which there is no apparent intention to express. Self-touch also appears in certain noncommunicative settings, for example, while solving a crossword puzzle alone. The presence of expressive intention also distinguishes gesture from bodily symptoms for certain emotional and physiological states, such as blushing. However, some of the affect-displays, such as frowning, can be produced under voluntary control. They can be intentionally produced to express certain affect. This type of behavior blurs the boundary between what is a gesture and what is not.

The issue of intentionality has raised both conceptual and methodological concerns in defining gesture. Many authors maintain that intentionality is an essential ingredient of gesture (Ekman and Friesen 1969, Kendon 1981). However, difficult questions arise once one tries to tackle the issue squarely. Does intentionality have binary states (presence vs. absence) or is it a matter of degree? How can one tell what is intended to be expressed? How can one tell whether a given act is intentional, or how can one assess the degree of intentionality? Kendon (1981) suggested that a solution to the problem of identifying intentionality may be to focus on whether communicational partners treat each other's acts as intentional or unintentional. However, this does not solve the problem for gestures that cannot be seen by the communicational partners, as in the case of gesturing during telephone conversation.

Going back to further definitional features of gesture, gesture encodes some aspects of what is intended to be expressed and/or how the accompanying speech should be interpreted. In other words, gestural body movement itself is the carrier of the information to be communicated. In this respect, gesture differs from 'placing,' in which the body moves an object to a meaningful position (Clark in press). For example, putting merchandise on the cashier's counter signals the intention to purchase the merchandise. In placing, the body movement brings about a meaningful spatial configuration, but in gesture, the body movement itself carries the meaning.

2. In What Way is Gesture Nonlinguistic?

One of the defining features of gesture is its non-linguistic nature. Gesture is distinct from sign language, which is language that transmits codes in the visuo-motor modality (see *Sign Language*). It bears different semiotic properties from language (Kendon 1993, McNeill 1992). Gestures vary as to the degree to which they are semiotically different from language.

2.1 Most Language-like Gestures—Emblems

Gestures that are the most language-like are ‘emblems’ (Efron 1941, Ekman and Friesen 1969) such as the Euro-American OK sign with a ring formed by the thumb and the index finger. Emblems share some properties with words in a language. Emblems have standards of form. Their form-meaning relationship shows a relatively high degree of arbitrariness. Standards of form and form-meaning pairing are shared by a community of users (Calbris 1990, Morris et al. 1979).

Despite the above similarities to words, emblems also exhibit important differences. First of all, emblems are extremely limited in their potential for sequential combination, that is, combinatorial rules that operate over multiple emblems, namely, something equivalent to syntax, are impoverished.

Furthermore, Sparhawk (1978) showed that Persian emblems are not built up on the basis of a unified system of contrasting formational features, namely, something equivalent to phonology. It was found that the palm facing up vs. down is a formational feature that contrasts many Persian emblems. However, for the emblems with a certain class of meaning, namely beckoning emblems (e.g., the ‘come here’ emblem), this feature is not contrastive, and thus the palm can be facing either up or down. This is because the feature is considered to be irrelevant for the iconic make-up of the emblems.

The conclusion that emblems are not governed by unified ‘phonology’ has an important consequence for the ‘Kinesics’ approach to the analysis of semiotic body movements (Birdwhistell 1970), which is inspired by structural linguistics. In this approach, the existence of a system of ‘kinemes,’ the gestural equivalent of phonemes, is a fundamental assumption. However, even in the most language-like class of gestures, ‘kinemes’ do not constitute a unified system.

In summary, emblems differ from words in a language in that emblems are not fully unified by formal principles that relate emblems with one another. In other words, formal systems that are equivalent to syntax and phonology organize emblems only to a very limited extent.

2.2 Least Language-like Gestures—Gesticulations

Gestures that are least language-like are called ‘gesticulations’ (Kendon 1993) or simply ‘gestures’ (McNeill 1992), which spontaneously accompany speech, and usually share semantic and/or discourse-pragmatic contents with the concurrent speech.

Gesticulation consists of two subtypes: ‘beats’ and ‘representational gestures.’ Beats are small rhythmic bidirectional movements, in which hands typically move up and down or flip out and back. They occur when the concurrent speech should be interpreted in a context different from the ordinary flow of discourse

(e.g., speech is being repaired, or speech is expressing the beginning of a new discourse unit) (McNeill 1992). Representational gestures express location, direction, action, movement of objects, and shape of object, by means of iconicity (i.e., resemblance between the gestural shape and the referent) and/or spatial indexicality (i.e., the spatial contiguity between gesture and the referent). Representational gestures can be metaphorical in the sense that they can spatialize abstract ideas (Calbris 1990, McNeill 1992).

Gesticulations share fewer semiotic properties with language than emblems. The form of gesticulations is less constrained by conventionalized standards. The iconic representation in a gesticulation is largely idiosyncratic moment-by-moment creation. Thus, gesticulations are flexibly shaped in accordance with the variation in the spatial or actional characteristics of the referent. A sequence of gesticulations can comprise a larger meaning unit only by virtue of iconicity, as a multigesture depiction of a ‘picture’ of the referent(s).

3. In What Ways Does Gesture Have an Essential Connection to Language?

In the previous section, the difference between gesture and language as semiotic systems was highlighted. Gesture, however, has essential connections to interactional, conceptual, and psychological aspects of language.

3.1 Gesture in Face-to-face Conversation

Gestures contribute to face-to-face conversation in various ways. First, gesture can express some aspects of the content to be conveyed, which may or may not be expressed in the concurrent speech, and gesturally expressed information is taken up by the interlocutor (Kendon 1994). The interlocutor’s attention to gesture is also evidenced by the fact that gestures elicit verbal acknowledgement like ‘uh huh,’ and nonverbal acknowledgement like nodding from the interlocutor (Goodwin and Goodwin 1986, Streeck 1994).

This leads to the second way in which gestures contribute to conversation. Gesture is a part of complex cues as to when nonspeaking interlocutors can jump in and take the speaking turn (Schegloff 1984, Goodwin and Goodwin 1986, Streeck and Hartge 1992). One of the relevant features of gestures is that they are initiated slightly prior to the portion of speech that expresses the related content, and their temporal extent typically overlaps with the co-expressive speech (Schegloff 1984, Morrel-Samuels and Krauss 1992, McNeill 1992). The temporal precedence of gesture projects that the speaker is going to deliver speech further, and this can preempt the interlocutor’s attempt to take the turn.

The third way in which gestures contribute to conversation is to mark discourse-pragmatic status of the concurrent speech. Kendon (1995) reports Southern Italian emblems that indicate discourse-pragmatic status of the concurrent speech. More specifically, they mark the topic-comment structure and the illocutionary force (e.g., demanding information, making a plea for understanding) of an utterance.

3.2 *Gesture and Deixis*

Gesture plays a crucial role in spatial deixis (see *Deixis*), in which the attention of the interlocutor is directed to the direction along which the referent (or the physical clue to the referent) can be found.

Gesture also plays a crucial role in 'abstract deixis,' in which a pointing gesture creates a referent in seemingly empty space in front of the speaker (McNeill et al. 1993). The speaker can point repeatedly to a locus in the empty space, as the same entity is referred to in the concurrent speech. The referent that such gestures spatialize can be something that could exist in space (e.g., a person who is not present), or something inherently nonspatial (e.g., time, plot-line of a story). Thus, the role of gesture in deixis is not only a passive one, in which a gesture is oriented toward a pre-existing target, but also an active and creative one, in which the act of gesturing materializes conceptualization of the speaker as a spatial entity in the extralinguistic context.

3.3 *Gesture and Speech Production*

Gesture and speech are produced in close temporal and informational coordination. As noted in Sect. 3.1, a gesture typically is initiated prior to the co-expressive portion of speech, and the gesture and the co-expressive speech temporally overlap. In addition, the production of gesture has a systematic relationship to intonational units. A gesture rarely crosses tone unit boundaries, and typically, there is one gesture per tone unit (Kendon 1980, McClave 1991). These findings suggest that there is a mental process that coordinates speech and gesture production (Kendon 1980, Morrel-Samuels and Krauss 1992, McNeill 1992) (see *Speech Production, Psychology of; Speech Production, Neural Basis of*).

3.3.1 *Gesture and ideophones.* The exact meeting point of gesture and speech production processes is a highly debated issue (see McNeill 2000). One phenomenon that sheds some light on this issue is the fact that linguistic entities that have imagistic and emotive meaning are highly associated with iconic representational gesture. One such entity is the class of

words called 'ideophones' (also referred to as 'mimetics'). Ideophones are sound-symbolic words, for which native speakers report vivid imagery and emotion as their meaning. They include onomatopoeic words such as animal cries, but their referential domains go far beyond sound emitting entities (e.g., color, smell, wetness, density, emotion, and manner of motion).

Japanese is one of the languages in which ideophones comprise a large word class and they are commonly used. It was found that when Japanese speakers used an ideophone in narrative, it was almost always accompanied by a co-expressive iconic gesture (Kita 1997). This suggests that iconic gestures and ideophones are produced from common underlying mental representation that is imagistic in nature. In other words, iconic gestures are produced from imagistic representation that is evoked in the speaker's mind.

3.3.2 *Gesture and psycholinguistics.* Gestures that spontaneously accompany speech can be used as a 'window' into speech production processes, through which one can gain insights into the speaker's on-line conceptualization (McNeill 1992). In such a line of inquiry, representational gestures have been in the focus. Since the shape of representational gestures is not completely determined by convention, there are ample degrees of freedom left for idiosyncratic expression of the speaker's thought.

Representational gestures are created on-line by the speaker, and are typically co-expressive with the concurrent speech in the sense that they express the same object, action, event, or spatial relation as the speech, albeit from a different perspective and with a different mode of expression. As discussed above, the form of a representational gesture and its meaning are mediated by iconicity and spatial indexicality. Furthermore, ideophones, whose semantics is inherently imagistic, are almost always produced with a co-expressive iconic gesture. In short, representational gesture is imagistic, idiosyncratic, and non-linguistic; in contrast, speech is mainly propositional, and based on a conventionalized system of signs.

It has been argued that the underlying mental representation for a gesture-speech complex is produced by a single mental process involved in the verbalization of thought (Kendon 1980, McNeill 1992). McNeill stresses the significance of the semiotic duality of a gesture-speech complex. He argues that when the speaker tries to verbalize thought, he or she is engaged in two kinds of thinking: imagistic thinking and linguistic thinking. When the speaker finds a connection between idiosyncratic imagery and socially-constituted linguistic signs, a mental seed from which a gesture-speech complex develops is formed. In this process, imagery is grounded in a socially shared linguistic system, and words are con-

nected to a specific image in the speaker's mind. According to McNeill, the formation of a unified representation that integrates idiosyncratic and social sign systems is a crucial initial step in the verbalization of thought.

It has been suggested that gestures are not only the reflection of the speaker's thought, but they also facilitate verbalization of thought. There is controversy as to the exact nature of the facilitation (see McNeill 2000). Some argue that representational gestures facilitate retrieval of lexical items from the mental lexicon (Morrel-Samuels and Krauss 1992), but others argue that conceptual planning for speaking is facilitated (Alibali et al. 2000).

4. Conclusion

Gesture is a semiotic system distinct from language. At the same time, it is intimately linked to various aspects of linguistic performance. Gesture is an integral part of the organization of face-to-face conversation. Pointing gesture is an essential part of referential acts by means of spatial deixis. The production of intonation and ideophones are tightly coupled with the production of a gesture that is co-expressive. The speaker's imagistic thinking during verbalization of thought is revealed by gestures that spontaneously accompany speech. Because of the interactional, referential, and psychological unity of gesture and language, the understanding of language is not complete unless gesture is taken into account.

Gifted and Talented Individuals: Developmental and Educational Overview

Some individuals stand out among their peers because of their remarkable abilities; they are called gifted or talented. What do these two terms mean? How many can be labeled gifted or talented? Are some youngsters much more gifted/talented than others? Are they more at risk developmentally than their average ability peers? What are their major educational needs, and how do school systems answer these needs? These are the major themes covered by this brief overview of a field traditionally named Gifted Education.

1. The Nature of Giftedness and Talent

Most published definitions of giftedness and/or talent use these two terms as synonyms (Sternberg and Davidson 1986). Yet, most scholars recognize at least implicitly two distinct manifestations of that phenomenon: (a) a natural, nondeveloped form manifested as precocious early development and presented as a 'potential', and (b) an adult well-developed form characterized by outstanding achievements in a field of human activity. Gagné (1993) proposed a developmental model that uses this distinction to create differentiated definitions for the two key concepts of giftedness and talent.

1.1 Gagné's Differentiated Model of Giftedness and Talent (DMGT)

In the DMGT, *giftedness* designates the possession and use of high natural abilities (called aptitudes) in at least one of four ability domains (see Fig. 1), so that the level of performance places the person among the top 10 percent of same age peers. *Talent* is the

demonstration of systematically developed and trained abilities in any field of human activity at a level such that the individual is among the top 10 percent of peers having had equivalent training. The six components of the DMGT bring together in a dynamic way all the recognized determinants of talent emergence in any field of human activity.

Natural abilities, which have a partial genetic origin, can be observed more directly in young children because environmental influences and systematic learning have exerted their moderating influence in a more limited way. However, they still manifest themselves in older children, even in adults, through the *ease and speed* with which individuals acquire new skills. The easier or faster the learning process, the greater the gifts. Many laypersons call these gifts 'natural talent.' Talents progressively emerge from the transformation of high aptitudes into the well-trained and systematically developed skills typical of a particular field of human activity. Thus, natural abilities act as the raw materials or *constituent elements* of talents: one cannot become talented without being gifted. However, the converse is not true: it is possible for outstanding natural abilities not to be translated

Figure 1
Gagné's differentiated model of giftedness and talent

into talents, for instance when intellectually gifted children achieve poorly in school.

The process of talent development manifests itself when the individual engages in systematic *learning and practicing* (courses, music conservatory, competitive team, etc.); the higher the level of talent sought, the more intensive these activities will be. This process can be facilitated or hindered by two types of *catalysts*: *intrapersonal* and *environmental*. Among the intrapersonal catalysts, motivation and volition (or persistence, see Corno and Kanfer 1993) play a crucial role in initiating the process of talent development, guiding it, and sustaining it through obstacles, boredom, and occasional failure. Genetic predispositions to behave in certain ways (temperament), as well as acquired personality traits and attitudes, also contribute significantly to the talent development process. The environment manifests its significant impact through four agents, either physical or social. *Chance* appears in the model as a fifth causal factor; it affects the others in different ways (e.g., the randomness of the genetic endowment for abilities or temperament, the chance of having good parents, accidents, etc.). In summary, talent emerges progressively from natural gifts thanks to a complex choreography between numerous causal influences.

1.2 How Many Are There?

Giftedness and talent are *normative* concepts. Such concepts define populations that are different from the norm (e.g., obesity, poverty). Good definitions of normative concepts must specify to what extent the target population differs from the norm and what it means in terms of their prevalence. In the DMGT (Gagné 1998), the threshold for both the giftedness and talent concepts is placed at the 90th percentile. That threshold applies to *each* giftedness domain or talent field; thus, the *total* percentage of gifted and talented persons probably exceeds 30 percent. This generous minimum threshold is counterbalanced by a system of levels of giftedness and talent. Within the top 10 percent of 'mildly' gifted or talented persons, the DMGT recognizes four progressively more selective subgroups, respectively labeled 'moderately' (top 1 percent), 'highly' (top 1:1,000), 'exceptionally' (top 1:10,000), and 'extremely' (top 1:100,000).

1.3 Focus

The field of gifted education traditionally has focused on one form of giftedness (intellectual) and one form of talent (academic). There is also some theoretical interest for creative giftedness, although identification procedures rarely include creativity measures. This article will respect that tradition and redefine the gifted and talented as *intellectually gifted and*

academically talented (IGAT) students. Intellectual giftedness usually is measured with individual or group intelligence (IQ) tests, whereas academic talent is assessed through grades or standardized achievement tests.

2. Developmental Overview

Except when noted, statements in this section apply best to mildly and moderately IGAT children, who account for 99 percent of that population.

2.1 Personal and Social Development

Most gifted children manifest some form of precocity (e.g., speaking, reading, counting). The degree of precocity is moderately correlated with the level of giftedness. Within the realm of intrapersonal catalysts, the picture is frequently ambiguous. For instance, gifted students do not appear more intrinsically motivated to learn than their average peers (Shore et al. 1991). But there is a tendency for those who achieve well to manifest slightly more persistence. That slight superiority extends to most measures of personal adaptation, whether global ones, like self-administered personality tests, or more specific indicators, like scales for anxiety, depression, or suicidal ideas. IGAT students tend to manifest fewer behavior problems in school, and the incidence of drop outs and delinquents is lower (Neihart 1999). In the case of self-esteem, study results reveal no clear tendency; differences between studies could be associated with the type of educational environment.

Social adaptation refers to friendships, popularity, leadership, and so forth. Socially, gifted youths fare usually as well, sometimes slightly better, than their average peers. Their achievements will often provoke envy, but, most of the time, it is positive envy (admiration, emulation). Are exceptionally gifted individuals more at risk for social or personal adaptation because of the larger gap with their average peers? The scientific literature shows inconsistent results; some studies indicate an increase in the frequency of maladjusted individuals—who still remain a minority (at worst 20–25 percent)—others do not (Norman et al. 1999). Some of these problems could result from inadequate responses to their educational needs.

With regard to environmental catalysts, statistics show clearly that the parents of IGAT students have on average a higher socioeconomic status. According to Herrnstein's syllogism (Herrnstein and Murray 1994), both the partial genetic inheritance of intelligence and the moderate relationship between IQ and educational attainments could account in large part for that modest over-representation.

In summary, the research base tends to invalidate the 'nerdy' stereotypical image of gifted youths.

Moreover, it proclaims loudly that IGAT students differ much more among themselves than they do when compared, as a group, with average ability peers.

2.2 Educational and Life Achievements

Intellectual giftedness is synonymous with easier and faster school learning, which leads to academic talent for most of them as long as their progress is not impeded by unfavorable intrapersonal or environmental catalysts. The close relationship between IQ scores and academic achievement is probably the best documented causal relationship in education. IGAT students have much better chances of completing high school, and earning a university degree. As the level of talent increases from moderate to exceptional, the DMGT's catalysts and practice component play an increasingly important role, especially will-power (Simonton 1994). Nobel prizes, Olympic medals, or international careers in music require intense and prolonged efforts. But such high achievements are extremely rare. In fact, according to the results of Terman's famous longitudinal study of 1,400 moderately gifted students (Oden 1968), only a minority of IGAT youngsters ever achieve eminence. Other studies with shorter time span confirm that result. This is not surprising since the prevalence of eminent individuals is well below 0.1 percent of the total adult population.

3. Educational Overview

3.1 Educational Needs

Because of their high cognitive abilities, gifted children can easily understand more abstract concepts and more advanced reasoning processes; and they can do that at a much faster pace than average. It is not rare for highly IGAT students to outpace age peers academically by 3 to 5 years. For instance, the US 'talent searches' (Assouline and Lupkowski-Shoplik 1997) identify thousands of mathematically precocious students in grades 7 or 8 by administering them the *Scholastic Aptitude Test*, a test normally used in grade 12 for college admission. Unfortunately, compared with their prevalence in schools, a very small percentage of IGAT students enjoy a school environment that meets their educational needs. The school curriculum targets regular students, and US studies have shown that (a) teachers adjust the normal pace to students close to the 30th percentile, and (b) that the content of school manuals has decreased in density ('dumbing down') since the 1980s (Reis et al. 1993). The short-term consequence is recurring boredom due to lack of challenge. The long-term risks are partial loss of interest for school learning and underdeveloped emotional and strategic skills to overcome obstacles. In summary, IGAT students need a chal-

lenging school experience, both in pace and content. Responses recognized as most appropriate differ from the regular curriculum in terms of both content and format.

3.2 A Specific Curriculum: Enrichment

Curricular adaptations specific to IGAT students are grouped under the general concept of *enrichment*, which can take four major forms—the four Ds. The first, enrichment in *Density*, corresponds to a faster learning pace, allowing for more content per unit of time. It corresponds to Renzulli's 'curriculum compacting' (see Reis et al. 1993). Not only does it make the learning process more enjoyable, but it also frees time for other enrichment activities. Enrichment in *Diversity* allows IGAT students to explore subjects outside the regular curriculum of a given grade level (astronomy, genetics, museum visits, history, etc.). Enrichment in *Difficulty* introduces concepts and explanations well beyond the level planned for regular students. For instance, IGAT students will understand very rapidly the extension of the binary system to any form of non-decimal measurement system. Enrichment in *Depth* allows students to pursue a personal interest through a long-term research project. Most large-scale enrichment programs in schools combine the four Ds in varying proportions.

3.3 Appropriate Formats: Grouping and Acceleration

In theory, thanks to curricular individualization, teachers should be able to respond to the particular educational needs of every student in their heterogeneous classroom. In reality, it is rarely done. An important US survey of classroom practices (Archambault et al. 1993) revealed that little differentiation is made, except for occasional special activities when IGAT students complete their schoolwork early. That demonstrated lack of individualization confirms the imperative need for ability grouping, either part-time or full-time. Numerous studies have shown the academic and socioaffective benefits of full-time grouping (Kulik 1992), subject to one essential condition: offering these students a truly enriched curriculum. Full-time grouping is rarely used below high-school level, except in special schools. The most popular grouping format in elementary schools, called 'pull-out classes,' uses resource rooms where students gather, usually for one or two half-day periods a week. A specially trained teacher supervises enrichment activities, combining the four Ds in various ways to tailor activities to the students' interests.

The concept of school acceleration encompasses various administrative procedures that allow students either to begin earlier than normal or to progress faster through the grade levels. It includes, among others,

grade skipping, covering in one year the curriculum of two grade levels, early entrance to school, credit by examination, and radical acceleration (skipping three years or more). Because it is made possible by intensive enrichment in density, it should be considered a true form of enrichment. Acceleration is undoubtedly the most controversial of all format prototypes. The major fear is the personal and social maladjustment of younger students among older peers due to insufficient maturity. Yet, hundreds of evaluative studies have shown little factual support for that fear (Southern and Jones 1991). When school acceleration is carefully planned and implemented, with appropriate follow-up, the large majority of students adapt very well to their new academic and social environment. But, in spite of compelling scientific evidence for its effectiveness, parents and educators alike remain very reluctant to choose it.

4. Conclusion: The Politics of Gifted Education

Worldwide, IGAT students remain the most underserved of all special school populations. Compared with the millions of dollars spent by ministries of education for all forms of disabling conditions, gifted education receives almost no direct subsidies. Advocates for these children face many objections: fear of elitism, fear of increasing the gap between the highest and lowest achievers, the need to prioritize those at risk, feelings that intellectually gifted students will succeed anyway. The accusation of elitism is based on the already mentioned observation that IGAT students come disproportionately from affluent families; but the disproportion in percentages conceals the fact that, in terms of numbers, many more IGAT students belong to families with average or below average socioeconomic status. Moreover, why should fast learners be denied an appropriate learning environment because of their social origin? As stated in the UN Bill of Rights of children, all children have a right to an education that will foster the maximum development of their abilities and personality.

Giftedness, Psychology of

1. Historical Perspectives

The history of giftedness is over 3000 years old. Interest in giftedness is evident in several cultures, with examples to be found in ancient Greek (Athenian) and Judeo-Christian traditions as well as in the Chinese Ming Dynasty. In the twentieth century there were fluctuations in public as well as scientific interest in this theme (for greater detail see Tannenbaum 2000).

Although the German personality psychologist William Stern promoted the research and diagnosis (identification) of giftedness in a 1916 publication and the American intelligence researcher Lewis M. Terman started the most comprehensive to date ('Genetic Studies of Giftedness' in California in 1922–1923, for which the most recent follow-up research report was presented in 1995), intensified psychological interest in

giftedness only gathered true momentum in the last 30 years of the twentieth century. This was prompted, above all, by two events and their consequences: the Threat of Sputnik in the USA and the Cultural Revolution on the mainland of China. The influential conflict of the 1960s between egalitarianism (or 'democracy') and excellence was, in the 1970s and 1980s, increasingly overshadowed by the economic demand for the activation of human resources through gifted education. Under these conditions, the number of gifted programs grew globally in the last decades of the twentieth century. Accordingly, research questions at the beginning of the twenty-first century are dominated by applied research rather than the acquisition of knowledge in the sense of basic research. Even so, experimental and field studies in the paradigms of cognitive theory, lifespan, social psychology, learning, and instructional psychology have, in recent years, won growing significance (Sternberg and Davidson 1986, Colangelo and Davis 1997, Heller et al. 1993, 2000).

2. Definition Problems and Newer Conceptions of Giftedness

The terms giftedness and talent are used synonymously in everyday language and the scientific literature (Heller et al. 1993, 2000, Colangelo and Davis 1997). Because gifted or talented individuals are a very heterogeneous set of persons, a comprehensive theory is hardly possible. Furthermore, Ziegler and Heller (2000) identify a series of empirical, ontological, and meta-theoretical difficulties with conceptions of giftedness and talent.

'For example, several conceptions of giftedness incorporate genetic influences as a significant component of the basic meaning of talent. In fact, there is a large body of research that proves that genetic influences account for some inter-individual differences. Wagner (1999) indicates ... that these genetic influences have only been proven by untrained persons.' Ericsson drew the plausible conclusion that 'the estimated performance barriers seen as genetically fixed upper boundaries can be overcome through suitable learning processes' (Ziegler and Heller 2000, p. 3).

Eysenck and Barrett (1993) view giftedness as a 'fuzzy concept' that can be defined as synonymous with general intelligence, creativity, and special (e.g., artistic or scientific) ability. Gallagher and Courtwright (1986) point out two distinct meanings based on the psychological context (with a focus on individual differences) and educational practice (with a focus on individual needs and special educational programs). Sternberg and Davidson (1986) analyzed no less than 17 different conceptions, which they divided into explicit and implicit terms. An example of an implicit conception was delivered by Tannenbaum who viewed the interaction of five factors—

general ability, special ability, nonintellective (motivational, etc.), environmental, and chance factors—as resulting in gifted/talented performance. Also Renzulli's giftedness model is counted by Sternberg and Davidson among the implicit theories, while Gagné's or the Munich psychometric model as well as Sternberg's cognitively-based triarchic model of intellectual giftedness are examples of explicit (empirical, experimentally confirmable) theories. A common basis shared by these newer conceptions is that giftedness is conceptualized as a differential construct. For greater detail see Ziegler and Heller (2000).

Contrary to the older IQ-based definitions (e.g., Terman defined giftedness by IQ-scores of 135 and higher), models of giftedness developed in the 1980s and 1990s represent multidimensional or typological conceptions. The following is a list of examples:

(a) The *Three Ring Model* by Renzulli (1986). According to this model, giftedness is a result of above average intelligence, creativity, and task commitment. This was expanded by Mönks to include family, school, and peer group, making a dynamic *Six Factor Model*; see Renzulli (1986), Mönks and Mason (2000).

(b) Gardner's *Theory of Multiple Intelligences*. Originally Gardner (1983), Gardner postulated seven distinct human intelligences: linguistic, logical-mathematical, spatial, bodily-kinesthetic, musical, intrapersonal, and interpersonal. Recently he has added 'naturalistic' (the ability to discern patterns in the living world) as an eighth intelligence and two further candidates (8 1/2): 'existential' and 'spiritual' intelligences, which have not yet been confirmed empirically (Ramos-Ford and Gardner 1997). This typological model synthesizes psychometric, cognitive psychological, and neuropsychological approaches to conceptualize *giftedness* (a more accurate label than 'intelligence').

(c) Gagné's *Differentiated Model of Giftedness and Talent*, the newest version of which was presented by the author (2000). Gagné differentiates between three concepts: genetically determined gifts (aptitude domains), talents (fields of exceptional performance), and catalysts (personality vs. environmental supportive factors). The gifts—intellectual, creative, socio-affective, sensorimotor, and other factors—are transformed, with the assistance of catalysts as well as learning and training processes, into domain-specific talents, e.g., in arts, sports, science, and technology.

(d) The *Munich Typological Model of Giftedness* by Heller et al. (see Heller and Feldhusen 1986, Heller 1992/2001). This multidimensional giftedness model consists of seven relatively independent ability factor groups (*predictors*), various performance domains (*criterion variables*), as well as personality (motivational, etc.) and social environmental factors which serve as moderators for the transition of individual potentials into excellent performances in various domains. High ability or giftedness is defined as an individual (intellectual, creative, etc.) potential for

Legend:

talent factors (predictors)

- intelligence (language, mathematical, technical abilities, etc.)
- creativity (linguistic, mathematical, technical, artistic, etc.)
- social competence
- practical intelligence
- artistic abilities
- music ability
- psycho-motor skills

(non-cognitive) personality characteristics (moderators)

- achievement motivation
- hope for success vs. fear of failure
- control expectations
- thirst for knowledge
- ability to deal well with stress (coping with stress)
- self-concept (general, scholastic, of talent, etc.)

environmental conditions (moderators)

- home environmental stimulation ("creative" environment)
- educational style & parental educational level
- demands on scholastic performance made at home
- social reactions to success and failure
- number of siblings and sibling position
- family climate
- quality of instruction at school
- differentiated learning and instruction
- school climate
- critical life events

performance areas (criteria)

- mathematics, computer science, chess, etc.
- natural sciences
- technology, handicraft, etc.
- languages
- music and artistic areas
- social activities, leadership, trade, etc.
- athletics/sports

Figure 1
The Munich typological model of giftedness

outstanding achievements in one—not too narrowly defined—domain (one-sided talent) or two—seldom more—domains (multi-talent). Hence giftedness is conceptualized as a multifactorized ability construct within a network of noncognitive (motivational) and social moderators as well as performance-related variables. For diagnostic purposes (identification), the differentiation between predictor, criterion, and moderator variables (in Gagné's model, so-called 'catalysts') is of particular interest (see Fig. 1). The validity of this model of giftedness has been confirmed in several enlarged studies both in Germany and in international settings (cf. Heller 1992/2001, Perleth and Heller 1994, pp. 77–114). The *Münchener Hochbegabungs-Testbatterie (MHBT)* [Munich High Abilities Test] by Heller and Perleth (eds.) which measures the various model variables (predictors, moderators) has recently been published.

(e) The *Triarchic Theory of Intellectual Giftedness* developed by Sternberg in 1985 (see Sternberg 1986, 1997) represents a process-oriented conception. In cognitive psychological research paradigms, thinking and problem-solving *processes* stand in the limelight. The triarchic theory consists of three subtheories: a) the *componential-subtheory*, whereby *metacognitive* competencies regarding the planning, monitoring, and control of actions, *performance* components in the sense of encoding and the solution of problems, and *knowledge-acquisition* components are of major significance; b) the *experiential- or two-facet-subtheory* with the aspects of *automatization* or *subroutine* vs. insight or creative thinking in the solution of (new kinds of) problems; and c) the *contextual subtheory*, which refers to sociocultural dependence of talent definitions.

Further process-oriented conceptions of giftedness are discussed by Siegler and Kotowsky in their literature survey (1986). Their two levels of giftedness correspond to those delineated by Renzulli through his division into 'schoolhouse giftedness' (intelligence) and 'creative-productive giftedness' (creativity). The diagnostic implications of these have often been confirmed, in that (multifactorial) intelligence tests can predict scholastic success, although they cannot be (exclusively) used to predict academic or career success. On the other hand, creativity tests have proved to be unreliable predictors of scholastic success, although they can often explain significantly larger portions of the variance in career success than intelligence tests. This brings us to our next question regarding the advantages and disadvantages of various research approaches.

3. Research Paradigms in the Field of Giftedness

The field of giftedness research differentiates among several types of paradigms, whereby synthetic approaches have recently been accorded a large amount

of attention. The psychometric paradigm is based on the trait and factor approach (e.g., Terman, Gagné, Gardner, Heller) already proven in the field of psychology. It focuses on the description of the phenomenology and structure of giftedness and talent (nomothetic function) and is indispensable for identification (diagnosis) of giftedness. Investigations based on the cognitive theory paradigm focus on the explanation of differences in the learning and thinking processes of highly gifted versus less gifted individuals (idiographic function). Such information about the mechanisms of cognitive processes and their individual causes provides not only new theoretical recognition but also useful contributions to the practice of gifted education and counseling. Hence both paradigms are needed, and they should be viewed in terms of how they complement one another. Furthermore, the expert-novice paradigm enriches cognitive theory in terms of the motivational effort variable 'deliberate practice' (cf. Ericsson 1996). While cognitive and metacognitive components are the focal point of cognitive componential approaches, in the expert-novice paradigm these are neglected in favor of the quantity and quality of learning and training processes. This approach has particularly proven its worth in the explanation of expertise in the domains of chess, physics, music, and athletics, but the extent to which this approach can be useful for explaining expertise in other domains must still be empirically confirmed. Even more interesting are recent attempts to combine prospective (psychometric) and retrospective (process-oriented) approaches in the form of the expert-novice paradigm. The intention here is to avoid the weaknesses inherent in the trait-oriented psychometric approach (underestimation of the influences of long-term deliberate practice) in so-called 'testing the limits' conditions (see Howe et al. 1998) and of the incremental (implicit) ability theory (according to Dweck) as well as those of the experience-oriented approach in the expert-novice paradigm (underestimation of innate talents in favor of learning processes); for recent contributions to the genetic influence vs. environmentalism controversy see Howe et al. (1998) including the 30 open peer commentaries. In the genetic and brain research-related approach the focus is on a biological explanation of giftedness and talent (cf. Thompson and Plomin, Eysenck and Barrett 2000).

Although the research paradigms sketched out here conceptualize giftedness more or less as individual resources, the following approaches concentrate on social and learning environment-related conditions. The *interactionist* theories try to balance the position between innate capacities and socialization influences with respect to the development of giftedness and excellence in various performance domains. Here lifespan developmental psychology is interested in the description and explanation of the individual's change of behavior throughout the life course (cf. Mönks and Mason 2000). *Psychosocial* and *cross-cultural*

approaches primarily analyze the external context conditions of the development of giftedness and outstanding achievements (cf. Tannenbaum 1983). From cross-national, cross-cultural, and cross-societal research approaches one can expect not only information about various social-cultural influences on the individual developmental and gifted education processes within specific social settings (*-etic* approach), but also explanations regarding the universality of gifted behavior characteristics (universalism hypothesis in the *-emic* approach). The latter function is, above all, indispensable for examining universality assumptions of many theories—here, in the field of giftedness.

4. Identifying and Programming (Gifted Education and Counseling)

Perspectives related to the application of results of research in giftedness include the identification of the gifted and the nurturing and counseling of gifts or talents. Both aim to optimize the development of personality in individual and social developmental conditions. To this end, diagnostic information is necessary, i.e., about characteristics of the individuals and their learning environments. Provided that one can conceptualize the development of giftedness as an interactive product between internal (cognitive and motivational) factors and external socialization conditions, multidimensional tests for the identification of the gifted are necessary. Correspondingly, a comprehensive diagnosis of giftedness cannot be defined by one type (for example within the framework of talent searches for specific promotional courses, scholastic programs, contests, etc.), but rather have to keep individual differences in moderation styles in mind (cf. Fig. 1). It is these moderating variables which frequently offer opportunities to provide effective counseling or intervention, for example underachievers or other at-risk groups. Here, 'at-risk groups' refer to highly gifted and talented girls, gifted handicapped, gifted underachievers, or disadvantaged and culturally different talented, because for these groups a higher risk not to be identified as gifted exists (cf. Yewchuk and Lupart 2000). In order to expand on status diagnostic methods, approaches involving *dynamic assessment* (cf. Kanevsky 2000) are available to assist in the identification of gifted underachievers. Since most norm-oriented ability or intelligence tests, including creativity tests, have proven to suffer from *ceiling effects* in application, they are inadequate for identification, particularly on the basis of IQ-scores. More suitable are multidimensional cognitive abilities tests, such as the Munich High Abilities Test (MHBT) by Heller and Perleth (cf. Heller 1992/2001), developed along the lines of the Munich Giftedness Model (Fig. 1). Here, differential talent predictors with respect to various aspects of intelligence, creativity, musicality, psychomotorics, social and practical intelligence as

well as relevant noncognitive (motivational) and social moderators are measured in order to determine outstanding performance (criterion) in various domains.

In order to reduce the bandwidth fidelity dilemma, or so-called alpha and beta errors as defined by Cronbach and Gleser, a *sequential decision strategy* can be used. Initially a *screening* (e.g., with teachers' checklists) comes up with a rough estimation for the reduction of the beta error ('oversights' of gifts and talents), after which in the second and possibly third steps, domain-specific (multidimensional) abilities tests etc. are probed in order to reduce the alpha error (in order to avoid false identifications). For more detailed explanations see Heller and Feldhusen (1986), Mönks and Heller (1994), Colangelo and Davis (1997, pt. II) or Heller et al. (1993, 2000, pt. III).

Gifted education strives for both the promotion of effective, creative learning environments versus a fit between stimulating family and scholastic settings and the individual needs for learning, e.g., striving for knowledge, exploratory urges, challenges in the sense of testing one's limits, etc. The Aptitude Treatment Interaction (ATI) Model provides the theoretical basis for these constructs. Quick information processing and accelerated cognitive and metacognitive competencies afford these children and adolescents effective self-regulated, discovery learning without a high risk probability for the acquisition of misconcepts (as among low gifted). In order to avoid understimulation and boredom among highly gifted and talented students, multifaceted scholastic differentiation measures are necessary, whereby two prototypes can be delineated: enrichment and acceleration, which can also be effectively combined. For more information regarding various instructional models and programs of nurturing the gifted and talented see Colangelo and Davis (1997, pts. III and IV), Heller et al. (1993, 2000, pts. IV and VI).

Finally, *gifted counseling* is often needed for enhancing the socialization processes in gifted education, especially with respect of the at-risk groups mentioned above. Opportunities for counseling regarding themes relevant to the highly talented differ with respect to quality and quantity, particularly with respect to gender and age of the clientele, but also regarding family and scholastic socialization as well as regional counseling offerings. Furthermore, relationships to socioeconomic family status have been confirmed. For more detailed information see Colangelo and Davis (1997, pt. V), Heller et al. (1993, 2000, pt. V) or Heller and Feldhusen (1986, Chaps. XI and XII). Counseling the gifted and talented should be an integral part of gifted education.

K. A. Heller

Global Environmental Change: Human Dimensions

1. Introduction

Global environmental change is as old as planet Earth. Physical, chemical, and biological processes have been shaping and reshaping the earth's environment since its infancy 4.5 billion years ago. In recent time, however, humankind has been one of the major driving forces of change on the planet, including climate change, stratospheric ozone depletion, deforestation, loss of biodiversity, acidification, pollution, and desertification (see, for example, Turner et al. 1990).

Research on the human dimensions of global environmental change is concerned with the human causes of change, the consequences of such changes

for individuals and societal groups, and the ways in which humans respond to the changes.

The causes include processes like industrialization and urbanization, which themselves are driven by human needs and wants, such as the needs for water, food, and shelter. The impacts include water and food shortages, floods and droughts, health risks, and conflicts about resources. Responses to these changes include adaptation, for example, through planting different crops, and even migration from areas most affected by environmental changes and mitigation, for example, by reducing emissions of gases into the atmosphere.

Individuals and teams carry out research on the human dimensions of global environmental change in many universities and research institutes worldwide.

The range of social science disciplines involved in research related to global environmental change is wide, including political scientists studying the effectiveness of environmental agreements, demographers looking at the links between population growth and environmental change, economists considering the possibilities for delinking economic growth and environmental impacts, anthropologists debating human needs and wants and global environmental change, and scholars looking at the psychological dimensions of global environmental change. In addition, the International Human Dimensions Programme on Global Environmental Change (IHDP) coordinates research at the international level (IGBP/IHDP 1999, IHDP 1999a, 1999b, 1999c).

2. The Causes of Global Environmental Change

As pointed out in the introduction, global environmental change has been taking place throughout the earth's history, our focus here is on anthropogenic causes. Changes in the global atmosphere (climate change, stratospheric ozone depletion, and acid rain) are a result of emissions of a number of gases into the atmosphere due to a range of human activities. The increasing greenhouse effect, leading to a warming of the earth's surface and lower atmosphere, is the result of the accumulation of gases including carbon dioxide, methane, nitrous oxide, and chlorofluorocarbons in the atmosphere. The Intergovernmental Panel on Climate Change (IPCC) has documented these changes. Chlorofluorocarbons are also responsible for stratospheric ozone depletion (WMO 1999). Transboundary acidic pollution is attributed to emissions of sulfur dioxide, nitrogen oxide, and other acidifying emissions (e.g., Soroos 1998).

What are the main human activities that lead to these emissions? In the case of climate change the burning of coal, oil, and natural gas, as well as deforestation and various agricultural and industrial practices are altering the composition of the atmosphere and contributing to climate change. It has been

estimated that the use of fossil fuels currently accounts for 80–85 percent of the carbon dioxide being added to the atmosphere (UNEP/WMO 1997). Fossil fuels are burned to produce energy used for transportation, manufacturing, heating, cooling, electricity generation, and other applications. Research shows that patterns and environmental impacts of fossil fuel use vary widely by country and national-level consumption varies with technology, population and other factors, such as the level of industrialization. Land use changes, e.g., clearing land for logging, ranching, and agriculture as well as for urban development, also lead to carbon dioxide emissions (e.g., Turner et al. 1990). Over the past several hundred years, deforestation and other land use changes in many countries contributed substantially to atmospheric carbon dioxide increases. Most of the net carbon dioxide emissions from deforestation are currently occurring in tropical regions. The human activities that lead to methane emissions include rice cultivation, cattle and sheep ranching, and creation of landfills. Methane is also emitted during coal mining and oil drilling and by leaky gas pipelines. It is estimated that human activities have increased the concentration of methane in the atmosphere by about 145 percent above what would be present naturally (UNEP/WMO 1997).

Chlorofluorocarbons (CFCs) have been used in aerosol spray cans, refrigeration, air conditioning, and solvents. However, the production of CFCs is being eliminated as a result of international agreements, in particular the Montreal Protocol signed in 1987 and subsequent amendments agreed to in London (1990) and Copenhagen (1992). Soroos (1998) shows the sharp drop in the production and use of CFCs and other ozone-depleting substances in the 1990s and concludes that the level of stratospheric ozone is likely to reach its lowest level around 2000 and then begin a gradual rise back to its natural level.

The accumulation of gases in the atmosphere that can give rise to climatic change, stratospheric ozone depletion, and acidification is increasingly the result of a wide range of human activities like energy production, agriculture, and transportation. These activities in turn result from the satisfaction of human needs and wants. The topic of 'needs and wants' was tackled in detail from a social science perspective by Douglas et al. (1998).

An ongoing debate with regard to the causes of global environmental change is whether population growth in less developed countries is the main cause of environmental change or whether the main factor is the high level of consumption in industrialized countries. As MacKellar et al. (1998) point out, the population-consumption debate has become the focus of the broader debate about equity and fairness, demonstrated, for example, at the UNCED in Rio in 1992. Some case studies have shown that population growth can be correlated with increasing rates of tropical deforestation, while others have shown that

population growth need not lead to increasing deforestation, if alternatives to land-clearing are provided.

Demographic research does point to some important trends that will play a role in determining future global environmental change: there will be further population growth, a further tilt towards less industrialized countries in the world distribution of population, and further population aging (MacKellar et al. 1998). Another important trend is urbanization. At the beginning of the twenty-first century, more people will live and work in the urban centers of the world than in rural areas for the first time in history (Board on Sustainable Development 1999). The 'rush to the cities' of rural populations in developing countries during the second half of the twentieth century was dramatic. The largest cities of the poorer countries are growing much faster than similar cities in the industrialized world.

In addition to the changes occurring in the global atmosphere, global environmental changes are occurring at the earth's surface. In recent years the question of biodiversity loss has been on scientific and political agendas. As defined in the UN Framework Convention on Biological Diversity, biodiversity is the diversity of species, genetic material and ecosystems or, more generally, the variability among living organisms. Human activities contribute to the loss of biodiversity in many ways. Studies of the human causes of biodiversity loss have to deal with issues such as cultural beliefs, religious teachings, social history, and property rights. In fact, of course, it is not only the issue of biodiversity that encompasses these factors. These forces also influence many other issues related to global environmental change. There is a large body of environmental ethics literature in particular that deals with such issues (see, for example, Gardner and Stern 1996).

A related issue for global environmental change is that of land use and land cover change. In addition to playing a role in biodiversity loss, land use and land cover change can affect the global climate system through emissions of greenhouse gases (carbon dioxide, methane, and nitrous oxide) as well as changes in climatic variables, such as the reflectivity of the earth's surface. Over the course of human history, land use change has contributed as much to increases of the atmospheric carbon dioxide concentration as fossil fuel combustion has (Meyer et al. 1998). The human activities that can change land cover include sedentary agriculture, shifting cultivation, navigation, water supply, forest plantations, settlements, transportation corridors, mining, and habitat and scenery preservation (Meyer et al. 1998). The study of Kasperson et al. (1995) identified world regions where misuse of land and water resources seriously threatens human wealth and well being in the near to medium term. There has also been considerable progress in recent years on questions such as the social causes of

deforestation in areas such as the Amazon River Basin and Southeast Asia and the role of social, political, and economic institutions in land-use decisions (Entwistle et al. 1998).

Recently, advances have been made in combining social science and remote sensing perspectives, techniques, and data (US National Research Council 1998). Studies have shown how remotely sensed and social data can be combined to understand human-environment linkages, especially with regard to land use and land cover changes on the regional level. The combination of social data and remotely sensed data can lead to improved understanding of the consequences of climate variability, including improving famine early warning systems and dealing with serious human health issues.

3. The Human Consequences of Global Environmental Change

Much of the research on the consequences of global environmental changes has focused on the impacts of climatic change, although there have been some studies of the impacts of stratospheric ozone depletion and acid rain.

In recent years assessments of the impacts of climate change have been carried out under the auspices of the UNEP/WMO Intergovernmental Panel on Climate Change, which produced reports in 1990 and 1996 (IPCC 1990, 1996). Given uncertainties in both the expected climatic changes (especially when considering the regional or local scale) in the twenty-first century and the calculations of socioeconomic impacts of such changes, the studies of the impacts of climate change do not produce predictions but generally generate plausible scenarios of future impacts.

The IPCC scientific assessment (UNEP/WMO 1997) estimated that the globally averaged surface temperature will increase by 1–3.5°C by the year 2100, with an associated rise of sea level of 15–95 cm. One of the topics that received wide attention after the IPCC report was the potential impact on human health. The report concluded that the projected increase in the duration and frequency of heat waves would be expected to increase mortality rates as a result of heat stress, especially where air conditioning is not available. McMichael et al. (1996) have discussed the general impacts of climate change on human health.

Many studies have looked at the potential impacts of climate change on agricultural production. The 1996 IPCC assessment concluded that it may be possible for global agricultural production to keep pace with increasing demand over the next 50–100 years if adequate adaptations are made, but that there are likely to be difficulties in some regions. The report concluded that there is likely to be an increased risk of famine, particularly in subtropical and tropical semi-arid and arid locations.

With more than half of the global human population currently living in coastal areas, future sea level rises, alterations in storm patterns, and higher storm surges could have significant effects. About 46 million people are currently at risk by flooding in coastal areas as a result of storm surges. In the absence of measures to adapt, it is estimated that even with current populations a sea level rise of 50cm would increase the number of people whose land would be at risk from serious flooding or permanent inundation to about 92 million, while a 100cm rise would increase this number to 118 million.

As the IPCC report also shows, climate change is likely to affect numerous other human activities and resources valued by humans such as river flow and water supply, transportation systems, energy demand and supply, human settlement patterns, and tourism. These impacts are the topics of research. For example, a range of studies has looked at impacts on energy supply and demand from an economic perspective and these studies are reviewed by the IPCC. Multisectoral regional assessments of the consequences of climate change have also been carried out).

The methods for assessing climate impacts have developed considerably since around 1970. As Parry and Carter (1998) point out, the efforts up until the mid-1970s focused mainly on the (one-way) 'impact' of climate on human activity, while more recently there has been more emphasis on the 'interaction' between climate and human activity by assuming that a climatic event is merely one of many processes (both societal and environmental) that can affect humans and their activities. The interaction approach also introduced adaptation into climate impact assessment, such as changes in crops and irrigation at the farm level and policy responses at the subnational, national, and international levels (Parry and Carter 1998).

Until recently, most scientific assessments of global environmental risks devoted little attention to the possibly endangered entities. Now, questions about the 'vulnerability' of social and ecological systems are emerging as a central focus of policy-driven assessments of global environmental risks in a number of arenas.

4. Human Responses to Global Environmental Change

There are basically three possible responses to global environmental change. First, humans could decide to 'do nothing,' because they don't believe scientific results, because they think that the changes will be gradual and easily accommodated through technology, or simply because they are convinced that it would cost more to do something than the benefits the environmental changes might bring. In doing nothing, they might find that they are forced to undertake

responses, such as migration from flood-prone areas, in the event of global environmental changes (forced adaptation). Second, humans can choose to 'mitigate,' for example, reduce net emissions of greenhouse gases, acidifying substances or ozone-depleting substances into the atmosphere or reduce the rate of deforestation or land-cover change. Third, humans can choose to 'adapt' to global environmental change (anticipatory adaptation).

Humans have shown great capacity to adapt to environmental changes and extreme events in the past and the assessment of the research of past research on adaptation may provide useful insights for the future. However, adaptation in a globalized world with a population of 10 billion people promises to be much more challenging than adaptation in the past.

At the international level, steps to mitigate global environmental change have been taken in recent years. The Convention on Long-Range Transboundary Air Pollution (LRTAP) and its associated protocols have been dealing with emissions reductions of acidifying substances. The Vienna Convention on the Protection of the Stratospheric Ozone Layer and the Montreal Protocol on Substances that Deplete the Ozone Layer, signed in 1987 has led to the phase-out of production of most ozone-depleting substances. At the Rio Conference (UNCED) in 1992 the Framework Convention on Climate Change and the Convention on Biodiversity were signed and have subsequently gone into force with subsequent negotiations on protocols. Clearly, it is not enough to negotiate and sign international agreements to deal with the issues of global environmental change (Underdal 1998, Weiss and Jacobson 1998). Research on policy instruments at the national and international levels of relevance to the implementation of international environmental agreements shows the strengths and limitations of strategies such as regulation, financial incentives and penalties, inducements for technical development, etc. (US National Research Council 1999). Research at the end of the twentieth century and the beginning of the twenty-first century is also showing how social institutions have succeeded and failed in the management of global environmental risks (Ostrom 1990, Young 1999).

Methods for evaluating adaptive responses are discussed by Parry and Carter (1998), who point out that many of the adaptation options are likely to be subject to legislation, influenced by prevailing social norms related to religion or custom, or constrained physically or biologically. This might encourage, restrict, or totally prohibit their implementation. However, it is clear that an assessment of possible constraints must accompany any evaluation of available options. To date, relatively little analysis has been made of the efficacy of different adaptive strategies, partly because of the very wide range of available options.

On balance, however, it seems that much more attention has been paid to the assessment of mitigation

options than to adaptation options. Serious study is still needed of the true costs of adaptation of both plants and people and the differential ability to undertake it.

A controversial topic related to the question of adaptation is the relation between global environmental change and migration. The IPCC report in 1990 suggested that the greatest effect of climate change may be on human migration, as millions of people could be displaced due to shoreline erosion, coastal flooding, and agricultural disruption. Loneragan (1998) attempted to clarify the numerous issues surrounding the linkage between environmental degradation and population displacement. He concluded that generalizations about the relationship between environmental degradation and population movement mask a great deal of the complexity, which characterizes migration decision-making. Environmental degradation and resource depletion may play a contributing role in affecting population movement, often filtered through contexts of poverty and inequity.

5. Attitudes, Behavior, and Lifestyle

While there is ample evidence that public concern about ecological problems and technological risks has increased in Western industrialized societies, as well as some other countries, since around 1980, at the same time there has been a continuing deterioration of the environment on a global scale with some dramatic regional consequences (Brand 1997). Data on the development of environmental consciousness have been and are collected in many countries, although they are difficult to compare especially because the results depend on the wording of questions and the cultural contexts within which surveys are made. As Brand (1997) documents, taken together the empirical findings point to a high, and globally growing, concern about the environment. However, a high degree of environmental consciousness does not necessarily mean that there is environmentally sound behavior. Unfortunately there are fewer comparative data on environmental behavior, and different national contexts make it difficult to make intercomparisons. Empirical findings show that the effects of environmental knowledge and consciousness on behavior are insignificant and that other factors have to be taken into account, i.e., psychological, economic, institutional, and contextual factors.

6. Integrated Assessment

An important contribution to research on the human dimensions of global environmental change has been provided by 'integrated assessment.' According to Parson (1995):

Assessment consists of gathering, synthesizing, interpreting, and communicating knowledge from various expert domains and disciplines, to help responsible policy actors think about problems or evaluate possible actions.

An 'integrated' assessment means that the information is assembled from a broader set of domains than would usually be provided by good research from a single discipline. Integrated assessment of global environmental change issues therefore requires knowledge from all relevant disciplines, natural and social sciences, and the assessment is building a bridge between the science and policy realms. Summaries of available results, for instance in the reports of the IPCC, have illustrated the strengths and weaknesses of available approaches. At the end of the twentieth century methodologies have been developed for 'participatory integrated assessment,' in which stakeholders and even lay citizens are involved in the assessment process (Kasemir et al. 1999).

7. Conclusion

There is no doubt that global environmental changes have occurred and are occurring. Social sciences are playing an increasingly important role in improving understanding of the human causes and impacts of, and responses to, such changes. In a recent report, the US National Research Council (1999) pointed to the following areas in which major advances in knowledge were achieved through human dimension research:

- (a) The nature and role of socioeconomic uncertainties in impact assessments.
- (b) The determinants of environmentally significant consumption.
- (c) The importance of vulnerability analysis in understanding the consequences of global environmental change.
- (d) The role of institutions in determining human-environment interactions.
- (e) Estimation of the costs of global environmental change and of policy response options.

The challenges remain large, especially in the area of obtaining, archiving, and using socioeconomic data and in conducting research on a range of unresolved and difficult questions that can only be tackled by international, interdisciplinary approaches.

Global Governance

Global governance is the combination of intentional and patterned human interactions that regulate action worldwide for the common good. It is a purposeful order that emerges from institutions, processes, norms, formal agreements, and informal mechanisms that provide a field of action for human activities. Governance is based on shared expectations, as well as on intentionally designed institutions and mechanisms (Rosenau and Czempiel 1992).

In the context of national government, the authority of public institutions lies ultimately in the government's monopoly of the legitimate use of force. In the global context, no such authority exists; there is no world governmental body that enjoys a monopoly of the legitimate use of force. Yet commerce among countries and firms expands, information is communicated across national boundaries in an orderly fashion, and expectations about rule implementation are shared through transnational networks. Cooperative action is based on rights and rules that are enforced through a combination of financial and

moral incentives as well as through the use of threat or force. How this happens is the domain of global governance.

Global governance is distinguished from international governance. International refers to relations among states. Global encompasses activity at the international, transnational, and regional levels. For some, the term also includes a recognition of the effects of local activity on the global, such as individual auto emissions of carbon dioxide on the atmosphere, and global effects on the local, such as transnational capital flows on the health of subnational economies. For most, global refers to those activities in the public and private sectors that transcend national boundaries.

1. Governance in the Context of Rapid Globalization

Heightened attention to concepts of global governance at the end of the twentieth and beginning of the twenty-first century comes as a result of increasing consciousness of the interconnectedness of human activity on the planet. Basic discoveries about the interdependence of species and habitat for survival, about the effects of human activity on the biosphere, about the volatility associated with rapid capital flows across national borders, and new inventions that permit people to talk to one another around the globe contribute to a sense of the globalization of human society. It is in this context, and in the growing knowledge of the harm that such global processes may bring about, that the idea of global governance takes on greater importance. The problems of shaping societies so that their activities do not produce irreversible harm to the biosphere and to the sustainability of human species prompt increased attention to the possibilities of improved global governance for the public good.

2. Perspectives on Global Governance

Ordered and patterned interactions on a global scale are the result of international agreements, of harmonization of laws between countries, of transnational cooperation among functional agencies, of self-enforcing contracts between private firms, and of standard operating procedures encoding daily activities of governmental and nongovernmental organizations. Taken altogether, this array of formal legal arrangements, informal codes of conduct, and habitual practices based on shared expectations about legitimate action, constitute global governance.

So, for example, the United Nations is a formal international arrangement based on legal agreements among states and is considered to be part of global governance. It is one of many formal institutions,

however. Others would include the World Trade Organization, the North Atlantic Treaty Organization, the Organization of American States, as well as other regionally based treaty organizations. In addition, transnational cooperative actions among national law enforcement agencies also are part of global governance. Combating illegal criminal activity, for example, is accomplished through cooperation among agencies in apprehending offenders. In civil law, courts set precedents and decide cases based on case law from other national judicial systems. And in commercial law, private mediation is used by business firms from different countries to settle disputes (Slaughter 1997).

Many of these informal institutional arrangements are supported by networks among individuals and agencies. Cross-national professional relationships provide opportunities to learn from the experience of judges, policy officials, or executives from other countries. The annual World Economic Forum at Davos, primarily for business people, is just one rather visible example of informal forums. Through these and other meetings, professionals and executives begin to develop shared goals and values that can contribute to common standards and rules for conducting business, protecting human rights, conserving the environment, or implementing humanitarian missions.

The development of networks has accelerated with the introduction of high-speed electronic communications technology. Even before the advances in this area, however, increased travel and telephone communication contributed to a worldwide human rights movement, a global environmental movement, an international women's movement, the development of transnational corporations, and of international professional societies. Such networks have played a distinctive role in helping to establish common standards in a number of fields. In the case of human rights, for example, the diffusion of norms about the rights of prisoners came about through the use of international media to publicize cases of abuse. Such public 'shaming' of governments is based on a shared norm about the value of individuals and the need to protect their rights. Some of these values have been codified in formal national and international laws, while others are observed because they enhance the public reputations and legitimacy of governments or of businesses.

In sum, the concept of global governance builds on behavioral understandings of law and society. These perspectives suggest that norms of appropriate behavior emerge from daily interactions and the development of community consensus about what is fair and just, and is then codified in law. Law is a dynamic and changing reflection of shared standards. Implementation and compliance are understood as rather more voluntary than enforced, although the threat of sanctions—either criminal or civil—is recognized as an underlying motivating force for compliant action.

The simple example of stop signs illustrates the dual character of rules. Individuals obey stop signs because they may be afraid of getting caught breaking the law; but perhaps more important for some, they obey the stop sign because they wish to avoid being hit by another car. Both the threat of sanctions and an interest in avoiding harm are thought to be at work. In another example—of the private adjudication of transnational business disputes—firms wish to preserve flexibility and avoid undue government interference, which they may view as harmful. So they are willing to comply with the judgement of an agreed-upon private mediator rather than insist on taking the issue to a public institution for settlement.

3. Elements of Global Governance

It is possible to identify fundamental elements that constitute the building blocks of contemporary global governance. The most prominent of these are standards, norms, and states.

3.1 Standards

One means of coordination among private actors is the setting of standards. For example, the standardization of time through the use of Greenwich Mean Time permits coordination of communications, airline schedules, television broadcasting, and a myriad of daily transactions that we now take for granted. Rules of international navigation and airline procedures ensure the safety of air travel across national borders. A standard railroad gauge eases transborder crossings. Product standardization rationalizes the multinational manufacture of automobiles, televisions, refrigerators, and so forth. We begin to see how useful these standards are when we do not have them. The lack of standardization in electrical plug and socket connections across continents is an example of a lack of common standards.

In general, standards are accepted because they are thought to be voluntary and are arrived at through reason, that is, through the exercise of professional expertise, in which fundamentally equal actors reach decisions through rational deliberations that are open to interested parties. In practice, the process of standard setting by bodies such as ISO 9000 is completed by those with expertise in a field (in accounting or engineering, for example), representing users and pledged to serving the public interest. Efficiency in operations is essential to the acceptance of standards. Furthermore, the legitimacy of standards is based on the desirable consequences of the rule, which allows no exceptions or variations. To the extent that efficiency is a value in itself, and to the extent that professions embody and transmit a set of values, standard setting is not entirely value-neutral.

Yet, in comparison with hierarchy, markets, or norm-based communities, standardization is a minimal form of coordination.

3.2 Norms

Norms are internalized rules based on commonly held values. In the international security area, non-use of nuclear weapons is cited as a shared norm, as well as a major achievement. The norm is based in part on a shared revulsion at the devastation to human life and society that is inflicted indiscriminately in a nuclear explosion. The success of the human rights movement is based on publicizing human rights abuses perpetrated by national governments. To the extent that ‘shaming’ governments is a successful strategy it is because a norm is widely shared about the rules for appropriate treatment of individuals by their governments.

Communication of common values through informal and professional networks is critical to the development of shared norms. It is through informal networks, those that include representatives from international institutions, national governments, and nongovernmental voluntary associations, and in some cases from private business, that common understandings and values are established. These commonly held values in turn, contribute to the management of environmental issues, human rights abuses, humanitarian relief, and security relations. Some analysts view these networks as an essential component of global governance, providing a way of governing without government (Reinicke 1998).

3.3 States

The organization of nation-states in the twentieth century has included a dependence on and growth of bureaucracy, or hierarchy, as a means of governing. The growth of the modern state has included regulation of markets, of educational institutions, of environmental conditions, of criminal activity—in fact of nearly every aspect of daily life as a means of coordinating action for the common good. While some of this regulation has come through standard setting and norms development, the characteristic mode of hierarchical government is through directives. These directives are enforced through the use and threat of punitive sanctions, including imprisonment and fines.

As noted earlier, the enforcement power of the state is based on its monopoly over the legitimate use of force. This monopoly, in turn, is thought to be based on a notion of a social contract, whereby citizens give up some rights to a sovereign government, in return for protection and through the establishment and preservation of social order. The central problem for

theorists and practitioners of global governance is that no world government exists, yet transnational activity generates needs for coordination as well as problems of collective action. We turn next to a discussion of methods of coordination, problem-solving, and conflict management currently in use—methods that constitute global governance in practice.

4. *Methods of Global Governance*

4.1 *Harmonization of Laws*

The implementation of international agreements is accomplished through the adoption of national laws to bring local and national practices into compliance with international rules. For example, carrying out the provisions of the Montreal Protocol to protect the atmospheric ozone layer is done through legislative action in each country to bring manufacturing practices into conformity with the Protocol's agreed directives to reduce production and release of chlorofluorocarbons (CFCs).

Legislative action is one path to harmonization of laws. Another is through the courts and judicial systems of countries. A body of transnational law is developing informally in which judges in one country are basing their decisions on precedents and case law from other countries (Slaughter 1997). This is taking place in areas of civil and commercial law, where standard rules help to smooth business and legal transactions. In the area of human rights law courts are also citing cases in other national systems, in addition to the United Nation's Universal Declaration of Human Rights, to lend credibility to decisions about the protection of civil and political rights in their own countries.

4.2 *International Regimes*

International regimes are defined as a 'set of implicit or explicit principles, norms, rules, and decision-making procedures around which actors' expectations converge' (Krasner 1983). The effectiveness of a regime rests on the operations of institutions, organizations, governments, and international bodies that share a set of principles, rules, and norms in a particular area of international action. Although regimes include formal treaties and national law, they also rely on informal norms and networks to develop and enforce standard behavior in an area of global policy.

For example, regimes to control the development and spread of nuclear weapons had been relatively successful in the context of the Cold War. They were critical to controlling the US–Soviet arms race, to preventing nuclear war, and to limiting the spread of nuclear weapons technology and weapons. These regimes had their basis in a number of formal treaties

and international agreements, such as the Anti-ballistic Missile Treaty of 1972 and the Nuclear Non-proliferation Treaty of 1968, as well as some enforcement powers through the United Nation's International Atomic Energy Agency. For compliance, however, regimes relied on a number of formal and informal surveillance techniques and the trust that emerged from shared norms about the dangers of nuclear weapons, their development, production, and proliferation (de Nevers 1999). A decade after the end of the Cold War, we are beginning to see how much trust the USA and the Soviet Union had in one another, and in the shared norm of the non-use of nuclear weapons, as the arms control regime is being tested by the actions of several parties to these regimes.

4.3 *Global Policy Issue Networks*

Development of global policy and implementation of common laws also depends on informal networks of organizations and individuals. These networks are composed of individuals who share an interest in providing a public good that may not be provided by any single nation-state. Through communication networks, sometimes built around professional associations and scientific bodies, these transnational action networks (Keck and Sikkink 1998) or epistemic communities (Haas et al. 1993) provide information, documentation, and alternative policy solutions to global policy problems.

Some of the most visible networks have formed since the mid-1970s on human rights, environmental protection, and women's issues. In each of these areas, lawyers, scientists, and political and cultural leaders have found counterparts in other countries to form worldwide movements that have publicized the harm to people and the environment brought about by current national policies and practices. In the case of women's issues, the role of nongovernmental organizations at the official United Nations conferences on women and on population has been dramatic. The adoption of women's empowerment as a major path to fertility reduction, rather than an emphasis on birth control, at the population conference in Cairo in 1995 demonstrated the influence and effectiveness of issue networks in shaping global policy.

4.4 *Hybrid Institutions*

As transnational activity has increased, as non-governmental actors have become more prominent, and as national governments have devolved authority to private sector bodies, new institutional arrangements have developed to manage global relations. These arrangements are referred to as hybrid institutions or public–private partnerships because they mix

private sector organizations and a variety of incentive systems with governmental agencies to achieve public goods. They will often combine standard rules, private market arrangements, nongovernmental norm-based organizations, and government agencies—both national and international.

Some of the most inventive have emerged in the area of environmental protection. The certification of sustainably harvested forest products is just one example of a hybrid global governance process. Presented as an alternative to governmental regulation of the timber industry, environmental nongovernmental organizations have worked with major private enterprises in the forest products industry to convince them of the economic benefits of sustainable forest practices. They have demonstrated that consumers will pay premium prices for furniture and other lumber products that are sustainably harvested. They have shown that profits can be achieved over a longer period of time, and that reducing dependence on clear-cutting provides livelihoods for those people, mostly in developing countries, dependent on forests for their survival.

The major method of ensuring compliance with sustainable practices is through certification of wood products. Private firms participate in a council that includes producers, scientists, and other independent interests. This council, in turn, inspects production operations and certifies that manufactured products are derived from sustainably harvested lumber. The manufacturer can use that certification to advertise products and, in most cases, to charge higher prices to consumers. This process takes place without government intervention; it includes market incentives and relies on professional expertise and standardization to enforce rules that will contribute to the protection of natural resources—to the conservation of a public good.

Another example of hybrid institutions can be found in the area of prosecuting transnational criminal activity. Local and national law enforcement agencies, federal bureaus, banking regulation bodies, international police forces, and banking and financial institutions are developing transnational relationships and standard operating procedures to root out and prosecute international criminals. Organized crime has become relatively border-free, especially as liberalization of economic relations has proceeded; yet law enforcement remains within fixed territorial legal frameworks. To deal with this challenge, national law enforcement agencies have developed cooperative relationships with their counterparts in other countries to share information and to apprehend criminals. For example, US and Russian law enforcement agencies—the Federal Bureau of Investigation and the FSB (Federal Security Service, former KGB)—have set up cooperative relations to investigate and help prosecute corruption in banking and industry in their two countries.

To investigate and report money-laundering activity, the US Treasury Department has set up a Financial Crimes Enforcement Network. This network includes US Treasury Department bureaucrats, law enforcement officials, banking regulators, and private banking and financial institutions around the world. Through a series of agreements, government agencies and private sector organizations have established shared authority in identifying suspicious financial transactions. Banks have opened up their accounts to greater scrutiny and, in exchange, government authorities allow banking operations themselves to determine when activity is suspicious, and thus susceptible to further investigation by law enforcement agencies. Standards have been set about what constitutes suspicious behavior, and data about transactions is shared electronically between the private and public sectors (Reinicke 1998, pp. 135–72).

5. *Issues in Global Governance*

While new modes of coordinating transborder activity are emerging that hold the promise of effective global governance, a number of theoretical and normative challenges have been identified. Two are addressed here: the legitimacy of authority and democratic values.

5.1 *Legitimacy and Authority*

Successful governance requires the consent and compliance of those whose activity is being governed, that is, practices and institutions that constrain actions must be seen as legitimate for them to be effective. In contemporary conceptions of governance, this aspect remains problematic. In contrast to theories of governance at local and national levels, the idea of a social contract between citizens and institutions of global governance has not been developed sufficiently to be credible. Such social contracts have depended on theories of participation and representation by citizens in decision-making processes, few of which figure centrally in global governance. Other sources of legitimacy, such as claims of monarchs to ‘divine right,’ or to hereditary rights, are not recognized in twenty-first century conceptions of global governance. Finally, however, legitimacy claims may also be based on what works well, what is efficient, or what is reasonable; contemporary justifications for global governance mechanisms are often based on efficiency warrants.

Issues of authority and legitimacy become even more vexed with the increased participation of nongovernmental organizations in issue networks and hybrid institutions. While the authority of governments and the legitimacy of private firms are based, in some measure, on implicit contracts with citizens or consumers, respectively, the authority and legitimacy

of nongovernmental organizations is based on their claims of acting in the public good—as they define it. Whether by protecting individuals from the human rights abuses of their own governments, or conserving biodiversity in the face of extractive private industry, or saving women from customary rituals that cause physical harm, nongovernmental actors believe they are upholding standards that are in the long-term interests of humanity. These organizations, however, are not assembled through an election process or any other democratic procedure. They are self-appointed and claim to be acting on the basis of values that serve a global public interest. Without an authoritative institution that provides a process for establishing common values and agreement on what constitutes the public good, issues of authority and legitimacy in global governance will most likely remain unresolved.

5.2 Democratic Values and Global Governance

While some definitions of global governance emphasize the neutral management of human affairs, there is a strong normative component to any discussion of the term, in addition to an underlying assumption about who governs and upon whose standards. Some of the normative implications are acknowledged, but others need to be surfaced and examined before agreement can be reached on a standard definition.

In its current conception, global governance implies democratic governance. Most authors are careful to make the distinction between the term ‘world government’—that is, a set of procedures and mechanisms based on a single authority with power to enforce laws, by force, if necessary—and the notion of governance. This conception also recognizes that a greater number and range of organizations, individuals, institutions, and governments participate in decisions that have consequences beyond national borders (Mathews 1997). The informal and pluralistic nature of global governance both recognizes and requires the contribution of many of these nongovernmental actors to policymaking. In its own terms, then, global governance incorporates democratic values including those of equitable participation and the use of representative institutions for resolving conflicts. Yet the reliance on scientific and professional bodies to set standards, rules, and procedures, on bureaucratic agencies to implement policies, and on voluntary organizations to monitor compliance, raises questions about the compatibility of democratic values and the concept of global governance.

K. Benedict

Global History: Universal and World

1. Historiographical Traditions

Global histories have been written since Herodotus (495–425 BCE), whose cosmopolitan concerns were commended by Cicero but deplored by Thucydides—who opined that Greeks had no business investigating alien mythologies, religions, customs, and traditions. History writing, Thucydides suggested, should be modeled upon his own study of the Peloponnesian Wars—sharper in focus, shorter in time horizons, based upon verified facts and prescriptive in purpose. Fortunately Herodotus ignored his ‘Eurocentric’ advice and ranged widely beyond the Hellenic world to include Egypt, India, Babylonia, Arabia, and Persia in his histories in order ‘to preserve the memory of the past by placing on record the astonishing achievements of both our own and of the Asiatic peoples.’ He used

oral testimony, archeological remains as well as written sources and imposed some chronology and order on streams of events that had occurred on several continents and over long spans of time. His (still popular) book ends in 'European triumphalism.' Its story turns into celebration of the victories of the Greek *polis* (especially Athens) over the Persian Empire, which Herodotus represented as a conflict between occident and orient, despotism and freedom.

Global historians applaud Herodotus for his reflexive interest in barbarian virtues and regret the long hiatus that occurred in the writing of secular world histories until Voltaire and his generation carried the project forward again during those brief decades of Enlightenment, before the outbreak of the French Revolution. They are puzzled, however, to observe that with the exception of a few Stoics (Diodorus, Polybius, and Dionysius) and a handful of geographers and ethnographers (Strabo, Ptolemy, and Pliny), histories of the world did not attract more scholars writing during Graeco-Roman times. Although they lived in empires that maintained contact with an array of cultures (African, Arabian, Persian, Indian, and Chinese) historians of the classical era remained overwhelmingly concerned with Europe. Their histories (e.g., Tacitus) deal mainly with the politics and scandals of Rome, or (e.g., Thucydides) with wars among Greeks. Their equally provincial oriental contemporaries, residing in that celestial empire on the other side of the world, asserted with quintessentially Chinese superiority that they remained unimpressed with anything the Romans had to impart, or to trade for, China's silks, ceramics, medicines, perfumes, and spices.

In Europe, steps in an ecumenical direction occurred when Christian and Jewish historians started their narratives with the Creation and set out to ensure that Greeks and Romans should not be left (in the words of Josephus) 'as the arrogant possessors of antiquity.' That was why Orosius (a student of St. Augustine) proclaimed that 'The Roman Empire arose in the west but was nourished in the east.' Narratives in Christian historiography is dominated by chronicles about the evolution of mankind over stages of history, no longer bounded by the frontiers or cultures of the Greco-Roman world. In 1158 Bishop Otto of Freising recognized that 'all human power and learning had its origins in the East.' Medieval historians included Oriental and African civilizations right down to the Reformation when Catholic and Protestant intellectuals began to look for a usable past to help princes to integrate populations and secure the frontiers required for the formation of nation states. Even then both parties to Europe's conflict over religion and national identities remained aware of places, peoples and cultures not merely outside the borders of their enclosed and ideologically encompassing polities, but beyond Christendom itself, and that is hardly surprising.

Residing on an underdeveloped promontory on the western edge of the great Eurasian landmass, with ice to the north, uncharted oceans and territory to the west, and the hostile power of Islamic communities to the south and east, Europeans had not secured their frontiers, religions, cultures, and technological superiority over other civilizations, long before the eighteenth century. It took centuries to clear the Iberian peninsular of Arab power. Moslem fleets threatened European shipping in the Mediterranean for another two centuries after the surrender of Grenada. Turkish armies crossed into the Balkans in 1350, took Constantinople in 1453 and menaced Vienna as late as 1683. For nearly a thousand years after the fall of Rome, Christendom braced its defences, imported useful knowledge, shaped its collective identity and composed ideologically charged histories in the context of conflicts (and encounters) with the powerful civilization of Islam on all its frontiers. Memoirs, travelogs, diplomatic correspondence and investigations into Arabic medicine and astronomy, together with commercial intelligence on societies under Ottoman dominion, flowed from east to west. Much of this knowledge came through Genoa, Florence and Venice, along with spices, herbs, sugar, botanical drugs, jewels, chinaware, silks, cottons, and metal goods, imported through the Middle East, from India and China. The expense of procuring and transporting luxuries moving slowly, over long distances and subject to extortionate charges for protection along the way, prompted Europeans to seek ways to surmount the barriers to commerce with South Asia and the Far East by their Islamic enemies.

Shortly after the voyages of discovery Europeans broke out of their political, commercial and mental encirclement by Islam. Over the sixteenth century flows of information into Europe widened to include the Americas, and increased exponentially as a result of the establishment of regular and direct trade and contacts by sea with India, China, South East Asia and Africa. Yet nearly two and a half centuries elapsed before Europeans produced a secular and enlightened school of world historians. Its godfather was Voltaire, who composed a history concerned with 'only that which is worth knowing; the spirit, the customs, the practices of the principal nations based on facts which one cannot ignore.' Voltaire and his followers in France, the Netherlands, Scotland, Naples, Germany and other parts of Europe, deliberately constructed histories of their expanding world in ways which they conceived as a departure from the providential narratives of their clerical predecessors and the 'nationalism' of historians writing for princes and their obedient subjects. That aspiration was propitious. As a result of regular contacts and commerce the trickle of information about peoples, geographies, technologies, politics, warfare, customs, manners, and the import of all sorts of commodities and artefacts turned into a river of knowledge about places, populations, societies, and

economies beyond Europe. For radical intellectuals China became an alternative model, favorably contrasted with Europe's political systems, social arrangements, and religious beliefs. European histories became not only wider but deeper as scholarship took over from propaganda, sycophancy, fantasy, religion, and national ideologies.

For something like half a century before the French Revolution and the takeover of India and South East Asia, European historians resituated Europe's and Christendom's place in world history by including more ancient as well as classical Mediterranean civilizations and by widening their gaze to take China, India and Japan as well as the newly discovered Americas into account. Europe's new school of world historians dealt with the natural histories, religions and ethnographies of most parts of an increasingly interrelated universe. Favorable interpretations of oriental polities, societies, cultures, and religions by philosophes and physiocrats did not go unchallenged. Bernier and Leibniz, Montesquieu, Defoe, Winckelmann, and Hume remained resolutely unimpressed with the Chinese empire. Nevertheless historians of that era engaged in debates about cultures, geographies, and spans of time that their modern counterparts (confronted with libraries of knowledge and professional interpretations), can only envy.

Alas, the ironic reflexion that their narratives of Enlightenment brought to the task of repositioning Europe in a secular history of the world was overshadowed by a tradition of Western triumphalism which emerged in the aftermath of the Revolutionary and Napoleonic Wars, 1789–1815; when Europeans acquired massive additions to the populations, territories and natural resources of other continents under direct or informal control. During an 'imperial meridian', European naval and military superiority over the states and societies of other continents emerged as irresistible. Furthermore, by 1825, European settlers throughout the Americas and the South Pacific had escaped from all metropolitan and aristocratic restraints upon their economic activities and their relations with the indigenous peoples of colonized worlds. White settlers became free to exploit 'their' heritage under rules of their own making, tempered only by religion. As its technological and economic lead over other continents widened, Europe moved clearly onto a path which led, as time went on, to clear divergences in levels of productivity and living standards between East and West and North and South.

Against this background, the writing of history by Europeans departed from its moment of cosmopolitan enlightenment, moved in a Hegelian direction and returned to the introspection and cultural arrogance associated with imperial Rome. Here and there aspirations to write universal histories survived. Isolated scholars eschewed the condescensions embodied in nineteenth century science, technology, liberalism, and

colonialism, and a scatter of historians continued to work outside the encompassing national frameworks, and dominant teleologies associated with the rise, rationality, and hegemony of Europe. Nevertheless, it took the destruction and cultural shock of two world wars in the twentieth century to encourage a return to the rewriting of histories of mankind. That program, conducted by a small group of erudite scholars, began in the climate of pessimism and breakdown in the liberal consensus that followed the Great War, when Spengler, Toynbee, Sorokin, Wells, Mumford, and Dawson wrote universal histories of humanity to help Europeans comprehend the decline and barbarity of the West. In history they attempted to find some substitute for Nietzsche's proclaimed demise of Christianity and rationality. Their scholarship is inspiring, but their explicit search for spiritual meanings in the histories of the rather amorphous entities called civilizations did become a compelling framework for scholars and students to work within. The attempt by UNESCO, after the World War II, to fund the writing of a multivolume collaborative history of the world (designed to promote peace across nation states) failed to provide a paradigm for the reconstruction of secular histories on an ecumenical scale. Long after the war, historical scholarship continued to be located where its founders had situated it from the time of the Renaissance and Reformation onwards—namely, within the confines, chronologies, and parameters established for comprehending the origins and evolution of European (including North American and Australasian) societies and nation states.

2. Globalization and the Revival of Global History

Fortunately pockets of global history survived—notably at the universities of Chicago, Northwestern and Leipzig. Complementary branches of scholarship continued to flourish in the forms of: survey courses in Western civilization; area studies, histories of trade and imperialism, investigations into the impact Western technology and culture upon other peoples and above all, as flows of encyclopedias, chronicles and textbooks for schools and popular education concerned with the world as a whole. Thus, 'tribes' of professional historians with interests in fields that transcended nation states and Europe possessed the credentials and remained ready to refashion their intellectual identities, when demands for global history reappeared from the late seventies onwards. That revival could be retraced to canonical publications by M. Hodgson, W. McNeill and L. Stavrianos, but research and teaching has only matured into university programmes for the sustained study of world history over the past quarter of a century of 'globalization.' Although there is nothing particularly new about the current phase of economic integration and inter-

dependence which are the core features covered by that label. Long distance trade goes back millennia to prehistory, and the exchange of commodities across frontiers and overseas had always involved arrangements for counterpart flows of funds, conversions of currencies and the operation of transnational, commercial and financial organizations of a more or less sophisticated kind within and across Europe, Africa and Asia.

Nevertheless real discontinuities had occurred. For example, by the late nineteenth century, supported by steam-powered ships and trains, the volume of commodities and services traded across national borders, continental boundaries and oceans had increased dramatically compared to 1800. Commerce was promoted and sustained by movements of capital, migrations of labour and transfers of technology and information around the world on an unprecedented scale and at ever increasing speeds. Political impediments to international flows of exports, imports, money, credit, capital, labor, technology, and information diminished sharply during the liberal international order that prevailed between 1846 and 1914.

State controls revived again during nearly four decades of neomercantilism that succeeded World War I; when governments everywhere sought to insulate their domestic economies from inflows and outflows of commodities, from the emigration of their nation's capital and skilled labor, and from fluctuations associated with unregulated rates of exchange. In the interests of narrowly defined national competitive advantages and political stability, sovereign states proceeded to de-link economies from participation in an evolving global economy. Between 1914 and 1948 overall levels of world trade fluctuated in volume, but ceased to grow. Warfare and political regulations depressed movements of capital and labor across frontiers. Controls on the convertibility of currencies hampered international exchanges of every kind.

Normalcy returned after World War II when a discernible shift towards liberalism in the political and legal framework for commerce among nations was also promoted by even more radical improvements in new technologies for the transportation of goods and people across space and time; and by vastly more efficient communications systems for the widespread diffusion of commercial intelligence, messages and cultural information between distant locations and separated populations. Revolutions in transport, television and communications widened markets and created opportunities for the organization of trans-continental and multinational business across an expanding range of production, distribution, finance and commerce.

Unsurprisingly, the implications of 'globalization' for hitherto separated communities, bounded spaces, distinctive cultures, partially connected local eco-

nomies and nominally sovereign states have been analyzed by social scientists. Intensified demands have appeared for historians to supply perspective on trends towards integration—that often appear to economists, political scientists, sociologists, and philosophers (as well as natural scientists) to represent profound discontinuities in the ways that ubiquitous technological, economic, and cultural forces are clearly shaping our interconnected world. This demand is supported by Western governments, uneasily aware that their powers to control societies, nominally under their rule, are transforming their claims to effective sovereignty over the populations, territories, and assets within their borders into something more tenuous than used to be the case during the long era of competing nation states. Their anxieties (eloquently fostered by 'official' intellectuals) have been compounded by recent military, technological, and economic achievements of several Asian societies, especially Japan and, the 'Tigers' but latterly (and more significantly) by the reawakening of China. The rest are perceived to be catching up and modern mercantilists (who continue to conceive of the world in terms of winners and losers or clashes of civilizations), worry about the relative decline of Western hegemony. Politicians and publics turn to historians for explanations of the past and more reassuring predictions for the future.

National frameworks for political action and academic enquiry are now widely recognized as unsatisfactory. That comprehension is patently functional for natural sciences investigating environmental issues, for biological sciences concerned with the health of human populations, and for social sciences analyzing international relations, crime, migration, communications, and whole ranges of economic activity, which can no longer be regulated within the boundaries of nation states. It is also clear that national and local cultures are being subverted by advertising, by fashion, and by the popular arts, especially music. The means and media of modern transportation, travel and communications (cheap and available to the masses), are opening up cosmopolitan discourses (usually in English) that contribute to the reshaping of personal identities around the world and transform frameworks for behavior, especially among younger generations.

3. Traditional, Postmodern, and Global Histories

Pressures to make, write and teach histories of the world that might become more contemporary and relevant has encouraged the discipline to become less intellectually, politically, spatially and chronologically confined. They are intensifying, seem irresistible and are being welcomed as a return to the ecumenical programmes of Herodotus, Vico, Voltaire, Leibniz and von Ranke who opined 'there is no history but universal history as it really was.'

Intellectual arguments for resituating national and European histories into frameworks that might better address the problems of the new century have been persuasively rehearsed by proselytisers for global history in recent years—as indeed have their anti-theses—recommendations to concentrate attention upon microhistories of difference, diversity and a stance of humility towards the complex histories of ‘unknowable others.’ That postmodern exhortation is understandably suffused with a concern that the revival of global history will implicitly celebrate ‘triumphs of the West’ in science, technology, military power, and economic development. Unfortunately that has already occurred in several recent publications by journalists and even by historians whose pretensions to offer overviews of world history seem truncated in time, confined in space and selective in areas of social endeavour emphasized for recognition as universal achievements; and whose understanding of environmental, biological, and other natural constraints on human action look unscientific.

As humanistic scholarship, global history aims to mature into a renaissance and not a return to the arrogance of Rome or to Victorian triumphalism. Modern history has matured into a capaciously catholic subject, willing to take many kinds of hitherto myopic exclusions into its narratives, to reposition knowledge of the past into more relevant spaces, models and chronologies and to plunder the natural and social sciences (as well as archeological remains) for insights into the evolving human condition. In finding voices and viewpoints to construct histories on a global scale, historians (alive to the second cosmopolitan enlightenment that emerged during the closing years of an otherwise dark twentieth century) have not found it difficult to detach their narratives from another politically correct but romanticized appeasement of the underprivileged on the one hand, or from the implicit denigration of non-Western people and cultures, that flows from Eurocentric convergence and modernization theory on the other.

In an ongoing search for strategies to teach and to write compelling histories on a global scale, they will respect the preferences of their colleagues, whose postmodern anxieties about their capacities to comprehend ‘others’ or to offer plausible conjectures and metanarratives about major trends and significant events, leads them towards dense description, microhistories, and biography. Such flowers should certainly bloom, but the intellectual effort required to landscape the garden also demands attention and imagination from historians.

Global historians confront more challenging intellectual problems in trying to persuade the majority of their academic colleagues (writing bounded histories and bunkered in the security of national archives), that their attempts to write on a global scale could meet the standards of a discipline deeply concerned with detail and documentation that dis-

courages generalization beyond strictly confined geographies and periods. Having rejected Toynbee’s quest for spiritual guidance as a tenable mission global historians tend to make a general case behind arresting metaphors extolling the need for histories constructed as: ‘maps on the largest scale,’ as ‘photographs taken through the lenses of wide-angled cameras,’ as ‘architectural frameworks’ and ‘as views; contemplated from space.’ Many contend that the boundaries and chronologies of parish, let alone national or continental histories, seem equally problematical to define. Nevertheless, coming as most do, as recognized specialists in but one or two fields of history, global historians remain conscious of their credentials and are entirely sensitive to their epistemological vulnerability. It continues to be much easier to conduct research, claim territory and acquire status as national or local historians.

4. Current Paradigms: Connections and Comparisons

Nevertheless, historiographical and methodological discussion as well as the volume of publications (off and on line) has increased exponentially. Most of the bibliography is concerned with connections and comparisons across national frontiers and cultural boundaries. Most of it displays a scientifically informed appreciation of evolutionary environmental and biological constraints on all forms of human activity, and represents a welcome reunification of natural and human history. Celebrated and influential books display a talent for the construction of synoptic histories about matters that have been important for humanity as a whole. As more historians risk writing on a grand scale, the field looks set to produce plausible, but competing metanarratives into which the overwhelming flow of parish, regional and national histories could be reconnected.

Meanwhile two distinct approaches have already developed. First (and central) is the model, persuasively exemplified and elaborated in several books by McNeill. He has inspired a programme of historical investigation into connections across continents, countries and geographies as well as through very long spans of time. McNeill’s assumption is that such connections, interactions, encounters, contacts with outsiders can be represented as the origins and engine of economic, social, political, military, cultural, religious, technological, and all other conceivable types of change studied by historians; and that connection can be pursued with scholarly detachment and a proper appreciation of the long chronologies required to construct histories that aim to select and analyse *major* forces at work in the evolution of humanity, McNeill’s recommendations aim to avoid the condescension of cultures, the restrictions of time and the arrogance of nations built into currently dominant

styles of history. His (and Crosby's) books show that 'interactions' were often malign: the spread of plagues, diseases, and parasites; those waves of destructive invasions by nomads; wars of conquest, plunder, and imperial expansion; forcible conversions to alien systems of religious belief; and the subversion of indigenous traditions, cultures, societies, and communities by strangers, have been part of the universal experience of suffering.

Well-specified types of connection can be investigated over significant periods of contact and transformation. Its taxonomical divisions include: trade, investment, warfare, religion, migrations, transfers of useful knowledge, technological diffusion, botanical exchanges, and the spread of diseases. Proper attention is also accorded to the means of transportation and modes of communication that secured, facilitated and cheapened contacts by sea, land and latterly by air. Once a relevant range of major connections are traced, understood and their significance evaluated global history will broaden our education and provide the spatial and chronological perspectives required for the appreciation of the histories of nations, peoples, localities, and groups embodied within particular histories that the majority of their colleagues study in greater depth and sophistication, but too often in isolation.

Put simply, the second major approach extends geographical catchment areas for comparative histories of topics that could be the subject of illuminating study across national boundaries, continents, and separable cultures. Although the linguistic qualifications for such research are extremely difficult to acquire, and the scholarship needed to make sense of contrasts discovered is formidable, the methodological problems are similar to those encountered for exercises conducted within European, national, or indeed regional frameworks.

Comparative history helps scholars to surmount the complexity and tyranny of local detail and seeks to offer coherent but sensitive answers to a great variety of questions that historians select for investigation. For global historians, the illumination derived from the method tends to be realized when they can concentrate upon well-defined artefacts, institutions, organizations, social practices, attitudes, and beliefs that are found in dispersed cultures, and which have already been studied in scholarly depth, in the context of particular locations and which exhibit comparable, but, more importantly, dissimilar geographical economic, political, social and other features. Then, as Marc Bloch anticipated, the 'comparative method can elicit from the chaotic multiplicity of circumstances those contrasts which were generally effective.'

In order to communicate salient differences global historians will be tempted to aggregate and average contrasts across wider spaces and larger populations (continents, oceans and civilizations) than their colleagues who have the sources to engage in exercises in

comparative history within circumscribed boundaries. For purposes of research, designed as building blocks for the production of metanarratives that are truly universal, the comparative method looks set to dominate the field for years to come. It has, for example, already generated a bibliography of global histories concerned with the family, youth, marriage, diet, housing, health, military organization, government, human rights, parliaments, nationalism, religions, fundamentalism, and revolutions, and there are serious debates on two seminal topics: gender and long-run economic growth.

5. Comparative Histories of Gender and Material Progress

Gender is perhaps the quintessential 'analytical category' for purposes of universal social history and it interacts with other categories including class, ethnicity, race, nation citizenship, and colonialism for purposes of constructing world histories that 'keep humanity in view.' Yet no surprise will be occasioned by the appearance in recent decades of histories seeking to encompass the world economy—going way back in time and written to expound and to explain the disparate levels of material progress achieved by countries, societies, and communities located on all continents. Most people, in most places for most of history, have been preoccupied with obtaining food, shelter, clothing, and other manufactured artefacts that they required to sustain either a basic, a comfortable, and, only latterly, an agreeable standard of living.

A modern generation of historians is resituating the scientific, technological, and economic achievements of Western societies in global context. They call upon libraries of books and articles dealing with African and Asian agricultures, industries, towns, commercial networks, communications, trade, science, technologies, cultures, business organization, taxation, state systems, Government policies etc., etc., covering the last millennium and written in large part by historians from universities not long emancipated from imperial rule. This enormous, but still far from comprehensive, volume of historical research has, moreover, been communicated to the West by specialists in area studies from North American, European, Australian, and Japanese universities. Not long after World War II and during an era of decolonization, historians were offered the opportunity—provided by the accumulation of a large body of archival knowledge—long available in Europe and North America, but emerging in Asia, the Middle East and Africa and Latin America—to reposition their hitherto disconnected histories of wealth and poverty one against another in order to construct global histories of material progress that might have satisfied the aspirations of Montesquieu, Voltaire,

Smith, and their 'enlightened' followers, and pleased Max Weber.

Recent attempts to survey this monographic literature has been dominated by scholars from Western universities. Syntheses from China, Japan, India, Africa and the Near East would be a salutary correction to what is a plural but nevertheless European perspective. Meanwhile, scholars have carried forward a Weberian program for teaching and writing a truly global history of material progress. They have found that the quantitative evidence for such purposes would certainly not be regarded as sufficient to underpin a serious programme of historical research designed to account for long-term economic success and retardation among the national economies of Western Europe, North America, and Australasia. In the absence of hard data or even of an acceptable range of contemporary observations (which could be included in a narrative designed to track chronologies of divergence in productivities and living standards between Europe and Asia), global histories of material progress continued to be marred—by three powerful Marxist and Weberian assumptions. First, that Europe's technological and economic superiority over Asia (which became first visible in the eighteenth century and then unmistakable during the nineteenth and twentieth centuries) had evolved gradually, but cumulatively, over several centuries before 1815. Over that time Europe's political, legal, cultural, and institutional heritage for the conduct of economic activity continued to be exceptionally favorable for the promotion, first, of Smithian growth, and, following on from that, for technological progress. Thirdly (and in contrast to Europe), other populations lived and worked in more hostile environments and this big ecological fact restrained and often arrested long-term economic development in Asia and Africa—although our knowledge of pre-colonial African economies remains entirely thin.

Those who follow Weber, Marx, and a tradition of writing that can be tracked back to Montesquieu, insist that Europe's competing economies had been on a potentially more promising trajectory for long-run growth for centuries. They emphasize persistent contrasts between European and Asian institutional arrangements, political systems, legal frameworks, cultural conditioning, and religious beliefs, within which economic activities continued to be embedded for at least four centuries before 1815. Cruder Weberians juxtapose the preconditions for long-run Smithian growth that they found operating efficiently in Europe (or rather in some societies in north western Europe) in sharp contrast to Asia, where political, social, familial, cultural and other negative institutions and beliefs restrained the emergence of competitive markets for commodities, capital, land and labor.

Their critics, who seem more deeply and widely read in the now massive bibliography of economic and social history dealing with South, East and South East

Asia, and the Ottoman Empire, have produced samples of data (related largely to population growth, levels of urbanization, balances of commodity trade, yields per hectare and real wages) for selected regions of Asia and the Middle East that at the very least qualify any impression that labor productivity levels and standards of living afforded by European economies to their populations were discernibly (let alone significantly) superior long before the outbreak of the French Revolution. Of course at this level of 'continental' aggregation, the selection of samples of data for comparative history remains problematical because the Asian economy includes much larger shares of the world's cultivable land, resources, income, and population than early modern Europe.

Nevertheless, economic historians are a long way from offering statistically secure comparisons for average levels of productivity and living standards. Meanwhile, the accumulating volume of research now available on Asian agricultures, industries, trades, credit systems, mercantile enterprise, transportation networks, markets for commodities, and factors of production degrades simplistic Weberian perceptions that Europe alone had evolved the political, institutional, legal, cultural, and religious frameworks required for an effective process of Smithian growth long before other continents into dubious propositions. As Marshal Hodgson observed decades ago: 'All attempts to invoke premodern seminal traits in the occident can be shown to fail under close historical analysis.' Braudel, Chaudhuri, Frank, Pomeranz, Goldstone, McNeil, Sugihara, Washbrook and other historians of long-run material change concur. Jones would probably (as he did in *Growth Recurring*, 1988) continue to revise and reformulate some of the positions he adopted in the first edition of the *European Miracle* in 1981. From his comparisons of levels and types of development achieved by Europe and Asia for the early modern period, Braudel inferred that 'the populated regions of the world faced with demands of numbers seem to us to be quite close to each other.' But there is he continued 'a historiographical inequality between Europe and the rest of the world. Europe invented historians and made good use of them. Her own history is well lit and can be called as evidence or used as claim. The history of non-Europe is still being written. And until the balance of knowledge and interpretation has been restored the historian will be reluctant to cut the Gordian knot of world history.'

That acute observation applies across the entire field because histories of gender and capitalism are but two current areas of controversy that display the unrealized potential of universal history. In truth, it seems difficult to conceive of any grand theme that attracts attention from scholars engaged in writing national and local histories that could not be repositioned within wider geographies and longer temporal periods. For purposes of research, teaching and

debate, comparisons and connections are now the two dominant styles of global history. Pursued with sensitivity they should deepen our understanding of difference and diversity. In time they will meet demands for perspective from those trying to comprehend accelerated trends towards interdependence and integration on a world scale and allow for a less ethnocentric appreciation of the manifold achievements of more peoples, communities and cultures over long spans of human history.

Global Population Trends

During their evolution of tens of thousands of years, humans have progressively, although not without setbacks, learned how to better feed themselves, make clothing, provide shelter, cure and prevent diseases, improve their health, and modify their fertility. People have learned how to interact in societies which were at first based on gathering, hunting, and fishing. Many societies then experienced the agricultural revolution combined with the domestication of animals. The evolving increases in labor productivity and scientific advancements generated the industrial revolution and urbanization, the foundations of contemporary soci-

eties. In the process, populations have grown from very small numbers to the six billion global population reached in 1999. Demographically speaking, for many centuries and millennia changes were erratic and slow until several centuries ago mortality started to decline, life expectancy increased, somewhat later fertility commenced its decline, and populations around the globe began to grow at increasing rates. The more pronounced and rapid changes have occurred in the most recent 100–200 years, although the roots of change reach much further into the past.

1. The World's Population

In 1695 Gregory King (1973) was among the first scholars who attempted to estimate the size of the world population. His estimates were within a range of 495–700 million—preferring 630 million as the base for his projections—in line with what scholars engaged in similar exercises since then consider as realistic (Table 1). In 1999, the size of the world population was estimated to have reached six billion inhabitants. 'Estimated' because even at the end of the twentieth century uncertainties about the exact size of the world population persist, as there are numerous countries which lack a recent reliable census, and which have inadequate population registration systems or none at all.

Through most of human history the increase in the world population was slow and punctuated by periods of decline. The technologies of food production, as well as the ways and means of health protection, were relatively primitive and humans were thus quite significantly exposed to the vagaries of nature. A

notorious case was the epidemic of the plague or Black Death which in the fourteenth century spread from Asia to Europe and Africa and is believed to have decimated Europe's population by one-third.

The growth of the world population gained momentum in the seventeenth to nineteenth centuries. However, the critical acceleration occurred after World War II. During the second half of the twentieth century the global growth rate has been close to 2 percent per year. Improved personal health behavior and public health measures as well as the application of curative and preventive medicine which had been attained and practiced in the industrial countries earlier were rapidly spreading in the developing world (see *Mortality: The Great Historical Decline*). It was during this period that the peak and the turning point in global population growth was reached. Since its climax in the 1960s with an annual rate of 2.0 percent, this rate has declined to 1.4 percent in the 1990s. In many parts of the world, in developed and developing countries, fertility has been declining rapidly (see *Fertility Transition: Cultural Explanations and Demographic Transition, Second*). It is worth noting that the absolute annual additions continued to increase through the end of the twentieth century. They had also reached their peak and were commencing their decline. Around the year 1900 the annual absolute global population increase was about eight million. In the year 2000 it was around 80 million.

Through the end of the twentieth century the number of years required to add an additional one billion population has been decreasing. The first billion was reached around 1804, the second in 1927 (123 years later), the third in 1960 (33 years), the fourth in 1974 (14 years), the fifth in 1987 (13 years),

Table 1

and the sixth in 1999 (12 years). Indications are that this number of years will start to increase in the twenty-first century (see *Population Forecasts*).

The distribution of the world's population has been changing over time. For several centuries large populations have been living in China and the Indian subcontinent. In the year 2000 each had about 1.3 billion inhabitants constituting 21 percent of the world population (Table 2).

In the course of the nineteenth century it was the population of the industrial countries in Europe and North America which grew more rapidly than in other regions. Its proportion increased from a quarter of the world's population to one-third between the beginning and the end of the nineteenth century. In the twentieth century, population growth in the developed countries slowed down. Subsequently, during the second half of the century, rapidly declining mortality in Third World countries combined with a fertility decline led to rapid population growth so that their proportion of the world's population increased from two-thirds around 1950 to 80 percent around the year 2000.

2. Mortality

As best as can be estimated, the average human lifespan in prehistoric and during most of historic times was rather short. The scarce archeological evidence available suggests that most adult deaths occurred between the ages of 20 and 30. In the Iron Age in France average life expectancy was presumably 10–12 years. A life table for ancient Greece, prepared from burial inscriptions, indicates an average life expectancy of 30 years around 400 BC. Life expectancy in Geneva was estimated at about 21 years in the period 1561–1600 and about 26 years in 1601–1700.

The latter and other estimates based on fragmentary data in various European countries from the thirteenth to the eighteenth centuries indicate that mortality was very unstable and variable with life expectancy between 20 and 40 years (United Nations 1973). A relatively comprehensive estimate covering Northern and Western Europe, Northern America, and Oceania (The 'West') for the middle of the nineteenth century still resulted in an average life expectancy of 40 years. From thereon health conditions improved and life expectancies grew quite steadily in these countries. Elsewhere in Europe and the former Russian empire mortality started to decline later. In Southern Europe, in Italy, for instance, in 1871–80 life expectancy at birth did not exceed 35 years and a steady fall of mortality started after 1875. Japan was another country where mortality was low quite early. Its crude death rate at the end of the nineteenth century was comparable with many European countries.

Malnutrition, poor hygiene, parasitic infections, and disease were, and in many parts of the world still are, the principal causes for high mortality. It took many centuries of gradual progress to have a visible effect on survival. Changes in diet, personal and public hygiene, reinforced by advances in science and medicine, generated dramatic increases in life expectancy. During the past 100–150 years, life expectancy has essentially doubled from 30–40 years to 70–80 years in those societies where most people at the beginning of the twenty-first century enjoy a decent standard of living.

In the Middle Ages most people lived in primitive living quarters with their domesticated animals and their excrements, with an open fire fueled by wood and manure in the middle of the floor and a hole in the roof to let out smoke and cinders, without any toilets and bathrooms, without soap, windows, furniture, dishes,

and cutlery. Individual societies around the world were better equipped in some respects, for instance, the Chinese employed coal as a fuel, and soap was commonly used in the Islamic world. Frequent failures of harvests and major epidemics were commonplace everywhere. It took many centuries for standards of living and hygiene to improve and thus provide favorable conditions for better health. Residential chimneys in Europe became common around 1200 and it was Marco Polo who discovered in 1306 that the Chinese used coal to heat their homes. Soap was manufactured for the first time in London presumably in 1259. Frequent bathing, however, was considered unhealthy and as late as in the sixteenth century Queen Elizabeth I was considered eccentric for her frequent bathing—once a month. It was not until the Industrial Revolution of the eighteenth and nineteenth centuries that the way people lived changed considerably and irrevocably. Significant increases in productivity, including agriculture, provided for the possibility of improved nutrition, shelter, and living conditions in general. In combination with the gradually increasing application of personal hygiene, the installation of indoor plumbing and introduction of sewage systems, the accumulation of scientific and medical knowledge as well as the spread of health services networks, this all led to the gradual improvements in health and the decline of mortality.

The profound long-term changes in patterns of death, disease, and disability have been labeled the *epidemiological transition* (see Omran 1971 and *Mortality, Epidemiological, and Health Transitions*). It has three courses of change: a shift from infectious and parasitic to chronic and degenerative diseases, a shift in the burden of death and disease from the younger to the older population, and a shift from a health picture dominated by mortality to one dominated by morbidity. In general, these directions of change occurred in the developed countries before the middle of the twentieth century. In developing countries, during the latter part of the twentieth century, often the increase in chronic and degenerative diseases coexisted with

relatively high levels of infectious diseases (Bobadilla et al. 1993). Most of the morbidity of contemporary advanced societies is preventable because in large part it is due to ills and imperfections of social and individual behavior. It is due to undesirable side effects of industrialization, urbanization, and mass consumption such as atmospheric pollution, environmental degradation, accidents, mental tension and distress, consumption of tobacco, alcohol and drugs, unhealthy diets and obesity (Jozan 1998). Efforts to control and reduce this morbidity are underway, but results are mixed. The complexities are numerous. Consequently, there are large differences regarding success and failure in lowering mortality and morbidity between countries, within countries among regions and social strata.

The progress and problems of mortality and morbidity change in the past 50 years are illustrated by data in Table 3. In most countries around the world major improvements were achieved during the second half of the twentieth century. Nonetheless, there were two types of exceptions. Hungary exemplifies the stagnation in mortality decline of the formerly socialist countries of central and eastern Europe and Uganda represents the countries of sub-Saharan Africa where mortality declines were reversed mainly as a result of the HIV/AIDS epidemic. At the same time, significant improvements in the health conditions of infants have been achieved around the globe, but major differentials persisted through the end of the twentieth century (United Nations 1999).

3. Fertility

In the long run, additions of births have to at least match attrition by death if a society is to survive and perpetuate. That is what has been happening throughout humanity's history and before. Fertility could not decline from traditional levels prior to any significant decline of mortality without causing the extinction of human populations.

As long as mortality was high and a large proportion of infants, children, and adolescents died before entering their reproductive ages, women would bear on average 5–8 children. Such high fertility is persisting at present in a number of countries with high mortality, especially in sub-Saharan Africa. There are, however, only few such countries remaining. For the most part, fertility has either already declined to very low levels or countries are on their way between high and low fertility.

The biological maximum a woman can bear during her childbearing period is between 13 and 17 children. As a rule, this does not happen as there are numerous deliberate/conscious as well as unintended/unconscious mechanisms limiting births. Until the nineteenth century in the advanced countries, and until only several decades ago elsewhere, breast-feeding—occasionally combined with taboos in intercourse during lactation—was the decisive factor bringing down the number of children born to between 5 and 8. In premodern times almost exclusive breast-feeding tended to be the rule for infants and for many children at times until they reached their second or even third birthday. For most women this practice prevented a further pregnancy. An extreme example are the San of the Kalahari Desert who were not subject to any taboo and yet they achieved four-year birth intervals through the contraceptive effect of frequent (four times an hour) breast-feeds. The physiological process taking place is such that when the baby suckles on the nipple, nervous impulses pass from the breast to the brain to inhibit the release of hormones responsible for ovulation from the pituitary gland (see Potts and Short 1999 and *Fertility Control: Prevalence and Consequences of Breastfeeding*).

Women breastfeed as it is the most natural and convenient way to feed infants, at the same time the conception preventing effect was apparently known for millennia and in some societies widely realized. Aristotle stated in the *Generation of Animals* that ‘while women are suckling children, menstruation does not occur according to nature, nor do they conceive.’ In 1792, Mary Wollstonecraft wrote in the *Vindication of the Rights of Women*: ‘Nature has so wisely ordered things that did women suckle their children, they would preserve their own health, and there would be such an interval between the birth of each child, that we should seldom see a houseful of babies.’ Lactation has other critical salutary effects. Maternal milk is the most beneficial source of nutrition finely adjusted to the needs of the offspring. It is also a living secretion, rich in antibodies that protect against disease. Therefore, particularly in developing countries, breastfed babies tend to be healthier than their bottle-fed peers.

Other critical factors reducing fertility are delayed cohabitation of partners/marriage, the use of contraceptives, and the prevalence of induced abortions. Prior to the latter part of the nineteenth century, these

were known, however, they were not widely practiced and therefore they were not decisive in modifying fertility. Western European marriage patterns were the exception. Hajnal (1965) observed that since the eighteenth century fertility had been relatively low and at times declining in countries west of a line between St. Petersburg and Trieste precisely because the age of marriage was high. Later, the considerable fertility decline in western countries in the late nineteenth and early twentieth centuries was apparently brought about by the application of relatively unsafe induced abortions as well as the use of traditional methods of contraception, such as coitus interruptus (Santow 1995). There is, however, scarce statistical hard evidence to support this statement.

During the second half of the twentieth century safe induced abortions became increasingly available for a large proportion of the world population and unsafe abortions were widely practiced in Latin America and Africa (see *Infanticide and Induced Abortion*). A ‘contraceptive revolution’ was underway throughout the developed countries and increasingly in the developing ones as well. In most countries the use of contraceptives increased, modern contraceptives such as the IUDs and oral contraceptives found extensive application, and female as well as male contraceptive sterilization was widely adopted, although differences between countries were considerable. The prevalence of contraceptive use rose to between 70 and 80 percent of married women in the developed countries, and in countries such as Taiwan and South Korea, the use of contraceptives increased from 20 to 80 percent within a period of about three decades (see Frejka and Ross 2001 and *Family Planning Programs: Development and Outcomes; Eyewitness Memory: Psychological Aspects; Fertility Transition: Economic Explanations; Fertility Transition: China; Fertility Transition: East Asia; Fertility Transition: Southeast Asia; Fertility Transition: South Asia; Fertility Transition: Middle East and North Africa; Fertility Transition: Latin America and the Caribbean*).

Relatively late marriage, the use of contraception, and induced abortion are the *means* of modifying fertility (see *Fertility: Proximate Determinants*). The motivations and decisions to regulate fertility, subconscious or conscious, have numerous economic, social, cultural, and political roots. The following developments are critical. With economic progress children have evolved from being an asset to their parents to become a costly investment. Growing proportions of young women and men remained in school or found employment outside the household and therefore entered marital or consensual unions later than their parents. The family, particularly the younger generation, used to take care of older members of the household; increasingly older people have to take care of themselves possibly assisted by the state. As recently as in the nineteenth century women everywhere were oppressed and disadvantaged, now-

ere did they have the right to vote, for instance. In various parts of the world many women are still battered, sequestered, mutilated, or exploited, but a basic trend supporting their empowerment is in progress. Thus, increases in women's education and employment, their earning potential in the marketplace, and growing equality vis-à-vis laws have enabled women to partake in decisions regarding fertility behavior.

Population policies—deliberate interventions to influence a population development—have frequently been formulated and employed by governments or international institutions (see *Population Policies, Politics of*). With respect to fertility, governments perceiving it to be too low may devise policies which they believe will raise fertility; those regarding high fertility as a burden implement measures to diminish it. Berelson (1977), for instance, demonstrated that there are numerous policies which may conceivably reduce fertility. He clarified how policy makers taking local circumstances into account should and usually do consider whether the policies they wish to employ are *acceptable* to the political elite and to the public, whether they are *feasible* with given resources and administrative infrastructures, and how *effective* they will be.

Particular social, economic, political, cultural, and religious circumstances sometimes in combination with population policies shape people's fertility desires, motivations, and behavior which is expressed in their marriage patterns, breast-feeding practices, contraceptive use, and prevalence of induced abortion and thus result in a certain level and trends of fertility.

The unprecedented changes in fertility which occurred during the second half of the twentieth century are illustrated in Table 4. The total fertility rate, a measure which can be interpreted as the average number of children borne by a woman, on a worldwide scale declined from about five children in the early 1950s to just over two-and-a-half in the year 2000. In the developed countries, represented by Sweden, Japan, and Hungary, fertility declined from an already low level in the early 1950s to significantly below the replacement level of about 2.1 children per woman. The decline was not linear, some fluctuations did occur, however, at the end of the twentieth century not much less than half the world's population lives in countries with below replacement fertility (see Frejka and Ross 2001). In developing countries around 1950, fertility was high, between six and seven children per woman. In a significant number of countries it declined close to the replacement level, such as in Brazil. In

others like in India fertility was considerably reduced. In some countries, however, no discernible change took place. Uganda is typical of sub-Saharan countries with stable high fertility, although there are some where a decline has commenced.

Even though there has been a considerable fertility decline in most developing countries in the past several decades, continued population growth can be expected and will be forthcoming during the first half of the twenty-first century. Past high fertility has produced large cohorts of young people who are presently in the childbearing stage of their life cycle or who will enter their childbearing years. Even if these generations will have low fertility, the total numbers added to the populations of the developing countries are almost sure to be much larger than the number of people dying (see *Population Dynamics: Momentum of Population Growth and Population Forecasts*).

4. Concerns

Table 5 illustrates basic demographic developments which are frequently causes for concern among policy makers, scientists, and the general public. The world population has grown more rapidly during the second half of the twentieth century than ever before. Rapid population growth, even though at a moderating pace, will continue for some decades. Extraordinarily fast population growth has occurred in developing countries. Brazil's and India's populations, for instance, have grown threefold, Uganda's 4.5 times. Such growth creates obvious dilemmas and pressures for governments, the private sector, and international organizations striving to raise educational levels, improve health conditions, broaden employment opportunities, and elevate living standards in general. Population growth coupled with increasing consumption in developed and developing countries increases dangers of specific resource depletions, environmental degradation, selective plant and animal extinction, which ultimately could pose problems for and harm the human species. Concern is also voiced that rapid population growth can be a factor exacerbating poverty and political instability.

Hungarian population change exemplifies a shrinking population. There were more than 10 such nations in Europe in the late 1990s and thus concerns for a diminishing labor force, declining international stature, the potential of dying out as a nation, and others have surfaced.

Rapidly declining and low fertility gives rise to changes in the age structure and together with increasing longevity are the root causes of population aging. In the late 1990s in many developed countries 15 percent or more of populations were of age 65 and over. The numbers and proportions of the elderly have been increasing and there is no doubt that they are going to continue to do so. This is one of the major

concerns of governments in the developed countries because considerable state expenditures go toward social security benefits of the elderly as well as their health care. As fertility is declining rapidly in many developing countries, population aging is becoming an important social and political issue.

Global Positioning System

From the beginning of time man has striven to answer three fundamental questions: where am I now, where I am going next, and what is the best route from here to there? The observation of the sun and stars, and then later the use of the compass, the sextant, navigational

maps, and charts of the heavens, have all been essential aids and instruments in this never-ending quest. GPS is the most recent contribution to this search.

1. *Origins and Instances*

Over the years the need to answer these questions has been the driving force behind the development of many civil and military applications. During World War Two, one of the nations in combat realized that, even if they managed to build warships relatively rapidly, it was much more difficult to find suitable commanders for the ships. Such positions required candidates with a high level of experience, especially for mapping the ship's course. From this dilemma LORAN (Long-range Radio Navigation) was born, a system essentially for use at sea, based on the reception and phase difference of radio waves transmitted from two antennae. These two stations transmitted a continual flow of coordinates to navigators equipped with the correct passive antenna, which they then used to pinpoint their exact location on the earth's surface. This facilitated the commander's decision-making enormously, as he knew the ship's position at any time and, by using additional electronic aids or by simply mapping the points already crossed on a nautical chart, he also knew exactly where the ship was headed. The GPS (Global Positioning System) was the natural evolution of LORAN.

At any given moment and point in the area covered by the system, GPS is capable of providing the three-dimensional coordinates (x, y, z, or latitude, longitude and height). Rapid progress in electronic component design, has miniaturized GPS equipment to the extent that even watches and telephones can contain GPS and can provide the wearer with their exact position, the route they followed, and where they have to go.

On certain commercial flights a screen displays a schematized map of the territory below and, using GPS, a pointer indicates the current position of the airplane, the flight path, and, amongst other information, how much time remains before landing. Passengers draw comfort from knowing where they are and when they will arrive. From the cabin they may be able to use the features mapped on the screen to recognize the physical characteristics of the territory below.

Aside from the passive and temporary use of GPS to determine position, route and destination, the system is also important for activities with long-lasting and consequential effects. The most important example is the use of GPS in cartographic or topographic research, and, by extension, to many forms of inquiry in social science. With GPS, the earth's surface becomes an enormous digitizer, and any point can be identified instantly by its three-dimensional coordinates and archived in a suitable information system, potentially increasing the intensity of sampling events and objects in space and time by several degrees

of magnitude. Such measurements affect research and practice in archaeology, economics, geography, planning, and sociology, as well as in the natural sciences. By determining precise coordinates of points on land or on the surface of water, GPS makes it possible to update maps by locating physical and social features from which GPS gathers data instantaneously and/or detecting changes that have occurred in reality but have yet to be recorded (e.g., new construction, physical changes in the environment, transient events, or those in constant transformation such as people, vehicles, coastlines, woods, glaciers and so on).

2. *The General Principles of GPS Functioning*

GPS receivers use radio waves to determine positional coordinates. The radio waves are emitted by a constellation of orbiting satellites, which function as a reference system for GPS. The constellation consists of 24 satellites, which are located in six orbits, inclined at an angle of approximately 50 degrees, at a height of around 20,000km. Known as NAVSTAR, the constellation is the property of the US government and is controlled and managed by the Department of Defense. The orbits and the distance between the satellites are organized in such a way that, ideally, every point on the earth's surface can be seen by at least five satellites at the same time, although this is not always this case in practice. The GPS carries out the triangulation of three satellites visible at the same time above the horizon, measuring the distance that separates it from each of these by calculating the time between each satellite (transmitter) to the GPS itself (receiver) using precise time signals emitted by the satellites. The triangulation allows the GPS to determine the latitude and longitude, though a fourth satellite is also necessary to determine a third coordinate giving the height at which the GPS receiver is located. To measure the time required by the signal to travel the distance from each satellite to the receiver, it is essential to use extremely precise equipment to transmit the signal, to calculate the time lapse, and also to pinpoint with extreme accuracy the position of each satellite in space. To this end each satellite is equipped with an atomic clock and its position is constantly monitored and regulated by a series of earth stations.

It is essential to consider the problem of errors incurred by external agents when dealing with instruments as sophisticated as the GPS. To determine the exact time the signal takes to reach the GPS receiver, it is also necessary to understand all the modifications and distortion the signal may undergo while passing through the ionosphere and the atmosphere. The causes of error and/or the malfunctioning of the system are varied, and can range from atmospheric conditions to the position of the satellite constellation in the sky and their visibility from the receiver. The location of the GPS receiver itself may cause problems.

For example the receiver may be unable to detect a satellite if it is located under a canopy of thick vegetation or in a city canyon, where its horizon may be modified by the height of surrounding buildings.

Those managing the system itself may introduce certain deliberate errors. GPS, for example, has been subject to SA (Selective Availability), a randomized error deliberately incurred in the time signal from the satellites to degrade the positional accuracy of the receiver to the order of 10 to 100 meters. Acting on a declaration made in 1996, on May 1, 2000, the President of the USA announced the end to the use of SA in GPS, with the immediate effect of increasing and encouraging the use of GPS for civil and commercial purposes throughout the world. In fact, the demand for GPS precision was such that, as soon as the system was recognized by civilian users as being of major importance, they also wanted instruments of reduced size and low cost to have the same excellent functionality found in the military. While knowing one's position with reasonable approximation (within tens of meters, or at least under 100m) is satisfactory for most marine or aerial navigation purposes, this level of approximation is not acceptable in other contexts. In an urban situation for example, the user may wish to know what side of the road he is on or which traffic lane to be in, and in the development of technical charts, cadastres, and engineering plans, the precise coordinates of the point on the ground are needed in order to represent it on a topographic map. In the latter case it is necessary to reduce approximation to within a few decimeters or centimeters. In reality, GPS is capable of reaching precision of less than a millimeter, if certain components of the technology are exploited and if the period of observation can be maintained for a sufficient length of time.

The precision of GPS measurements is also influenced by factors such as whether the station is mobile or fixed (at least for the time being) and whether the receiving station functions alone or in connection with other stations. The ability for a station to operate in conjunction with at least one other fixed station provides optimal precision. This technique is called Differential GPS and it is based on the registration of signals transmitted by the satellites and simultaneously picked up by a fixed or base station (Master), of which the precise geographical coordinates are known, and by a mobile station (Rover), located anywhere within a range of around 150km from the Master station. Post processing the data eliminates the errors in reception by the Rover. The precision of the GPS in the Rover station is able to satisfy all the requirements of civil use from cartographic applications, to support systems for the management and control of transport fleets, and personal mobility.

The late 1990s have seen an increase in the demand for differential correction and it is now easy to find

private and public companies that broadcast the data necessary for differential correction in their zone over the radio waves. Certain GPS models are already equipped to receive such radio signals. In the future GPS will continue to improve, in particular after the announcement by the US military controller of the system, with the launching of new satellites, of which 18 are planned in the near future, and with the refinement of certain technical characteristics. The future will also probably see full integration with the Russian-developed GNSS system, which is already integrated with GPS in certain commercial devices.

3. *The Relationship Between GPS and Information Systems*

The most relevant aspect of GPS to the information society in 2001 is the ability to provide the geographical coordinates of any object on the earth's surface and to increase our knowledge of the object's characteristics with ancillary data, collected in real time and directly from the field, at very low cost. Without doubt, the geographical component is an essential part of current databases and is generally deduced from a classification of objects by name (city, road, house number, etc.) or is represented by the cartographic coordinates of the single object gathered from maps (for example the centroid of a manhole cover, telephone or electricity pole, the axis of a water or gas pipe). In each case the geographical component, obtained by traditional means, is approximate, expensive, or unreliable in relation to both time and space. Time, because things can change from one moment to the next (an electricity pole can be moved relatively rapidly in reality but not so rapidly on the charts representing it). Space, because an element located in a certain territory undergoes continual transformation, the shores of a lake or a coastline for example can be modified by environmental factors.

Conferring a geographical address on each item of data allows for the application of the analytical, inquiry, and management functions of a geographic information system (GIS). Real time availability of the geographic address means that the spatial analysis can be carried out instantaneously in the field. Typical spatial analysis functions include: investigating relationships of proximity to, or distance from, the object, superimposition of information layers, the search for the shortest or any route that satisfies specific conditions, identification of spatial environments that group objects with specified characteristics, monitoring transformations of the object, and so on. Typical functions of inquiry analysis are those that allow us to understand the information linked to an object by selecting that object from a spatial database rather than selecting an object from the alphanumeric database and obtaining thematic charts *ad hoc*. Typi-

cal functions of information system management are those that permit us to continually update the constituent elements by refreshing the data and integrating the geographic database whenever necessary.

The continual information flux is one of the major problems in information society and updating coordinates in three-dimensional space is even more challenging. Connecting GPS to other techniques helps solve this problem. For example, we can consider digital cartography, necessary for a decision-making process in a territorial or urban context. This is archived in appropriate databases and territorial information systems use it to undertake analysis and to aid in making the above-mentioned decisions. But what happens when digital cartography no longer reflects reality? A city or region can sometimes change very rapidly and if the digital map is not updated, then we run the risk of the information system elaborating data that is no longer. Invalid information may be merely inconvenient or lead to serious social or legal complications. GPS helps greatly, but it is not only maps that need continual updating but also the geographic address of data that is particularly useful in social science. Among these are census tracts, political districts, administrative units, pollution zones, and epidemiological information, or research concerning traffic and movement. More controversially we may monitor individuals.

4. Examples of the Use of GPS and its Social Implications

The development of GPS and its diffusion is a step towards having geographic address (x, y, z coordinates in space, or longitude, latitude and height) and exact time as a component of any type of information. GPS equipment is already widely used by utilities companies for the identification of the components in their networks (poles, pylons, wells, technical components, etc.), while among the earlier applications we should remember the use of GPS for the positioning and identification of submarine oil wells from offshore oil platforms. Additionally anyone, at any moment in time, can visualize the location or destination of any vehicle transmitting its coordinates to be collected in real time by GPS. For example when mounted on a public bus, a GPS can supply immediate information on the vehicle's location, the journey time and anything else that is necessary to satisfy the needs of the driver, passenger, or manager alike. For some time now, insurance companies have been using this system to reduce the incidence of car thefts. Car manufacturers are now equipping cars across the range with navigators: electronic navigation systems containing a digital map of the area in which the car is travelling and on which the positioning and movement of the vehicle itself is traced, thanks to the continual tracking of its location through GPS. Integrated with other

systems, GPS permits a vehicle to proceed automatically, without the aid of the driver or pilot. Systems already exist in marine and aeronautical applications that are capable of functioning as autonomous autopilots. Exact details of military applications are not public knowledge, but it is easy to guess that the same basic technology is used with more sophisticated developments. An internal GPS in a cellular phone provides the user with their exact coordinates, and can be used to visualize the location of similarly equipped phones. Such devices are in regular use at large conventions to facilitate (or avoid) meetings. The same device alerts emergency services to incidents on lonely stretches of unfamiliar road or, worn as clothing, GPS may guide the sight-impaired or protect children against becoming lost. All fields that use geographic coordinates may derive benefits from the use of GPS.

There are two principal problems linked to the use of GPS: a reduction in the capability of orientation and the limitation of privacy.

The problem of the reduction in the capacity to orientate oneself is due in part to the use of digital coordinates, rather than analog information such as: go to the square, turn right at the newsstand, go straight on to the white building, etc. With GPS a person can supply a visitor with the coordinates of their position by simply pressing a button; the visitor receives the coordinates and transfers them to his autopilot or navigation system, and the vehicle navigator directs the visitor to the location they require. Nothing will remain in the visitor's memory, unless he has paid attention to the features of his route and not simply paid attention to the screen. It is a question of personal choice whether to learn to navigate in one's environment or to rely wholly on digital assistants.

The privacy problem is a crucial aspect of the use of GPS in society. The power of knowing in a given moment the location of someone equipped with a GPS can be a source of enormous security in certain cases; for example for those suffering from an accident or particular illness who may require treatment as quickly as possible. But knowing someone's movements is potentially a great intrusion on personal privacy. For example, with GPS and GIS we could discover the shop, office or facility someone is currently visiting, or recreate their activities during the past 24 hours or longer. The surveillant society is the flip-side of the information society. Separating valuable monitoring from unwarranted intrusion into personal privacy, and deciding who has the power to distinguish between them, poses a major problem for society.

5. Summary

Cartographers, engineers, planners, archaeologists, and geographers have drawn enormous advantages from the active use of GPS and will continue to enjoy

the benefits of a new technology that allows for rapid and much less costly collection and updating of geographic information. The integration of engineering designs realized with CAD, digital mapping, and GPS, introduces the possibility of devices capable of elaborating designs for civil engineering and proceeding through interactive surveys, to the construction of roads, buildings, etc. GPS also integrates well with the analysis of data that has been collected via satellite for the observation of the earth, in that it allows for the exact identification of the coordinates of specific features on the satellite image. Social applications range across all walks of life. Inevitably, as with all technological innovations, its use should be evaluated critically, and the limits of its appropriate use determined.

Globality

In the English language the word globality is of relatively recent coinage, although the noun 'globe' has been used rather a lot since the sixteenth century along with the adjective 'global.' The concept of globality has come to be employed widely since the early 1980s (Robertson 1984), along with the concept of globalization. Both globalization and globality became significant terms during the 1980s, in the wake of expanding scholarly use of the adjective global, in primary reference to the dual aspects of the intensifying connectivity (Tomlinson 2000) and of the spreading and deepening consciousness of the world-as-a whole (Robertson 1992, 2001a). This development

within intellectual discourse has proceeded in tandem with the ever more conspicuous invocation of the adjectival form in promotional and advertising contexts. Both these trends were largely sparked by the phrase 'global consciousness,' meaning consciousness of the world as a whole, in particular, but not sole, reference to environmental or ecological issues. Note must also be made of McLuhan's extremely influential conception of the global village (McLuhan 1964, p. 93, Gordon 1997). This was centered on the expansion of forms of communication since the invention of movable type and then the printing press in the fifteenth century up to global communication via radio and television, but prior to the World Wide Web, the Internet, and other by now commonplace features of the contemporary period of electronic communication.

Throughout most of human history there have been different civilizational conceptions of the scope, features, and conditions of the world. Scholars have, over thousands of years, speculated and theorized about the place of terrestrial earth in the cosmos. Of particular import in this regard was the period of the European Renaissance, an era of radical restructuring of philosophy, the arts, and the sciences in the fifteenth and sixteenth centuries (Cassirer 1963). A pivotal occurrence of this period was when the Polish scientist-philosopher Copernicus showed in 1512 that the earth was not the center of the universe, but that planets exist in a heliocentric universe. This perspective had truly major historical ramifications, in that the Renaissance as a whole, to put it all too simply, involved within Christendom an increasing valorization of *humanitas*, in contrast to previous worldviews that stressed the preeminence of God. The Renaissance view, well articulated by Cusanus (Cassirer 1963, pp. 7–45), did not, however, elevate humanity to the level of God. For Cassirer, the significance of Cusanus was in the latter's exposition of a move from the pre-Renaissance idea of a metaphysical world of transcendence to the Renaissance view of a scientific world of immanence. This shift represented not a triumph of the latter over the former, but rather a complex form of complementarity (Domandi 1963).

Closely intertwined in the European context with the crystallization of ideas concerning humanity were voyages and travels of 'discovery' to other parts of the world, particularly to Asia and to the Western Hemisphere. The 'discovery' of Africa, from the European standpoint, was not to come until a little later (Wills 2001, pp. 32–44). This expansion of the heliocentric world added a crucial spatial dimension to the more scholastic ruminations of leading figures of the European Renaissance, helped greatly by map-making becoming much more expansive, detailed, and accurate than had been the norm prior to that. It is of great importance to recognize the intimacy of the relationship between the motifs of humanity and globality, which were brought closely together during the Euro-

pean Renaissance and were to come even closer, up to and including, the European Enlightenment of the eighteenth century. This involved, again, an enrichment of the conception of humanity and an even broader and more concrete extension of the ideas concerning global variety. Consciousness of the latter was not often explicitly expressed via the specific concept of globality, this being a latent rather than a manifest theme.

Ever since the Moon landing of 1969, consciousness of what has come to be known as globality has increased. Space travel generally, as well as much of science fiction and the modern cinema, have greatly enhanced our tendency as human beings to gaze upon our global habitat, to become increasingly conscious of and sensitive to our globality. Even though this exact term may not yet have been used much, the ancient Greek notions of *oikoumene* and *okeanos* have remained central to conceptions of what are now considered under the rubric of globality. For example, the recent work of the Swedish anthropologist, Hannerz (1996, pp. 1–13), is centered on the concept of the global *ecumene* (*oikoumene*), a term which he has borrowed from the cultural anthropologist, Alfred Kroeber. Kroeber (1945, p. 9) saw the scope of anthropology to be the global, ecumenical circumstance, suggesting that humanity at large consists of interwoven relationships among a variety of societies and civilizational regions, with particular reference to culture.

In spite of this long etymological history, had it not been for the enormous and still growing degree of attention given to the contested concept of globalization (Robertson 1992, 2001a, 2001b), the notion of globality would not have acquired the contemporary significance that it now has. The discussion of globalization in a considerable number of social sciences and humanities has led to increasing talk about our now living in a global age (e.g., Albrow 1996), even though, as has been stressed, the philosophical, metaphysical, and theological interest in this topic, in a diffuse sense, dates back to ancient speculation about what we would now call the human species and the shape, configuration, and place of the earthly world in the universe.

In fact the phrase, 'the global age,' has become a common, although not unproblematic, characterization of the present condition of humankind. In this regard, there is a controversy in a number of disciplines concerning the relationships between such themes as tradition, modernity, postmodernity, and globality (Robertson 1992, pp. 138–45). Indeed, it is not fully possible to delineate the contours of globality without situating this concept, in contemporary terms, within this array of themes. Likewise, it is not possible to neglect the issue of locality in relation to globality, largely because the two have often, although very simplistically, been viewed as opposites, within the debate about globalization and related issues in recent

decades of so-called modernity. In fact the relationship between globality and modernity is particularly controversial, basically because some have claimed that the process of globalization and the consciousness of the condition of globality have been a consequence of modernity (e.g., Giddens 1990), while others (e.g., Robertson 1992, 2001a) have insisted that globalization was a precondition for the rise and spread of different types of modernity in, or to, different parts of the world.

Globalization as an analytic concept first began to be used rather widely in sociology, religious studies, and, and to a lesser extent, anthropology in the early 1980s, although the theme of world, or global, history had been thematized in different civilizational contexts much earlier in the twentieth century than that, falling, however, into temporary decline from the 1920s until the 1980s. The concept of globalization came to be employed in a truncated and increasingly politicized way in some social-scientific, political and journalistic circles, but particularly in the field of business studies, from the late 1980s onward (Robertson and Khondker 1998, Robertson 2001a). This narrowing of the concept of globalization has had the consequence of pushing the theme of globality into the background. Even so, even were this circumscription to be comprehensively embraced, the theme of globality would not thereby be eliminated. This is so in spite of the fact that many academics, not to speak of the 'informed public,' do not appreciate that the concept of globalization was being debated quite extensively before it was more or less independently taken up in business studies, policy-making, and ideological forms. The theme of globality has very little to do in any significant respect with conceptions of globalization that limit it primarily to economic change and politico-economic policy. But the notion of globality is not necessarily marginalized as a consequence. The great attention that has been given to human rights and related concerns since the late 1970s helps to demonstrate this. For the virtually worldwide interest in and controversy about human rights have become closely bound-up with concrete matters of politicoeconomic policies.

When the term globality is explicitly employed, it usually refers to an historical circumstance of human life, and it is the extent to which this circumstance marks a new phase in the history of humankind as a whole that is particularly important, as well as problematic. More specifically, it may be defined as the intensification of more-or-less worldwide connectivity and increasingly reflexive global consciousness (Beck 2000, Robertson 1992). Overall, the condition of globality is accentuated greatly by the compression of the world. To this definitional statement must be added that, in a simply objective sense, this worldly planet was as global millennia ago as it is now. In this regard the world has always existed in-itself, but over many centuries it has become more and more for-itself, this meaning that as human beings we

have become more and more conscious of and have acquired doctrines and views about the future of the world.

Looking at this from the opposite direction, the notion of globophobia (Burtless et al. 1998) may be invoked. Globophobia, a term coined originally by a group of economists to characterize resistance to the opening of national economies to free trade and globewide economic competition, may be defined, more generally, as a sentiment involving resistance to globewide, more loosely what are perceived to be foreign or alien, phenomena and trends. Such trends are regarded as threatening the integrity and primordality of a particular collectivity. Globality is in this sense a form of complexity, a complexity that is seen by some as going beyond the complexity of what has usually been called modernity—or, more recently, postmodernity. For example, in the USA, so-called Christian fundamentalists have spoken vociferously of the evil of (American) secular humanism. In more recent years, however, the enemy has become secular globalism (Bowen 1984). Even though parallel conflicts are to be found in many societies around the world, that between the self-proclaimed antiglobalists and those who subscribe in one way or another to a much more open society within the USA is, given the paramouncy of the USA in the world, of unavoidable—indeed global—significance (Robertson 2001b).

The perceived threat of globalism as a conspiracy against core American values has intermittently been, but particularly in recent years, a conspicuous feature of political discourse in the USA. Many societies have traditions of belief in conspiracy, but the USA has been one of the most prominent in this respect. This has partly been a response to the opposite trend—to be found in many American educational circles—involving the advocacy (often, but by no means only, for economic reasons) of teaching about other cultures and languages, as well as the condition of the world as a whole. This leads to a much more general—indeed, global—issue concerning the ways in which, to greatly varying degrees, people experience existential difficulty in being confronted by alternative ways of life. This is often encapsulated in the idea of alterity, or otherness. Rigid rejection of ‘the other’ is to be seen most clearly in what has come to be declared by some as fundamentalism (Robertson 1995). Thus, when normatively embraced, globality involves an eager acceptance of the idea of the global-human condition. At the other extreme, fundamentalism entails adamant rejection of the latter, at least insofar as one confines the concept of fundamentalism to specific societies or localities. A complication here, however, is that there is a form of global fundamentalism, one that stresses the priority in everyday life of globality and humanity over such aspects as international relations, features of particular societies or the life-cycles and identities of individuals.

The quotidian problem of alterity arises primarily from processes of relativization. Relativization involves the situational problems arising from the challenges posed to a particular way of life by the problematic realization that there are other, alternative ways of life. In a world marked by its high degree of connectivity, confrontations between different forms of life are ever-increasing. For, as the world becomes more connected and people around the globe become increasingly aware of both their differences and their shared fate, the likelihood of dilemmas and ambivalences concerning ‘others’ greatly intensifies. Indeed, probably the most general feature of long-term globalization, over many centuries, has been the persistence of relativization processes.

Although the notion of globalism is often used, even by mainstream academic contributors to the discourse of globalization, in its broad, comprehensive—as opposed to its narrow economic—sense, it is misleading so to do. Specifically, the sentiment, or even ideology, of globophobia often involves the presentation of ‘the enemy’ as the ideology of globalism or what is also often called, in a pejorative sense, one-worldism. Thus, even though some social scientists use the idea of globalism with the best of intentions, that is, to indicate their or others’ cognitive and moral commitment to a global perspective, they nonetheless unwittingly engage in the rhetoric of resistance to the idea that we now live in a condition of shared globality. So globality is a much more preferable concept in relation to much, but by no means all, of the talk about globalism. The two terms have very different connotations, although they are often used interchangeably, with subsequent confusion. Globality indicates—for the most part—a condition, or circumstance, while globalism is an ambiguous term, ranging in its meaning, on the one hand, from the relatively innocuous expression of adopting a so-called global perspective to a pejorative, condemnatory declaration, on the other hand, of the evils of subscription to the view that there is a general, inclusive conception of humanity and that, moreover, we all, every single human being, live in and share a single, global place (Robertson 1992).

When we read or make such statements as ‘we now live in a global world,’ ‘the world is my home,’ or ‘we must take the feeling of home into exile’ (see Iyer 2000), we are drawing attention to global complexity and at the same time welcoming it. This is indeed a personal and seemingly positive kind of globalism, but at the same time, from the analytic standpoint, such attitudes are merely symptomatic of the condition of reflexive globality. The question necessarily arises as to whether these orientations are merely to be found among certain kinds of intellectual or more privileged people, such as those who flit from one habitat, or habitus, to another. Thus it is not unreasonable to ask the question as to whether it is only certain global elites who dwell in and welcome the circumstance of

globality. However, in many ways it is the world's most deprived peoples, not to mention those, such as students, who move back and forth between 'tradition' and 'modernity,' that are most reflexively conscious of the global condition. Moreover, the everyday life of people all over the world, even though they may be relatively, or even absolutely, immobile geographically is becoming increasingly global, not least through representations of 'other cultures' in movies on cable or satellite TV, through popular culture generally, or everyday interaction, including electronic communication. In other word, vicarious, virtual interactional communication is increasingly part-and-parcel of everyday life. Even though celebrities, business elites, and some academics are increasingly conscious of the condition of globality, they do not in fact have a privileged position in this respect; for in one way or another people all over the planet earth are evidently becoming more and more 'global.' While it has to be conceded that there is much resistance all over the world, at the beginning of the twenty-first century, to strangers, it has been argued persuasively that this, often violent, opposition to polyethnicity and poly-religiosity (in the symbolic form of ethnic cleansing), constitutes the dusk of the norm of homogeneity and the contested return of what has been described as the polyethnic norm (McNeill 1986).

Whether 'the average person' is or is not fully conscious of their 'global membership,' many 'average people' nonetheless participate in increasingly reflexive global consciousness. The development of such has been proceeding for a very long time, at least since the crystallization of the so-called world religions in what has been called the Axial Age (Jaspers 1953), for example, through pilgrimages, world map projections, voyages of 'discovery,' and so on. In much more recent times such a variety of phenomena as two World Wars, the Cold War, the European and other holocausts, the global AIDS pandemic, awareness of global ecological problems (notably global warming), the World Soccer Cup and other world championships, rapidly burgeoning touristic travel, global festivals, and so on and so forth—the list could be vastly extended—amply illustrate this.

While, in its most simplistic formulation, globality may be interpreted as referring to planetary territoriality and the beings (including nonhuman forms of life) that inhabit this earthly place, it is increasingly clear that globality involves and indicates variety and difference with respect, *inter alia*, to gender and sexuality, 'race' and ethnicity, nationality, and so on. Moreover, each of these, and other, attributes of human beings have become increasingly elective. In our time, to varying degrees, one choses one's body, one's 'roots,' one's gender, one's ethnicity, one's nationality, even one's own form of globality. For some (e.g., Beck 1999) we now live in a global risk society, a world in which we are continuously confronted with a multitude of choices, choices that we

make without the firm norms and values of tradition and in the absence of secure agencies of authoritative trust. In short, our planetary circumstance is 'a runaway world' (Beck 1999, 2001).

When the idea of the global-human condition is invoked, the aim is to underline that we would not now be talking about globality were it not for the connection of this theme with that of humanity. The latter certainly has had a very long, although until fairly recently, rather abstract, history. But since the European Renaissance and particularly since the European Enlightenment, the theme of humanity has become increasingly concretized. The intersection of the concept of humanity with that of globality is to be seen with particular clarity in the French philosophical and sociological tradition from the early nineteenth century through the first quarter of the twentieth century. This was a period during which theological ideas were widely rejected, but also one when a new kind of, or surrogate, religion was deemed to be required. For example, a disciple of Saint-Simon wrote that 'there is in fact only one branch of knowledge, that of humanity, which includes everything and epitomizes everything' (Merle 1987). Saint-Simon's followers elaborated his thinking in a new journal, the *Globe*. August Comte, who had been Saint-Simon's secretary, was to advocate a religion of humanity in his later years. In sum, major French writers of the first half of the nineteenth century maintained not merely that globality and humanity were complicitous, but that a new form of social-science (sociology) inevitably arose from this connection. In the late nineteenth century this relationship was further elaborated by major sociologists such as Emile Durkheim and Marcel Mauss.

Since the 1960s there has been a strong predilection to conceive of 'the local' as the opposite of 'the global'—as reflected in the maxim 'think globally, act locally.' However, recent demonstrations in various countries against global institutions—such as the World Bank, the International Monetary Fund, and the World Trade Organization—have clearly involved a severe modification of this maxim. Protesters against global institutions have come to recognize that global targets require global movements (Robertson 2001a, 2001b). This is probably the most obvious way in which the condition of globality has become inexorably central to the life of many people across the globe. For ostensibly, antiglobal movements have, paradoxically, become part of the process of globalization itself.

Globalization and Health

Recent revolutions in communication have resulted in the development of a global village. Isolated areas of the world have 'joined' the technologically sophisticated world and developed, and sometimes, parochial regions have been increasingly faced with the realities of life in less fortunate parts. Growing awareness of the disparities in lifestyles and health around the world are forcing an increasing recognition that global health policies and practices are a need, not for the future but for the present.

Health care in this increasingly disparate community must shift from the high-technology focus, which has gained predominance in technologically sophisticated societies, to incorporate broader social, cultural, and psychological concerns. For example, it is probably of far greater importance in the fight against disease to provide clean water in most parts of the world than it is to even provide doctors. Concerns with malaria, TB, AIDS, and HIV dominate global health while poverty, discrimination, inadequate education and environmental contamination provide fertile growth for even greater social epidemics. Health-care disparities are extreme with most of the world's health-care money, interest, and attention being focused on those with the least need. Ultimately, however, health care in both the developing and the developed world are interrelated and setting priorities as to how these issues can be addressed with mutual benefit is needed.

A number of themes characterize health in the global environment in the past and future decades. These will be dealt with in turn.

1. Technological Development

Health care in the industrialized world has mirrored the dominant ethic of the twentieth century: technology development. The remarkable advances in technology that have resulted in a rapidly changed and changing environment at the close of the millennium have also brought with them increasingly complex challenges.

As technology is developed, so too is the commercial basis for its adaptation and use. Overuse of technology

in health care has been the result, with new advances being applied for the benefit of all rather than only the few for whom the technology is specifically directed.

On the other hand, technology is not readily available in less affluent societies. We need to ask whether it is acceptable to have a two-tiered system of health care with regard to appropriate use of technology for developing and developed countries? How well have we addressed issues of equity regarding access to appropriate medical care? How do financial considerations influence who receives differing types of care? To what extent does remuneration of health care providers and/or health care services influence the quality of care provided or the use of available technology? How well are we monitoring the appropriate use of technology and the medical model worldwide? Are the currently available indicators of health sufficient to assess the influence of this level of functioning or are alternative indicators needed to address this issue? How should we evaluate the appropriate use of technology worldwide?

2. Evidence-based Medicine

Evidence-based medicine is one response to emerge in reaction to the technological explosion. Demanding that technology be applied when, and only when, it is effective, and ensuring that the strictest scientific rigor be applied to judge such effectiveness is leading caregivers to question the overuse of technology (Cochrane Collaboration 2000, Entin et al 1996).

We have developed a computer-based globe, moving increasingly into cyberspace in addition to its more earthly properties. Health and health care have become enmeshed in this web so that medical information and knowledge are moving more readily into the hands of the layperson than ever before. Medical practitioners are having to share their knowledge with their clients, raising issues such as shared decision making, collaborative care, information exchange, confidentiality, and informed choice by recipients of care. Decision making regarding health care, by both professionals and by families, needs to be evidence based: a fair challenge to achieve. Central to these developments are also legal and ethical issues which surround the management of health care and influence health-care decisions. Health-care services, to cope with these demands, need to move from a physician-focused service to a client-centered approach.

3. Family-centered Care

The client too is changing and is being viewed not just as a single entity but as a member of a family unit (whatever that may be), so that care is becoming family-centered care (Chalmers and Levin 2001). The family itself is changing rapidly too, meaning that

health care is directed to anything from nuclear, extended, or single-parent families, or to same-gender couples. The traditional role of the doctor-patient relationship is becoming chameleon-like in its complexities.

4. Psychosocial Health Care

The need to incorporate holistic components of care into health has never been more strongly felt than now, although this is not a new idea. As long ago as 1948, the World Health Organization's Constitution (World Health Organization 1948) defined health as 'a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.' It is far preferable to care for the client as a whole person rather than as separated fragments. In earlier medical texts, support was often expressed regarding treating the 'patient as a whole person with thoughts, feelings, and fears, and not only as a body progressing through the health care system.' Unfortunately, in technologically sophisticated societies, superspecialization also occurs. Physicians no longer care for all aspects of a client personally: For example, in reproductive health, some specialists are focused on care of the cervix, others on the endometrium, ultrasound diagnosis is delegated to specialized technicians, and even such simple procedures as taking blood are relegated to yet other caregivers. Research has documented that as many as 16 different caregivers in a 6 hour period (Enkin et al. 1996) may look after a woman during a normal birth. A holistic or psychosocial approach to care hardly exists in this structure.

Assessing people's perceptions of their satisfaction with care is one approach to monitoring the integrity of their health care. Feedback regarding educational programs is well accepted in technologically sophisticated societies. No conference ends without a delegate evaluation being completed. Why is this not similarly integrated into health-care services? Is it because the clients' voices are still not acknowledged as an integral part of healing and are weighted as of far less significance than the biological basis of their illness? Becoming partners in care, rather than simply clients, is still the challenge for the future. 'Humanizing' the medical setting has become a clichéd term, yet it is still needed.

5. Cultural Differences in Understanding of Health and Illness

Cultures differ widely in their beliefs and understanding of health, illness, and appropriate health care. Many regard the biological level of functioning as of primary significance. In contrast, significant sections of the global village regard this level of functioning as of least importance with spiritual, social, and psycho-

logical concerns playing a primary role in illness etiology, treatment, and prognosis (Chalmers 1990). It is as unacceptable to the latter to neglect consideration of spiritual rites in diagnosis and treatment of illness as it would be to fail to take a woman's blood pressure during pregnancy in technologically sophisticated societies.

While these differing approaches to care have existed peaceably side-by-side for centuries, recent global population movements have encouraged the intermingling of cultures through migration, refugee relief and more temporary forms of translocation, with resulting conflicting health care paradigms. Compounding the problem are language differences combined with status inequalities which may make it extremely difficult for the foreigners' health care needs to be met or, indeed, understood in their adopted country. As multicultural societies continue to develop rapidly in the coming decades, the challenge of integrating their health care needs will become increasingly evident.

Traditional practices of healing should be considered with sensitivity and tolerance, and encouraged unless evaluated as distinctly harmful. Condemning or disallowing such practices because they are different is insufficient for although they may not contribute to biological health, they might be important for psychological health and should be encouraged. They should be evaluated as biologically beneficial, inconsequential, or harmful with only the latter forms of care being discouraged.

6. Education

Education to prepare for a multicultural, psychosocial, and evidence-based approach to health is a prerequisite in the twenty-first century. A number of medical institutions have introduced teaching psychosocial issues to medical and allied students. For the most part these have failed. Frequently based in Social or Behavioral Science Departments, they tend to be offered in preclinical years and to focus on theory. They are often perceived by students as programs to be endured, or which are undemanding, and not central to their ability as future caregivers. When offered at a graduate level, as the real challenge of caring for people is encountered in clinical practice, their worth is sometimes reconsidered.

Rather than being offered as distinct, independent course modules, the psychosocial and cultural issues involved in clinical practice should be integrated into mainstream medical teaching programs, e.g., when clinical management of a fetal death is discussed the psychological impact of diagnostic and treatment procedures in addition to longer-term family adjustment issues should be considered. Teaching should be shared by the physician and social scientist concurrently and such joint teaching programs, when tried,

have shown much promise of a new and better model to develop for educational success (Chalmers and McIntyre 1993). In addition, providing an integrated model of teaching in the classroom will also establish a model for integrated clinical practice.

It is evident that health science faculties will need to undertake radical curriculum reforms in the twenty-first century to incorporate new, and fundamental, principles of education into their teaching. At the very least, these reform programs need to incorporate evidence-based medicine, family-centered care, multidisciplinary approaches, and psychosocial and multicultural aspects of care. Educational institutes need to be structured in such a way that facilitates the advocacy of both medical and social models of health care. How many medical schools teach social and cultural components of care as an integral component of medicine and how many simply pay lip service to this? Do we even know?

7. Efficiency of Care

A significant contributory factor to unease about care are the lengthy delays often encountered when seeking consultations with specialists, diagnostic assessments and their results, and treatment. Once a problem has developed, anxiety levels are high, particularly when fear of severe illness (such as cancer) or potential surgery becomes a possibility. Yet people frequently have to wait weeks or longer for simple diagnostic procedures such as ultrasound and even longer for more sophisticated tests. Further delays before receiving the outcomes of tests compound the problem. It is not surprising that frustration, fear, and helplessness are aroused with concurrent irritation and suspicion of the health-care services.

We frequently use the term 'consumers' to describe health-care clients. If customers in commercial stores were treated with similar delays in service and impersonal attention they would simply shop elsewhere. Within the health care service, with its more threatening and intimate experiences for clients, and its lack of real alternatives from which to choose in many instances, there is reluctance to apply a similar model. This does not mean that all is well in the state of health care, however. That dissatisfaction exists is evident in the increasing reality of litigation.

8. Conclusion

This article highlights some of the critical issues surfacing in the health-care services of the developed world from a broader global perspective. These kinds of concerns underscore the importance of those long-held values: concern for the whole person and not only the body, respect for people (and their families) and for their perceptions and needs when undergoing

medical care, a sincerely gentle and caring approach to care with sensitivity rather than routine politeness being the order of the day combined with evidence-based practice. It is apparent that while we have long recognized the importance of providing respectful treatment and care and have gone far in introducing systems which encourage such approaches, we are still grappling with the effective application of this fundamental tenant in many parts of the world, both developed and developing.

Globalization and World Culture

1. Globalization and the Construction of World Culture

Globalization involves expanding worldwide flows of material objects and symbols, and the proliferation of organizations and institutions of global reach that structure those flows. World culture refers to the cultural complex of foundational assumptions, forms of knowledge, and prescriptions for action that underlie globalized flows, organizations, and institutions. It encompasses webs of significance that span the globe, conceptions of world society and world order, and models and methods of organizing social life that are assumed to have worldwide significance or applicability.

While many types of global flows have been rising cyclically for centuries, it was only in the second half of the nineteenth century that a transnational cultural

complex took a sufficiently organized form to constitute an emerging world culture. The primary locus of this nascent world culture was Europe, particularly the powerful Western European countries whose empires extended to most corners of the globe. Europeans promoted political and philosophical principles, societal and individual goals, modes of organizing, and ways of conceiving and manipulating reality that they deemed universally applicable. Epitomized above all by technical and scientific principles and practical knowledge presumed to be invariant across time and space, emerging world culture also included more historically bound constructs and ideologies, such as nationalism, citizenship, and individualism. This early version of world culture, more properly called ‘transeuropean’ culture, was carried far and wide by missionaries, traders, military expeditions, colonialists, intellectuals, and travelers.

In this same period, transnational organizations and global structures emerged with increasing frequency, eventually to form a structural backbone or framework for world culture. The vast majority of these transnational organizations were products of international or global ‘civil society’—voluntary associations founded and operated by individuals from many countries to pursue specific goals through democratically coordinated action. Typical early examples include the International Charity Association (1855), the International Sugar Union (1864), the Scandinavian Dental Association (1866), the Permanent International Committee of Architects (1867), and the International Meteorological Organization (1873). By the 1890s, such international nongovernmental organizations (INGOs) were appearing at the rate of more than 10 per year, across a wide range of social sectors, drawing participants mainly from Europe and North America but also from Latin American and some Asian countries, particularly India. These bodies defined themselves as global actors and sponsored periodic conferences at which universalistic issues, problems, methods, and solutions were proposed and debated. They came to constitute a formalized global public realm in which world culture was defined, documented, elaborated, and propagated to what the growing number of participants in this public realm were beginning to think of as a single world society.

The calamitous world wars of the twentieth century severely interrupted world-cultural structuration, but after each war the process rebounded quickly. States became increasingly engaged in transnational cooperative relationships through intergovernmental organizations (IGOs, which were rare before 1920). After World War II, the IGO population burgeoned to a total of several hundred organizations, while the number of INGOs soared into the thousands. This expanding complex of global organizations came to center on the United Nations, whose agencies and programs became axes of global governance

regimes in such major institutional areas as education, health, and development.

Until the 1970s, the content of world culture remained primarily Anglo-European, increasingly dominated by the USA. American popular culture and products proliferated throughout the globe—rock music, soap operas, bluejeans, Coca-Cola, fast foods, Hollywood movies. The globalization of tastes in food, dress, and music also promoted a global identity model, that of the freely choosing, pleasure-seeking consumer. At a deeper level, the plethora of global organizations, both nongovernmental and intergovernmental, produced a range of standardized principles, models, and methods for the organization of social life. For example, a basic world model of the modern nation-state crystallized, stipulating that the state was to be responsible not only for internal order and external defense but also for building a modern society and promoting citizen welfare and civic engagement. States were therefore expected to generate national educational systems, health care programs, retirement and unemployment insurance schemes, and cultural promotion programs, among many other duties. In particular sectors, globally legitimated models emerged to guide states in meeting these responsibilities, such as the standardized educational models that took shape under UNESCO's aegis in collaboration with a range of educational INGOs. Despite enormous variation in national circumstances and resources, states have implemented these models in remarkably uniform ways.

By the 1980s, world-cultural structuration had produced largely standardized global models for an enormous range of activities—in science, medicine, health, business, technology, even recreation and leisure (sports, tourism, entertainment). Pushed by the carriers of these models, including INGOs and IGOs but also business consultants, technical advisers, and academic consultants who explain and interpret the models, states, local governments, corporations, social movement organizations, and many other types of social units go to considerable lengths to keep up with the leading edges of world-cultural development. The net result is a tremendous force for the homogenization of the world.

2. Globalization and Cultural Differentiation

World culture is not only a homogenizing force; it also engenders and supports diversity and differentiation. Recognition of this feature of world culture was slow in coming; through the 1970s, most analysts interpreted globalization as essentially equivalent to homogenizing Americanization. Five factors are important for understanding world culture's promotion of heterogeneity; ironically, several of these are also important elements of world culture's homogenizing capacity.

(a) *Success of the nation-state political form.* Rapid decolonization after 1945 produced a world organized almost entirely as independent states. Most new states have eagerly joined global governance organizations, debating and helping to shape agreements expressing world-culture principles and prescriptions. Citizens of the new countries became avid joiners of INGOs, expanding the range of their memberships much faster than citizens of older countries. Thus, the voices and views of the Third World are increasingly prominent in world-cultural development, and debates about proper social organization and action are often less consensual than in the past. Cultural controversy has been especially acute in such domains as women's rights, environmentalism, and human rights.

(b) *Cultural relativism and the ideology of cultural authenticity.* Intellectual movements in the social sciences and humanities, coupled with the ideologies of nationalism and national self-determination, have made the principle of the fundamentally equal value of all human cultures a central assumption of world culture. Ethnocentrism has come to be seen as both trap and injustice; tolerance and, indeed, the championing of difference occupy the moral high ground. Of particular moral virtue in contemporary world culture are the poor, the excluded, the oppressed—marginal peoples whose right to their own cultures has been violated by the onslaught of globalization (some see this as a return of 'noble savage' idealization). This universalistic form of particularism impels peoples to emphasize or invent tradition and distinctiveness in counterpoint to universalistic world-cultural principles that are supposed to operate uniformly in all places. In Western societies, such particularism is stimulated by cosmopolitan connoisseurs seeking authentically exotic cuisine or ethnically distinct 'world' music, as the genre is known. At the same time, politically astute groups understand the power of purported cultural authenticity as a fulcrum for prying rewards from global systems, so distinction and difference have become strategic resources for collective mobilization. In consequence, ethnonationalist movements of many sorts (Basques, Biafrans, Bretons, Croats, Eritreans, Quebecois, Scots, Tamils, etc.) and multiculturalist restructuring by states, churches, schools, and other organizations have become the order of the day.

(c) *Regionalism.* Roughly half of the international organizations founded since 1950 have been regional in scope, activating European, Latin American, Asian, francophone, Islamic, Andean, and many other sub-global identities. Like ethnonationalism, regionalism has flourished in the wake of world-cultural intensification. Global structures, ideologies, principles, and models provide an overarching framework of commonality and shared meaning for disparate social units. With the framework well in place, diverse regional organizations and movements have expanded to implement, modify, and argue about the frame-

work's content and implications. We see the same process at work within international organizations and global corporations. For example, Cable News Network International (CNNI) began as a unitary organization bringing a standardized English-language product to televisions around the world, but it eventually established numerous regional centers producing local-language broadcasting adapted to specific target audiences.

(d) *Consumerism as adaptive interpretation.* While global popular culture contains products and symbols that penetrate most local markets, its accompanying ideology of economic freedom and consumer choice encourages varied uses and interpretations of standardized consumption patterns. For instance, consumers in Hong Kong might appreciate a McDonald's restaurant as much for its clean facilities as for its food. They expect fast, not smiling, service, and reserve the right to eat at their leisure. In a city pressed for space, the restaurant can become a gathering spot for youth or a favored locale for birthday parties. By adapting marketing to local attitudes, McDonald's has lost its foreign aura, blending into Hong Kong's diverse, cosmopolitan culinary scene. In Beijing, meanwhile, McDonald's American origins can be attractive to upwardly mobile Chinese as a symbol of participation in global society, but among many Koreans in Seoul those same origins evoke criticism. While not denying the power of multinational corporations to foster acceptance of their products and logos, recent research suggests that they must take into account the distinctive tastes of potentially fickle consumers. Popular culture increasingly creates global tastes, but it also creates critical consumers who keep this culture from becoming entirely uniform.

(e) *Creolization.* In many domains, the homogenizing force of world culture encounters ingrained local tastes and traditions, which may in turn be the residue of earlier such encounters with neighbors or colonizers. Due to creative interaction processes, common elements take different forms in different places. The spread of world culture therefore produces not homogeneity but new cultural melanges, each 'creolized' in its own way. A case in point is West-African popular music. Popular styles that themselves are blends of variegated traditions (Brazilian, blues, British rock) become the ingredients of new and distinctive styles. Adapting indigenous instruments or rhythms, African musicians participate in a global musical movement. Cultural flows come from many directions, intersect in unpredictable ways, and continue on in new forms to yet other places. How they continue, and the publics they eventually reach, depend in part on the global commercial media system's marketing and genre-promotion efforts, but that system is only one factor shaping local aesthetic orientations. Moreover, commercial interests have much to gain from promoting diversity. Thus, as new musical or other fads make their way across the globe, they produce new forms of

localized diversity and unforeseen local reactions and interpretations. In the expressive realm, the varied forms of local-global interaction are not inexorably yielding to a standardized, stifling, hegemonic world culture.

3. Dimensions of World Culture

Most discussions of world culture focus on its expressive or normative dimensions. Expressive (popular) culture includes media products, consumable goods that assume iconic status as symbols of modernity or avant-gardism, foods and clothing styles originating in particular cultures that become worldwide fads, and so on. Normative culture comprises the values and goals promoted by global corporations and organizations—fetishistic consumerism and capital accumulation, individualism and human rights, democracy and political participation, gender and racial equality. The expressive dimension has received the greatest attention, particularly with respect to the global popularity of American films, television shows, sports figures, and lifestyle elements. Some scholars decry the obliteration of local cultures; others argue in favor of creative interpretation and adaptation, as local cultures integrate new cultural elements while retaining their basic identities (hybridization or creolization). Similarly, analysts decry some aspects of normative cultural globalization and praise others, often sharply disagreeing about the desirability of particular global norms and values and disagreeing as well about the extent to which a global normative consensus is emerging or even possible.

Less attention has been paid to the ontological and cognitive dimensions of world culture. At the ontological level, the reorganization of social life in accordance with dominant world-cultural models engenders increasing individualism, the disenchantment of nature, reliance on rationalized images of society, and an action-oriented model of the individual. Put another way, world-cultural penetration changes prevailing views of 'the nature of things,' promoting the worldview that underlies such major modern institutions as formal education, experimental science, national accounting and statistical systems, and advanced-technology engineering. These and similar institutional complexes bring with them broad bodies of knowledge and distinctive cognitive styles, but the depth of cultural reconstruction they engender remains largely unexamined because few attempts have been made to come to grips with their cultural implications. Science, mathematics, bookkeeping, organizational structure, technology, tools, construction materials, land surveying—all these have achieved the status of almost unassailably universalistic activities, uninteresting because they are mundane, routine, matter-of-fact. Thus, these highly formalized arenas seldom become the focus of ideological debate,

with the notable exceptions of such issues as nuclear power, genetically modified organisms, global warming, and large dams. The most highly institutionalized forms of cultural globalization remain largely invisible.

4. Globalization and Cultural Conflict

World culture engenders conflict in world society through a process that has, as it were, turned the West against itself. By the 1970s, when scores of new states had formed in Africa and Asia, vociferous opposition to continued economic and cultural domination by Western countries (labeled neocolonialism and cultural imperialism, originally formulated in the West) began to penetrate global organizations, especially UN bodies. Various associations of less developed countries called for a restructuring of world society—a New World Economic Order and a New World Information Order that would put restraints on the operations of transnational corporations and shift resources to the poorer countries. Former colonies began assertively invoking world-cultural principles of equality and development as basic human rights. Further tensions arose as the global human rights sector (itself increasingly involving individuals and groups from outside the West) turned its scrutiny on the new states, decrying their selective championing of certain global universals while ignoring or severely violating others, especially those relating to the integrity and political participation of citizens. Thus, both the particularism of world culture (the moral legitimacy attributed to national or ethnic units) and its universalism (the insistence that all units abide by basic principles and values) yield forms of disagreement and conflict that would not emerge in a less globalized world.

As non-Western cultures and regions have become more prominent in the world polity, it makes increasing sense to speak of world cultures (in the plural) rather than a singular world culture. Dominant Western models have penetrated deeply in most places, but they have also evoked resistance as well as efforts to revivify and globalize alternative models. Most notable in this regard is the assertiveness of Islamic cultural carriers, particularly since the 1970s. Many Muslim leaders and organizations promote a societal model that infuses the state with religious precepts and recasts the relationship between state and citizen (codified in 1981 as the Universal Islamic Declaration of Human Rights). African and Asian models of social organization and development have also emerged, and some observers argue that conflict in the twenty-first century will revolve primarily around grand civilizational axes rather than the nation-state clashes that have dominated in recent centuries.

By the same token, more fine-grained analyses of world culture(s) identify multiple models of central

world-cultural constructs. For example, derived from the Western tradition are liberal, socialist, corporate, and welfare models of the state; from Asian sources, quasifamilial and state-led development models. Multiple models of the individual, the business enterprise, and the national polity are further examples. World-cultural complexity has increased rapidly in recent decades, perhaps most sharply since the collapse of Communism and the end of the Cold War, as ever more cultural centers generate more alternative cultural constructions. Poorer and more peripheral societies are less able to bring their cultural models to the world-cultural table, but many participants in the global arena from richer societies have become strong advocates of the poor and peripheral, helping to ensure that world culture becomes yet more complex and incoherent but also more significant for national and local structuration and change.

5. Religion and World Culture

Since the early period of European expansion, many of the symbolic flows, organizing institutions, and foundational assumptions that constitute world culture have been religious in origin. Through conquest, evangelization, and migration, Europeans made much of the world 'safe for Christianity,' giving emerging world culture a distinctively Christian cast even though most of the world did not become Christian. In the current phase of cultural globalization, the overall role of religious institutions may have diminished but various religious actors on the global stage vitally affect world culture in new ways, notably by providing alternative worldviews. Religious globalization has been important in constructing world culture, contributing to its heterogeneity, and producing new forms of conflict, as explained below.

Religion played a distinctive role in the construction of world culture, providing motivation for some globalizers and legitimating the actions of others. It also contributed to the foundations of contemporary world culture. The conception of societal progress that prevails almost everywhere stems in part from the Christian legitimation of rational world mastery; the global view of the individual as agent and citizen similarly has roots in Christian views of the person; the global script for organizing society in a rational-legal manner and legitimating authority voluntaristically derives indirectly from Christian precedents. More concretely, missionaries not only spread their faith, they also provided education and health care in far-flung places, diffusing secular commitments that since have become globally entrenched. Their actions prefigured the efforts of later movements in global civil society referred to above. Today distinctly religious views are less obviously influential in world culture, yet they still shape its evolution. According to some, a vigorous Pentecostal movement, successfully expand-

ing to Latin America, Asia, and Africa, carries with it the 'American' gospel of material success and individual well-being, thus supporting global corporate culture. The World Council of Churches, others argue, contributed centrally to global environmental concerns with its initiative on 'Justice, Peace, and the Integrity of Creation,' launched in 1983.

Religion's promotion of world-cultural heterogeneity reflects in part the increasing prominence of Third World voices in global religious organizations. Pope John Paul II has appointed a record number of non-Western bishops and cardinals. In the Anglican Church, non-Westerners significantly aid opposition to gay rights. Non-Western Pentecostals have not only grown dramatically in numbers, they have also devised their own spiritual practices to suit local circumstances. Cho Yong-Gi, pastor of the large Yoido Full Gospel Church in Seoul, initiated a world mission program that has sent hundreds of missionaries and established seminaries in several developed countries, including the USA.

Religion's relation to cultural relativism, another aspect of heterogeneity, varies greatly by tradition and is therefore more complex. In some cases, such as that of Hindu nationalism, religion becomes the primary vehicle for expressions of national distinctiveness. While few Christian churches accept the equal value of all cultures, many have in fact accommodated major cultural differences within loose doctrinal parameters. In Korea and Brazil, for instance, Pentecostal churches incorporate elements of traditional non-Christian spirituality. Islamic fundamentalism presents yet another variant, claiming global legitimacy for its defense of 'authentic' Islam while rejecting the value of other traditions. Finally, religion helps to promote heterogeneity through the creolization process mentioned earlier. Pentecostalism is once again a case in point. An American-inspired movement with a core evangelical message and a secular commitment to material progress has become a mosaic of styles and practices as local congregations have adapted global models to their own needs without direct outside control. As new global movements make inroads in 'national' religious traditions, they produce new juxtapositions that creolize religious cultures. Of course, this process is not unprecedented. Many successful religious traditions have balanced universal ambition with local creativity to produce hybrid religiosity 'on the ground' in counterpoint to unification at the doctrinal level.

Religion also contributes to world-cultural pluralism and conflict. Religious traditions contain diverse views of the good society, leading to varying interpretations of seemingly shared global values. Some view the dominant form of world culture as a coercive, Christian-biased Western force that threatens the integrity of their own traditions. Islamic fundamentalists oppose what they perceive as a godless consumer culture that undermines people's faith and

serves the political interests of the West. Pope John Paul II has criticized an amoral, neoliberal world order that puts profits ahead of the needs of the poor.

Specific elements of world culture also provoke distinctly religious opposition. In recent decades, for example, the principle that women are citizens—individuals to be granted equal rights and opportunities—has been institutionalized in world culture. Within many traditions, however, equality for women is problematic. The result is severe contestation of women's equality in some places, most notably by the Taliban in Afghanistan. These religiously inspired actors have helped generate a more general backlash against globalization, even while they accept many basic elements of world culture. Religion becomes a vantage point from which to oppose the threat represented by globalization as such. The struggle, as some groups see it, is between globalization and their cultural survival.

In sum, religion is a central aspect of cultural globalization, as traditions spread, transnational networks expand, national cultures become more mixed, and new ways of experiencing the world emerge. In many countries, religion mediates the pluralizing effect of world culture. It plays an important role in the intense contest concerning global values and world order. Yet the construction of world culture has become a mainly secular process; it has no transcendent content in the conventional sense. Cultural heterogeneity and conflict themselves take many forms, only some of them religious. While world religion is intimately connected with globalization and involved in the latter's dynamics, it is by no means a dominant force. Whether it can, or should, take on a greater role in defining the desirable world order is likely to be a central issue in future global cultural contestation.

Globalization, Anthropology of

1. The Disciplinary Context

Anthropological interest in globalization is difficult to trace precisely but can be recognized as early as Appadurai's work on the global cultural economy (1990, 1996), Hannerz's analysis of cultural complexity and creolization (1987, 1992), and Friedman's work linking global capitalism and cultural processes (1988, 1994), all of which built on earlier anthropological interest in cultural exchange and world systems. From the start, such work has been part of two sets of scholarly exchanges and debates. The first links anthropology with a wider debate about globalization in other social science fields, notably geography, political science, and sociology. The other is internal to anthropology and links it to longstanding concerns with diffusion, comparison, ethnography, and the study of large-scale historical change. A brief look at each of these contexts might help to frame the anthropological perspective on globalization.

As regards the social sciences in general, anthropologists in the late 1980s found themselves, like many

other scholars, trying to understand the processes that led to the breakdown of the Soviet world and to guess at the shape of things to come. They soon found themselves having to engage powerful perspectives on the emergent world order, which came out of the Marxist tradition in geography (exemplified by Harvey 1989), by a renewed interest in global political culture, exemplified by the polemical and much discussed work of Samuel Huntington (1996), and some prescient studies of the new forms being taken by global capitalism in the last decades of the twentieth century (Lash and Urry 1987). In addition, anthropologists found themselves in a rich, sometimes competitive dialogue with scholars in literary and cultural studies, notably those influenced by British cultural Marxism, and most powerfully represented by Stuart Hall (1986). In addition, the publication of Benedict Anderson's landmark study of nationalism (1983) provoked a strikingly wide debate about the links between politics, the imagination, and national identification. These stimuli helped to shape anthropological research on globalization, which in many ways is marked by the ongoing effort to link broad structures and processes in the world economy to the subtleties of communication, interpretation, and translation that govern everyday life in all societies.

Within anthropology, the study of globalization built on several well-established currents of interest. In the United States, the study of globalization fit well with Boasian traditions in the study of diffusion, cultural change, and culture contact and with a longstanding interest in urban settings and complex societies. In Europe, anthropologists were slower to take an interest in globalization, but here too longstanding interests in problems of scale, social cohesion, and structural change made globalization a subject of growing interest after 1990. In other parts of the world, such as Latin America, Africa, and India, the anthropological interest in globalization was more closely linked to problems of ethics, development, and inequality.

In spite of these various currents of research and theorization within which the anthropological interest in globalization has developed, from the beginning there were serious doubts about whether globalization by its nature was a topic suitable to the special strengths of anthropology in the study of intimate social relations and of societies governed by non-market social principles. Many of these anxieties have been translated into methodological concerns, reflected in a significant body of methodological work about how anthropology ought to address the emergent world of globalization (e.g., Fox 1991). There is still a considerable body of opinion among professional anthropologists that globalization may well be a mere trend, an artifact of academic fashion, and that in any case, it is not an ideal subject for anthropological research because of its conceptual and social scale. But this rearguard anxiety, not always easy to distinguish

from fear of disciplinary failure, has not prevented a rich set of theoretical debates and empirical studies from emerging out of anthropological traditions, both in the Atlantic world and beyond. These studies, largely a product of anthropological work in the 1990s, are discussed in the following sections.

2. *Global Cultural Flows*

The image of 'flow' has been a central trope of anthropological work on globalization. In the work of Appadurai (1990, 1996), the idea of 'flow' was used to capture a complex dynamic in which objects, ideas, ideologies, technologies, and images were placed in a single economy of circulation, with an eye to distinguishing different emergent mosaics of cultural form and social design. In Hannerz's use of this concept (1992, 1996), it was fruitfully linked to Kroeber's idea about large-scale civilizational and interactional spheres—ecumenes—as well as to ideas about creolization, cosmopolitanization and the professional networks associated with rapid flows of cultural commodities.

In these early usages of the idea of flow, and in subsequent elaborations of them by others, the idea of flow was sharpened to redress the assumption that cultural flows in the era of globalization were unrestricted in scope and range. A salutary emphasis on boundaries, limitations, selectivities, and exclusions reappeared, thus placing the classic debate between Marxist and cultural approaches once again at the center of attention. This broad interpretive struggle continues, and the choices it poses are reflected in many studies associated with the anthropology of globalization, on such subjects as migration (Basch et al. 1994), nationalism (Chatterjee 1993), colonialism and postcolonialism (Comaroff and Comaroff 2000a), media (Feld 1999), diaspora (van der Veer 1995), and markets (Hart 1999).

The positive contribution of the idea of flows was to open up new questions about the relation between legal and illicit flows of commodities and persons, about the changing nature of borders and boundaries, about the implications of new regimes of financial circulation and cybercommerce, and about the evolution of new forms of diasporic identification and mobile tradition building. The image of flows also opens a potential conversation, yet to be fully exploited, between economists and anthropologists on the question of the changes in the world economy suggested by the idea of globalization, and of the best ways of measuring their scale and significance. In a general way, the engagement with cultural flows, their associated economies and interpretations, has decisively marked a shift, in which anthropologists are no longer confined to the study of simple market societies but are addressing such complex phenomena as

cybercommerce, intellectual property, and new forms of genetic engineering and marketing. Likewise, the anthropological focus on cross-border flows, as we will see shortly, has opened up a useful conversation between anthropologists, political theorists and sociologists on new forms of citizenship and sovereignty.

Above all, the focus on flows, regardless of context, commodity, or sphere, has brought anthropology back to one of its earlier insights, namely that most human societies have always been in interactive relations with others, forming spheres of exchange and circulation. Thus the images of social stability, impermeable boundaries, and natural divisions between ethnic groups, polities, and communities, sometimes implicit in anthropological practice, have been put under sharp scrutiny. In turn, the widespread recognition that societies in the era of globalization are inevitably parts of wider circulatory systems and networks, has posed new challenges for how anthropologists will need to theorize classical models of cohesion, consensus, and order. At the end of the twentieth century, there is some uncertainty about how to reconcile the undoubted significance of large scale cultural differences with the reality of the velocity of cross-border flows and the uneven thickness of the membranes between societies, whether organized as nation states or not. It seems probable that the question of how social order and cultural coherence in lived communities are maintained in the face of complex and uneven cross-border flows will be a major theoretical challenge for twenty-first century anthropology.

Many of these concerns have produced a special interest in the anthropology of nationalism and a series of contested views about the salience, form, and future of the nation state as a form of global political organization. The pendulum appears to swing between those (both inside and outside anthropology) who predict the early demise of the nation state, and those who see it as growing stronger than ever. Sometimes these debates are reflections of actual differences between existing states and sometimes they are the result of blurring the lines between nations and nationalism on the one hand, and states and their powers on the other. The emerging consensus seems to be that while nation states are unlikely to disappear in the near future, they are evolving their own powers in a transformed ecology of sovereignty. This ecology is affected by changes in the velocity of global capital flows, in the scale and speed of cross-border shadow economies, and in the geography of dual, mobile, and diasporic political identifications among citizens. These processes are discussed further below (see Sect. 4).

The interest in various forms of global cultural flow, and in the nonisomorphic relationship between them, has provoked a strong debate about whether, and the extent to which, globalization is a new social regime. Many voices within anthropology argue vigorously that globalization is no more than a semiotic con-

spiracy of the media and of global capital and its allies in the world of development. In this view, globalization is only a clever way to repackage colonialism, imperialism, modernization, or various combinations of these ideologies. It is old wine in new bottles. This view runs into the difficulty of having to accommodate too many new animals into an existing theoretical Ark, and suffers from the further disability that it does not provide any criteria for recognizing genuine systemic change. It ends history in the name of theory. The more widespread band of opinion among anthropologists is that something surely has changed. The challenge is, as always, to establish what has changed and how it affects the things that have not changed. Thus, there is a renewed interest in how identities are negotiated across multiple locations, how existing structures like witchcraft (Geschiere 1997) become vehicles and sites for new anxieties and energies, and of how new legal and economic arrangements (those sometimes lumped together under the rubric of neoliberalism) call forth new perceptions of danger, wealth, and risk (Comaroff and Comaroff 2000b).

Finally, ideas and debates surrounding the idea of global cultural flows have cast fresh light on a classic concern of anthropology, namely the process of identification and the production of identities. These processes have to be reexamined in a world characterized by massive information flow, heightened media images of life possibilities for ordinary people, and new fantasies of wealth and mobility. The rapid growth in mass-market media penetration across national boundaries, the associated growth in the battle between global and national media barons, the projected increase in various kinds of bandwidth, and the emergent possibility of new, hybrid instruments for cheap, high-speed communication, all combine to change the grounds on which stable cultural identities are produced and secured. Likewise, these factors make it impossible to presume the image of the local as an unchanging ground against which the tableau of global change is played out. Indeed, many anthropologists now have come to take as great an interest in 'the production of locality' (Appadurai 1996) as in the dynamics of globalization.

With its special interest in language, everyday life, and small-scale social interaction, anthropology is evolving a special purchase on the vast terrain represented by globalization, by paying particular attention to the vagaries of translation and localization and to the special role of language and semiotic mediation in producing new forms of lived experience. This has resulted in a sustained effort to examine the cultural dimension of objects and technologies that have their primary home in the spheres of law, science, and the market. Therefore, anthropologists at the beginning of the twenty-first century study the organ trade, refugee incarceration, NGOs, musical copyright law, and derivatives, to name just a few examples of social and technical forms whose cultural design is sometimes

overlooked. In this proliferation of topics (some of them addressed by other authors in the Encyclopedia), there are some major crosscutting themes, three of which are briefly discussed below.

3. Heterogeneity or Homogeneity?

Most anthropologists share the widespread presumption that globalization is a new phase in the integration of the world economy, principally powered by new scales and speeds in the circulation of financial capital and the associated explosion in electronic communication technologies. When we recall that the major models of global economic processes have come out of the Marxist tradition, it helps to explain why there is a tendency among some anthropologists to argue that globalization is no more than a new phase in the generally history of capitalist commodification. From this follows the possibility that, from a cultural point of view, the forces of commodification will produce increasing levels of cultural homogenization and social standardization, particularly in the realm of media icons, social styles, and consumption values. The further extrapolation, rarely stated explicitly, is that these processes will in turn erase cultural differences both within and across societies. This is the nightmare of globalization as coca-colonization (Hollywood, McDonald's, and Disney are the favored icons of this line of speculation). Yet the evidence that societies appropriate various forms of commodification in their own terms, that media messages are downloaded idiosyncratically, that weapons of standardization are frequently subverted to produce further brand differentiation, and that the best laid plans of the standardizers are frequently thwarted by local entrepreneurs and customers, is mounting.

A splendid example of this process of differentiation is provided in a collection of anthropological essays on the role and style of McDonald's, as it functions in six distinct East Asian settings (Watson 1997). The ethnographic essays in this collection illustrate that, as a global profit-making organization, McDonald's is certainly eager to create uniformity in its products and in its outlets wherever possible. But the essays also shows that in each of these settings McDonald's encounters a quite different set of needs, anxieties, and possibilities and is drawn into a specific local mosaic of social patterns and cultural orientations, involving age, leisure, work, and freedom. Though McDonald's is a heavily capitalized multinational corporation, with an unerring eye for its local and global profits, its sensitivity to local markets inevitably contributes to the emergence of different desires and practices in its outlets. This does not make it any less a global corporation, but its strategies are regularly bent to fit local wishes and projects. However, these essays also show that this is not a simple matter of Goliath being repackaged to suit David, culturally speaking. In fact,

what McDonald's produces in these settings are new and unintended styles and contexts for consumption, for sociality, and for public interaction, each culturally distinct but not in any obvious or predictable way. Many other studies, especially in the sphere of consumption (involving clothing, music, food, leisure, and housing) also confirm this process.

Heterogenization is not a mechanical product of the sphere of consumption. It is itself produced by local makers of ideas, images, and commodities who give to the culture industries of different societies and nations their own distinctive stamp. Thus, anthropologists have been able to show that the simple distinction that places global producers and uniformity on the one side, and local consumers and difference on the other, is overdrawn. We have a growing series of studies of cultural production worldwide, especially in the areas of music, film, and advertising, which let us look into the sites and institutions through which global commodities are locally interpreted by producers as well as consumers. The study of 'world music' by ethnomusicologists is perhaps the best developed of these subfields. In general, these studies have produced a broad consensus that cultural differentiation tends to outpace homogenization, even in this most interactive of economic epochs. Naturally, this conclusion fits with the methodological and ethical proclivities of anthropology, with its professional investment in cultural difference and its ethical commitment to cultural diversity. Nevertheless, there appears to be substantial empirical basis for this consensus. But anthropological interest has by no means focused solely on the good news of cultural differentiation and has not been uncritically celebratory in its treatment of globalization, as the following section will show.

4. Sovereignty, Citizenship, and Violence

Anthropologists have not failed to notice that the world of global cultural flows is hardly free of suffering, injustice, and dislocation. They have certainly been aware that the incidence and brutality of forced population movements have in some respects increased, producing many pockets of human dislocation and frequently of ethnic violence. They have paid attention to the dilemmas of proletarian labor migrants, who struggle with their own translocal loyalties—frequently to religious formations which are themselves increasingly transnational in scope—against the pressures of the varied ideologies of cultural and legal inclusion which characterize their new homes.

Considered transnationally, poorer migrants face bewildering new combinations of democratic ideology and racist reality. In some cases, such as the oil kingdoms of the Middle East, nonimmigrants monopolize most of the benefits of citizenship. In others, the benefits of citizenship are more widely shared, but

everyday racism is a constant threat. In some cases, all refugees are drawn into multinational ethnic wars (as in Central Africa in recent years), while in other cases, the revitalization of longstanding ethnonational boundaries flies in the face of intermarriage and ethnic mixing as social realities. In Central Europe after the death of Tito, the new national constitutions frequently encouraged political campaigns that exacerbated genocidal identities parading as 'primordial.' Many nation states now practice various forms of cultural fundamentalism and majoritarianism, as they struggle for new forms of legitimation in a global economy. In the process, they increasingly both produce and demonize 'minorities.' In many of these cases, language, blood, and race are overdetermined icons of peoplehood which force anthropologists to reconcile their own knowledge of the fragility and historicity of these constructions against the popular, lived sense that these realities are timeless, natural, and nonnegotiable.

As anthropologists examine these bloody sites of ethnic violence and violent social purification (Appadurai 1998, Das 1995, Feldman 1991, Malkki 1995), they find themselves having to study a variety of antecedent and emergent social realities. These include new forms of 'flexible' citizenship (Ong 1999); new ideologies of citizenship and law (Comaroff and Comaroff 2000b, Sassen 1996); new battles over indigenes and outsiders (Meyer and Geschiere 1999); and new patterns of state-sponsored violence and legality. In engaging with these topics, anthropologists discover that they need to link longstanding professional interests in conflict, bodily ritual, mythologies of origin, and ethnocultural ideology, with new regimes of law, incarceration, borders, and migration.

In particular, anthropologists are now tackling the ways in which the forms of violence and dislocation produced by globalization may be related to new structures of sovereignty, new forms of nationally sponsored globalization, and new niches for the location of the global economy. They thus find themselves in a productive dialogue with scholars in adjacent fields who are making important contributions to these subjects (Castells 1997, Held and McGrew 2000, Sassen 1998). This engagement promises a more sophisticated answer to the question of how new forms of global linkage are also producing new forms of cultural fundamentalism, a question to which somewhat Manichean answers have been provided in the popular media and its favored public intellectuals in many national contexts.

In the United States, and to some extent in Europe, there have been strong alarms raised by economists and development specialists to the effect that globalization is producing both greater wealth and greater inequality. Yet, in popular opinion, especially among the wealthier countries and classes, there seems to be an emergent sense that globalization is a world of the victors in the Cold War and their global allies who

have cracked the codes of the global market, the information economy, and the new international order. The losers are frequently viewed as cultural holdouts at best, cultural terrorists at worst, people who have not understood the new alphabet of the globalized world. Anthropological work on globalization, in this context, has a challenge and an obligation. The challenge is to take its classical strengths in the study of intimate relations, everyday life, and cultural difference and use them to cast light on circulatory processes that yield local and global results simultaneously. The obligation is to provide a way of thinking about why this era of global integration is yielding at least as much genocidal violence as it is democratic voice. That may not seem like a particularly anthropological obligation, but given that anthropology has long tried to create new ways of showing how broad human processes are found in translation, globalization may need anthropology at least as much as vice versa.

5. Looking Ahead

It is not easy to predict what topics will find special favor among anthropologists interested in globalization in the coming decades. It is likely that some of the broad themes discussed in this essay will continue to elicit empirical research and theoretical debate, but it also seems likely that the institutional and geographical range of the anthropological debate is likely to widen. Research institutes, conferences, workshops, publications, and translations concerned with anthropological contributions to the study of globalization are appearing in Brazil, Turkey, Hong Kong, India, and in many other sites outside of the North Atlantic region. In these many sites, anthropologists are building their own critical resources as they engage with specific kinds of national debate, cultural conflict, and research tradition (Appadurai 1999). Whatever the individual outcomes of this process, two results seem likely. Anthropology is unlikely to remain a bystander in any important national debate about globalization. Moreover, these debates are increasingly unlikely to be determined by scholars, projects, and institutions confined to Europe and the United States. What more appropriate topic could there be for international research than globalization, and what opportunity could be more appropriate for anthropology to contribute to a global scholarly debate about the world we are about to build?

A. Appadurai

Globalization: Geographical Aspects

1. Introduction

Space, place, distance, proximity, maps, boundaries, territoriality, and spatiality. These are some of the keywords of geography; keywords that distinguish the interest of geographers in the phenomenon of globalization, from that of others in the social sciences. The distinction is not clear cut by any means, not least because 'globalization' so centrally evokes geography: the rise of world-scale processes and phenomena, the intensification of linkage between distant places and cultures, and the associated unmaking and remaking of territorial boundaries and identities. Perhaps where the key difference lies, however, is that the other social sciences are not interested primarily in the intrinsic spatiality of globalization.

In economics and business studies, for example, studies of globalization focus on the implications of the borderless economy (driven by international market integration, global flows of money and information, and transnational production and regulation) on national and subnational economic sovereignty, competitiveness, and growth. The optimists celebrate the offer of new market opportunities, the pessimists warn of the real and discursive dangers of neo-liberalism and international dependency, the historically minded reassure us that there is nothing much new (Drache 1999, Hirst and Thompson 1996), while the measured observers of qualitative change reveal the new aspects of combined and uneven development (Dicken 1998, Held et al. 1999).

In politics and international relations, the debate has centered on the erosion/reformulation of the nation-state as a unit of authority, following the rise of nonstate institutions of regulation and governance, and on the challenge to citizenship and democracy posed by the rise of transnational political organisations (e.g., global NGOs) as well as plural, non-national sources of political rights and identification (e.g., EU citizenship). Here too there is no consensus. Some herald a new era of reduced nation state influence, eroded national welfare commitment and crisis of parliamentary democracy (Garrett 1998),

some assert the continuity of national social models (Hay and Marsh 1999, Weiss 1998), others signal the rise of new forms of unsettled jostling between the nation-state and other organizations organized at local, national, and international scales (Jessop 1994, Keil 1998), while others still find new prospects for cosmopolitan government, democracy, and civic mobilization (Held et al. 1999, Scholte 2000).

In social anthropology and media and cultural studies, the attention has fallen on the implications of global consumerism, media communication, and international mobility and cultural mixture for individual and social identities and lifestyles in different local settings. Early warnings of the erosion of local difference under the weight of the same world products and consumption norms and the same global corporations (i.e., the so-called MacDonaldization of society), have given way to sensitivity to the persistence of local difference, but also the nuances of local change resulting from heightened global exposure and virtual and real linkage with different parts of the world (Robertson 1992, Albrow 1996, Hannerz 1996, Morley and Robins 1995).

Geography, to repeat, is everywhere in these studies of globalization, but the spatiality of social relations, or put differently, how place, space, and spatial difference are being reconstituted is not the prime interest. Geographical theory, in contrast, has been concerned with the spatiality of the contemporary world, and is interested in understanding whether places—cities, regions, and nations—are perforating as geographically contained spaces, how the insertion of places into geographically stretched relations matters, and how new geographical scales of organization and influence associated with globalization are challenging old scales of identification and action.

This geographical imagination, to be clear, is not confined to the discipline of geography. In fact, some of the most influential accounts of the spatiality of globalization have come from social theory outside the discipline. For example, the sociologists Giddens and Held have long argued that a key aspect of globalization is spatial connectivity and reach, such that the conceptualization of place/locale as 'in here' happenings and space as 'out there' happenings is no longer tenable. Held (1995, p. 20), building on Giddens's idea of contemporary time-space distancing (Giddens 1990), proposes:

...globalisation can be taken to denote the stretching and deepening of social relations and institutions across space and time such that, on the one hand, day-to-day activities are increasingly influenced by events happening on the other side of the globe and, on the other hand, the practices and decisions of local groups can have significant global reverberations.

The sociologist Therborn (1998, p. 7) too asserts that globalization should force us to think 'seriously

about space, about the spatiality of the social, about territories and their delimitations.' Two examples of spatiality that he identifies are: first, in a world seen as system, the 'flattening of social processes,' associated with the gradual global spread of dominant social practices (e.g., the triumph of capitalism on a global scale, the hegemony of neoliberalism, the Americanization of culture); and second, echoing Giddens and Held, the 'world as an arena where nationally determined actors meet, interact, and influence each other.'

In contrast, the international studies scholar Scholte (2000) interprets the spatiality of contemporary globalization (compared to preceding periods of intense internationalisation) as 'deterritorialization.' He notes that the rise of a 'social space that transcends territorial geography' is new (composed of such phenomena as transnational production, instantaneous worldwide communication, consumption of the same commodities and images, etc.), such that:

'global' relations are social connections in which territorial location, territorial distance and territorial borders do not have a determining influence. In global space 'place' is not territorially fixed, territorial distance is covered in effectively no time, and territorial frontiers present no particular impediment.

He concludes that 'while territoriality may continue to be important, globalization has brought an end to territorialism (that is a condition where social space is reducible to territorial coordinates alone).'

In all three accounts, it is the spatiality of globalization that is stressed, albeit in very different ways, from the emphasis on new territorial scales and connections, to warnings of interterritorial clash or territorial annihilation.

The interpretation shared, and explored further, in this contribution is the one offered by Giddens and Held. It sees the growth of world-level influences (e.g., transnational corporations and banks, common consumption patterns, world ideologies, international authority structures) and the intensification of global spatial connectivity (e.g., flows of people, goods, ideas, and information, facilitated by rapid transport and communications technologies) less of a threat to, or reinforcement of, territoriality, than a loosening and stretching of social geographies of linkage and identification. This is because a key aspect of globalization is:

A process which embodies a transformation in the spatial organization of social relations and transactions—assessed in terms of their extensity, intensity, velocity, and impact—generating transcontinental or interregional flows and networks of activity, interaction, and the exercise of power (Held et al. 1999, p. 16).

The first part of this article discusses recent claims in geography on the changing relationship between place

and space associated with globalization. It argues that the legacy of seeing places in scalar terms, either as geographical sites of proximate links or as territorial units, remains strong within the discipline. The second part—using the example of contemporary urbanity—dissents with the latter interpretation, to advance a very different sense of place. It argues for the need to see places under contemporary globalisation in non-scalar terms, and as perforated entities: as sites immersed in varied geographies of proximate and distant links, within which things no longer cohere as a bounded whole.

2. Geographies of Scale

Marston (2000) has reviewed the work of political geographers such as Neil Smith, Eric Swyngedouw, John Agnew, Kevin Cox, Peter Taylor, and Neil Brenner, to conclude that for them spatial scales—from home and locality to city, region, nation and continent—have no pre-given or fixed ontological status, but are produced and reproduced and continually transformed socially by the imperatives of capitalism. Importantly, they associate contemporary globalization with the rise of new territorial scales of organization, and new territorial boundaries, rather than the replacement of old, national scales and boundaries by a unitary global field of meaning and action. They do not see the replacement of an old world 'space of places' with a new 'space of flows' (Castells 1996).

Brenner (1999, p. 435), for example, asserts that 'the post-1970s wave of globalisation has significantly decentred the role of the national scale as a self-enclosed container of socio-economic relations,' and we are witnessing a 're-scaling of territoriality' which includes the increased 'importance of both sub- and supranational forms of territorial organisation.' Similarly, Swyngedouw (1997) mobilizes the term 'globalisation' to indicate that globalisation represents the break down and reconstitution of spatial scales; producing a new 'politics of scale' involving clashes of scale and contested boundaries. Globalization, thus, represents the 'relativisation of scale' (Jessop 1998, p. 90), with governance and political conflicts articulated at urban, regional, national, and supranational level, with no one scale privileged. The result is a re-scaling of territories, such that, for example, national states gear towards enhancing international competitiveness and capturing global investments cities, and cities or regions decouple from national economic circuits, to become locked into global ones (e.g., as investment sites).

The emphasis of these geographers on the produced and contingent nature of territories and scales marks, in Agnew's (1999, p. 504) terms, the 'historicity of spatiality.' He demonstrates, for example, that the present period contains a number of historical models

of power organized spatially: the model of dynastic preservation in a world of distant communities; the model of state–military conflict in a world of rigidly defined territorial units; the model of hierarchical conflict between centers and peripheries in an international economic system; and the model of nodal conflict within the networks of an integrated world society. The ‘geographical embeddedness of power relationships today, therefore, signifies something quite different from what was the case in the past’ (p. 512), for example, contemporary globalization elevates the tensions between state territorial relationships (e.g., equating nation with citizenship or property rights) and transterritorial developments (e.g., the rise of globally mobile identities and property rights).

Through these readings, globalization can be seen as the multiplication of geographical scales of social organization, linked to the changing spatial requirements of the latest phase of capitalist development. These are not seen as parallel or mutually exclusive scalar geographies, but intersecting and overlapping ones, with places/territories implicated in the full variety of scalar reorientations. Thus, not an end to geography in a globalizing totality, but a rescaling of boundaries (upwards, outwards, and downwards) and a reconfiguration of territories as they engage in multiscale processes and politics.

The strength of this interpretation of the spatiality of globalization lies in the scope it leaves for recognizing the persistence of geographical diversity, and the varied ways in which different places, with their unique legacies, are implicated in the balance between territorial and transterritorial influences. Its weakness, however—although Agnew is an exception—is that it fails to address whether the ontological status of place/territoriality itself is significantly altered as a result of the rise of world-scale processes and transnational networks and flows. The language continues to remain that of scalar geographies and territorial units. Reterritorialization follows deterritorialization and spatial scales are relativized under globalization.

Places such as cities and nations continue to exist as territorial units, but now with different external orientations (e.g., as sites in global production networks or places dependent upon international investment or competitiveness) and different scalar involvement (e.g., national welfare policies, continental trade agreements, global environmental regulations, local tax regimes). The boundary between place and space is not seen to be bending or disappearing—a line in shifting sand—but as a remaining line of distinction between ‘in-here’ relations and institutions, and those ‘out-there.’ Global connectivity is seen as leading to the nesting of territories into multiple scales, not territorial disorientation away from a geography of scalar nesting.

Cox’s (1998) work on localities as particular sorts of spaces (of association and politics) in a multiscale world provides a good example of this lingering

territorial logic. He distinguishes within a locality the spaces of dependence or localized connections that he claims define ‘our sense of significance,’ from the spaces of engagement within global relationships, which he sees as threatening the place-specific ‘essential interests’:

Spaces of dependence are defined by those more-or-less localized relations upon which we depend for the realization of essential interests and for which there is no substitute elsewhere; they define place-specific conditions for our material well being and our sense of significance. These spaces are inserted in broader sets of relationships of a more global character and these constantly threaten to undermine or dissolve them... In so doing they construct a different form of space which I call here a space of engagement: the space in which the politics of securing a space of dependence unfolds (Cox 1998, p. 2, cited in Marston 2000, p. 226).

In this account, localized relations are posed as distinguishable from global relations, and somehow more authentic and politically progressive: the local can be mobilized to resist the global. While Cox is clearly right to note that local societies continue to retain political potential in an age of allegedly globalized power, his dualist distinction between the ‘local’ and the ‘global’ as separate scalar fields remains methodologically problematic. To highlight the weakness of this dualist logic, should we, for example, judge the often charged diaspora connections of ethnic minorities or cosmopolitans in a locality to be less significant or progressive than the daily contact among local residents? Surely a key aspect of the transnationalisation of local relations is that we can no longer make an easy distinction between local and global geographies? How localized or global, for example, are the associational politics of worker, immigrant, and NGO groups campaigning for local recognition, but relying on international financial and other support networks?

Or, what makes everyday practices and customs grounded in local encounters and traditions any more ‘essential’ than nonlocal practices and customs? This desire to see places as territorial units in which local relations are counterposed to global relations leads to a peculiar politics of place in which relations within localities are cast as good and meaningful, and contrasted to bad and totalizing external relations. Its peculiarity follows from the ontological separation of place (read as in here, and intimate) and space (read as out there, and intrusive) as distinctive scalar realms.

Taylor’s (1999) recent attempt to conceptualize place and space in nonscalar terms helps us get around this particular ontological straightjacket, but replaces it with another rather stark binary distinction. Following the pioneering work of the humanist geographer Tuan (1977), Taylor claims that both terms should be used to identify human activity at all geographical scales—local, national, and global—but that they are distinct and always in dialectical tension

with each other. Taylor defines space in modernity as the realm of abstract principles, rules, rationality, science, administration, bureaucracy, and institutions. He judges it to be politically disenabling. In contrast he sees place as the substantive, politically enabling, lived realm involving intimacy, experience, belonging, feelings. The two are said to always exist in tension with each other, for example, the abstract realm of the state, combined with the felt realm of the nation, has yielded the nation-state, in which 'sovereign territory has been merged with sacred homeland to convert a space into the place.' Similarly, Taylor sees the modern home converting the space of the household into a place, and the techno-social space of the one-world (capitalist) system becoming a place through developments such as the rise of a global consciousness (e.g., global ecological fallibility).

Taylor's is an odd usage of the terms space and place, counterposing as it does, the abstract (disenabling) from the lived (enabling). Are not the spaces of science and technology, for example, R&D laboratories or domesticated science, just as lived and 'enabling' as more obviously emotional sites? Isn't the realm of experiences one that blurs the distinction between formal and informal practices? Why, for that matter, choose the labels of space and place to distinguish between the abstract and the lived? What remains helpful in Taylor's schema, however, is his rebuttal of space and place as separate geographical sites or realms, thus allowing the ontological presence of both the proximate and the remote at the same geographical level (e.g., the recognition of systemic rationality or state-sponsored science in the home, or the proximate warmth/odium of nationalist sentiment or universal causes).

The next section pursues this reasoning, but retains the geographical connotations of the terms space and place, rather too quickly abandoned by Taylor. It retains a geographical imaginary because it considers the reconfiguration of the spatiality of social relations a central aspect of contemporary globalization, and importantly, because it sees this reconfiguration shaping the meaning of what goes on in places (localities, cities, regions), how places coalesce or not as entities, how social relations in places are constructed, and how the politics of place matter. In short, it illustrates that place still matters, but no longer as a scalar unit.

3. 'A Global Sense of Place'

The section heading borrows a deliberately oxymoronic phrase of Massey (1994) to conceptualize localities in nonscalar terms, or, in her words, 'relationally,' as sites of juxtaposed social realities, shaped by the layered historical connections and geographical links that are to be found within and beyond them. Their character as sites of agglomerated activity, thus, has far less to do with the properties of a territorial system

(e.g., localized linkage, self-regeneration, local governance, etc.) than with the effects of spatial and temporal exposure and connectivity (e.g., continual and open-ended change, juxtaposition of difference, overlap of networks of different global connections). Two of Massey's now famous examples of places as 'open, porous, hybrid' (Massey 1999, p. 21) are Mexico City, with its varied architectures revealing layers of global Spanish and American-Indian historical connections, and Kilburn High Road in London, with its juxtaposition of English, Irish, and Indian diaspora lifestyles and connections.

It is important to note that since Massey defines the spatial in general 'as the sphere of the juxtaposition, or co-existence, of distinct narratives, as the product of power-filled social relations' (Massey 1999, p. 21), a global sense of place is needed not only for cosmopolitan places, but all places. For, each and every one:

...may be imagined as particular articulations of these social relations, including local relations 'within' the place and those many connections which stretch beyond it. And all of these embedded in complex, layered, histories. This is place as open, porous, hybrid—this is *place as meeting place*... This is a notion of place where specificity (local uniqueness or sense of place) derives not from some mythical internal roots nor from a history of relative isolation—now to be disrupted by globalisation—but precisely from the absolute particularity of the mixtures of influences found together there (Massey 1999, p. 22, emphasis in original).

Through this lens we might re-imagine Bamako as richly as Bombay, Boston as richly as Bermuda, and mobilize them against persisting views of globalization as place homogenisation. Massey defines places as socially constructed 'envelopes of space-time': relational settings and meeting places, not closed local systems. How does contemporary globalization fit into this picture? Massey's response is:

...globalisation, imagined through the lens of this conceptualisation of space-time, the globalisation we are facing now, is a thoroughgoing, world-wide, restructuring of those space-times, along particular lines. It is a re-making of those, inherited but always temporary and provisional, spaces, places, cultures which are themselves the hybrid products of previous restructurings.

We can take this to mean that a relational or global sense of place will interpret the spatiality of globalization—however defined—rather differently from a territorial perspective. Let us stay with the example of cities, and focus in turn on the spatiality of two aspects—economic transactions and urban politics—to illustrate this point.

3.1 Urban Economic Space

In economic discussions, the language of scales or territorial boundaries, as discussed above, has tended

to interpret the rise of transnational phenomena such as global informatics, international production and finance, and powerful international organizations, in terms of the boundary between a territorial inside and a territorial outside. Consequently, accounts which continue to see an economic place for cities contrast the global as the realm of distanced links, fast flows, and world-scale processes, with cities as the sites of face-to-face-contact, or centers of agglomeration among global networks (e.g., clusters of HQs, creativity and knowledge, communication hubs). Against the economics of space and distance are posed the economics of agglomeration and clustering, the powers of spatial proximity and interiority. The argument posed is that in the global age, the locally embedded still counts as a source of economic dynamism and competitiveness because spatial proximity encourages trust and reflexivity, reduces transaction and communication costs, facilitates technological and knowledge spill-over, and offers specialized services and institutions to the business and professional communities (Maskell et al. 1998, Krugman 1991, Audretsch 1998, Glaeser 1998).

A sense of place that sees cities as a meeting place for diverse geographies of linkage, in contrast, offers a different reading of the urban economy. The geography of cyberspace is a good example for questioning the distinction between an alleged real world of direct contact and a virtual, telemediated world. As Kitchin (1998, p. 387) argues, 'whilst information on-line might seem geographically dislocated, information is only as useful as the locale within which the body resides', and in any case, 'cyberspace depends on real-world spatial fixity—the points of access, the physicality and materiality of wires.' Consequently, there is a continuity of communication in geographical space and place, such that, as Graham summarizes, 'power to function economically and link socially increasingly relies on constructed, place-based, material spaces intimately woven into complex telematics infrastructures linking them to other places and spaces' (Graham 1998, p. 175). Similarly, in daily contact, there is an unbroken line of communication linking physical and human technologies, and it is of varying geographical reach, mobilized to source information, strike a deal, exchange knowledge, and so on.

The different realms of communication do not offer different social worlds, for example, 'there is not one single, unified cyberspace; rather there are multiple, heterogeneous networks, within which telecommunications and information technologies become closely enrolled with human actors, and with other technologies, into systems of sociotechnical relations across space' (Graham 1998, p. 178). And this is precisely why the speeding up of time within communications networks should not be read as the speeding up of people and their lifestyles (Thrift 1996).

Seen in the context of linked communications

architectures, there can be no privileged economic role for spatial proximity. First, co-presence or agglomeration need not imply association and interaction, for firms can mobilize a variety of contact networks to establish economic links with firms, markets, and institutions located elsewhere nationally and internationally. The near immediacy of distanced communications networks enables economies of association to be established without the need for spatial propinquity. The city is no longer a bounded, but spatially stretched, economic sphere. Second, spatially proximate interactions, where they appear, need not privilege particular types of economic transactions such as those based on trust, reciprocity, and reflexivity through physical interaction.

Intimacy may be achieved through the frequent and regular contacts enabled by the distanced networks of communication and travel (how else do transnational firms, institutions, and social movements work?), as well as the unbroken interplay between face-to-face and telemediated contact. The city is, therefore, not a place of unique or systemic transactional assets. Third, the agglomeration in some parts of some cities of large volumes of specialised inputs—from knowledgeable and creative people and clusters of inter-related industries, to sites of R&D, corporate power, public bureaucracy, and business services—no longer implies increasing local returns (as theorized by agglomeration economists). These sources of economic dynamism (which may well draw on local resources, for example, schools and college, leisure amenities, transport hubs) are nested into economic networks that stretch beyond the city (from transnational production networks and national or international supply chains, to global market relations).

A global sense of urban economic space recognizes places as clusters of overlapping network sites, without seeing in them only local economies of association feeding a localised economic system. It views with scepticism the territorial metaphors such as 'local fixity vs. global flow,' 'embedding the global,' or 'the local in the global' which have grown in recent years to 'defend' the space of local economy against global 'encroachment.' Instead, it highlights that local economic activity is part of, and inseparable from, proximate and distanced transactions, and that whatever counts as the local has to be seen as a network site, not a territorial system.

3.2 Urban Political Space

Similarly, a global sense of place implies an interpretation of the implications of globalization on urban politics that is different from one based on a territorial sense of place. The territorial perspective anticipates either the loss of the urban as a political space under the barrage of national and global institutions and

movements, or, as exemplified by the work of Cox above, as a particular zone of engagement. It sees politics as undergoing scalar differentiation, as exemplified by waning interest in universalist causes and nation-state institutions, and the rise of ethno-nationalist sentiment at regional level or global political institutions and movements.

In this schema, localities, when viewed positively, are expected to perform a certain kind of place-based politics: tribal, as implied by Cox, through his claims for local authenticity and feelings; formative, through involvement in 'militant particularisms' (Harvey 2000); lived, through conflicts over lifestyle, consumption, and social reproduction issues; experimental, via either the politics of difference forged around the diverse social and cultural voices gathered in the city (Sandercock 1998), or the politics of citizenship based on participation in the city's public spaces and public sphere (Sennett 1977). In short, a new politics of place serving unique purposes in a world of multiscale politics (note, however, the different position of those political geographers who mobilize the concept of relativization of scales, in order to capture the new combined politics of local, national, and global action).

There is, however, another way of viewing place politics in age of global connectivity. Instead of seeing local political activity as somehow unique, places might be seen as sites that juxtapose or combine the varied politics—local, national, and global—that we find today. What matters is this juxtaposition/combination.

This forces, for one, recognition of actor participation in nonlocal political activity. To return to the urban example, as Sassen (1998) puts it, if globalization involves the urbanization of a world capitalist class (at least in some global cities) as well as people and cultures from different parts of the world, it also generates the possibility of claims in the city which are at once local, national, and transnational in orientation. This might include, for example, business leaders campaigning against the local homeless, national government tax policies, or international trade agreements; ethnic minorities campaigning against local racism, but also through the support of national antiracist groups, and international diaspora organizations; office workers gathered together with other groups outside the municipal offices protesting against local closures, but also linked up with workers and unions elsewhere through Internet discussions of world trade barrier removals. In this perspective the city is no longer a site of place politics, but a place of engagement in plural politics, and through multiple spatialities of involvement.

Why does this shift in emphasis from the politics of place to politics in place matter? Because, it marks the necessity to see political activity in places as plural, open, and contested (Amin et al. 2000). First, the juxtaposition of difference in close spatial proximity

generates political challenges associated with this juxtaposition, for example, the contest between the business community and the homeless over the spaces of the city, or the competing demands of different classes, social and ethnic groups over the city's cultural resources. There is no automatic intimacy or consensus here against any perceived global intrusion.

Second, the idea of politics in place marks a significant change in the nature of contemporary politics, from one based on participation in singular, all-encompassing, political institutions and movements, to another based on participation in multiple causes and multiple networks of affiliation, and resulting in people, more than ever before, bearing multiple political identities as well as forging new ones. It recognizes a cosmopolitan politics that features at all spatial scales of organisation and activity (Soja 2000). Third, however, such a politics remains open-ended, and highly dependent upon cultural context and the balance of power, for its outcomes. Thus, no formative place politics of militant particularisms, but a cosmopolitan politics that is xenophobic and reactionary here, progressive and hybrid there, tolerant or particularly militant elsewhere.

4. Conclusion

This article has staked out a case for a nonscalar interpretation of the geographies of place and space associated with contemporary globalization. Its principal claim has been that the rise of a world of global flows and processes, and intensified transnational connections, signals the perforation of boundaries and the sharp combination of variety and difference at different geographical sites, rather than a shift in the balance of power between different spatial scales, or the deterritorialization and reterritorialization of activity. Thus, it has stressed the fluidity of cultural/political practices in space and place, against the emphasis elsewhere in geography on new scales of fixity. Of course, in matters of regulation and governance associated with globalization, there is a very real and felt contest of jurisdiction between local, national, and global state and nonstate organizations. It has not been the intention here to deny the state, but simply its legal and institutional inscription on other on-goings within places. Instead, the aim has been to look into how the very terminology of geographical boundaries, caught up in concepts of place and space, proximity and distance, has been challenged by globalization.

Beyond these largely silent differences of opinion within geography, the distinctive contribution of this discipline within the congested study of globalization, has lain in the study of the spatiality—social, economic, cultural, and political—of what is increasingly being seen as a single and interdependent world. The work of geographers has shown that this new world remains as varied, uneven, and contested as ever

before, with little evidence of spatial homogenization or the end of geography.

Globalization: Legal Aspects

1. Introduction

In light of the dramatic intensification of transnational interactions since the 1970s and its impact on the legal field, one might be tempted to conceive of the 'globalization of the legal field' as a radically new phenomenon without any roots in the past. Though

such legal globalization, or, at least, some aspects of it represent a qualitatively new development, it should be borne in mind that the modern world system, within which the globalization of social interactions occurs, has been in place since the sixteenth century and that the roots of the most recent legal, as well as cultural, social, political, and economic transformations are to be located in this historical development. Moreover, the existence of a transnational legal culture antedates the modern world system, as is dramatically illustrated by the reception of Roman law in the twelfth century and onwards.

Even at the end of the nineteenth century, at a time when liberal political theory had imposed the equation among nation, state, and law, the idea of a global or world law continued to flourish as a legal subculture. Though cultivated at the time mainly by legal comparativists who were quite marginal to mainstream legal science, this legal subculture was part and parcel of a widely hegemonic cultural constellation, the idea of the seamless and irreversible uniformization of the conditions of social life throughout the world brought about by progress, capitalism, and scientific and technological development. In contrast with earlier movements for transnationalization that were the products of an intellectual crusade by well-meaning jurists and philosophers, the transnationalization of the legal field at the beginning of the twenty-first century is promoted by multinational corporations, practicing lawyers, state bureaucrats, and international institutions, as well as by popular movements and transnational advocacy NGOs. It is an extremely diverse phenomenon combining uniformity with local differentiation, top-down imposition with bottom-up creation, formal declaration with interstitial emergence. It cannot be accounted for by any monocausal explanation and defies integration in any unidimensional cultural postulate, be it the idea of progress or the critique of progress, capitalist mass culture or anticapitalist popular culture, modern science, or postmodern knowledge. It mirrors the complexity and ambiguity of the much broader seemingly all-encompassing process of transnationalization, of which it is only a very partial manifestation. Seven major types of legal globalization may be distinguished.

2. Transnationalization of Nation-state Regulation

Transnationalization of nation-state legal regulation refers to changes in the state law of a given country that have been decisively influenced by formal or informal international pressures by other states, international agencies or other transnational actors. Despite the fact that the impact of the international context on nation-state legal regulation is inherent to

the interstate system and can be traced back to the Westphalia Treaty itself (1648), the current process of transnationalization of state legal regulation seems to be a qualitatively new phenomenon for two main reasons. First, it is a very broad and far-reaching phenomenon covering a wide range of state intervention and calling for drastic changes in the pattern of intervention. The core pressure is relatively monolithic as it stems from the 'Washington consensus,' in whose terms the market oriented development model is the only feasible model for a new global regime of accumulation and, accordingly, the structural adjustment it calls for must be carried out worldwide. Other pressures reinforce it, such as the end of the Cold War, the dramatic innovations in communication and information technologies, the new systems of flexible production, the emergence of regional blocs, a newly packaged ideological mix of economic liberalism, and liberal democracy. The scope of these pressures is wider ranging than previous processes of transnationalization, because the current ones take place after decades of active state regulation of the economy in core, peripheral, and semiperipheral countries. The creation of the 'market friendly' model involves massive normative and institutional destruction and construction. The second factor for the novelty of current legal transnationalization is that the asymmetries of transnational power between the core and the periphery of the world system, that is, between the North and the South, are more dramatic today than ever. The sovereignty of the weaker states is now threatened directly not so much by more powerful states, as used to be the case, but rather by international financial agencies and other 'private' transnational actors, such as the multinational corporations.

In the field of the economy the legal transnationalization of state law assumes greatest salience. The policies of 'structural adjustment' cover an enormous range of economic, commercial, and social intervention of the state, provoking turbulence in wide legal fields and institutional settings. Trade liberalization, privatization of industries and services, agricultural liberalization, dismantling of regulatory agencies and licensing mechanisms, deregulation of the labor market and 'flexibilization' of the wage relation, reduction and marketization of social services, less concern with environmental issues, educational reforms geared to job training rather than to citizenship building, family policies that further aggravate the condition of women and children—all these intended or unintended features of the 'Washington consensus' require massive legal changes. Because these changes take place at the end of long periods of state intervention in economic and social life (notwithstanding sizable differences across the world system) the shrinking of the state cannot but be achieved by wide-ranging state intervention. The state must intervene in order not to intervene.

3. The Law of Regional Integration

This type of transnationalization of the legal field occurs whenever a group of states combines to create supranational institutions and legal competences which will assume direct regulatory functions that previously did not exist or, if they did, were performed by the individual states as prerogatives of their sovereign powers. Though there have been attempts at regional integration in different parts of the world system, in South and Southeast Asia, in the Middle East and the Magreb, and in the Americas (lastly, the NAFTA), the European Union remains so far the most advanced instance of regional integration and, for that reason alone, deserves to be singled out. Built over four decades by a mixture of diplomacy and interstate democracy, of intergovernment politics and supranational institutionalism, the EU is today an innovative transnational entity both in legal as well as in political terms (see *European Union Law*).

According to the Treaty of Rome, the balance between the market and regulation was to be accomplished by the member states. The harmonization of laws that should have ensued failed, not only because the member states revealed a nationalistic bias, but also because the legislative processes at the European level suffered recurrent bottlenecks. As a consequence, the European Court of Justice, in co-operation with the Commission, had to assume the role of decision maker, a role that has been very active indeed. Performed both with a federalist and a deregulatory bias, it has favored the Union to the detriment of individual members, and the market to the detriment of the state. This development is significant in itself because it reveals a new dimension of the relations between the legal and the political fields. The judicial engineering carried out by the Court from the 1960s onwards decisively affected the European integration process. Through the doctrines of direct effect and supremacy of the European law, the court 'constitutionalized' the community legal structure as a legal order of its own. Much of this occurred without political debate, as a judicial rather than as a political process, which led Weiler (1991) to state the apparent paradox that while European law developed firmly in a continuing process of evolution, the Union went through one political crisis after another.

4. Global Capital's Own Law: Lex Mercatoria

Understood as a set of customary principles and rules which are widely and uniformly recognized and applied in international transactions, *lex mercatoria* or law merchant is probably the oldest form of transnationalization of the legal field (see *Lex Mercatoria*). *Lex mercatoria* was a supranational law whose most distinct features were the following: the ease with which it permitted binding contracts; the stress on

security of contracts; the speed of adjudication; the variety of mechanisms for establishing, transmitting, and receiving credit; the normative value of customs and usages of the commercial world. Medieval *lex mercatoria* underwent profound changes in the modern period, which indeed caused its seemingly irreversible decline. On the one hand, as trade expanded and more and more diverse trading communities emerged, customs changed and became more diversified themselves. The diversity of customs made *lex mercatoria* less predictable, less transparent, and thus vulnerable to the critique of lacking impartiality. On the other hand, as the modern states gained control over their territories, the existence of a deterritorialized law, which did not derive its normative claims from treaties among sovereign states, was viewed as a threat. As a result, merchant courts were often either forbidden or assimilated into the domestic court system, and transnational business customs were made to comply with law. The expansion of transnational practices and the need to protect them legally led the states to develop a private international law. Since this was a national state law and could therefore conflict with the private international law of other states, efforts were made to harmonize these bodies of laws through the creation of international uniform laws.

The scope of uniform laws has always remained very limited and unable to account for the tremendous growth, in number, complexity, and variety, of transnational contracts and other business transactions, especially after World War II. These relationships, which committed generally larger amounts of money for longer periods than domestic relationships ever did, and engaged partners often separated by great distances, and cultural and linguistic differences, had a greater degree of insecurity and required, therefore, a common normative foundation. Such foundation was sought in a deterritorialized set of normative principles and rules, expressed in such formulas as 'general common principles,' 'principles of equity,' 'principles of good faith and good will,' 'principles of international law,' 'international trade usages,' etc. Because such normative references aimed at circumventing submission to national laws and to the traditional conflicts of law, transnational contracts were deemed to be self-regulatory, subjected only to their own provisions: *contrats sans loi, contratti senza legge, rechtsordnunglose Verträge*. In fact, a new supranational legal order was emerging. It was the new *lex mercatoria*, which was to expand enormously in the last quarter of the twentieth century, by reason of the sheer intensification of transnational transactions and in the wake of a new worldwide regime of accumulation in search of adequate institutional structures. The new *lex mercatoria* comprises several elements, including general principles of law recognized by commercial nations, rules of international organizations, customs and usages, standard form contracts, and reports of arbitral awards. Though this

is disputed, *lex mercatoria* may be conceived of as comprising also uniform laws and public international law. Concerning the latter, though public international law governs the relations among nation-states, and not among private parties, *lex mercatoria* shares with it the 'general principles of law recognized by civilized nations,' such as *pacta sunt servanda*, *rebus sic stantibus*, and the prohibition of undue enrichment. But the relation between *lex mercatoria* and public international law may also be conflictual whenever the first is used to create forms of immunity which operate both vis-à-vis the national law and the public international law. As regards international uniform laws, once they have been adopted by the nation-states and become part of the national law, they are not, in themselves, part of *lex mercatoria*. Before that process of adoption and to the extent that they represent a crystallization of international trade usages, such laws are *lex mercatoria*.

However informal, the new *lex mercatoria* is neither amorphous nor neutral, the customs and usages being not necessarily universal and much less traditional or immemorial. The new *lex mercatoria*, as an emerging transnational legal field, is constituted by thick cognitive expectations and thin normative allegiances reproduced by the routine repetition of myriads of transnational contractual relations originally framed by transnational corporations and their lawyers, international banks, and international organizations dominated by both. Depending on the power relations between the parties and their stakes in the transaction, the new *lex mercatoria* can operate in either a high rigidity mode (the iron cage mode) or in a high flexibility mode (the rubber cage mode). Even in its rigidity mode, *lex mercatoria* is often ephemeral, an instantaneous customary law, so to speak, as in the case of a new type of contract drafted by a leading transnational corporation and its lawyers, which must be accepted as drafted by the weaker partner, irrespective of the fact that such contract type may not be used again in its entirety. Two issues raised by *lex mercatoria* deserve special attention: *lex mercatoria* and the world system and *lex mercatoria* and legal cultures.

4.1 *Lex mercatoria and the World System*

It has been claimed that transnational contracts are purely contractual in that they contain their own rules of recognition and validation and that, as a result, *lex mercatoria* is nonpolitical, needing no reference to noncontractual elements to sustain itself as a normative order. Grounded on a legal formalistic reasoning, this conception unduly abstracts from the hierarchies and unequal exchanges that characterize the world system. A relative balance of power between partners in the transactions is only rarely obtainable. In most cases, the dominant practices at the basis of

this global law are the practices of the dominant actors. The most prominent among these do indeed enjoy state-like political prerogatives, immunity privileges, special access to political resources (tax incentives, special rights on infrastructures, etc.), and they often negotiate directly with the host states the conditions under which the private transactions will be carried out. The political facilitation made possible by the state is a crucial noncontractual dimension of the transnational contracts.

Since stable property rights are exceedingly difficult to establish across national boundaries, the international extension of capital, which is an original feature of the modern world system, has always been an inherently problematic activity. This interstate legal field, created by the core states and imposed on the semiperipheral and peripheral states, has changed substantially in the last 150 years, but has prevailed as a framing, boundary-setting legal and political structure within which *lex mercatoria* has evolved apparently unencumbered by noncontractual constraints. The use of overt or covert interventionary force and economic sanctions by the core countries in the case of expropriations or debt renunciations in the periphery and semiperiphery has been for a long time an integral part of an 'international regime,' closely reflecting the hierarchies in the world system.

4.2 *Lex Mercatoria and Legal Cultures*

The internationalization of capital has always been the motor behind the development of *lex mercatoria*. *Lex mercatoria* is, thus, basically a transnational business law or, more broadly, an economic law. Within the national legal field, economic law traditionally has been one of the laws most permeable to foreign influences and transplants, an area of law in which the ethos of the national legal cultures has always been less determinant. Not by mere coincidence has this area of law been the area of harmonization, uniformization and conventionalization *par excellence*. For this reason, and also because of its deterritorialized character, *lex mercatoria* has often been considered as the expression of a 'global legal culture,' a kind of 'third culture,' independent of the various national legal cultures and hovering above them in its specific domain.

If a new regime of global capital accumulation is indeed emerging, its most visible institutional features, aside from *lex mercatoria* itself, are the rise of transnational corporations and the international organizations that back up their activities, the adaptation of the nation-state regulatory legislation according to the transnational finance capital requirements, the globalization of the market for legal services, and the rise of international commerce arbitration. Particularly visible is the American or American-style law firm. It stands at the core of the

new international market in consultancy and its rise to prominence contributes to the Americanization of international legal services. The type of juridicization it produces is symbiotic with the economic relations it covers and leads toward the infusion of high level competition and market imperatives in the practice of law itself.

5. *Transnational Third Worlds: The Law of People on the Move*

Greatly increased cross-border movements raise myriad sociolegal issues, from international contracts, binational marriages, adoptions of foreign children, legal protection of tourists, and cross-border consumer rights, to civil, political, and social rights of legal and illegal foreign migrant workers, refugees, and asylum seekers. But the international community has paid relatively little attention to the movement of people across national borders, compared with the elaborate regulation of the movements of goods and services. Since traditional international private law only covers a very small number of issues, the international movements of people are in many respects a legal no-man's land. As a result, the legal protection of human beings remains much more territorialized than the legal protection of goods and services. International movements and interactions of people, thus, imply a net loss of legal protection. The challenges posed by this 'black hole' heavily underscore the need to analyze the movements of people across national borders, particularly of those who are less autonomous and run higher risks in moving across borders: migrants and refugees.

5.1 *International Migration*

The slave trade was the first major form of international migration in the modern world system. From the nineteenth century until the 1960s, a period of dramatic emigration from Europe, the major form of international migration emerged based on migrant recruitment through economic inducements. This form of international labor flow was at mid-point between the coerced labor extraction of the slave trade and the self-initiated or spontaneous flows that came to dominate in more recent years.

The state and the national boundaries it controls have, thus, performed crucial roles in the creation of international migration regimes throughout the history of modern capitalism. This control has become more central lately in light of the convergent impact of two recent trends. On the one hand, the trend of core states to favor, if at all, only temporary migration and only in restrictive terms (available only to those whose skills and expertise are in demand), with the consequent tighter control over borders; on the other hand,

the increased pressure to emigrate and the potential for large-scale population movements motivated by the struggle for survival resulting from the immiseration of significant regions of the world system and the growing disparities between the North and the South. Whence the potential increase of illegal, clandestine, or undocumented migration and the consequent strengthening of the receiving states as monopoly holders of the legal status of migrants and of migrant life chances and expectations attached to it.

No international consensus has been reached on the possible terms of a compromise between the principles of international human rights applicable to nationals and nonnationals, and to legal and illegal aliens, on the one hand, and the principles of territorial sovereignty, on the other; in other words, no international migration regime has come into existence.

5.2 *Refugees and Displaced People*

As in the case of undocumented migrant workers, refugees concern us insofar as they raise specific new issues in the broad conceptualization of the transnationalization of the legal field outlined here. Such issues have to do, in this case, with two clear-cut distinctions upon which the international refugee regime was built in the postwar period: between voluntary and involuntary international migration, on the one hand, and between economically motivated and politically motivated migration, on the other. These two distinctions have collapsed in recent years, thereby producing new inadequacies between the hegemonic principles of territorial sovereignty and the dynamics of transnational movements.

According to the United Nations Convention of 1951 and 1967, a refugee is any person who, 'owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality or being outside the country of his former habitual residence as a result of such events, is unable or, owing to such fear, is unwilling to return to it.' This definition excludes most of the world's displaced populations who are mainly victims of massive conflicts, human rights abuses, civil wars, external aggression and occupation, foreign domination, etc. Since they have not been personally persecuted and often have not crossed borders, they are not entitled to the refugee status, even though the political nature of the causes of their flight offers no doubt. They are considered internally 'displaced persons' and at the most may receive some humanitarian assistance. The core countries repeatedly have expressed their opposition to an expansion of the concept of refugee; in recent years, when

confronted with the potential rise of applications for asylum, they have even adopted more restrictive legislation on (or rather, against) refugees and asylum seekers.

The last three decades of the twentieth century have witnessed other 'involuntary' flows of people still more at odds with international and domestic refugee legislation: hundreds of thousands of people fleeing from famine, starvation, and natural disasters (droughts, earthquakes, volcano eruptions). In many cases extreme poverty and environmental crises have acted together with civil war or political repression to provoke massive displacements of people. In these dramatic situations the distinction between economic and political factors have been blurred, if not totally dissolved.

One type of 'involuntary' transnational migration is most likely to grow in the coming years. It will be caused by environmental catastrophes, directly or indirectly caused by anthropogenic climate changes and often coupled with over-population. Refugees will be environmental refugees, seeking ecological asylum. Environmental refugees occupy the outer fringes of a generally precarious system of international protection. Environmental refugees are most likely to collide with the territorial logic underlying social protection as a matter of right.

The high vulnerability of refugees derives from a double adverse condition. On the one side, international human rights applicable to them are highly restricted by a highly restrictive definition of refugees that leaves out most of the current and massive situations of forced migration. On the other side, the few rights they are entitled to are grossly violated with almost total impunity. Refugees are often confined to camps and detention centers where, aside from the lack of freedom of movement and access to the outside world, refugees are subjected to the most degrading human conditions.

6. *Ancient Grievances and New Solidarities: The Law of Indigenous People*

The collective rights of indigenous peoples, is surely an old issue—at least, as old as European expansion from the fifteenth century onwards—which, however, gained a new prominence in the last quarter of the twentieth century. This new prominence is due to a transnational-local linkage which has to do with the most recent step of the secular trend of capitalist world economy to incorporate the whole planet, even its most remote regions, in the process of capital accumulation. As a result, many indigenous peoples saw their traditional lifestyles, customary rights, and peasant economies threatened by new or more powerful development claims by multinational corporations or the national state or, in most cases, the two combined. They represent another and probably more

powerful wave of imperial globalization. One of its specific features is the extent to which the national state itself intervenes as a transnational actor. Pressed by the 'Washington consensus' on debt, stabilization, and structural adjustment, the peripheral and semi-peripheral states embark in new 'development projects,' often in joint ventures with transnational corporations and with the support of international financial institutions, be they extractive—oil, minerals, biodiversity—agro-industrial, road construction, or hydroelectric projects. Some of these projects are to be carried out on indigenous lands, further destroying their traditional lifestyles and economies, forcing them into new and massive relocations.

What is truly new in the new prominence of the indigenous question is the emergence of a transformative, transnational coalition consisting of indigenous and nonindigenous NGOs, which have been drawing the attention of world public opinion to the violations of indigenous historical rights and pressing both international organizations and the national states to condemn the violations, stop the destruction, and take active measures to effectively right (or begin to right) such massive historical wrongdoing. The struggles of the indigenous peoples thereby are transnationalized. The legal dimension of this transnational transformative action lies in the struggle for the transnational recognition of indigenous collective rights and local autonomous legal regulation within territorially defined areas.

7. *Cosmopolitanism and Human Rights*

In the post-World War II period a new cosmopolitan, legal culture emerged out of a transnational understanding of human suffering and the transnational constellation of progressive (legal, political, humanitarian) social actions devised to minimize it; it has gradually evolved into an international human rights regime supported by transnational coalitions of local, national and transnational nongovernmental organizations, which have been growing dramatically, in number, range, and effectiveness in recent years.

The international human rights regime is built around three major documents and sets of standards which together comprise 'the global human rights regime,' a system of rules and implementation procedures centered on the United Nations, and whose main organs are the UN Commission on Human Rights and the Human Rights Committee.

This global human rights regime allows for internal differentiation across the interstate system. Four regional subregimes usually are identified and ranked as follows by decreasing order of strength: the European, the Inter-American, the African, and the Asian and Middle-Eastern (lack of) regime. What distinguishes the *European regime*—established by the members of the Council of Europe in 1950—is the very

strong monitoring powers of the European Commission of Human Rights and the binding decision-making powers of the European Court of Human Rights. Without questioning the overall strength of the European human rights regime when analyzed in comparative terms, one of its weaknesses, which is indeed bound to expand in the coming years, refers to the massive violations of human rights that may be in store for noncommunity citizens, as the internal borders are eliminated and the external borders strengthened.

The *Inter-American regime* is substantively narrower than the European one. Similarly to the European regime, its main organs are the Inter-American Commission of Human Rights and the Inter-American Court of Human Rights. In practice, however, the two institutions have been operating very differently from their European counterparts. As to the *African regime*, the African Charter on Human and Peoples' Rights (1981) contains two major innovations: as the title of the Charter itself indicates, to individual human rights it adds collective rights, as well as the right to development; it also introduces the concept of duty of individuals vis-à-vis the family, the community, and the state, but the provisions that establish the African Commission on Human and Peoples' Rights are exceedingly vague, conferring it no enforcement powers of any sort and only very modest investigatory powers, and there is no regional human rights court. Though in *Asia* and *The Middle East* the human rights debate is widening and deepening, there are, among other reasons, important cultural barriers to the establishment of a human rights regime. Human rights are often viewed as an exotic, foreign, Western conception whose worldwide circulation is nothing but a manifestation of the overall cultural imperialism of the West.

International regimes refer to international normative consensus among nation-states and, as such, they raise two interrelated questions: the extent to which the normative consensus collapses whenever the overriding imperatives of national sovereignty are considered to be better served by the violation of human rights; and the extent to which the inherent statism of implementation and enforcement mechanisms stays in the way of the emergence of new international legal subjects with a more cosmopolitan orientation and a transnational advocacy of greater efficiency. The optimistic predictions of a brighter future for human rights, in the wake of democratic transitions and the collapse of the communist bloc, may prove to be displaced and utterly wrong themselves.

8. *The Global Commons: Jus Humanitatis*

Of all forms of transnational legality *jus humanitatis* is the one that pushes the idea of globalization further, for it takes the globe itself as the object of its

regulation. *Jus humanitatis* expresses the aspiration to a form of governance of natural or cultural resources which, given their extreme importance for the sustainability and quality of life on earth, must be considered as globally owned and managed in the interest of humankind as a whole, both present and future. In this sense, *jus humanitatis* clashes with two fundamental principles of the dominant paradigm: property, upon which the capitalist world system is based; and sovereignty, upon which the interstate system is based. Little wonder, then, that its application has been so little so far. Nevertheless, its prolegomena are already quite visible in the doctrine of the *common heritage of humankind* that has been adopted by international law. Though the doctrine has its own limitations, it is grounded on principles which, were they to be fully developed, would bring about the bankruptcy of the dominant paradigm, and hence of international law itself as it is conceived today.

The concept of the common heritage of humankind was formulated for the first time in 1967 by Malta's Ambassador to the United Nations, Pardo (1968), in relation to UN negotiations on the international regulation of the oceans and the deep seabed. Pardo's purpose was 'to provide a solid basis for future worldwide cooperation ... through the acceptance by the international community of a new principle of international law ... that the seabed and ocean floor and their subsoil have a special status as a common heritage of mankind and as such should be reserved exclusively for peaceful purposes and administered by an international authority for the benefit of all peoples.' Since then, the concept of the common heritage of humankind has been applied not only to the ocean floor but also to other 'common areas' such as the moon, outer space, and Antarctica. Five elements usually are associated with the concept of the common heritage of humankind: nonappropriation; management by all peoples; international sharing of the benefits obtained from the exploitation of natural resources; peaceful use, including freedom of scientific research for the benefit of all peoples; conservation for future generations.

The concept of the common heritage of humankind transcends by far the field of traditional international law. International law deals traditionally with international relations among nation-states, which are supposed to be the main beneficiaries of the regulation agreed upon. Such relations are based chiefly on reciprocity, that is, granting advantages to another state or states in return for equivalent advantages for oneself. The concept of the common heritage of humankind is different from traditional international law on two accounts: as far as the common heritage of humankind is concerned, there is no question of reciprocity; and the interests to be safeguarded are the interests of humankind as a whole, rather than the interests of states. The Law of the Sea Convention, signed in Montego Bay on December 10, 1982,

contains in part XI the most developed formulation of the concept of the common heritage of humankind to date.

Globalization: Political Aspects

Globalization is the process by which the economies of many different nations and regions are being transformed into a single, integrated economy which is worldwide or global in scope. The elimination of national barriers and the expansion of international transactions are being carried to their ultimate conclusion, where the exchange of goods, capital, and services occurs within a global market. This profound economic transformation is having great consequences for national states and their societies. Some nations and groups are winners in globalization and some are losers. The result is that globalization is accompanied by major political actions and by intense intellectual debate.

1. The Term 'Globalization'

The term 'globalization' came into common usage in the early 1990s. The decline of Marxism, the end of the Cold War, and finally the collapse of the Soviet Union in 1991 meant that there was no longer any formidable ideological and political competitor to liberal democracy and the free market. The end of the socialist or Second World meant that the capitalist or First World could expand into the entire world or globe, hence 'globalization.' Also in the 1990s, new information technologies reached the critical mass where they became an entire information economy. The conjunction of computers, telecommunications, the internet, and the worldwide web greatly facilitated and expanded the exchange of goods, capital, and services on a global scale.

Globalization is often described as a process: steadily progressing over time, pervasively spreading over space, and clearly inevitable in its development. In this conception, the economics of globalization are all-important; the politics of globalization are practically nonexistent. But globalization can also be seen as a revolution, one of the most profound revolutions the world has ever known. (It is certainly more of a world revolution than communism ever was.) Revolutions produce reactions, however, and the interactions between revolutionaries and reactionaries produce a particular kind of politics. The first decades of the twenty-first century are likely to be dominated by the politics of globalization, so much so that they could give the name to the era, in the same way that the first

half of the twentieth century was known as the era of the World Wars and the second half was known as the era of the Cold War.

2. Previous Eras of Globalization

The contemporary period is not necessarily the first era of globalization; in some ways it can be seen as the third. There have been at least two previous periods when there was a rapid and massive expansion in economic exchange on a world, even global scale. Consideration of these earlier eras may help in understanding the current one.

The first era of globalization was in the sixteenth century, at the time of the commercial revolution and when European powers opened up the Americas, Africa, and Asia to new or greatly expanded trade. Facilitated by new technologies in shipbuilding and navigation, a vast system of seaborne commerce in goods, capital, and slaves came into being, connecting five continents. This first global economy did not come into being by the spontaneous operations of the free market, however. It had to be promoted and protected by a great political and military power, one that was worldwide in scope. This global hegemon was the Habsburg empire, whose centers were Spain and Austria but which ruled large territories on or near the five continents (Wallerstein 1974, 1980).

The first wave of globalization washed over many old and traditional political authorities. Many feudal and local entities were diminished or disappeared entirely, but others reinvented themselves to become absolutist monarchies and national states. The process was not steady and gradual, but disruptive and violent. It contributed to the Wars of Religion and culminated in the catastrophe of the Thirty Years War (1618–48). At the end of that war and with the Peace of Westphalia, the major surviving powers created an entirely new political order, one composed of sovereign and independent states. Most of these states now developed systematic policies (known as mercantilism) to protect local interests from foreign imports. Thus, the first era of globalization ended in what can be seen as a new era of localization.

The second era of globalization was in the nineteenth century, at the time of the industrial revolution and when European powers and the USA opened-up even larger (now inland as well as coastal) areas of the Americas, Africa, Asia, and Australia to new or greatly expanded trade. Facilitated by the steamship, the railroad, and the telegraph, a vast system of seaborne and overland commerce in goods, capital, and immigrant labor connected six continents. This second global economy also did not come into being by the spontaneous operations of a free market (although the economic theories of the time often assumed that it had). It had to be promoted and

protected by a great political and military power that was worldwide in scope. This global hegemon was the British Empire, which in the late nineteenth century ruled one-fourth of the land surface of the globe and which was the supreme naval power in every ocean (Polanyi 1944).

The second wave of globalization also washed over many old and traditional political authorities. Again, many local entities were diminished or disappeared entirely (particularly in Africa, the Middle East, and East Asia), but others reinvented themselves to become strong national states (particularly in Europe but also Japan). The process was not steady and gradual, but disruptive and violent. It contributed to a series of nationalist wars and culminated in the catastrophic World War I and II, which some historians have called a second thirty years war (1914–45).

At the end of that war and with the onset of the Cold War, a bipolar system was created, composed of the USA (liberal-democratic in its politics and free-market in its economics) and the Soviet Union (authoritarian in its politics and statist in its economics). The Americans promoted free markets and open economies in their alliance system (the Free or First World); the Soviets promoted command and closed economies in theirs (the Socialist or Second World). The existence of the Soviet Union and the Second World acted to contain the spread of the free-market policies of the USA, even within the First World itself. Thus, the second era of globalization ended in another era of economies that were closed or protected in important ways.

3. The USA as the Leader of Globalization

We are now in the third era of globalization. With the collapse of the Soviet Union, the USA could pursue its grand project of promoting and protecting free markets throughout the globe, unconstrained and uncontained by any comparable power or 'peer competitor'; it has been the leader and the energizer of the process of globalization. It serves as the new global hegemon, the successor to the Habsburg and the British Empires. Acclaimed as 'the sole superpower,' the 'high-technology economy,' and 'the universal nation,' the USA has vigorously and consistently supported this great transformation by systematically pressing to remove any national barriers to the free movement of capital, goods, and services. Its leadership is facilitated and legitimated by the three great international, now global economic institutions, the International Monetary Fund (IMF), the World Bank, and the World Trade Organization (WTO).

US leadership in globalization is also facilitated and legitimated by the particular American worldview or ideology. Americans have long advocated liberal

democracy and free markets as political and economic ideals. In foreign affairs, this ideology has been known as liberal internationalism, and its most prominent proponents were Presidents Woodrow Wilson and Franklin D. Roosevelt (T. Smith 1994). This familiar ideology has been revised in the era of globalization into a new American ideology which promotes human rights and the open society. This is a version of liberal internationalism, one that is more accurately termed liberal globalism; its most prominent proponents in the 1990s were President Bill Clinton and Secretary of State Madeleine Albright, but it is held by most American political, economic, and intellectual elites. The ideology of human rights and the open society advocates the limitation of state sovereignty and the weakening of the nation state. As such, it poses a fundamental challenge to traditional conceptions of international relations.

This ideology of human rights and the open society—liberal globalism—also provides the justification for a new kind of US military operation. This is humanitarian intervention, as in Somalia, Haiti, and Bosnia; the culmination of this development was the US-led NATO war against Serbia over Kosovo. Intervention in support of human rights is not supported by all parts of the American public; it is primarily advocated by political and intellectual elites, especially those in the media and in academia. Political opposition to humanitarian interventions and more generally to globalization comes from other American groups and interests, especially those who see themselves as losers in the global economy (e.g., labor unions and domestic industries). But the major sources of political opposition to globalization are found outside the USA.

4. The Resistance to Globalization

The US-led revolution of globalization has generated resistance and reaction. Immediately after the collapse of Soviet communism, the principal sources of resistance seemed to be major nation states, especially Japan, France, and reunited Germany. However, by the end of the 1990s these nations offered little resistance to globalization; one reason was the stagnation of their economies, compared with that of the USA.

With the paralysis of the major nation states, the principal sources of resistance to globalization have become several of the great religions. Some of these have undergone a revival and transformation into a political religion. Especially strong in their resistance have been revivalist Islam and neo-Confucianism (sometimes referred to as 'Asian values'). Also resistant have been revivalist Hinduism and Eastern Orthodoxy. The great religions see the globalization led by the USA to be closely connected with secularization and therefore a threat to themselves. These

four sources of religious opposition correspond to four large countries or areas. Two of these, Russia and the Middle East, have been losers in the new global economy, and two, China and India, have been winners.

Russia and, more generally, most countries with an Eastern Orthodox religious tradition, for a variety of reasons have been unsuccessful in making the transition from a communist regime to a liberal democracy and market economy, which are able to adapt well to an open society and global economy (e.g., Russia, Belarus, Ukraine, Moldova, Romania, Bulgaria, and Serbia). Conversely, most countries with a Roman Catholic or Protestant tradition have been successful in making this transition. This contrast among ex-communist countries, between the more western and the more eastern, between the Roman Catholic or Protestant and the Eastern Orthodox, means that the political and economic developments of the 1990s revived and reinforced an historic divide, one that corresponds to the great schism between Western Christianity and Eastern Christianity and even to the ancient division between the Latin and the Greek halves of the Roman Empire.

With their condition of political and economic weakness, the governments of Russia and the other Orthodox countries cannot mount an effective and sustained opposition to globalization. But among the populations of these countries, there is now substantial resentment and resistance directed at the USA and its global project. The Middle East and, more generally, most countries with an Islamic religious tradition have also been unsuccessful in establishing a viable liberal democracy and market economy, which are able to adapt well to an open society and global economy. For those that experienced the heady years from 1973 to 1985, when OPEC seemed to be a world power, a long decline in oil prices deepened their sense of failure and their alienation from globalization. Here, too, the governments are not willing and able to mount opposition that is effective and sustained. But among their populations there is widespread resentment and resistance, whose most obvious representatives are militant organizations based upon Islamic revivalism.

Conversely, there is growing opposition even from some of the winners in the global economy. These include China and, more generally, most countries with a Confucian tradition. Most Chinese, both in China itself and among the 'overseas Chinese,' see their economic success as resulting from their own culture or 'Asian values,' from engaging in the global economy in their own way. This conception has been reinforced by their interpretation of the Asian economic crisis of the late 1990s. The countries with the most open currency markets (South Korea, Thailand, Indonesia) suffered the greatest disruptions and declines. Those whose currency markets were most regulated (China and, ironically, Taiwan) experienced little disruption and continued their economic growth.

The entry of India into the global economy has been more recent, and its benefits have been unevenly distributed. It has occurred, however, at the same time as the growth of Hindu nationalism, the development of Indian nuclear weapons, and an increased confidence in rejecting certain Western ways. The sources of opposition to globalization led by the USA are thus very disparate. But together these sources of opposition comprise a vast region, really all of Eurasia and more, which stretches from Russia and Eastern Europe, through the Middle East, through South Asia, to China and East Asia. In this vast region are found the four great civilizations that Samuel Huntington has identified as most likely to oppose the West in 'the clash of civilizations' (Huntington 1996). These are, in his terms, 'Slavic-Orthodox,' Islamic, Hindu, and 'Sinic-Confucian' civilizations. In this region, too, are four nuclear powers, Russia, Pakistan, India, and China, each of them seeing themselves as the center of their civilization. Singly or collectively, they may develop the capacity and will to disrupt and contain globalization. If so, it will take American leadership of the highest ability to insure that the third era of globalization does not end with a clash of civilizations which culminates in a third thirty years war.

Globalization, Subsuming Pluralism, Transnational Organizations, Diaspora, and Postmodernity

Globalization, the historical process by which all the world's people come to live in a single social unit, brings with it religious changes as well. Prime among these is that globalization encourages religious pluralism such that religions identify themselves in relation to one another. Religions also become less rooted in particular places because of diasporas and transnational organization. In postmodern fashion, global religious pluralism creates a situation in which absolute visions end up living side by side.

1. Globalization and Religion

Since the 1980s, the term globalization has taken on a certain currency in social scientific as well as in popular discourses. Its meaning in both these areas varies; but what unites economic, political, cultural, and even theological conceptions of globalization is the sense that, for better or worse, all people around the world live today in a single social unit much more than they ever have before. There is now and has been developing for some time a world society which serves as the encompassing social context of all more local social units. In this regard, most of the debates about globalization, whether scholarly or popular, have centered around the relation and even polarity between the global and the local. Robertson (1992), perhaps the first social scientist to use the term globalization in a technical and consistent sense, talks about the dialogical relation between the universal and the particular. What this means is that the global

context, rather than only leading to a certain homogenization of culture and social structure around the world, also provides new conditions for constructing social and cultural difference. Global society, while single, is inherently pluralistic, not only permitting but even favoring a multitude of local and particular identities, both individual and collective.

The status of religion in debates about globalization has varied, to a significant extent according to academic discipline. Perspectives that see the development largely in economic terms, for instance as the increasing dominance of global capitalist institutions, tend to ignore religion almost entirely. Many of the approaches originating in the fields of international relations, political geography, and communication studies also pay little attention to religion, with the occasional exception of the role of Islam in many Muslim states (see, e.g., Anderson et al. 1995). Overall, it is primarily the works of certain anthropologists and sociologists that accord religion a more visible place. Yet even here, analyses vary a great deal, for the most part depending on how the term is understood. Two overlapping lines of variation appear to be central: the distinction between functional and substantive notions of what counts as religion and whether one sees religion as an aspect of culture or as a differentiated and independent social domain.

A functional conception of religion regards as religion any social process that addresses certain problems, for instance the question of the ultimate meaning of life, or social integration and control. Here religion, or at least the religious, almost automatically becomes a necessary dimension in the formation of world society because problems of meaning or of self-description (integration) have to be addressed in any society, especially one as diverse as the global one. As examples under this heading, some authors have sought to analyze the emergence of a global culture that is the equivalent of a new global 'sacred canopy' (Meyer et al. 1997). One might even include a growing discussion about the development of a global 'civil society' under this heading (Rudolph and Piscatori 1997, Braman and Sreberny-Mohammadi 1996). In addition, a functional approach allows questions of national, regional, ethnic, or civilizational identity in world society to take on religious character (Huntington 1996, Robertson 1992); and thus will tend to see religion largely as an aspect of culture. Substantive ideas of religion, by contrast, insist on the presence of identifiable and institutional sorts of activity that refer to a posited supraempirical, transcendent reality. From this perspective, the relation of various specifically religious groups to globalization becomes the focus of attention, groups ranging from the Roman Catholic Church and Islamic organizations to Western Buddhist groups and Pentecostal movements (Cox 1995, Robertson 1992, Rudolph and Piscatori 1997). Such approaches perforce also see religion as an independent domain of social activity and as more

than an expression of something else, whether economics, politics, or culture (see Beyer 1998, Hexham and Poewe 1997).

This variety in ideas about what counts as religion in the global context by itself already points to important aspects of the relation between globalization and religion. The fact that most of the literature which deals explicitly with globalization ignores religion or functionalizes it suggests that substantive or institutional forms are for these observers somewhere between irrelevant and antiglobal. One manifestation of this orientation is the great amount of attention that so-called 'fundamentalisms' receive, and this, ironically, very often from scholars who are oriented quite positively toward institutional or substantive religion. Thus, e.g., the volumes issuing from Appleby and Marty's *Fundamentalism Project* (see Marty and Appleby 1994), although not directly about globalization, nevertheless assume globalizing processes. They judge a wide variety of important religious movements all around the contemporary world as particularistic and usually local reactions against them (see also Juergensmeyer 1993, cf. Beyer 1994). Among some of these authors, however, designating 'fundamentalisms' as, in effect, antiglobal movements parallels a positive attitude to the idea of a single world society, especially as manifest in the search for a specifically global ethos. In these cases, the search is on an explicitly religious basis, albeit not on the basis of a particular religion. What is somewhat ironic is that the resulting global ecumenical ethic (see especially Küng 1991) corresponds reasonably well to the intention of those who functionalize religion at the global level: i.e., it avoids reference to a particular religion while addressing what it assumes to be the urgent and globally relevant religious task of providing ethical ideals and values that people all around the world can accept. In short, this sort of discussion seems to suggest that the distinction between functional and substantive conceptions of religion overlaps in a certain way those between universal/global and particular/local. Since these latter are principal organizing polarities in the entire globalization debate, it is best not to decide for one conception of religion or the other; but rather to consider the potential insights that flow from both.

2. Theoretical Perspectives

An excellent example of how a functionalized conception of religion can enter the globalization debate at the theoretical level is to be found in the work of Meyer and his co-workers. In a 1997 article that clearly presents their basic outlook, they carry to the level of global society an analysis that the classical sociology of Max Weber and Emile Durkheim made for modern societies. For these scholars, the world polity, as they call it, is an extension of modern

Western values and their corresponding rationalized structures to the rest of the world. Western religion had a critical role in bringing about this modernization and rationalization; but today the old religious elites have lost their power and have in any case also become believers in salvation through the pursuit of modern global values, especially progress (development) and equality. In their place there is now a new 'religious' elite who are 'the professionals, researchers, scientists, and intellectuals who write secularized and unconditionally universalistic versions of the salvation story, along with the managers, legislators, and policymakers who believe the story fervently and pursue it relentlessly. This belief is worldwide and structures the organization of social life almost everywhere' (Meyer et al. 1997, p. 174). Meyer and his co-workers support the existence of this world polity by showing how the concrete policies of most countries around the world conform to its goals and values. In arguing in this fashion, however, they present a rather alternativeless and homogenizing picture which leaves room neither for the assertion of any meaningful particular or local variation nor, not coincidentally, for any role for institutional religion other than as futile reaction or powerless supporter.

A significantly more nuanced vision, both as regards the question of homogeneity/heterogeneity and the possible role of institutional religion, is contained in the work of Robertson. This author also emphasizes what he calls the 'globalization of societal modernity' (Robertson 1991), which includes the sort of global religious function that Meyer and co-workers see. In addition, however, Robertson points much more positively to the proliferation of religious movements in the contemporary world, movements ranging from Latin American liberation theology and Kūngian 'ecumenism' to Islamic 'fundamentalism,' Japanese Soka Gakkai, and the Unification Church of Sun-Myung Moon. His theoretical model makes room for these more institutional and substantive forms of religion, and not just as local defensive reactions against incorporation into the global system. Instead, Robertson allows that they can also be attempts to define the 'global-human' situation as a whole; and at the same time ways of identifying a particular culture, region, or (in his terms) society in relation to the global whole and other subunits of it. The task of constructing such universalistic religious visions—whether functional or substantive—is always done on the basis of particular traditions, cultures, or movements. In consequence, the forms of institutional religion themselves change in the context of globalization, leading, for instance, to revisions of old traditions, syncretic or hybrid movements, and the rise of entirely new religions. For Robertson, then, the World Parliament of Religions, the Vishva Hindu Parishad (World Hindu Organization), the Church of Scientology, a peripatetic Pope or Dalai Lama, and Chinese Qi Gong groups are just as much aspects of

globality and contributors to the shape of global society as are the aims and pronouncements of social scientists and technocrats. They all reflect and share a common social context; and one is not more modern or global than the other.

3. Religious Pluralism

From these theoretical starting points, one of the important questions that emerges concerns religious pluralism. Only with a radically functionalized concept of religion, such as that of the world polity school, can it appear possible for global society to share a single religious vision, a single world view. All other conceptions point to the near impossibility of a hegemonic, global religion. Substantively speaking, contemporary global society shows no sign of moving in this direction. If anything, the opposite is the case: not only is there an increasing number of identifiable religions or religious traditions in the world, the variety of expressions within those religions is also growing. Indeed, some sociologists of religion, notably Luckmann (1967), have long suggested that the typically modern—and therefore now global—form of religious expression is a highly individualized one that carries pluralism to the point where Luckmann can call it 'invisible religion.' Put somewhat differently, the question of religious pluralism is not simply one of how different religions, each one claiming an absolute vision, can live side by side in world society; but also to what extent this society still favors authoritative institutions worthy of the name, religions. A partial answer is possible through a comparison of the idea of religion with those of culture and nation.

The model of global culture argues that, in the contemporary social world, the ideas of culture and nation serve as names for types of legitimate and fundamentally plural collective identities: cultures and nations, like individuals, have the right to equal existence. Within the context of homogenizing forces like global capitalism and mass media, one can assert one's difference and defend that difference in the name of one's culture or nation. Cultures and nations, like individuals, are legitimated agents or actors in global society: it is part of the world polity of which Meyer and co-workers speak, that their right to 'self-determination' should only be limited by the right of other such identities to assert themselves in like fashion (see Lechner 1989). Religion is both a similar and different concept. On the one hand, religion is often a part of cultural and national identities: it can help define them. On the other hand, global culture also allows that religion is something independent of these other two notions. Religions are something to which people assumedly adhere voluntarily as individuals; and this may or may not flow from their cultural or national identities. Religions also enjoy the same 'protection' as cultures and nations; at least such

freedom of religion is an ideal expressed in most of the world's state constitutions. Correspondingly, global cultural ideals regard religions, like cultures and nations, as inherently plural. Two seeming paradoxes emerge from this view. First, religious freedom is grounded in the individual's right to choose, but also in the right of the religious collectivity to exist and determine itself. Religious collectivities can therefore claim authority over their members, but only with the consent of these latter! Second, religions are particular and plural; and yet it is understood that they each offer a universal or cosmic vision, a total way of life. This holist emphasis therefore includes the possibility of exclusivist religions, ones that deny the validity of all others. Thus, in true postmodern fashion, religions provide ways of multiplying ultimate narratives about how the world is and they do this in such a way that each is regarded as of equal value, the choosing of one or the other being deemed a matter of preference, or upbringing, or culture. Ultimately, each is grounded only in the conviction of its adherents, and this in the knowledge that most others in global society have different convictions: even by the most generous estimates, the largest religion, Christianity, can claim far less than half the world's population.

4. Religion in Postmodernity

The postmodern character of religion in the context of world society is manifest in other features as well. Embedded in the idea that religion is fundamentally plural are the questions of how religions distinguish themselves from one another and what the difference is between religion and nonreligion. Neither question is susceptible to a simple and clear answer. The idea that there are a plurality of distinct religions is one that dates historically only from the European seventeenth century in the context of post-Reformation religious conflicts and as European expansion brought its people into protracted contact with a much wider variety of other cultures, civilizations, and hence religious traditions. Which traditions emerged from this historical process as 'one of the religions' depended both on what Westerners observed as religions and on what non-Westerners were willing to style according to the implied model of a religion. Different and even diametrically opposite outcomes resulted. Thus, the elite carriers of Hinduism took up the suggestion of Western observers and cooperated in reimagining South Asian religious traditions as somehow a single religion, whereas corresponding Chinese intelligentsia refused, in spite of Western observation, to reconstruct their Confucian thought and ritual traditions as a religion (see Beyer 1998). The contemporary list of (world) religions therefore has an inductive and even arbitrary character that cannot be reduced to abstract characteristics. Like nations and cultures, what comes to be seen as one of the religions

depends in large part on how well the supposed members succeed in having others accept it as one.

The boundary between religion and nonreligion exhibits comparable ambiguities, the difficulty of deciding between functional and substantive ideas of religion being one example. At the core of this problem lies the notion that religion refers to an overarching view of the world and thus to a complete way of life; and yet religions are, in principle and in fact, plural. A prime symptom of this ambiguous status of religion in world society is that, over the past century and a half, key representatives of almost all the so-called world religions have claimed that 'ours is not a religion.' Most often, protests of this sort favor a broad functional conception of religion for their tradition, and reject the sort of substantive one that limits religion to a special category of human action, say one dealing only with the interaction with gods or spirits. Similarly, opponents of various new religions have sought to exclude these from the category, in these cases so as to eliminate them from the range of legitimate religious choices. Such conflicts over categorization are, on occasion, ways of circumventing the global cultural value of 'freedom of religion,' justifying in these instances the obligatory adherence of everyone to the tenets and practices of a particular 'religion'; or preventing such adherence to another. Thus, does the category of religion in global culture allow a post-modern juxtaposition of absolute narratives without offering an overarching narrative through which to reconcile them.

5. Religious Authority, Transnational Organization, and Diaspora

Accompanying these various ambiguities regarding the category of religion and religions, the carrying out of institutional religion under conditions of globalization brings a number of other challenges and changes, especially with respect to questions of religious authenticity and authority. In any society, there exist a limited number of ways through which conformity to authoritative religious traditions can come about. Thus, e.g., in small scale societies a relative lack of alternatives, and social structures centered on face-to-face interaction could assure reasonable religious conformity. After the advent of writing and large scale political empires, dedicated priesthoods or monastic orders, political state support, along with distinctions between elite and popular religiosity (e.g., religion vs. superstition) could handle the problem according to hierarchical principles. Under conditions of globalization, neither relative social isolation nor hierarchical solutions are possible. Globalized communication media, from telephones and air travel to television and the internet assure that religious social networks need not be limited to local interaction or particular places. In fact, the existence

of these possibilities positively encourages global or translocal religious networks and religious organizations. Moreover, the global cultural valuing of equality for both individuals and collectivities severely militates against the notion that the orthodoxy practiced or advocated by a certain group of religious professionals or adherents in a certain place should serve as the unquestioned standard for all others. Even in religions that have traditional centers of such authority, e.g., Rome for Roman Catholics, al-Azhar for Sunni Muslims, or Salt Lake City for Mormons, these centers have limited resources for enforcing their authority; and those that choose to ignore them can use the same techniques of individual religious freedom, (alternative) tradition, separate organization, and transnational networking to circumvent it. The only real exceptions are situations in which state power helps enforce religious authority; but in those cases, such as Iran or Russia, the state boundaries themselves set effective limits to such compulsion.

A prime illustration of the way that globalization encourages the multiplication of local centers of religious authenticity is the effect on religion of global migration and transnational religious networking and organization. Although the migration of people from one part of the world to others is a constant of world history, what is new under conditions of globalization is both the extent of the phenomenon and the fact that migrants leave one place for another far less definitively. The possibilities for maintaining communicative and even physical ties with the places of origin are far more developed, meaning that migrants are less dependent on their new contexts and can still influence the places that they have left. From a different angle, the difference between migrants and nonmigrants is not as great as it used to be, just as the difference between travel/tourism and migration is not as clear. And the chief source of this new situation is the much greater and more rapid communicative links that now exist throughout the world.

Among the consequences for religion of migration and enhanced transnational or translocal linkages, two are of the greatest potential significance. The first is that, as migrants from a particular religion settle in different parts of the world outside of the traditional 'heartlands,' these diaspora communities will develop religious variations that respond to their new locations, and may furthermore re-export these to their places of origin as authentic and authoritative versions. Thus, e.g., the temples that Hindu migrants typically set up in diaspora communities of Europe or North America often allow the worship of a range of gods and goddesses in the Hindu pantheon, unlike in India where temples usually are dedicated to one deity only. The diasporic 'one-stop supermarket' temple is primarily a response to the fact that Hindus from different parts of India migrate to the same places and that these communities do not have the resources to build temples for each subgroup. In spite of these

strategic origins of the variation, however, the model is being transferred back to India, providing another authentic way of 'doing' this religion. Similar analyses could be made for Muslim, Christian, Buddhist, or other migrants as well.

The second major consequence for religion is related but also in a sense opposite. It consists in the possibility of tying together disparate versions of a religion across the globe, expressly in spite of the difference in local variations. The Roman Catholic church is perhaps the prime example of a religious organization that has taken great advantage of this possibility. The links among the world's Islamic populations have also strengthened significantly in this context (see Levitt 1998, Rudolph and Piscatori 1997). Another very illustrative example is global Christian Pentecostalism. Here, the concrete ways of doing Pentecostal Christianity vary enormously when one compares places like Korea, South America, North America, Asia, and Africa. Yet transnational linkages in such forms as common publications, regular world conferences, connections among professionals, and migration encourage a consciousness in most Pentecostals of being part of the same worldwide religious movement, and this in spite of the differences among them (see Van Dijk 1997).

6. Conclusion

What the foregoing demonstrates is that globalization creates and enhances conditions in which religion can become more pluralistic and yet at the same time more unified. The local and the global in religion, the universal and the particular, are not opposite poles between which religious forms oscillate. Rather local religion can now increasingly only be done with reference to the global context, especially in the awareness of religious pluralism. And global religious forms expressly include and are the expression of local manifestations. Global society does not present the choice between antiglobal, perhaps fundamentalist resistance and proglobal, liberal accommodation. Instead, it recreates the conditions under which religions form and operate in relation to one another.

Goddess Worship (Old and New): Cultural Concerns

Goddess worship is integral to many religions, old and new. The ancient Mediterranean world contained abundant Goddess lore; today, Hinduism and Buddhism are richest in female divinities. Academic studies of these traditions trace their texts, histories, rituals, iconographies, theologies, intersections with economics and politics, and—most recently—implications for female status. This article builds upon such scholarship, but it aims to describe the contemporary phenomenon of Goddess worship as a choice by women and men who believe that worshipping

God in a female form will empower them spiritually, socially, or politically. Who is turning to Goddess worship, and why? What does this say about history, religion, and society? Are Goddesses ‘good’ for women? Although the material investigated here derives largely from Western contexts, one can detect the same recourse to Goddess figures by people in other cultures who seek transformation through potent symbols and personalities. But the ‘new’ Goddess worship of today, embracing and refashioning the Goddesses of ‘old,’ is not everywhere the same. A Wiccan member of The Fellowship of Isis may differ radically from an Indian author involved with the feminist press, Kali for Women. Thus to nuance the picture of this emerging phenomenon, non-Western experiences of contemporary Goddess appropriation—particularly Indian—are brought in as test cases for claims made about Goddess worship here in the West.

1. Seeking New Symbols

In Western countries, Goddess worship is typically viewed as a religious alternative for those disillusioned with the overwhelming maleness of Jewish and Christian religious imagery and social structure. Symbols of God as father, conqueror, judge, and lord are believed to enforce the patriarchal domination of women. Moreover, Western philosophical dualisms—soul/body, sacred/profane, transcendent/immanent, rational/emotional, and changeless/changeable—justify the creation of hierarchy and demonize the lower halves, such that it becomes necessary to subdue sexuality, nature, emotion, and change. The new Goddess traditions also make historical charges—that Jews and Christians have wiped out indigenous Goddess-worshipping societies, Jews during the time of the prophets and Christians in the fourth to fifth centuries, when their emperors closed Goddess temples throughout the Roman empire. Indeed, as many critics claim, Jewish and Christian histories have systematically subordinated Goddesses and women, rather than according them equivalence in the theological and social spheres.

The most cogent justification for the need to reject the Judeo-Christian tradition for that of the Goddess draws upon theories about religious symbols. Following the work of Clifford Geertz, Carol Christ (1987, 1997) and other feminists have postulated that symbols have a direct relationship to sociocultural systems. Since symbols create powerful, pervasive, and long-lasting moods and motivations, shaping our understanding of the world and suggesting patterns of action, patriarchal symbols reinforce patriarchal social structures, which therefore appear uniquely realistic. Changes in the way women are perceived and treated can only come through the creation of new symbols, which empower women and undercut male

dominance. As Birnbaum states, quoting Gloria Anzaldúa, 'nothing happens in the "real" world unless it first happens in the images of our heads' (1993, p. 7).

2. *Varieties of Goddess Votaries*

Western Goddess spirituality is heterogenous and flexible, and sits at the intersection of four large groups (Eller 1993, Puttick 1997). The first, known loosely as spiritual feminism or women's spirituality, started in the early 1970s as a spontaneous grassroots movement. Cynthia Eller describes it as being founded on four premises: religion and ritual *can* be empowering for women; a healthy environment, peace, and community must be sought; Western history needs revising; and gender relations should be explored. Since many spiritual feminists stay within their birth traditions to work for justice and equality, not all women in this category worship Goddesses.

The second umbrella label is (neo-) paganism and Wicca, founded in the 1950s in Britain and based on the recovery of pre-Christian European religions such as Druidry and Odinism. In general, such groups believe in a dynamic balance between male and female; the centrality of fecundity; an immanent deity; care for the earth; the efficacy of ritual and magic; and the leadership of women. Goddesses are central to pagan religiosity, but not necessarily in isolation from male gods.

The concerns of spiritual feminists and Wiccans can be similar, as seen in the writings and practices of feminist witches Zsuzsanna Budapest and Starhawk. However, there are also frictions between the two groups. Since Wicca is not political, does not aim to strip away patriarchal domination, and advocates male/female complementarity, some spiritual feminists view Wiccans as sexist. Wiccans return the compliment; for them, politics and feminism are irrelevant to spiritual growth.

A third set of related groups is referred to collectively as the New Age. Famous for their crystals, chakras, channeling, past-life regressions, astrology, and mind-over-matter affirmations, New Age individuals create a pastiche of religious self-help devices, many of which involve Goddess figures. Spiritual feminists and pagans often critique the New Age for its tendency to whitewash and sweeten Goddesses; for its racism, misogyny, lack of commitment to community struggle, and exploitation of cultures from which it borrows; and for its naive optimism, unhelpful in times of crisis (Christ 1997, Sjöö 1992).

The final group—new since the 1980s—of contemporary Western Goddess worshippers are the eco-feminists, eco-spiritualists, and Gaians (from Gaia, or Earth). Though not all of them gynemorphize the earth as a Goddess (there are Jewish, Christian, and Buddhist eco-feminists as well), most worship the

earth as a mother Goddess and decry her desecration by modern industrial patriarchs. For Vandana Shiva, the Indian human rights activist, feminism is a form of ecology, and ecology is a revival of *prakṛti*, the demonized but potent Hindu feminine principle of nature (1988, pp. 38–54).

3. *Who is She?*

Like the variety of the Goddess movement, so also the Goddess herself. Her identity is multiple and fluid, changing depending upon the needs of her worshippers. Some women understand her as the affirmation of the female body, sexuality, and power, all of which have been downplayed in traditional Western religions. Although many feminists caution against too rigid a defense of female sexuality, as if biology were determinative of a women's 'essence' (di Leonardo 1998, pp. 98–108, Gross 1998, pp. 159–70), others argue that creating a space for women to reclaim the positive aspects of their sexuality is so important that the project is worth the risks.

Another method of affirming female strength is through a Jungian perspective, where the Great Goddess is an archetype of the feminine, dark side of life. Following Robert Graves, Erich Neumann, and Joseph Campbell, modern Jungians claim not only to empower women and men through the recognition of the positive aspects of innate femaleness, but also to explain, through the theory of archetypes, why women who have never encountered Goddesses in real life can suddenly start creating and dreaming about them. Not all feminists and Goddess worshippers approve of the use of Jungian archetypes, however. Some protest that in revalorizing the feminine unconscious, the banished 'other,' one is creating a new version of the old male/female dichotomy which subjugates women (Gross 1998, p. 190); others who worship a 'real' Goddess complain that Jungians relegate her to the 'unreal' realm of the mind (Christ 1998, pp. 86–8); and still others, drawing again upon Geertz's work on symbols, prefer to create new ones rather than to adopt those postulated by a patriarchal psychological system.

The Goddess also has material manifestations. As indicated above, some women and men view her as the earth. Since we are all part of nature, we must celebrate, and not attempt to control, its cycles. 'I feel deeply that the flight from finitude and death is at the root of the problems we face... Maybe something went wrong, massively wrong, when Platonism and Christianity became the dominant symbol systems of our culture. Maybe... the Goddess can help us... to love a life that ends in death' (Christ 1987, p. 210). Often linked with this conception of divinity is the assertion that the Goddess is a relational symbol of embodied, immanent love.

Although many Western Goddess votaries might assent to the interpretations given above, the majority

Figure 1
Artemis of Ephesus (reproduced by permission of the Mansell Collection/TimePix)

Figure 2
Cybele enthroned with her lions (reproduced by permission of the Mansell Collection/TimePix)

also worship the Goddess as a living presence. Some, choosing to stay within their Jewish and Christian contexts, derive inspiration from the feminine sides of God as revealed in the Bible or from their respective mystical traditions: Isaiah's 'womb language'; the emphasis on God's wisdom; the Kabbalists' Shekhinah, or presence of God; the Virgin Mary; feminine interpretations of the Holy Spirit; and Julian of Norwich's Mother Jesus.

Others, finding the traditions of their birth irredeemably patriarchal, go outside in search of Goddess figures whom they can approach in prayer and ritual. The most frequent destinations for such seekers are Western, often European, traditions, where, even if the Goddesses are no longer the center of living cults, they are believed to be waiting, still puissant, able to heal. Examples include the Greek Demeter and Persephone, Aphrodite, Artemis (see Fig. 1), and Athena; the Egyptian Isis; the Sumerian Inanna; the Canaanite Astarte; and the Anatolian Cybele (see Fig. 2). Sometimes, though more gingerly, for fear of causing offense, Western Goddess worshippers also turn to figures from Native American tribes, such as

Old Spider Woman, Corn Woman, and Serpent Woman, as well as to powerful ancestors and spirits from Africa.

Non-Western Goddesses also have devoted followings: the Japanese Amaterasu, the Hindu Durgā and Kālī, the Tibetan Buddhist Goddesses Tārā and Vajrayoginī, and the Chinese Buddhist Kuan-yin. Often these, and the Western deities mentioned above, are lumped together through superficial resemblances, archetypal links, and claims of historical connection, producing what Cynthia Eller calls the 'grab-bag approach to feminist spirituality' (1993, p. 75). Many criticize these dehistoricized approaches to Goddess worship as insulting, romantic, essentialist, and orientalist. The fact that some modern Goddesses have been created afresh, according to elite needs—for example, Asphalta, the parking Goddess (Grey 1989)—does not assuage such fears. Nevertheless, most modern Goddess worshippers are sincere seekers, turning to female embodiments of the divine in a genuine search for new life.

Before concluding this introduction to the meanings of the Western Goddess, it is worthwhile noting that

the reclamations under discussion appear not to be occurring among Muslims. There are three possible explanations: the minority status of Muslims in Western countries, which places them outside the liberal mainstream; the paucity of feminine images of the divine in the Qur'an; and the strict monotheism of Islam, which makes anathema the search for a Goddess figure.

4. *How Old is She?*

One of the most controversial elements of the Goddess spirituality movement is a claim about origins, or the 'Goddess Hypothesis.' Currently championed by authors like Christ, Eisler, Gadon, Gimbutas, Spretnak, and Stone, but relying on the earlier works of Bachofen, Engels, Graves, and Neumann, this hypothesis rests on a belief that 'there were past societies in Europe and the Near East, especially prior to the so-called invasions of the Indo-Europeans circa five thousand years ago, that were Goddess-worshipping, female-centered, in harmony with their environments, and more balanced in male-female relationships' (Conkey and Tringham 1995, p. 206). Drawing upon archaeological excavations of female figurines (fertility 'idols' of 'the Great Mother cult'), grave sites, and cave paintings, as well as anthropological research into modern-day 'primitive' societies who may be considered survivals from earlier eras, such authors see continuities from the time of the Upper Paleolithic period (32,000–10,000 BCE) and the Neolithic Revolution (9,000 BCE), down to the societies of Old Europe (6,500–3,500 BCE). What they have in common is a Great Mother cult and a social organization that is matrifocal (some claim matriarchal), earth-bound, and peace loving. Present-day clues of this earlier time, when the 'earth was believed to be the body of a woman and all creatures were equal' (Birnbaum 1993, p. 3), can be seen in the black Madonnas of Europe and South America, as well as in tribes that revere women for their reproductive powers. All such societies ended abruptly with the arrival of the patriarchal, war-oriented Indo-Europeans in the middle of the fourth millennium BCE; they subjugated human women and tamed, desexualized, or slew their Goddesses.

Although some women and men find such a vision of the past to be liberating for the future, others find much to criticize (Conkey and Tringham 1995, Eller 2000, Motz 1997, Puttick 1997). How do we know what the female figurines represent without an adequate knowledge of the social systems that produced them? Is it possible that they had the same symbolic meaning over nearly 30,000 years? Is it not feminist essentialism to argue that all the figurines connote fertility, as if women have always been defined biologically? Most historical Goddesses, indeed, are

not tied to fertility at all. And if it is allowable to read back to Old Europe by citing modern-day 'survivals,' what about contemporary groups in which there is matrilineality but male control, ritualized fertility but no Goddess worship, and Goddess veneration but little respect for women? The brunt of such criticisms is that the past is oppressive, not golden; it ill serves the women's movement to idealize something unproven.

5. *Is She 'Good' for Women?*

Definitions of women and Goddesses that rely too much on biological determinism, Jungian archetypes, and the 'Goddess Hypothesis' are not the only contested issues in the Goddess movement. Another is the relationship between Goddess-worshipping societies and the status of their women. Do Goddesses serve patriarchal interests, or feminist ones? The evidence is mixed; although some Goddesses appear to serve their human devotees by undercutting patriarchal subordination, and although some women find strength in images of the divine feminine, other Goddesses reinforce their societies' domination of women, such that feminists refuse to call upon them.

First, some positive correlations. Many modern Western women do indeed derive inspiration from their worship of Goddess figures: Luisah Teish, who looks to West African ancestor veneration; Charlene Spretnak, Christine Downing, and Carol Christ, who have found spiritual homes with the Goddesses of the Mediterranean; China Galland, whose life was changed by encountering Tārā; and Rita Gross, who testifies about the inner transformation she experiences through the worship of Vajrayoginī. Very often, one woman's metamorphosis leads to another's, as occurs through the women's pilgrimages to Crete led by Carol Christ.

It is not only Western women who are thus empowered. To take a few examples from South Asia, the audacity of the Goddess Rādhā vis-à-vis her lover Kṛṣṇa provides Bengali women with models of assertiveness and resistance (Wulff 1997); forms of Durgā empower Hindu devotees and holy women by their autonomy and puissance (Erndl 1997); women Tantrikas of the Tibetan Buddhist tradition find their spiritual aspirations mirrored in powerful images of the feminine divinity (Shaw 1994); and the activist Mother's Front in Sri Lanka worships Kālī for fortitude in the midst of the civil war (de Alwis 1999). Sometimes the Goddess herself overturns patriarchal values; the South Indian Goddess Kāṛumāriamman allows menstruating women into her temple (Narayanan 1999, p. 69).

But there are also contrary indications. All 10 Goddesses whom David Kinsley (1989) describes in *The Goddesses' Mirror* belong to societies in which men dominate women; the same is true for those

catalogued by Motz (1997). Other scholars find similarly depressing inverse correlations between Goddess worship and freedom for women. Again, from South Asia: William Sax investigates the north Indian devotion to Nandādevī and finds that while the Goddess represents the trials of out-married daughters, her cult enables rather than undercuts their sorrows (1991); China Galland visits Bhaktapur, Nepal, and describes both her delight in the beauty of Durgā worship and her horror at the thriving trade in child prostitution which exists alongside it (1998); and Lisa Hallstrom discovers that although devotees view the modern saint Ānandamayī Mā as an incarnation of the Goddess, she is not considered a 'woman,' and feminist interpretations of her significance are discouraged (1999). The frustration of such a disjunction between expectations and reality is summed up by an eight-year-old girl in a story by Mrinal Pande: 'when you people don't love girls, why do pretend to worship them?' (1990, p. 63).

Many women's activists in countries such as India, therefore, eschew Goddesses as aids in their struggles. For Goddesses can validate a sexist model, as in the case of Sītā, the virtuous wife of Rāma, or represent a romanticization of the past and a glorification of motherhood. Indian feminists, after initially turning to Kālī and Durgā as symbols of empowerment, found them usurped by Hindu nationalists and deployed for divisive ends (Agnes 1995). One example is Durgā Vāhinī, or Durgā's Army, a Hindu nationalist women's group. The Vāhinī has revived female militancy—not in the service of women's issues (caste, divorce, dowry, sati, or marital violence), which are not debated or fought for, but against Muslims (Pathak and Sengupta 1995). The eight-armed Durgā gives women a new identity, but an identity that serves patriarchal values.

6. Trends, Evaluations

Goddess worship, wherever it is found, is diverse and controversial. Particularly since 1985 in the West, it is also a place where the popular and the scholarly meet and spar. Sometimes academic authors bemoan the theoretical backwardness that characterizes the public enthusiasm for Goddess spirituality and matriarchal histories, complaining that exhorting women to realize that 'we're all Goddesses within!' vitiates the need for external change (di Leonardo 1998, pp. 104–7). But sometimes the meetings between popular and scholarly are not so antagonistic: Goddess-revering people of all stripes can and do join hands when it comes to issues of social justice and eco-spiritualism.

The revived Goddess spirituality of the West also provides opportunities for encounters of other types. The increasing ethnic mix of Western societies means that 'new' Goddess worshippers come into contact with

those for whom Goddesses are a traditional part of their religious backgrounds. Sometimes Western votaries find this an inspiring, deepening encounter, and sometimes they do not. How, for instance, is one to incorporate the traditional practice of goat sacrifice into one's Western worship of Kālī? By the same token, many first- and second-generation immigrants find the appropriation of their Goddesses by mainly white Americans to be offensive. The Goddess movement is obviously a fertile field for intercultural exchange.

How then to evaluate this refashioning of 'old' Goddesses in the service of 'new' ideals and hopes? While from an academic perspective one might deplore the 'Goddess Hypothesis,' biological determinism, the perceived exploitation of 'other people's symbols,' and a naive assumption that all women everywhere benefit from the Goddess, the debate, creativity, and diversity characteristic of 'new' Goddess worship in the West are evidence of laudable cultural vibrancy. Goddesses may not always, or even often, provide alternative models for women in today's global societies. But as various studies have shown, in religious groups where women do have a leadership role, there is typically a feminine aspect to God (Sered 1994). Rita Gross makes the point differently when she asserts that even if Goddesses do not confer status or independence to women, they do contribute to psychological well-being. 'Though the presence of goddesses does not guarantee equity for women, their absence almost certainly guarantees inequity for women' (1998, p. 161). A final example from India: just because the slain Mrs. Gandhi was depicted in the press as a mother Goddess killed by her ungrateful Sikh children, who therefore deserved the violence unleashed upon them, there is no reason that Goddess symbolism, wrested from nationalist agendas and purposely reworked, could not be used for healing and hope. To echo Christ, echoing Geertz: people change as symbols change, and vice versa. That the denizens of the Goddess movement are trying to push this mutual process forward to their own ends is neither surprising nor unprecedented, though where the Goddesses 'take hold' and in what forms are matters for future interest.

R. F. McDermott

Goffman, Erving (1921–82)

The work of the sociologist Erving Goffman is regarded as a classic by most of his professional colleagues. Randall Collins (1988, p. 41) even considers him 'the greatest sociologist of the latter half of the twentieth century.' Goffman's influence, particularly on many younger researchers, is still powerful at the beginning of the twenty-first century and is by no means restricted to sociology. Goffman's works have been influential in numerous parallel disciplines, above all in social psychology, linguistics, philosophy, literature studies, pedagogics, psychiatry, and media studies. It cannot be denied that Goffman made important empirical, theoretical, and methodological contributions. The following essay will discuss them against the background of a short biographical sketch and relate them to relevant sociological contexts of discussions.

1. Biographical Sketch

Erving Goffman was born in the small Canadian town of Manville on July 11, 1922, the son of Russian-Jewish immigrants. He began his academic career at the University of Toronto, where he took his BA in 1945. After completing his sociology studies at the University of Chicago, USA, where he primarily studied under Everett C. Hughes and W. Lloyd Warner, he took up his first post in Scotland, UK. From 1949 to 1951 he worked at the Department of Social Anthropology at Edinburgh University. After that he returned to Chicago, where he gained his doctorate with his thesis *Communication Conduct in an Island Community*, which he had prepared in Scotland. The empirical basis of his dissertation, which was supervised by W. Lloyd Warner, Donald Horton and Anselm L. Strauss, was a field study on the Shetland Islands. Following a spell as research assistant at the Department of Sociology at Chicago University, where his research included social stratification, Goffman was employed as a Visiting Scientist in the Laboratory of Socio-Environmental Studies at the National Institute of Mental Health (NIMH) in Bethesda (Maryland) from mid-1954 to the end of 1957. During this time Goffman carried out a one-year study in a mental hospital. This study on the basis of 'participant observation' formed the essential foundation of his book *Asylums* (1961a). In 1958 Goffman transferred to Berkeley as Assistant Professor of

Sociology and member of the Center for the Integration of Social Science Theory at the University of California. From 1962 he was a Full Professor in Berkeley. In 1968 he accepted the Benjamin Franklin Professorship at the University of Pennsylvania in Philadelphia, where he substantially advanced his research program and wrote his *chef d'oeuvre* 'Frame Analysis' (1974).

His works, which reached a wide academic and non-academic audience and have been translated into many languages, earned Goffman numerous honors. He received a number of prestigious awards and was Visiting Professor at several universities at home and abroad. In 1981 Goffman became President of the American Sociological Association (ASA). At the peak of his powers after an academic career of almost 30 years, Goffman died on November 20, 1982.

2. Goffman's Work

2.1 Research Program and Intellectual Context

Goffman's main theme was the forms of immediate social interaction, 'face-to-face' encounters. He saw in them a specific type of social system and a sociological field in its own right. In his Presidential Address delivered at the end of his term as President of the American Sociological Association shortly before his death, he declared: 'My concern over the years has been to promote acceptance of this face-to-face domain as an analytically viable one—a domain which might be titled for want of any happy name, the interaction order—a domain whose preferred method of study is microanalysis' (Goffman 1983, p. 2). This programmatic description of his position does not mean that Goffman regarded the interaction level as completely autonomous or socially fundamental. Rather he stressed the manifold 'relativity' of the autonomy of the interaction order. In many places in his works Goffman pointed out its historical variability as well as links ('a loose coupling') between the micro-level of the interaction and social macro-structures (e.g., social stratification or bureaucratic organization). However, Goffman did not systematically consider the historical and social conditions and dependencies of his subject. Rather he was primarily concerned with observing and discovering seemingly insignificant aspects of daily behavior. He focused on tiny moments of people's behavior, which they themselves find more or less natural and are unaware of: fleeting glances, physical contact and distance, apologies, greetings, compliments, silence, etc.

All Goffman's works, 11 books in total, are consistently oriented towards this empirical reality, but from the start Goffman also adopted means of interpretation from various sociological schools and traditions, including above all the 'classics' William James (see *James, William (1842–1910)*), Emile Durkheim (see *Durkheim, Emile (1858–1917)*) and

Georg Simmel (see *Simmel, Georg (1858–1918)*), structural functionalism (Alfred Radcliffe-Brown, Talcott Parsons (see *Mead, George Herbert (1863–1931)*)), representatives of the Chicago School (George H. Mead (see *Mead, George Herbert (1863–1931)*), Charles H. Cooley, Louis Wirth et al.), existentialism (Jean-Paul Sartre), ethology, ethnomethodology (Harold Garfinkel, Harvey Sacks), and sociolinguistics (Dell Hymes). But Goffman never regarded his theoretical references, models and metaphors as ends in themselves, they were rather means to the end of discovering and describing social order.

2.2 Approaches, Positions, and Results

In the following attempt to briefly summarize and appraise Goffman's work, a number of key sociological terms either coined or redefined by Goffman will be used as a guideline.

2.2.1 Dramaturgy. Goffman became known for his analysis of social life based on the model of the theater (see 1959), and his model has remained influential. It is too simple to speak of Goffman's work, as for example Jonathan Turner does, as the 'dramaturgical school of interactionism,' but it can be demonstrated that the dramaturgical perspective consistently played an important role for Goffman. It can similarly be proved that Goffman's dramaturgical approach partly anticipated and formed a basis for many of his later constructs. This particularly applies to his works on strategic interaction, ritual, territoriality, identity, and stigma.

Within the context of the theater model Goffman reconstructed above all the strategies of social 'face work': forms of concealment, lying, self-stylizing, mystification, the manipulation of 'facades,' etc. His aim here was not just to show how individuals, selfish subjects in the fight for social recognition, attempt to present themselves in the best light; rather he constantly also saw dramaturgical everyday life as producing and reproducing social order, a restrictedly open and widely endangered process that is to be permanently established.

Goffman's dramaturgical approach and his later reflections on social territories (1971) and frames (1974) also help us understand the spatial organization (social ecology) of modern society. For example, it becomes clear that normality is a fictional impression to be produced by differentiating distinct spheres of perception, audiences, and representations; it is the foundation for the actors' basic social trust. Goffman's differentiation between 'frontstage' and 'backstage' (see 1959) became famous in this context.

2.2.2 Roles and identities. Goffman's early works in particular are to be seen in the context of role theory,

influential at the time, which he criticized and developed further. Goffman treated role analysis primarily as interaction analysis, investigating the functioning and organization of the ‘actual’ practice of performing a role against the background of its normative frame. Thus Goffman developed concepts of patterns and styles of behavior, including the term ‘role distance’ (see 1961b), which has meanwhile acquired the status of a basic sociological term and which refers to a way of behavior which comments on the role and primarily serves either the interaction system or the selves relevant in the situation. For example, Goffman described a five-year-old boy riding a roundabout horse who by little irreverences in his behavior demonstrates that his current role does not correspond to his ‘true,’ ‘more adult’ self.

In *Stigma* (1963), Goffman differentiated the term ‘self’ in the context of an identity theory which distinguishes three types of identity in a basic sense that is still valid at the beginning of the twenty-first century: (a) social identity as a person’s role set, (b) personal identity as a person’s synchronic and diachronic individuality ascribed to him by observers, and (c) ego identity as a person’s inner self-reference. Goffman used these concepts of identity together with the instruments of his dramaturgical approach above all in analyzing stigmatized deviations and deviants. He focused on the techniques of information control and emotion management of the stigmatized people as well as on the consequences of the stigmatization for their identities and socialization.

2.2.3 Total institutions. Goffman’s book *Asylums* (1961a) represents an exception among his works in that it systematically goes beyond the interaction level. It describes a class of social organizations that has to do with confining, controlling and ‘altering’ people, such as mental hospitals, prisons, convents, homes, barracks, concentration camps, etc. However, Goffman’s (1961a) investigated such ‘total institutions’, where the most elementary matters of course and norms of everyday interaction are broken, with the aim of exposing the interaction order and the self connected with it. Beyond that, Goffman’s analysis demonstrated that total institutions form an ambivalent milieu for socialization. On the one hand they act as machinery for disciplining and normalizing behavior and interaction. On the other hand these institutions damage the moral self, e.g., self-respect and modesty, through various forms of humiliation.

2.2.4 Ritualizations. In his work Goffman repeatedly dealt with the moral sides of the interaction order. For Goffman the self is a moral fact which implies rights and duties when showing respect and which can be observed in ritual practices and codes of every-

day interaction. Every person appears as both subject and object of a ritual ‘language,’ a ‘language’ of politeness, decency, and tact, but also on occasion of contempt, wounding, humiliation, etc. (see Goffman 1967).

At the end of his career Goffman elaborated his early ritual model to include ethological and frame theoretical considerations, on the basis of which he analyzed gender interactions and the interpretative patterns they are based on (see 1979). Goffman depicted gender as a combination of ritual styles of presentation representing beliefs about gender-specific essential attributes. These beliefs amount to a schematic asymmetry similar to that of the parent-child relationship. In daily interaction life and its media depictions (e.g., in advertising) men appear as superior beings to women by ritualizations of dress, physical contact, smiling, activity, etc.

2.2.5 Strategic interactions. For Goffman, ritualizations represented the most important social condition of profit-oriented strategic action on the level of interaction. Totally ignoring their contents, he analyzed this action within the framework of a model of strategic interaction oriented towards game theory (see 1969). The main point of departure and aim of Goffman’s respective considerations were the social situation in which the subjects strive for control of the ‘definitions’ of the other players or rivals. Following on from his dramaturgical approach, Goffman above all investigated the conditions of competence and limits of ‘impression management,’ the strategically relevant interpretations of expression (e.g., of the body), the logic of reciprocal strategic observation and assessment, as well as the complexity of meaning and virtuosity of strategic moves. The empirical basis of the investigation consisted in particular in self-descriptions by a wide variety of strategic subjects (spies, confidence tricksters, adulterers, politicians, etc.). Goffman ‘translated’ their practical knowledge of action (knowledge of cleverness) into the categories of his analytic description, e.g., a typology of strategic moves.

2.2.6 Frames and framing subjects. *Frame Analysis* (1974) can be regarded as Goffman’s main theoretical work, because it integrates, or could integrate, the many various analytic perspectives and terminological distinctions of his earlier works. *Frame Analysis* itself therefore forms something like a frame. It is characterized by two basic orientations. On the one hand, the interest is directed at ‘structures’ and procedures for establishing meaning which are effective in generating normality in social situations and which are valid, independent of these situations. On this level, which can be compared with the grammar

of a language, Goffman revealed basic types of meaning and complex possibilities of transforming meaning (play, experiment, demonstration, etc.). On the other hand, on the level of the concrete situative events he aimed both at normal uncertainties, dangers, and the pressure to conform, as well as at extreme forms of abnormality, such as the 'negative experiences' of inmates of mental hospitals, whose habitual framings, which have proved their worth in everyday life, fail in the institution. The individual, whom Goffman revealed as the subject of the framing, is characterized by enormous powers of judgment and virtuosity, particularly in functionally complementing rules and also in manipulating them.

2.2.7 Forms of talk. In his last period, Goffman built on earlier studies and particularly concerned himself with conversations. The main result of this work is his book *Forms of Talk* (1981), which Goffman specifically placed in the context of *Frame Analysis*, one chapter of which was already devoted to conversations.

Goffman's late focusing on conversations can be seen in connection with the emergence of conversation analysis as a branch of ethnomethodology, which he approved of, but also criticized (see Bergmann 1991). In contrast to conversation analysis, which tends to conceptualize the process of communication as an autonomously organized system, Goffman stressed the importance of ritual order, which is always culture-specific and which permits selves and consequently psychological states to develop. Goffman basically rejected the assumption by conversation analysts that sections of a conversation can be analyzed without reference to their situational and extra-situational contexts. Moreover, Goffman was mainly interested in a sociological approach to the contextuality of social processes. *Frame Analysis* represents this approach.

2.3 Goffman's Methods

Goffman's work is essentially the result of the author's talents, in particular his personal sensitivity, the subtlety of his powers of observation, and his ability to classify his material in his search for order. He displayed these talents in the course of practical research, which struck most observers as unconventional, even puzzling. Among the most irritating points are Goffman's data, whose heterogeneity can hardly be exceeded. In his works the reader comes across personal everyday experiences, novels, autobiographies, the daily press, essays by film critics, photographs, etc. In many other respects Goffman also deviated from the normal forms of sociological discourse. He abbreviated the traditional terminological vocabulary of his field, avoided lengthy argumentation, frequently changed perspective, focused on seemingly unimportant

details, commented in an autoreflective manner on his own work, made ironic remarks and repeatedly told or referred to 'stories.' What is most important is that Goffman did not conform to any methodological canon, rather his methods entirely depended on the subject. This meant first of all that it was necessary to forgo certain traditional research methods. For example, the fact that those patterns of behavior that interested Goffman were generally unconscious ones meant that interviews were largely or totally impossible.

Goffman himself described his procedure as primarily 'naturalistic.' The scope of what he meant by that ranged from 'participant observation' (even in his own everyday life) to work with audio-visual recordings. His aim was always to get as close as possible to 'social nature' and to capture it as accurately as possible. On the other hand Goffman tried to achieve analytic distance and obtain information by various forms of 'alienation.' Alongside systematic work with models such as that of the theater, his most important technique was the strategy of alienation, which Paul Drew and Anthony Wootton (1988, p. 7) called 'the investigation of the normal through the abnormal.' Goffman employed totally different forms of abnormality, such as stigmatizations, espionage, accidents, or celebrities as approaches to the logic of everyday normality.

In order to convert into texts the results that were generated by his methodological dialectic of approaching and distancing Goffman combined two strategies. On the one hand he developed a formal analytical language which contains the basic features of the interaction order and the self connected with it. On the other hand he employed a strategy of 'thick description' (C. Geertz). By using a literary style, a metaphorical language suited to the specific subject, and extensive quotations from his material, cleverly combined with his analytical observations, he succeeded in making his subject appear alive and viewing it in a new light.

3. Goffman's Importance for the Social Sciences Today

It is not easy to judge how relevant Goffman's work is for the social sciences at the beginning of the twenty-first century; its main significance probably lies in his contribution to discovering the interaction order. In this way Goffman opened up a specific research area and at the same time provided central categories and strategies for exploring it.

But quite apart from interaction sociology, Goffman also had a strong influence on a number of other research areas and he remains influential today. This is especially true of many aspects of research into identity and socialization. Of prime importance among them are Goffman's reflections on institutional control and

discipline procedures, and on subjectivity. Goffman is especially appreciated today in research on normality and deviation as well as in gender studies, where some of his works are still standards now. In addition, he has a significant influence not only on the level of the everyday interaction order, but also on the sociology of certain social fields of action (politics, advertising, science, etc.) and in media research, where many of Goffman's analytical instruments have proved to be valid. Furthermore it can be seen that recently Goffman's works have increasingly been read and discussed from the point of view of general theories of civilization and society. For example, parallels have been drawn and connections made with the works of Norbert Elias (see *Elias, Norbert (1897–1990)*), Michel Foucault (see *Foucault, Michel (1926–84)*), and Pierre Bourdieu (see Willems 1997). In general it is a remarkable fact that widely differing and contrasting schools have incorporated parts of Goffman's works. The spectrum of positions Goffman is 'relevant' for, ranges from modern systems theory through critical theory, right down to the rational-choice approach.

Just as the reactions to Goffman's work have been wide-ranging and many-sided, so evaluations of its scope and its identity have differed greatly. While most people see the importance of Goffman's work essentially on the level of empirical micro-observation, others (e.g., Anthony Giddens) believe that in it there is to be found a systematic theory that goes beyond the level of micro-sociology and is highly significant for the development of the social sciences. Similarly, various labels have been attached to Goffman's thinking (symbolic interactionism, phenomenology, role theory, structuralism, ethnomethodology, etc.).

No matter how the situation of his reception is to be judged, it cannot be denied that Goffman left behind a series of studies that are still relevant and influential today and a network of concepts that is both highly complex and highly integrated. Perhaps an equally important part of his legacy is the paradigm he provided by the style and ethos of his research.

Goodness of Fit: Overview

Many statistical methods make assumptions about, or have consequences for, particular distributions of certain quantities. Goodness-of-fit methods assess the extent to which such assumptions or consequences are supported by the data. Similarly, in the process of model search or model selection within a particular choice of statistical distribution or model form, goodness-of-fit approaches are used to guide the process of arriving at a sensible parsimonious model that captures the main features of the data.

This article describes the general philosophy of assessing the goodness of fit of models and distributions in the context of statistical analyses. The following sections address, in turn, the distinction between significance tests and goodness-of-fit tests, the role of alternative test criteria, and distributional plots for assessing goodness of fit, the role of frequentist goodness-of-fit criteria in model selection, as well as Bayesian approaches. Because there is an inevitable trade-off between the desire for model parsimony and models that fit well, it seems wise to give up the notion that a model might be 'true,' and instead think about choosing a model because its usefulness is reasonable.

For a detailed consideration of some specific tests and diagnostic measures in the context of assessing the adequacy of distributional assumptions see *Goodness-of-fit Tests and Diagnostics*. For detailed uses of the different approaches to goodness of fit see *Multivariate Analysis: Discrete Variables (Loglinear Models)*; *Linear Hypothesis: Regression (Basics)*; *Linear Hypothesis: Regression (Graphics)*.

1. Goodness of Fit for Categorical Data

Karl Pearson (1900) originally proposed his chi-squared test as a way to test the fit of probability model involving k parameters, by comparing a set of observations $O_1, O_2, \dots, O_t$, in t non-overlapping classes with their expectations under the model, $E_1, E_2, \dots, E_t$:

$$X^2 = \sum_{i=1}^t \frac{(O_i - E_i)^2}{E_i} \quad (1)$$

In most practical situations, the values of $E_1, E_2, \dots, E_t$ involve estimates of the k parameters of the model. Then for large samples, the distribution of X^2 is approximated by the χ^2 distribution with $t - k - 1$ degrees of freedom when the probability model is in fact correct (see the discussion in *Goodness-of-fit Tests and Diagnostics* and in Bishop et al. 1975, for details on conditions associated with the estimates used, etc.). For categorical data problems such as those arising in the analysis of contingency table data (see *Multivariate Analysis: Discrete Variables (Overview)*), a widely used alternative to X^2 is the log-likelihood ratio test which is also referred to as the ‘deviance.’ Both of these are members of the power-divergence family of goodness-of-fit statistics proposed by Read and Cressie (1988):

$$K_\lambda(\mathbf{O}, \mathbf{E}) = \frac{2}{\lambda(\lambda+1)} \sum_{i=1}^t O_i \left[\left(\frac{O_i}{E_i} \right)^\lambda - 1 \right] \quad (2)$$

where λ is a real-valued parameter in the interval $-\infty < \lambda < \infty$. The statistic X^2 corresponds to $\lambda = 1$, and the log-likelihood ratio statistic corresponds to the limit as $\lambda \rightarrow 0$. All of the members of this power-divergence family of statistics are asymptotically equivalent. Read and Cressie (1988) describe some rationales for the choice of value of λ .

To test the fit of a specific model, e.g., the model of independence in a two-way contingency table, the chi-squared test uses an omnibus alternative, e.g., dependence. The p -value of the test, is the probability of observing a discrepancy as large or larger than that observed under the hypothesized null distribution, where ‘discrepancy’ is measured by the particular distance metric $K_\lambda(\mathbf{O}, \mathbf{E})$ of equation (2). But in many circumstances testing the goodness of fit of a model is not viewed as being the same as doing a test of hypothesis or test of significance. Not rejecting the null hypothesis at some arbitrary p -value is often taken as evidence that the model provides an acceptable fit to the data (cf. the discussion in Bishop et al. 1975).

Goodness-of-fit test statistics are, of course, sensitive to the sample size n , and to the real class of alternative models of interest. Suppose the null model is not exactly true (as is nearly always the case). Then,

with a large enough value of n , one will almost surely conclude that the null model does not fit the data. For modest values of n the situation is more complex, and will result in small p -values for some alternatives, while for others the model may appear to fit the data reasonably well. And if the data are sparse, i.e., if the sample size, n is small relative to the number of cells t , or the number of parameters being estimated k , then the p -value computed by reference to the corresponding χ^2 distribution will inevitably suggest that the model fits even when it does not (cf., Koehler and Larntz 1980). Thus, the p -value of a chi-square test alone gives limited guidance on whether the hypothesized distribution is close enough to being correct that the conclusions of the analysis can be relied upon. When goodness-of-fit tests are used for model comparison and model search some of these problems can be attenuated, as is described in Sect. 3.

2. Other Goodness-of-fit Approaches Focused on Empirical Distributions

Other classes of goodness-of-fit tests are of special interest when one is focused on the appropriateness of a specific parametric model for some underlying cumulative distribution function, $F(x)$. What is often done in such circumstances is to compute the empirical distribution function $F_n(x)$, whose value at x is the fraction of the sample with values less than or equal to x , i.e., $\{\#x_i \leq x\}$, and then compare $F_n(x)$ with $F(x)$. Well known examples of such tests include the Kolmogorov–Smirnov test, the Cramer–von Mises test, the Anderson–Darling, and the Neyman smooth test. These, and related diagnostics, are described in *Goodness-of-fit Tests and Diagnostics*.

One of the most widely used diagnostic methods for checking the fit of a model is the quantile–quantile or ($Q-Q$) plot, which plots the quantiles of the empirical distribution $F_n(x)$, against the quantiles of the assumed distribution $F(x)$. A straight line through the origin at a 45 degree slope indicates a perfect fit. The advantage of this method is that it can indicate where in the distribution the assumption is weakest. $Q-Q$ and other probability plots are described in Wilk and Gnanadesikan (1968) and are used in statistical practice. The interpretation of deviations from the line in such plots is, however, often subjective.

3. Classical Approaches to Model Comparison and Model Search

3.1 Model Comparison

Model comparison and model search are ubiquitous activities in modern statistical practice. When analysts

consider developing a regression model to describe a set of data, for example, they typically have a large number of possible variables available for inclusion in the model. What is well-known in the regression context is that the use of additional regression variables typically improves the ‘predictive fit’ of the model to the data (e.g., see Copas 1983) but including as many variables as possible is a poor strategy which does not hold up to scrutiny under cross-validation or when predictions are made for new observations (e.g., see the discussion in Copas, 1983, and Linhart and Zucchini 1986). Thus, at a minimum, statistical analysts engage in a series of model comparisons or tests in order to avoid the inclusion of ‘non-significant’ variables or terms in a model. This follows the scientific dictum known as ‘Occam’s razor,’ attributed to William of Occam (but see Thorburn 1918), which suggests that the simpler of two models should be the one chosen. For example, *t*-tests and *F*-tests are widely used in model selection procedures for regression and analysis of variance models (see *Linear Hypothesis*). Similarly, there are various chi-square test-based techniques for selecting among the class of loglinear models applicable for contingency table structures, and these typically (although not always) resemble corresponding model selection procedures for analysis of variance and regression models (see the discussions in Bishop et al. 1975, and Fienberg 1980).

3.2 Model Search

Several methods of penalizing large models to avoid overfitting have been proposed, many taking the form of choosing a model to minimize

$$-2 \log l + f(p_1, p_2, n) \quad (3)$$

where l is the likelihood ratio, f is the penalty assessed for choosing a model with p_1 parameters instead of a more parsimonious one with p_2 parameters, and n is the sample size. When the models are nested, i.e., one is a special case of the other, the quantity $-2 \log l$ is the likelihood ratio test for comparing them. Under the null hypothesis that the simpler model fits, this test statistic follows a χ^2 distribution when the sample size n is sufficiently large.

The choice $f(p_1, p_2, n) = 2(p_1 - p_2)$ corresponds to Akaike’s Information Criterion (Akaike 1973) or AIC, while $f(p_1, p_2, n) = (p_1 - p_2) \log n$ corresponds to Schwarz’s (1978), also referred to as the Bayesian Information Criterion or BIC. Other classical approaches to this problem include Mallows’s (1973) C_p statistic which is similar to AIC, and Allen’s (1974) PRESS which comes from a related prediction criterion.

These and other related penalized optimization approaches to model selection have been used in the regression setting involving continuous or categorical variables. Edwards (2000), for example, uses both AIC

and BIC and suggests variations on computationally efficient model search that take special advantage of the form of graphical models.

4. Bayesian Approaches to Goodness of Fit

Faced with the question of the adequacy of a particular parametric model, a natural Bayesian impulse is to embed the model in question in a parametric model of higher dimension (see Gelman et al. 1995). Having done so, how should a Bayesian evaluate the special model against the more general alternative?

One answer, espoused especially by George Box (1980) is to use a test of significance. However, the probability of observing an outcome as less or more extreme than that observed is only distantly related to goodness of fit, and violates the likelihood principle (see *Significance, Tests of; Likelihood in Statistics*).

A second answer, more in keeping with Bayesian ideas, is to impose a prior distribution on the larger parameter space created by embeddings. Every continuous prior distribution in this larger space has the consequence that the original model would have prior, and hence posterior, probability zero. It is for this reason that L. J. Savage advocated models ‘as big as an elephant’ (see Lindley 2000). A second type of prior distribution that might be used takes the form of a spike-and-slab, i.e., one that puts positive probability on the original model (the spike) and a continuous prior on the rest of the space (the slab). The posterior odds on the original model can then be expressed as the product of the prior odds and the ‘Bayes factor.’

Bayes factors have attracted attention because, in the case of only two alternatives, they give a quantity that depends on only the likelihood function and that indicates the strength of the evidence. Faced with more than two alternatives, and especially with a continuum of alternatives, the Bayes factor critically depends on the prior distribution in the alternative space. When the prior is close to the special model, the alternative is favored; when it puts most of its mass far from the special case, the special case is favored, as is reasonable. Attempts to overcome this dependence using heuristics claimed to be robust to changes in the prior on the alternative space include fractional Bayes factors (O’Hagan 1995) and so-called intrinsic Bayes factors (Berger and Perrichi 1996). Another difficulty with Bayes factors, highlighted by Kadane and Dickey (1980) is that the loss function associated with them is two-valued. Hence if the wrong model is chosen, one is assumed not to care whether the error is quantitatively trivial or not. This is an unreasonable way to think about model choice.

Each of these methods is based on the notion that a better model should fit the data better. If this were true, the very best model for any data set would put a probability of one on the data actually observed, so that whatever happened had to have happened. While such a model is useless for prediction, it does show that

other considerations such as prior beliefs about how the data might have been generated, and utility considerations, must enter into a full explanation of model choice.

Bayesians too have developed approaches that are analogous to the classical approaches discussed above which penalize large models to avoid ‘overfitting.’ For example, for the problem of variable selection for the normal linear model, George and Foster (2000) provide interpretations of AIC, C_p , BIC, and RIC (for Risk Inflation Criterion) under a specific hierarchical Bayesian formulation. Similarly, Madigan and Raftery (1994) suggest several such strategies using posterior model probabilities, including variations of Occam’s razor in order to discard models with low posterior probability. But there is limited agreement on the theoretical basis for such a strategy. Utility considerations should weigh heavily in choosing the form of a penalized search criteria, and there has not been (and it may not be possible for there to be) a convincing argument as to why a Bayesian’s utility ‘should’ be consistent with one of these forms and not another. By contrast, Leamer (1978) presents a more flexible, but *ad hoc* Bayesian view of what he terms ‘specification searches.’

Finally, we mention the proposal to use ‘Bayesian model averaging’ (see Hoeting et al. 1999), which combines posterior information across possible models instead of choosing directly from among them. This approach is closely related to some of the efforts to do Bayesian model selection, but has a further difficulty. The interpretation of parameters in a statistical model depends on other parameters in the model. Thus it remains unclear how to interpret posterior distributions for parameters based on combining results across posteriors for different models.

5. Conclusion

Given the goal of assessing whether a hypothesized statistical model or probabilistic distribution is so far from true as to jeopardize the intended use, it would seem wise to inquire as to the intended use. It would also seem wise not to expect a satisfactory procedure to be independent of the intended use. Second, it seems necessary to address the question of jeopardy, i.e., how much of what kind of departures might make invalid the intended inference. Clearly statisticians and others need to devote more effort to this important topic.

Part of the philosophy behind the objective of model search is to do what our recently deceased colleague Herbert Simon (1959) called ‘satisficing,’ that is to find a model that is good enough to capture the main features of the data but which we know is possibly imperfect in various dimensions. The late John Tukey often reminded statisticians and others that ‘the best is the enemy of the good.’ For many data sets and substantive problems, it is often a fruitless task to try

to choose the ‘best’ model—one which demonstrably dominates all others and whose assumptions can be shown to be correct. But there may be many ‘good’ models that serve the analyst’s purposes well without one that dominates. It is a good idea to pick one of them. Thus, it seems wise to give up the notion that a model might be ‘true.’ If, instead, models are thought of as useful ways of thinking about the world, choosing a model because of its usefulness is reasonable, even if formal ways of explaining that choice are now lacking.

For a detailed consideration of some specific tests and diagnostic measures in the context of assessing the adequacy of distributional assumptions see *Goodness-of-fit Tests and Diagnostics*. Raynor and Best (1989) provide a good technical discussion of specific goodness-of-fit test statistics, and Read and Cressie (1988) give an extended treatment of the power divergence family of statistics and their use for the analysis of categorical data models. Bishop et al. (1975), discuss model search and goodness of fit in the context of categorical data in a form consistent with the philosophical position presented here. Edwards (2000) and Linhart and Zucchini (1986) provide alternative, but useful discussions of related issues for various forms of linear and generalized linear models. Gelman et al. (1995) offer extended advice on Bayesian approaches to model checking.

Goodness-of-fit Tests and Diagnostics

The millennium year 2000 marked the 100th anniversary of the introduction of the first and possibly best known test of modern statistical inference: the chi-squared test of fit due to Pearson (1900). The purpose of a test of fit is to give an objective measure of how well a probability model agrees with observed data. Otherwise, as Pearson (1900, p. 171) said: 'the comparison of observation and theory in general amounts to a remark—based on no quantitative criterion.' Reviews of Pearson's paper may be found in Plackett (1983) and Rayner and Best (1989, Sect. 2.2).

Rayner and Best (1989) identify three benefits of having applied a goodness-of-fit test:

- a compact description of the data;
- illumination of the data generation mechanisms; and
- validation, if that is the outcome, of distributional assumptions necessary for the application of powerful parametric procedures.

Pearson's chi-squared statistic compares the *observed* counts from a histogram of the data with the counts *expected* assuming that the hypothesized probability model is correct. In this form, Pearson's test addresses the one sample goodness-of-fit problem (see also *Goodness of Fit: Overview*). The multiple sample goodness-of-fit problem seeks to assess if data from a number of populations are consistent with having come from the same population. If the answer is affirmative, then the one sample question may be appropriate. We shall not address the multiple sample goodness-of-fit problem further here, beyond recommending Scholz and Stephens (1987) and Rayner and Rayner (1988) for references and recent work.

For continuous data and for discrete data for which pooling is used, the grouping of the data used in forming the Pearson chi-squared statistic leads to a loss of information. Another approach that does not group the data is to compare the sample or *empirical distribution function* (EDF) with the distribution function specified by the hypothesized probability distribution. The Russian mathematician Kolmogorov (1933) proposed the first EDF test of fit. EDF tests of fit, especially for continuous distributions, are reviewed in D'Agostino and Stephens (1986). Tests of fit for discrete distributions using the EDF approach and Cramer–Von Mises statistics are considered in Choulakian et al. (1994). See also Spinelli and Stephens (1997).

Another problem with Pearson's chi-squared test is that it is an omnibus test, with some power against general alternative distributions to the hypothesized distribution, but with relatively poor power against important directional alternatives. Alternatives which are often of great practical importance are differences between the data and the mean, variance and higher moments of the specified distribution. A test that does have good power at detecting these moment alternatives is Neyman's (1937) 'smooth' test. It has the useful property that it can readily be partitioned into components that give a powerful and detailed scrutiny of the data. See Rayner and Best (1989, Sect. 4.1) for a review of Neyman (1937).

In a series of papers, Rayner and Best developed the Neyman smooth tests to cover both categorized distributions and distributions involving nuisance parameters. See Rayner and Best (1989) for an overview, and their subsequent related papers. In the main, Rayner and Best use orthonormal functions, as did Neyman (1937), but permit nuisance parameters, following Thomas and Pierce (1979) and Kopecky and

Pierce (1979). The Rayner and Best smooth tests may be used to test for very general distributions, provided orthonormal functions on the specified distribution may be constructed. The resulting test is omnibus, weakly optimal, and the test statistic has a convenient asymptotic chi-squared distribution. Components are readily available, and these are asymptotically independent, each asymptotically having the standard normal distribution. The components are often well known tests of fit in their own right, but more importantly, permit a detailed, convenient and informative scrutiny of the data.

LaRiccia (1991) and Pena (1998) have developed different classes of smooth tests of fit using this approach.

The chi-squared tests, the EDF tests and the smooth tests of fit are the main families of tests of fit. Other tests of fit have been suggested, but we shall not consider these here, except to note that correlation tests are sometimes suggested in conjunction with quantile–quantile or probability plots of the data. The Shapiro–Wilk test of normality, for example, may be considered a correlation test. Again see D’Agostino and Stephens (1986).

1. Chi-squared Tests

For Pearson’s χ^2 test, sometimes called the chi-squared test, observations $O_1, O_2, \dots, O_m$ are assumed to come from m non-overlapping classes that are expected to contain $E_1, E_2, \dots, E_m$ observations. The test statistic is

$$\chi_P^2 = \sum_{i=1}^m (O_i - E_i)^2 / E_i.$$

Pearson (1900) initially assumed that for his test of fit, parameters of the probability models were known, and showed that the asymptotic distribution of χ_P^2 is the χ_{m-1}^2 distribution.

There is a considerable literature on how, when there is choice, the cells may best be constructed. The recommendation that for the χ^2 approximation to be adequate, the cell expectation be at least 5, goes back to Sir Ronald Fisher writing in the 1920s. This advice is now seen as extremely conservative. Mann and Wald (1942) suggested that cells be constructed to be equiprobable and that there be a specified number, k say, of such cells. In their recommendation, k increases with the sample of size n , and for even moderate sample sizes this will lead to a relatively large number of cells. It is now known that this can lead to a considerable loss of power, that sometimes the fewer the number of cells, the greater the power. Recent studies suggest that the greatest power can be achieved for heavy tailed distributions with larger k , while lighter-tailed alternatives require smaller k . Roscoe and Byars (1971) recommend that, with equiprobable cells, the average cell frequency should be at least one

with a 5 percent significance level, and at least two with a 1 percent significance level. If cells are not approximately equiprobable, these recommended frequencies should be doubled.

Most interesting applications involve estimating parameters. Pearson asserted that estimating parameters makes no difference. If the cell expectations are calculated from parameters estimated efficiently from the grouped data, then Sir Ronald Fisher, again writing in the 1920s, proved that degrees of freedom for the asymptotic distribution of the test statistic, χ_{PF}^2 say, needed to be reduced by one for each parameter estimated. The asymptotic distribution is χ_{m-q-1}^2 if q parameters are estimated. Chernoff and Lehmann (1954) showed that Pearson’s statistic no longer had an asymptotic chi-squared distribution if parameters were estimated from the raw or ungrouped data. There is a ‘partial recovery’ of the q degrees of freedom ‘lost’ by estimation. Rao and Robson (1974) gave a test of fit statistic χ_{RR}^2 that had an asymptotic χ_{m-1}^2 distribution no matter how many parameters were estimated, provided they are estimated efficiently from the ungrouped data. So all the degrees of freedom ‘lost’ by estimation are recovered by their statistic. Rayner and Best (1989, Sect. 7.4) compared the power performance of the tests based on χ_{PF}^2 and χ_{RR}^2 , and concluded that neither is uniformly superior: recovery of the degrees of freedom does not necessarily give a more powerful test.

There are many possible generalizations of the Pearson’s test. Neyman’s version is based on

$$\chi_N^2 = \sum_{i=1}^m (O_i - E_i)^2 / O_i.$$

One interesting possibility is the Cressie–Read family, based on the test statistic

$$I_\lambda = \frac{2}{\lambda(\lambda+1)} \sum_{i=1}^m O_i \left\{ \left(\frac{O_i}{E_i} \right)^\lambda - 1 \right\}.$$

Taking $\lambda = 1$ leads to χ_P^2 , $\lambda = -1$ leads to a modified likelihood ratio statistic, $\lambda = 0$ is the usual likelihood ratio statistic, $\lambda = 0.5$ is the Freeman–Tukey statistic, and $\lambda = -2$ leads to χ_N^2 . Other choices can lead to tests with excellent properties; see Read and Cressie (1988). Read and Cressie (1988) also illustrate the application χ^2 to testing fit of loglinear models (see also *Multivariate Analysis: Discrete Variables (Overview)*; *Multivariate Analysis: Discrete Variables (Loglinear Models)*).

2. EDF Tests

If we have n data points, the empirical distribution function (EDF) is

$$F_n(x) = (\text{number of observations} \leq x) / n.$$

Tests of fit for a hypothesized distribution function, $F(x)$, can be made by looking at the difference between $F_n(x)$ and $F(x)$ for each data point. Kolmogorov (1933) suggested the statistic

$$KS = \max_x |F_n(x) - F(x)|$$

while a generally more powerful test, is based on the Anderson–Darling (1954) statistic. The formula for this statistic can be simplified for various applications, as we illustrate below.

As, for example, in Stephens (1974), it can be shown that the EDF test statistics are linear combinations of components similar to the smooth test components, with decreasing weights. If the null hypothesis specifies a discrete distribution where the number of classes is fixed and not too large (say five or less) we suggest calculating χ^2 to assess goodness-of-fit. Otherwise, the Anderson–Darling test is a good choice, as it weights the important early moment components heavily and gives a powerful omnibus assessment. Looking at the first few components of Neyman’s smooth test in an exploratory data analysis manner complements this omnibus assessment. See the discussion in Sect. 4 below.

2.1 Example 1: Testing Normality

Consider the following set of examination marks from 20 students:

53, 15, 70, 73, 79, 48, 91, 20, 24, 91,
87, 15, 3, 78, 78, 62, 16, 15, 20, 32.

Are these data normally distributed? We now apply the Anderson–Darling test to answer this question. Calculate $\bar{x} = 48.5$ and $s = 30.8$ and then find $y_i = (x_i - \bar{x})/s$ for $i = 1, \dots, 20$, where x_i are the 20 exam marks. Next use a computer routine or tables of the standard normal distribution to find

$$z_i = F(y_i) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{y_i} e^{-\frac{1}{2}x^2} dx$$

and order the z_i as $z_{(1)}, z_{(2)}, \dots, z_{(n)}$. Then the Anderson–Darling statistic, AD say, is

$$AD = -n - n^{-1} \sum_{i=1}^n (2i-1) [\log z_{(i)} + \log(1 - z_{(n+1-i)})],$$

which, for the above data, takes the value 0.931. From tables of critical values such as D’Agostino and Stephens (1986, Table 4.9), or using MINITAB’s Normplot routine, we find a p -value of 0.014. This implies the normality hypothesis is doubtful and the marks are not well summarized by $\bar{x} \pm s$. We suggest a better summary below.

2.2 Example 2: Testing the Poisson Assumption

Consider the number of people in a shopping mall contributing to a charity collector during five-minute intervals:

Number of contributors	0	1	2	3	4	5	6	7	8
Number of intervals	9	27	26	17	10	8	4	3	1

We have $n = 105$. Let the observed and expected counts assuming a Poisson distribution be o_j and $e_j = np_j$, respectively, for $j = 0, 1, \dots, 8$. Now let $z_j = \sum_{i=0}^j (o_i - e_i)$ and $h_j = \sum_{i=0}^j p_i$, in which case

$$AD = n^{-1} \sum_{j=0}^8 z_j^2 \hat{p}_j / [\hat{h}_j (1 - \hat{h}_j)]$$

where the ‘ $\hat{\cdot}$ ’ indicates we have estimated the Poisson parameter by the sample mean. We find that $AD = 1.17824$, and, using Spinelli and Stephens (1997 Table 1), the p -value is between 0.025 and 0.050. Thus the distribution is not well fitted by a Poisson model. We discuss a possible alternative distribution in Sect. 4. It seems plausible that contributors come in clusters rather than at random, as a Poisson model would imply.

3. Neyman Smooth Tests

Suppose we wish to test for a probability density function $f_x(x; \beta)$, where $\beta = (\beta_1, \dots, \beta_q)^T$ is a q by 1 vector of parameters (such as μ and σ in the normal case). This null probability density function is nested in the order k probability density function

$$C(\theta, \beta) \exp \left\{ \sum_{i=1}^k \theta_i \pi_i(x; \beta) \right\} f_x(x; \beta),$$

where $\theta = (\theta_1, \dots, \theta_k)$ is a vector of k real parameters, $C(\theta, \beta)$ is a normalizing constant and $\{\pi_i(x; \beta)\}$ is a set of functions orthonormal on $f_x(x; \beta)$, so that for $f_x(x; \beta)$ continuous,

$$\int_{-\infty}^{\infty} \pi_i(x, \beta) \pi_j(x, \beta) f_x(x; \beta) dx = \delta_{ij} = 1$$

for $i = j$ and zero otherwise.

Sometimes $C(\theta, \beta)$ may not exist but the statistic we are about to define will. Using a random sample $X_1, \dots, X_n$ we test for $f_x(x; \beta)$ parametrically, by testing $H_0: \theta = 0$ versus $K: \theta \neq 0$ with β a vector of nuisance parameters. For small k the alternatives vary ‘smoothly’ from the null, in the sense of Neyman (1937). As an example of this, in testing for the standard normal distribution, the order one alternative is a normal distribution with a mean shift, the

order two alternative is a normal distribution with both a mean shift and a variance shift, and the third order alternative is more involved, with skewness differences to what might be expected as the distribution normal.

Neyman (1937) developed this approach for the case of no nuisance parameters. In this situation the probability integral transformation converts the problem of testing for a completely specified distribution to testing for the uniform (0, 1) distribution. Thomas and Pierce (1979) and Kopecky and Pierce (1979) considered smooth tests for general distributions involving nuisance parameters. These tests are based on a family of alternatives specified using powers of the cumulative distribution function rather than orthogonal polynomials as Neyman (1937) used, and as a consequence they require tables of coefficients for their implementation. The Rayner and Best formulation permits nuisance parameters and uses orthonormal functions, eliminating the need for tables of coefficients. For a more detailed account of the history of the smooth tests, see Rayner and Best (1989, Sect. 1.2).

When nuisance parameters are present, the smooth tests involve their maximum likelihood estimators. In several important cases, such as the binomial, Poisson and normal, these estimators are the solutions to the equations

$$\hat{V}_r = \sum_{j=1}^n \pi_r(X_j, \hat{\beta}) / \sqrt{n} = 0, \quad r = 1, \dots, q.$$

In such cases the smooth test is now based on the statistic

$$\hat{S}_k = \hat{V}_{q+1}^2 + \dots + \hat{V}_{q+k}^2.$$

The $\hat{V}_r$ are components of $\hat{S}_k$, and provide directional tests with high power in one direction and poor power elsewhere, complementing the omnibus test based on $\hat{S}_k$, which has moderate power in the k directions corresponding to the non-zero components. The omnibus test statistic $\hat{S}_k$ has the χ_k^2 distribution, central under the null distribution and noncentral under contiguous alternatives. It can be shown that the score test for testing $H_0: \theta_r = 0$ against $K_r: \theta_r \neq 0$ is based on the statistic $\hat{V}_r^2$. Being score tests, these tests are weakly optimal. If there are no nuisance parameters, no estimation is required and the results indicated hold with $q = 0$ and the $\hat{\beta}$ s removed from the test statistics. Bouleau and Ducharme (1995) give an example of what happens when the maximum likelihood estimators are *not* solutions of $\hat{V}_r = 0$ for $r = 1, \dots, q$.

We should emphasize that different $\{\pi_i(x; \beta)\}$ detect different alternatives using different tests. Which $\{\pi_i(x; \beta)\}$ should be chosen depends on which alternatives one hopes to detect most powerfully. If the distribution were uniform, as in Neyman (1937), we could take the (non-orthogonal) series $\{x^i\}$. The r th component would still compare the data and moments of the hypothesized distribution up to the r th. How-

ever, we prefer, like Neyman, to use orthonormal functions because the components are simply defined and are, at least asymptotically, independent. If it were desirable to test for periodic alternatives we would consider using the series $\{\sqrt{2} \sin(i\pi\sqrt{x})\}$. The aim is to find an orthonormal series that represents the alternatives of interest in as few terms as possible. Greater power results from doing this.

Each family of distributions to be detected requires an independent study. Given the choice of orthonormal family, the small sample distributions of the test statistics and their components should be investigated. Usually we use regression techniques to calculate corrections to the asymptotic null critical points; see Rayner and Best (1989) for details.

Again for each family of distributions we may compare, via simulation studies, the powers of the smooth tests we propose and the commonly used competitor tests. We give the general advice that in a testing context the most powerful goodness-of-fit test is likely to be the sum of the squares of the first two, three, or four non-zero components; $\hat{S}_4$ perhaps. We recommend augmenting this by the use of its components $\hat{V}_{q+1}, \dots, \hat{V}_{q+k}$ in an exploratory data analysis fashion. However, in particular cases there are variations to this advice.

We have so far studied the continuous and discrete uniform, univariate, bivariate and multivariate normal, exponential, geometric, binomial, univariate and bivariate Poisson. Details are in Rayner and Best (1989) and their subsequent relevant papers. In all cases the smooth tests are generally at least as powerful as the competitors studied, and the smooth tests have the added flexibility of meaningful components being available. So if the null hypothesis is rejected, its failure can be attributed to particular θ_i being non-zero, and an alternative model is suggested, namely

$$C(\hat{\theta}, \hat{\beta}) \exp \left\{ \sum_{i=q+1}^{q+k} \hat{\theta}_i \pi_i(x; \hat{\beta}) \right\} f_X(x; \hat{\beta})$$

where the $\hat{\theta}_i = \hat{V}_i / \sqrt{n}$ are unbiased, consistent and efficient estimators of the θ_i . This density estimate is a fortuitous by-product of the testing, and may be used to graph the data or as a basis for further inference, as in Carolan and Rayner (2001).

4. Diagnostics

In Sect. 2 we suggested use of the Anderson–Darling statistic as a test of fit. However, this will only tell us whether a given probability model fits the data well or not. It does not suggest or ‘diagnose’ how the data differs from the probability model. A histogram, density estimate or a Q–Q plot might shed some light on this difference, but interpretation of these plots is subjective. A more objective data scrutiny is given by calculating the components of Neyman’s smooth test which are approximately distributed as independent

standard normal random variables. We now illustrate this ‘diagnostic’ approach in our previous examples and one further example. There is no guarantee the diagnosis is correct (see Rayner et al. 1995), but it will be suggestive.

4.1 Example 1: Testing Normality Revisited

For the exam mark data in Section 2.1, calculate $y_i = (x_i - \bar{x})/s$. The orthonormal polynomials appropriate for testing normality are often called Hermite–Chebyshev polynomials. We have

$$\begin{aligned}\pi_1(y) &= y \\ \pi_2(y) &= (y^2 - 1)/\sqrt{2} \\ \pi_3(y) &= (y^3 - 3y)/\sqrt{6} \\ \pi_4(y) &= (y^4 - 6y^2 + 3)/\sqrt{24} \\ \pi_5(y) &= (y^5 - 10y^3 + 15y)/\sqrt{120} \\ \pi_6(y) &= (y^6 - 15y^4 + 45y^2 - 15)/\sqrt{720}\end{aligned}$$

and given these values we can calculate, for the above data, $\hat{V}_1 = \hat{V}_2 = 0$, due to the estimation of μ and σ from $\bar{x}$ and s respectively, and $\hat{V}_3 = -0.0361$, $\hat{V}_4 = -1.4656$, $\hat{V}_5 = -0.0462$, $\hat{V}_6 = 1.8907$. Note that $\hat{V}_3$ and $\hat{V}_4$ are standardized versions of the usual skewness and kurtosis coefficients. As $\hat{V}_3, \dots, \hat{V}_6$ have asymptotic standard normal distributions, we see that $\hat{V}_6$ is near significance at the 5 percent level and that $\hat{V}_4$ and $\hat{V}_6$ are much larger than the odd-order moment statistics $\hat{V}_3, \hat{V}_5$. These observations suggest an alternative probability model that is symmetric and shorter tailed than the normal. Thus a uniform distribution is a possibility so that we could summarize the data as ‘evenly’ spread over the range (0, 100) rather than as 48.5 ± 30.7 . If the odd order $\hat{V}_r$ had dominated the even order values then a skewed alternative model is suggested, while if both odd and even $\hat{V}_r$ are large, $|\hat{V}_r| > 1.65$ say, then a symmetric alternative with longer tails than the normal, such as the Laplace, is indicated.

What should be done if one or more $\hat{V}_r$ are significant but AD is not? One possibility would be to obtain more data and test the significance of those $\hat{V}_r$ previously significant.

4.2 Example 2: Testing the Poisson Assumption Revisited

For the Poisson, the appropriate orthonormal polynomials are known as Poisson–Charlier polynomials. We have

$$\pi_r(y) = \sqrt{(\lambda^r/r!)} \sum_{j=0}^r [(-1)^{r-j}] ({}^r C_j) (j!) (\lambda^{-j}) ({}^r C_j)$$

where $y = 0, 1, 2, \dots$, from which the first two orthonormal polynomials are

$$\begin{aligned}\pi_1(y) &= \sqrt{\lambda} (y/\lambda - 1) \\ \pi_2(y) &= \sqrt{\lambda^2/2} [y(y-1)/\lambda^2 - 2y/\lambda + 1].\end{aligned}$$

Due to the estimation of λ , $\hat{V}_1 = 0$. For the data here $\hat{V}_2 = 2.12$, indicating a model which has greater dispersion than the Poisson. Note that $\hat{V}_2$ is a standardized version of Fisher’s Poisson Index of Dispersion.

4.3 Example 3: Testing the Ordered Categories Discrete Uniform Distribution

In a market research trial, 40 consumers were asked for their color preference of five orange cordial drinks with orange colors ranging from ‘pale’ to ‘deep.’ Arranged in order of increasing orange color, the preference counts were 5, 10, 11, 10 and 4. If there were no color preference, the counts would all be expected to be eight. As there are only five unambiguous classes, a Pearson χ^2 could be used here. We have

$$\chi^2 = (5-8)^2/8 + (10-8)^2/8 + \dots + (4-8)^2 = 5.25$$

which, on using the asymptotic χ^2_4 distribution, gives a p -value of 0.27. Using the same formula for AD as that used for the Poisson test, we find the Anderson–Darling statistic takes the value 0.89. Consulting tables in Choulakian et al. (1994) we find the p -value is about 0.30. It appears the data are consistent with a discrete uniform distribution. However, we now compare expected and observed moments via components of Neyman’s smooth test. Here the orthonormal polynomials are the Chebyshev polynomials and the first two are

$$\begin{aligned}\pi_1(y) &= \sqrt{[12/(m^2-1)]} [y - (m+1)/2] \\ \pi_2(y) &= \sqrt{\{180/[(m^2-1)(m^2-4)]\}} \{[y - (m+1)/2]^2 \\ &\quad - (m^2-1)/12\}\end{aligned}$$

where m is the number of categories and $y = 1, 2, \dots, m$. The higher order $\pi_r(y)$, if needed, can be found by recurrence relation as in Emerson (1968). As in Stephens (1974), it can be shown that for the discrete uniform model

$$\chi^2 = \sum_{i=1}^m V_i^2 \quad \text{and} \quad AD = \sum_{i=1}^m [i(i+1)]^{-1} V_i^2$$

where the components are defined by

$$V_r = \sum_{j=1}^n \pi_r(X_j) / \sqrt{n}, \quad r = 1, \dots, m$$

since no nuisance parameters need estimation.

For these data, neither χ^2 nor AD was significant. However $V_1 = \sqrt{0.05} = 0.22$ and $V_2 = \sqrt{5.14} = 2.27$, indicating possible extra dispersion in the data compared with what was expected for the discrete uniform. We find that V_2^2 explains almost all χ^2 , so that dispersion differences are all that can be important. The consumers seem to have preferred a mid-range orange-colored drink. Unless it is the first component, AD will not be powerful if only one component is important, as in the present example. However, for many data sets, more than one component will be important, so that AD should usually have reasonable power.

In the above examples, examination of smooth test components gives an informative and thorough scrutiny of the data. Formal tests of significance would require the Bonferroni adjustment to the α level; here we are recommending an informal exploratory data analysis approach.

5. Conclusion

Statistical model assessment is at the heart of good statistical practice, and is the genesis of modern statistics (see *Goodness of Fit: Overview*). In general we suggest using the Anderson–Darling test as an omnibus test, augmented by the use of the components of the smooth tests in an exploratory data analysis fashion. This will assist in diagnosing the type of deviation from the hypothesized distribution. To find out more about the chi-squared and EDF tests see D’Agostino and Stephens (1986). For more about the smooth tests see Rayner and Best (1989).

J. C. W. Rayner and D. J. Best

Government Lawyers

Government lawyers are those officers and agents that provide legal counsel to government policy makers and represent governments in judicial proceedings. The term ‘government lawyers’ is not common in social science literature, and, generally speaking, studies of government lawyering focus on individual

offices (such as attorneys general, ministers of justice, solicitors general, district attorneys, etc.), or the legal policies of particular governments or administrations (such as the Thatcher Government or the Bush Administration, etc.). The reluctance to treat government attorneys as a group stems from the fact that they perform a wide variety of roles, from routine criminal prosecution to advising presidents or prime ministers on the broad policy concerns embedded in constitutional or statutory law. Moreover, the role of government lawyers, like the role of lawyers and courts generally, varies a great deal from one political system to the next. Nevertheless, commonalities do exist, and scholarly attention to the role of government lawyers has grown as their political importance has expanded alongside the legal-administrative and regulatory state.

1. Size, Structure, and History of Government Legal Offices

The structure, number, and size of government law offices usually reflects the broader constitutional structures and policy making processes of the regime. Thus, federal or confederal systems usually have separate law officers at the national level and at the state, *Länder*, or canton levels. Likewise, separation of power systems tend to have more legal offices than parliamentary systems, as during periods of conflict each branch of government finds it necessary to access independent legal advice and representation. In countries such as the United States, where there is federalism, a separation of powers, and where courts exercise sweeping policy making powers, governmental lawyers are both numerous and important policy makers (Clayton 1995).

There is no accurate count of the total number of lawyers employed by governments around the world, but in the USA alone the Department of Justice employs nearly 11,000 attorneys and has a budget in excess of \$21 billion (DOJ website 2000). Thousands more are employed in the general counsels' offices of various executive branch agencies and departments, including the White House Legal Counsel's Office. Congress too employs numerous attorneys, either in the House or Senate Legal Counsel's offices, or as staff counsel to various committees. Even the Supreme Court, since 1972, has employed attorneys in its own in-house legal counsel's office to advise the Court and its members. At the state level, governmental law offices range in size from the Department of Law in California, which employs nearly 1,000 lawyers, to relatively small Attorney General's offices in states such as Montana. In addition, many more attorneys work for cities, counties, municipalities, and other local governmental units (Clayton 1994).

The premier government attorney in the USA is the Attorney General. The office was established under

the Judiciary Act of 1789, and originally operated as a quasi-judicial institution. By the time Congress created the Department of Justice in 1870, the office had become thoroughly entrenched as part of the executive branch establishment. The Attorney General is appointed by the President and confirmed by the Senate. The office is a member of the Cabinet and a key advisor to the President on judicial selection and the making of administration policy. The Attorney General's transformation from quasi-judicial to executive, however, left deep tensions in its normative relationship to the President, especially during periods of separation of powers conflict (see Baker 1992). The office's relationship to other government lawyers has also changed over time. Originally, the Attorney General had little authority over the US District Attorneys (prosecutors in each federal judicial district), or over the solicitors that existed in executive branch departments and agencies. The early history of the Attorney General's office is marked by struggles to consolidate control over the federal governments' legal activities. Eventually, a division of labor emerged wherein agency legal counsel have assumed primary responsibility for advising and counseling government agencies and departments, and the Justice Department, under the direction of the Attorney General, has assumed nearly complete responsibility for conducting federal litigation and prosecution (see Horowitz 1977).

The Attorney General is an administrator of a large department. The office is assisted by a Deputy Attorney General, an Associate Attorney General, and a Solicitor General. The latter has evolved into an elite barristers office, responsible for conducting nearly all of the federal government's appellate litigation, enjoying a special relationship with the Supreme Court (Sakokar 1992). The Justice Department is divided into 15 major divisions and offices, including important policing and corrections divisions such as the Federal Bureau of Investigation, the Drug Enforcement Administration, the Marshals Service, the Immigration and Naturalization Service, and the Bureau of Prisons. The most important legal divisions, each headed by an Assistant Attorney General, include: Antitrust, Civil Rights, Land and Natural Resources, Criminal, Civil, and the Tax divisions. Additionally, the Office of Legal Counsel, also headed by an Assistant Attorney General, is responsible for authoring the official opinions of the Attorney General. Typically, these are considered binding within the executive branch but not binding on courts, although they are usually accorded respect by the judiciary.

In the USA, most state attorney generals' offices or law departments mirror the subject-area structure of the Justice Department's legal divisions. Thus, they are likely to have divisions for antitrust, tax, consumer protection, corporate regulation, etc. Several important distinctions exist at the state level in the USA, however. First, in most states the attorney general is responsible for providing legal advice to all branches

of government. Second, responsibility for nonlawyering functions (police, prisons, etc.) and for most criminal investigations and prosecution are not usually under the control of the attorney general, but under the control of other state-level administrators or locally elected prosecutors. Third, most state attorneys general are elected directly and politically independent of the governor and legislature (Clayton 1994).

In most other countries, the lawyering activities that involve broad policy concerns are usually also separated from those related to routine prosecutions, corrections, and policing. In many, an attorney general, or some similar office, is responsible for advising the government on legal matters, and for litigation enforcing public or political rights, while responsibility for prosecution, police, corrections, and the administration of justice is vested in a Minister of Justice or a Home Secretary.

In England, the Attorney General's title dates back to 1472. The modern office typically is held by a member of the House of Commons and an elected member of the majority political party. By convention, the Attorney General is not usually a member of the Cabinet, although most attend Cabinet meetings. The Solicitor General serves as a chief deputy. These two officials are known collectively as 'the Law Officers of the Crown' (Edwards 1964). Unlike its American counterpart, the Attorney General in England is not an administrator or department head. However, the office has supervisory responsibility over the Treasury Solicitor, the Director of Public Prosecutions as head of the Crown Prosecution Service, the Director of the Serious Fraud Office, and the Director of Public Prosecutions in Northern Ireland, and answers for each of these departments in Parliament.

The Law Officers' primary responsibility is to represent the public interest in court and act as the chief legal advisers to the government. On matters of political importance, the Attorney General personally will offer legal advice to the government. Routine legal advice, however, is provided to each department or ministry by the Treasury Solicitor's Department, or by small in-house departmental legal staffs, which are analogous to the general counsel's offices in various departments in the USA. The Treasury Solicitor's Department is the largest in-house legal organization and provides legal advice to administrative officials across the executive, including the departments of Treasury, the Cabinet Office, the Ministry of Defence, and the Departments for Education and Employment, and Culture, Media and Sport. The Department employs several hundred attorneys and it also assists the Attorney General in litigation to protect the public interest.

The Home Secretary is responsible for the police, and for administering immigration, the correctional system, and other law enforcement agencies. The appointment of judges is handled exclusively by the Lord Chancellor's Office, a part of the House of

Lords. The chief prosecutor in England is the Director of Public Prosecutions, an officer appointed by the Home Secretary and located in the Home Office, but who is responsible to the Attorney General in the exercise of prosecutorial discretion. The Director heads the Crown Prosecution Service, which is divided administratively into 42 separate areas, each corresponding to the boundaries of local police forces. Each area is headed by a Chief Crown Prosecutor who works with panels of local attorneys and case workers to prosecute crime in the crown courts. Crown Prosecutors report to the Director of Public Prosecutions, but in routine matters they are locally accountable to the public and cooperate closely with the area Chief Constable and other agencies in the criminal justice system. If criminal prosecutions raise serious political concerns, however, the Director of Public Prosecutions or the Attorney General may become involved and assume responsibility for the prosecution. As with much else in English government, prosecutorial independence is protected through custom and convention. Ever since the famed Campbell case, which brought the downfall of the Macdonald government in the 1920s, the constitutional rule is that the Attorney General may seek advice from the Cabinet when making prosecutorial decisions but contacts initiated in the other direction give rise to serious questions of propriety.

In countries influenced by the French and German models, prosecutors are often a part of the judiciary, or under judicial supervision in an essentially inquisitorial system. In such systems, judges and government prosecutors are often located administratively in the Ministry of Justice, but they are buffered from direct political control. In Italy, for instance, public prosecutors are under the constitutional control of the independently elected Supreme Judicial Council, or *Consiglio Superiore delle Magistratura*. Likewise, in Japan, a hybrid system, the Office of the Public Prosecutor is part of the Ministry of Justice (*Homusho*), but the Prosecutor General (*Kenji Socho*) is appointed directly by the Cabinet, and the Minister of Justice (*Homu Daijin*) is prohibited by law from exercising control over specific cases.

Even in systems more clearly based on the Anglo-American model, certain prosecutions, especially those involving government officials, are institutionally protected from political control. In England, the Attorney General's prosecutorial decision-making is protected by custom and convention. In the USA, following the infamous Watergate scandal, Congress established the office of the Independent Counsel. Independent counsels were appointed by a special division of the court and buffered from direct political control of the President or the Attorney General (Harriger 1992). Controversy surrounding the Independent Counsel's investigation of the Whitewater scandal and the eventual impeachment of President Clinton, however, led to the office's disestablishment

in 2000. Nevertheless, Attorney Generals continue to have authority to appoint 'special prosecutors' inside the Department of Justice, who enjoy nearly complete independence from political direction by the elected executive.

2. *The Intersection of Politics and Law in Government Lawyering*

Protecting prosecutorial independence is one part of a larger concern regarding the role of politics in government lawyering. In this respect, two separate problems dominate the scholarly literature in this area. The first has to do with the separation of powers and the litigating role of government lawyers during periods of constitutional conflict. Administrations who use government litigation to challenge established judicial precedents, for example, are often charged by critics with violating the rule of law or other constitutional constraints (Caplan 1988). Moreover, in the USA it is not uncommon for government lawyers representing different branches to disagree in court about the meaning of a statute or a constitutional provision. In *Morrison vs. Olson* (1988), for instance, Justice Department attorneys argued against the constitutionality of the Independent Counsel Act, while counsel for Congress defended the statute.

Conflicts such as these put government attorneys in an awkward ethical position, and raise serious questions about the appropriate role of government lawyers in a system of separated powers. Moreover, in the USA such conflicts have become more common as prolonged periods of divided government have led partisans increasingly to turn to courts and the administrative bureaucracy, rather than the routine legislative process, for policy making. Scholars and practitioners have written a great deal about the principles that should guide government lawyers when two or more branches disagree about the law. However, such principles are usually just as controversial as the contested notions of separation of powers upon which they rest.

While government lawyers in parliamentary systems escape the political entanglements caused by a separation of powers, they cannot avoid the 'politics' of partisan abuse, corruption, and favoritism. There has been a great deal of scholarly debate about which institutional structures best safeguard government lawyers from 'inappropriate' political pressures. Anglo-American systems have experimented with structural reforms, such as the Independent Counsel's Office, as well as informal protections such as conventions that prevent political leaders from contacting government prosecutors in particular cases. All such efforts, however, suffer from the difficulty of distinguishing between proper and improper political influences.

In a well-known case in the USA in 1971, for

example, President Nixon ordered the Justice Department to drop a pending antitrust suit against ITT Corporation in exchange for a \$400,000 donation to Nixon's re-election campaign. This led critics to argue for the construction of a 'fire-wall' that would prevent White House officials from contacting the Justice Department in particular cases. However, contrast that White House intervention with President Carter's 1978 decision to reverse the Justice Department's position in *Regents of the University of California vs. Bakke* (1978), the first major affirmative action case to reach the Supreme Court. Or consider whether President Clinton should have had no role in deciding whether the Justice Department should file antitrust charges against Microsoft Corporation in 1999. Some cases, whether civil or criminal, present legal issues or involve individuals in a way that the rule of law properly requires direction from democratically accountable officials. Others do not. However, there is no entirely satisfactory way to distinguish *a priori* between proper and improper political influences. Moreover, removing prosecutors from political control only shifts, but does not remove, the influence of partisanship. Critics of the Independent Counsel's office in the USA, for example, long complained that most investigations, such as those surrounding Watergate or the Iran-Contra scandals, were politically motivated (Eastland 1989).

By contrast, countries relying on the French and German models tend to protect prosecutorial independence by trying to remove it entirely from 'political' influence and lodging the power under the direction of the judiciary. Such systems thus trade off democratic accountability over criminal prosecution for judicial control. However, they too only shift, rather than remove, the sources of political influence and must also confront the difficulty of distinguishing between proper and improper influences. Even judicial officials are accountable to broader regime structures and they too can be subject to corruption and partisan abuse. Determined political leaders have had no more trouble influencing prosecutors administratively lodged in the judiciary as those in the executive. In the well-known Credit Lyonnais case in France, for instance, President François Mitterrand was able to use party influence to control decisions in the Ministry of Justice over the prosecution of corruption charges involving government ministers, and the French and Italian Socialist parties, and leading businessmen with alleged Mafia ties. Likewise, in Italy, where the independence of prosecutors is fixed constitutionally, a well-known effort to prosecute political corruption charges against more than 400 political figures, including several ministers and members of Parliament in the mid-1990s foundered when Parliament approved a law fixing a deadline for the disposal of cases. In a system notorious for delay and inefficiency, the law effectively gave immunity to many of those who had been indicted.

The intersection of law and politics in government lawyering, and the administrative structures governing it, will likely continue to dominate scholarly attention in the future. As noted above, existing studies of government lawyering tend to focus on particular offices or administrations. Little work of a comparative nature, either within, or across, different political systems has been undertaken, and this remains perhaps the most fruitful direction of future research.

Government Statistics

Government statistics are vital to advance the economic well-being and quality of life of a nation's citizens. Without such statistics, policy making would be less effective, economic markets would be less informed, and the countless decisions of private

businesses and individuals would allocate economic and other resources less efficiently. But more, government statistics are vital to a democracy, as the information they convey provides the means by which citizens can hold their government accountable.

This article provides a general review of government statistics largely in the context of the USA, but it also addresses broader issues relevant to other countries. The focus is on the national government and, therefore, mostly on national statistics, but much is also relevant to governments at subnational levels, which also produce statistics.

The article begins with the purposes of government statistics and the rationale for why governments produce them. Next it takes up the principles by which the statistics should be produced to serve these purposes effectively; this is followed by descriptions of various types of data collection, and of how the responsibilities for collection, analysis, and reporting of statistics are organized among statistical agencies. Effective practices of these agencies are identified. The entry concludes with a discussion of some challenges faced by statistical agencies.

Statistics from government sources are referred to in many entries in this Encyclopedia (see *Censuses: History and Methods*; *Censuses: Comparative International Aspects*; *Economic Panel Data*; *Sample Surveys: Cognitive Aspects of Survey Design*; *Large-scale Social Survey, Analysis of*).

1. What are Government Statistics?

'Government statistics' means factual information that is reported upon for statistical purposes by a unit of government. Some countries also use the term 'official statistics.' In this articles, 'statistics' and 'data' are used interchangeably to mean factual information, and the terms are not restricted to quantitative information. Usually, the unit or agency of government that issues the statistics has collected or compiled the data to produce them. In most cases, the agency is a distinct entity of government entrusted with reporting the statistics. In some cases, the agency may analyze its data to provide more information about the statistics in its reports, especially information that makes the statistics more relevant to public policy concerns. For the agency to be effective, the focus of any analysis must be on ways to improve the relevance and accuracy for use in public policy analysis and decision making, independently of any particular policy.

The *sine qua non* of the definition of government statistics is that they are reported upon only for *statistical purposes*:

'Statistical purposes include description, evaluation, analysis, inference, and research. For these purposes, a statistical agency may collect data from individuals, establishments, or

other organizations directly, or it may obtain data from administrative records, but it does not do so for administrative, regulatory, or enforcement purposes. Statistical purposes exclude any interest in an individual person or economic unit. The data are used solely to describe and analyze statistical patterns, trends, and relationships involving groups of persons or other units' (Martin et al. 2000)

2. *Why do Governments Produce National Statistics?*

A government provides statistics to inform its citizens, satisfying an essential requirement of a democracy (see, e.g., United Nations Economic and Social Council 1994). The government, however, is most often the primary user of the statistics it produces. The statistics are used in the formulation of, and decision making on, public policies, as well as in their implementation and evaluation. And the statistics are used for much private-sector and individual decision making. Information from statistics is, for example, vital to inform economic markets.

In most cases, a government collects and reports the statistics itself, either directly or through the services of a private organization. In some cases, the private sector satisfies the demand for national statistics. Examples are the Conference Board's compilation of US leading economic indicators, abortion statistics for many countries compiled by the Alan Guttmacher Institute, and many private market-research surveys and reports of economic forecasting firms. But even when the private sector can do so, there are reasons for a government to collect the statistics. Alternative sources may not exist. Timeliness may be a critical factor. Statistics collected by government agencies are often deemed to be of greater quality. And the government may collect statistics because they contain confidential information.

A more compelling reason may be trust and credibility. Potential subjects of government data collection may be more willing to volunteer their time and effort, and divulge confidential information, for a government survey rather than for a private one. And the public and other important users may find data collected by the government to be more credible.

A fundamental reason, however, for a government to collect data has to do with the very nature of data. If a commodity can be consumed by many and consumption by one does not reduce the consumption of others, then the commodity is a 'public good.' Data are manifestly public goods: use of data by one party in no way diminishes their usefulness to other parties. Individuals benefit from a public good but, unless each individual is charged for the consumption of the good, they are unlikely to pay for them voluntarily. Consequently, the goods may not be produced, unless the government intervenes. In the case of data, the government may intervene directly by collecting the data, or it may intervene indirectly, for example,

by defining rights for a license or copyright to provide the means for the private sector to charge for the value added in producing secondary data. For these reasons, a government typically provides primary data and the information infrastructure. The private sector typically provides secondary data and may build on the infrastructure.

3. *Principles of Government Statistics*

The US National Academy of Sciences–National Research Council report (Martin et al. 2000) defines a 'statistical agency' as a unit of government whose principal function is the compilation and analysis of data, and the dissemination of information for statistical purposes. The unit is recognized generally as a distinct entity, which may be located in a cabinet department or independent agency. The mission of a distinct entity or agency of government that issues government statistics may or may not be solely statistical. The USA has a highly decentralized statistical system, with over 70 agencies having direct funding of over \$500,000 per year for statistical activities. Only some of these agencies are statistical agencies.

Statistical agencies are established to be a credible source of accurate, timely, and relevant statistics in one or more subject areas. Accuracy requires proper concern for consistency in spatial and temporal dimensions, as well as statistical measures of error. Timeliness requires concern for the frequency of issuing data, as well as disseminating data to users when they need them. Relevance requires concern for anticipating future data needs, as well as meeting current ones. And credibility requires concern for both the reality and appearance of impartiality, as well as the reality and appearance of independence from political control. It is essential to the mission of statistical agencies to work to ensure the goals of accuracy, timeliness, relevance, and credibility of statistical information.

Martin et al. (2000) identify three principles for a statistical agency. First is that the agency is in a position to provide information relevant to issues of public policy. That requires the agency to be knowledgeable about public policy issues and be able to provide objective information that is relevant to the needs of formulating, implementing, and evaluating public policies. Second is that the agency has a relationship of mutual respect and trust with those who use its data and information. To develop that relationship, an agency must strive to maintain credibility for itself and for its data. In particular, the agency must be perceived to be free of political interference and policy advocacy. Other aspects that contribute to credibility are a commitment to quality and professional standards, and openness about all aspects of the data, especially the quality of the data.

The third principle is that the agency have a relationship of mutual respect and trust with respondents who provide data, and with all data subjects whose information it obtains. Statistical agencies rely in large part on information supplied by individuals and organizations outside the federal government, such as state and local governments, businesses, and other organizations. Some of this information is required by law, such as employers' wage reports, and some of it is compiled from records of government programs. But much of it is obtained through the voluntary cooperation of respondents to surveys. Even when the response to a survey is required by law, cooperation by respondents promotes accuracy (Edmonston and Schultze 1995), which, in turn, promotes the credibility of the agency's data. In encouraging cooperation, it is important to statistical agencies that respondents perceive that the information they are being asked for is important; that it is being collected in an impartial, professional manner; and that their personal information will remain confidential.

Confidentiality of individual responses means that the information will be used only for statistical purposes and that, in particular, it will not be used for any administrative, regulatory, or enforcement purpose regarding the individual (see *Confidentiality and Statistical Disclosure Limitation*). Statistical agencies go to great lengths to maintain the confidentiality of individual responses (see Duncan et al. 1993, Mackie and Bradburn 2000). Some, such as the US Bureau of the Census, have legislation to protect confidentiality, and some, such as the US Bureau of Labor Statistics, have a history of successful reliance on executive order, custom, and case law. A Federal Statistical Confidentiality Order (US Office of Management and Budget 1997) directs 12 statistical agencies not to disclose or use data acquired for exclusively statistical purposes in identifiable form for any other purpose unless otherwise compelled by law. In Europe, the 1995 European Community Directive on Data Protection governs the transfer of individually identified or identifiable data.

The respect and trust of data providers are also essential for statistical agencies to achieve credibility for their data. Protecting the confidentiality of individual responses engenders trust, but, as was noted, agencies may be limited in their abilities to do so. In that case, agencies need to provide respondents with realistic promises of confidentiality that the agency can reasonably be expected to honor.

Respect for data providers also means valuing their time and effort to respond—in particular, designing data collection so that it is not unduly burdensome—and valuing their responses so that they are put to important uses. It is important too that respondents perceive that the agency collecting their information is trustworthy and credible; in particular, that the information will not be used for a particular partisan

interest. A statistical agency must be perceived, by its data providers as well as its data users, to be working in the national interest.

4. *How are Government Statistics Collected and Reported?*

Statistical agencies collect data through censuses, surveys, and compilations from administrative records. Many countries conduct a census of their population. In the UK and USA, one is conducted every 10 years; in Canada, every five years. Other examples of US censuses are the quinquennial census of agriculture, which covers agricultural production on farms that are defined as places from which \$1,000 or more of agricultural products were produced and sold in the census year; the quinquennial economic census, which covers the economic activity of nonfarm establishments; and the quinquennial census of governments, which covers employment and finances of state and local governments.

Examples of surveys in the USA include the Current Population Survey, from which monthly employment and unemployment data are derived; the Consumer Expenditure Survey, from which data on expenditure patterns are used periodically to adjust the weights of goods and services in producing the Consumer Price Index; and the National Health Interview Survey, which provides annual estimates of health conditions and use of healthcare services. Data in government surveys may be collected by field staff of an agency (e.g., the Census Bureau conducts the Survey of Income and Program Participation with its field staff); by state or local governments under a cooperative program (the Current Employment Statistics program of the Bureau of Labor Statistics is a monthly survey, based on payroll records of business establishments, conducted by state employment security agencies); by a private organization under a contract or grant from the agency (the University of Michigan conducts the Health and Retirement Survey under a grant from the National Institute on Aging); or by another federal agency (the Census Bureau conducts the Current Population Survey and the Consumer Expenditure Survey for the Bureau of Labor Statistics and the National Health Interview Survey for the National Center for Health Statistics). Many of these surveys have counterparts in other countries: for example, the Labour Force Survey of the Office of National Statistics in the UK and the Survey on Employment of the National Institute for Statistics and Economic Studies in France.

The units of observation in surveys may be individuals, households, families, schools, establishments, or other economic units. Surveys may be cross-sectional to provide an estimate at a point or interval of time, or they may be longitudinal in design in that they follow the same units of observation over time.

Longitudinal surveys can provide information on changes in a unit over time: for example, transitions of families in an out-of-poverty status from the Survey of Income and Program Participation (see *Longitudinal Data; Economic Panel Data*). Some surveys, however, may have a longitudinal component in their design to reduce error or increase efficiency, such as the American Housing Survey.

Statistical agencies also compile information from administrative records. For example, vital statistics are compiled by the National Center for Health Statistics from state agencies, and administrative records are the source of basic statistics for very small firms in the quinquennial economic census, thus reducing or eliminating the need to send these firms census questionnaires.

Statistical agencies may be dependent on the censuses and surveys of other agencies as well as their own data collection in order to produce national indicators. The Bureau of Economic Analysis relies heavily on economic statistics from other sources in compiling the national income and product accounts. And most agencies rely on the Census Bureau to produce the population denominators for reported rates.

Since the US statistical system is so decentralized, important information on a population of interest, such as children or the elderly, is often collected by many agencies and in different ways that may make relating the data difficult, if not impossible. Sometimes, agencies collaborate to fill important information gaps. Two examples are key indicators of well-being for older Americans (Federal Interagency Forum on Aging-related Statistics 2000) and for children (Federal Interagency Forum on Child and Family Statistics 2000).

Whatever the source of data, one of the most important activities of a statistical agency is measuring, controlling, and reporting upon error. Statistical agencies have been pre-eminent in the development of survey designs to reduce sampling error. And many require, as a standard for some forms of publication, that statistical errors be reported. The agencies too are concerned about measurement and other forms of nonsampling errors, and employ various means to study them, including reinterview studies, record checks, multiple indicators, and cognitive studies, which focus on how errors arise in the process of answering questions. Three statistical agencies, the Census Bureau, the Bureau of Labor Statistics, and the National Center for Health Statistics, have cognitive laboratories to evaluate questionnaires and conduct other research to better understand and reduce error (see *Sample Surveys: Cognitive Aspects of Survey Design*).

5. How are Government Statistics Organized?

Government statistical activities may be centralized into a single agency or not. The organization in the

USA, which is described first, is highly decentralized with activities dispersed among many agencies. Some of the trade-offs between centralized and decentralized systems are described at the end of this section.

5.1 The US Statistical System

The highly decentralized statistical system in the USA arose historically because, as new subject matter areas emerged as a national priority, new statistical agencies were created to meet the needs for new data. Little attention was paid to the relevant data-collection activities of other agencies. Efforts at collaboration have met with some successes, such as the interagency forums on aging-related statistics, and on child and family statistics, but efforts to assure systemic collaboration have failed. Attempts to achieve collaboration through centralization, or at least a major consolidation, have run into stakeholders with a special interest in retaining strong, relatively independent agencies within a particular department of government (see Norwood 1995).

Responsibility for coordinating the myriad statistical activities of the US government rests with a small unit in the Office of Management and Budget, the Statistical Policy Branch in the Office of Information and Regulatory Affairs. Authorization of that responsibility derives from legislation principally concerned with paperwork reduction. Despite its size, however, the Statistical Policy Branch has brought statistical agencies together to address many matters of common concern.

The 1995 reauthorization of the Paperwork Reduction Act created an Interagency Council on Statistical Policy, formalizing an arrangement whereby statistical agency heads participate with the Statistical Policy Branch to coordinate their activities. Ten agencies are recognized as having statistical activities as their principal mission: the Bureau of Economic Analysis and the Bureau of the Census in the Department of Commerce; the Bureau of Justice Statistics in the Department of Justice; the Bureau of Labor Statistics in the Department of Labor; the Bureau of Transportation Statistics in the Department of Transportation; the Economic Research Service and the National Agricultural Statistics Service in the Department of Agriculture; the Energy Information Administration in the Department of Energy; the National Center for Education Statistics in the Department of Education; and the National Center for Health Statistics in the Department of Health and Human Services. The heads of these principal statistical agencies, together with the head of the Office of Management and Budget Statistical Policy Branch and the heads of statistical units in the Environmental Protection Agency, the National Science Foundation, the Internal Revenue Service, and the Social Security Administration, are the members of the Interagency Council.

Through this council, its Federal Committee on Statistical Methodology, and other interagency committees it convenes, and its encouragement of the Committee on National Statistics of the National Academy of Sciences–National Research Council, the Statistical Policy Branch has addressed many methodological and other issues that cut across the interests of most statistical agencies. These include issues of poverty measurement, and the definitions of race and ethnicity and of metropolitan areas. It is also concerned with international comparability of statistics, and it represents the USA at the United Nations Statistical Commission and other international organizations. Moreover, the Statistical Policy Branch has striven to extend by regulation and law the protection of confidential data in ways that would allow statistical agencies to share needed information under that protection.

The Statistical Policy Branch is the only unit of government charged to be concerned with the government statistical system as a whole. It conducts an annual review of all major statistical programs for budget directors in the Office of Management and Budget, and publishes a special analysis of funds proposed for statistical activities in the President's budget (US Office of Management and Budget 2000).

5.2 Centralized vs. Decentralized Systems

Most large countries of the world have centralized most or all of their statistical activities into a single agency with broad authority for collecting and compiling government statistics. Coordination of the different activities occurs within the agency itself. Examples are Statistics Canada, the statistical agency of Canada, and the Office of National Statistics in the UK.

A central statistical agency is usually seen to be more efficient in resource allocation; in reaping the benefits of scale; in sharing information across different subject matter areas in order to enhance data and to avoid duplicating activities; in coordinating data activities, such as developing a single longitudinal survey of youth that serves the purposes of both health and education policy makers; and in arranging for the effective use of administrative data. Advantages of a decentralized system are that priorities for budget, relevance, and timeliness, and the urgency to meet needs for new data are set within the department with the most concern for the information and with policies that are most affected by it, and that different perspectives and ways of conducting statistical activities can bring strength to the system as a whole.

6. Practices of Effective Statistical Agencies

The operation of an effective statistical agency begins, first, with a clearly defined and well-accepted mission

and, second, with a strong standing of independence. With these prerequisites, a number of practices contribute to the agency's effectiveness: continual improvement of and development of more useful data, cooperation with data users, openness about its data, commitment to quality and professional standards, wide dissemination of data, advancing the effective use of statistics, analysis and interpretation, an active research program, a highly professional staff, and coordination and cooperation with other statistical agencies.

6.1 Mission

An agency's mission should include responsibility for assessing and meeting needs for information in its purview, determining the sources of the data and the measurement and collection methods, and ensuring that its data are available to the public. An agency mission statement often goes beyond its charge in legislation. In particular, it should articulate the principles that will govern all of its work. The mission should be well accepted externally by the agency's department and others who oversee the agency, and especially by data users. It should also be well accepted internally, so that all agency employees understand how their work furthers the mission.

6.2 Independence

A strong and widely acknowledged standing of independence is necessary for a statistical agency to have the credibility to carry out its mission effectively. In particular, the agency must be independent of other parts of its department engaged in policy making, enforcement, regulatory, or administrative activities. It must be impartial and avoid even the appearance that its data might be manipulated for political purposes, or that information on an individual might be used for enforcement, regulatory, or administrative purposes.

Forms of independence differ among statistical agencies. Agency heads may be required by law to be professionally qualified in the collection and analysis of the relevant statistics. They may be appointed by the highest levels of government for a specific term not coincident with the administration. And they may have direct access to the head of the cabinet department in which the agency is located.

Other characteristics of independence include authority for the following: to decide the scope, content, frequency, and manner of data collected, compiled, or reported; to select and promote professional staff; to release statistical information without prior clearance and with a clear separation from policy interpretations by others; to represent the agency's statistical program before legislatures and the public; and to establish and follow predetermined schedules for the release of important economic and other indicators.

6.3 *Continually Developing More Useful Data*

In order to make their data more useful and to meet changing public policy needs, statistical agencies must continually look to develop data systems that can serve broader purposes. Integrating data from surveys conducted by different agencies or integrating data from surveys with data from administrative records, such as tax or social welfare program records, are ways to achieve this goal. When separate data sets are collected and analyzed in such a way that they may be used together, the value of each may be greatly enhanced. Data sharing and statistical uses of administrative records, with appropriate safeguards for confidentiality, also make a statistical agency more efficient as well as more effective.

6.4 *Cooperation with Data Users*

An effective statistical agency consults with a broad range of users of its data in order to make its products more useful. It seeks advice on data concepts, methods, and products in a variety of formal and informal ways, from data users as well as subject-matter and other experts. It endeavors to meet the needs for access to data while safeguarding the confidentiality of individual responses. And it strives to provide equal access to all potential users.

6.5 *Fair Treatment of Data Providers*

To maintain a relationship of mutual respect and trust with data subjects and other data providers, an effective statistical agency observes fair information practices, which include: protecting the confidentiality of data identified with an individual, whether the data are collected directly or obtained from administrative record sources; informing respondents of the purposes of data collection and the expected uses of the information; informing those asked to report whether their participation is voluntary or mandatory, and using appropriate informed consent procedures for voluntary data collections; minimizing the contribution of time and effort asked of respondents, which may be achieved in seeking the advice of respondents in the planning and design of data collection; and respecting the willingness of respondents to contribute to society by representing accurately the information they provide, and by making it available for important uses.

6.6 *Openness*

An effective statistical agency operates in a completely open manner. Openness requires providing full documentation of the data with acknowledgment of any uncertainty, a description of the methods used and assumptions made, and measures or other descriptions of error, for both sampling and nonsampling error.

When a mistake occurs, the agency should acknowledge it promptly and publicly. For a correction to an important indicator, the agency should strive to inform as many current and potential users as possible.

6.7 *Quality and Professional Standards*

An effective statistical agency is committed to the highest standards of quality work and professional practice and ethics, in statistics and other relevant professions. For this reason, a strong and continuous relationship with appropriate professional organizations in statistics and relevant subject-matter areas is important.

6.8 *Dissemination of Data*

An effective statistical agency seeks the widest possible dissemination of its data through a variety of means, including public-use data files and the agency's website, and has policies to guide what data to archive and how.

6.9 *Advancing Effective Use of Statistics*

Statistical agencies should also advance the uses of their data through making them easily accessible to users in convenient forms, involving data users in planning data collection and dissemination, and providing full documentation and other forms of technical support to users.

6.10 *Analysis and Interpretation*

Agencies can make their data more relevant to public policy concerns by analyzing and interpreting the data. Care must be exercised, however, that analyses not be perceived as policy advocacy.

6.11 *Research*

An active research program is integral to the activities of an effective statistical agency. Research may be conducted on the substantive issues for which the data were compiled, especially concepts and definitions; methods of measurement, collection, analysis, and dissemination; and topics to improve the utility of the agency's data in policy analysis and decision making.

6.12 *Professional Staff*

A statistical agency must recruit and retain a professional staff of high caliber in statistics and fields relevant to its mission. Opportunities should be provided for staff to maintain and advance their capabilities, such as through appropriate activities of professional organizations.

6.13 Coordination and Cooperation

In the US context, an effective statistical agency continually seeks opportunities to cooperate with other statistical agencies to enhance the value of its own and other agencies' information. Statistical agencies cooperate, not only with each other, but also with state and local statistical agencies in the provision of data for subnational areas. They cooperate, too, with foreign and international statistical agencies to exchange information, on both data and methods, and to develop common classifications and procedures to promote international comparability of information.

Integrating data collected or compiled by different statistical agencies invariably requires much coordination and cooperation among the agencies, each of which have different missions. But the rewards are data more relevant to policy concerns, and a stronger statistical system as a whole. For these reasons, statistical agencies must cooperate as partners with one another, not only on the development of data, but also on the entire panoply of statistical activities, including definitions, concepts, measurement methods, analytical tools, professional standards, dissemination modes, ways to advance the effective use of their data, and means to protect the confidentiality of responses.

7. Challenges Faced by Statistical Agencies

We live in a rapidly changing, increasingly interdependent world with a global economy. Many countries face profound demographic changes. Primarily fueled by technological advances, widespread changes are occurring in society, the environment, and international relationships. Governments struggle to keep up with the changes. They are concerned with the need for new property rights, laws governing new markets, new forms of businesses, and investments in new technology for education. They are concerned too about mitigating human error in transportation, communications, healthcare, and other complex, critical systems; avoiding harmful effects on the environment and sources of food; and guarding against the loss of individual privacy. And governments are also concerned with disparities in economic growth and the distribution of income and wealth, to which disparities in access to technology may contribute, since these disparities could increase tensions among social groups and nations.

An efficient, flexible, and modern information system is essential for a government to address these and other concerns. The greatest challenge facing any statistical agency is for it to keep up with the times. 'Public policy analysis often cannot wait until new surveys are undertaken, but must rely on knowledge drawn from the existing statistical database' (Cook 2000). Those in charge of government statistics must anticipate and prepare for future needs.

Technology, which has induced so many rapid changes, itself can give statistical agencies the means to respond to those changes. The agencies must not only incorporate new technology into collecting, processing, analyzing, and disseminating government statistics, but they must also prepare for the plethora of new data in digital form.

Advances in information technology are also making it more and more difficult to protect confidentiality. If a statistical agency is to respect its data providers by putting their information to use in the best way to benefit society, stronger ways to protect confidentiality must be sought. Statistical agencies should lead in confidentiality research, including research on data encryption and altering or reconstituting data, and in fostering legal and administrative means to protect confidentiality.

8. Conclusion

Statistics are essential for a government to function effectively and to advance businesses and the well-being of its citizens. The nature of data as a public good provides an economic argument for a government to collect statistics, but there are many other reasons for it to do so. One is to assure accurate, timely, and credible information that its citizens may use to hold their government accountable on any issue. A statistical agency must be able to provide information relevant to current and future policy issues, and to establish credibility for itself and its data. Finally, the agency must be respected and trusted by respondents who provide it with data and with all data subjects whose information it obtains. That respect and trust can be fostered by protecting the confidentiality of individually identifiable information and by putting the information it obtains to use in the best ways to benefit society, including research.

More information on the principles and practices of statistical agencies can be found in Martin et al. (2000), and on the organization of US statistical agencies in Norwood (1995). Statistics for over 200 countries and areas of the world are compiled by the United Nations Statistics Division (2000), which provides links for the national statistics of countries online at www.un.org/Depts/unsd/ through a link to 'Global Statistics.' Links to the websites of statistical agencies in the USA are available at www.fedstats.gov.

Governments

Governments are universal. They exist in every social organization: there is always a body, normally relatively small, which has the task of running that organization; but the most visible governments are those of nations and of other public institutions. With the decolonization process, independent national governments have come to rule practically the whole of the planet and they have more than doubled in number, from well under a hundred in the early 1950s to nearly two hundred at the beginning of the third millennium.

1. Problems of Definition

Being at the center of political life, national governments tend to be rather small and, often at least, compact. Yet it is not possible to circumscribe them

neatly as their boundaries are not precise. In many cases, indeed most, an official list exists, but this list is typically not exhaustive, as key personalities, who may formally only be ‘advisers,’ but are in fact highly influential, tend not to be included. There are also often two or more ‘levels’ of the government: thus in the UK and in countries which have followed closely the British model, for instance, the ‘cabinet’ constitutes only an inner core, with ‘ministers of state’ and ‘parliamentary secretaries’ being below this core. In the USA, the government is typically referred to as the ‘administration’ or as the ‘executive’: however, both of these expressions remain imprecise with respect to those whom they cover.

It is therefore more appropriate to look for a definition in terms of the functions which national governments fulfill. In general, these are said to ‘run the affairs of the nation,’ although they only do this up to a point since they are helped and advised by a multiplicity of individuals and of groups, and, in modern democratic countries in particular, by parties and legislatures, while everywhere the bureaucracy is at their ‘disposal.’ One can in reality distinguish among three functions of governments. First, they have to elaborate realistic policies which can be implemented: this is the function of conception. Second, they have a function of implementation, as they must find the means of ensuring that the policies which have been elaborated are indeed turned into practice. There can be tensions between these two functions. The skills required to undertake each of them successfully are different: to conceive means to ‘imagine’; to implement means to ‘manage.’ Yet governments have also a third function, that of coordination: they must ensure that the policies which are elaborated and implemented do not pull in different directions but are complementary.

2. Types of Government, Liberal-Democratic and Authoritarian

A ‘revolution’ in the characteristics of governments has occurred since the eighteenth century, when ‘modern’ government began. This ‘revolution’ has had two main aspects. First, there has been a massive increase in the complexity of governmental activities, as states have come to be increasingly involved in the economic and social life of countries, especially from the late nineteenth century to the 1980s. Second, many governments have come to be (or have had to be) responsive to the demands of citizens, in particular where the representative system had been introduced: for the first time in human history, these governments had to abide by rules based on liberal democratic principles and enshrined in constitutions. Admittedly, Greek cities, the Roman Republic, and, during the Renaissance, some parts of Italy, had experienced forms of ‘limited’ government; but only from the end of the seventeenth century did representative govern-

ment take root in a nation, England, which hitherto had been a traditional monarchy, while, almost a century later, American independence marked the emergence of the first liberal Republic.

England and America were indeed the originators of the two main forms of constitutional government which have existed to this day, the cabinet system, which was gradually adopted in almost every Western European country and in the Commonwealth, and the presidential system, which spread to Latin America, though with only limited success. Thus, at the beginning of the third millennium, approximately half the national governments could be described as being broadly responsive to their people. Meanwhile, in the rest of the world, including in many countries of Africa, of Asia and, at least in the past, especially up to the mid-1980s, of Latin America, governments have tended to be authoritarian. The Communist form was particularly harsh, both in what was the Soviet Union and in Eastern Europe up to the late 1980s, as well as in China and a number of other Asian countries: it was based on the dominance of a single party whose leaders formed the real government and controlled the formal executive. Independence from colonial rule which started in the 1950s and gathered momentum in the 1960s, especially in Africa, also led to many dictatorships, sometimes based on single-party arrangements but relying even more on the 'charismatic' figure of a president, often drawn from the military and having come to power through a coup. Admittedly, since the 1980s, a move towards responsive governments occurred in many countries hitherto ruled by dictatorships, in Latin America, in what had been the Communist block, in East and Southeast Asia and in parts of Africa; but authoritarian rule continued to characterize many countries of the contemporary world, sometimes on the basis of old-fashioned monarchical governments but more often on 'modern' types of dictatorships, in many cases of the military type.

3. The Organization of Governments: Cabinet and Presidential Systems. The Role of Leaders

Partly as a result of these differences, governments vary widely in organization, duration, composition, and powers. The distinction between the cabinet system and the presidential system remains the main one among liberal democratic governments, although there are variations within each of these two models and some cases are intermediate. The cabinet system is based on the division between a symbolic head of state, often a monarch, and a government, responsible to parliament, headed by a prime minister: the prime minister has to operate in the context of a collegial system in which those members of the executive who are part of the cabinet (normally referred to as 'ministers') are entitled to participate fully and col-

lectively in decision-making: in practice, this is far from being always the case and there are substantial differences from country to country and within each country. Some cabinets are controlled closely by their prime minister, while others are more egalitarian. By and large, the British government and the governments of many Commonwealth countries tend to be tilted toward prime ministerial dominance, while a number of continental European governments, at least those which are based on complex party coalitions, give more elbow room to ministers. Yet, even though cabinet members may be more or less collectively involved, there is a real sense in which the government constitutes a team. A variation on this model is provided by the French system, in which the picture is somewhat complicated by the fact that the president, elected directly by the people, plays a significant part in policy making, at least when the party of the president also dominates parliament: this model has been adopted by some of the post-Communist governments of Eastern Europe as well as in the developing world.

The presidential system, on the other hand, is based on the separation of powers principle, with both president and legislature elected directly by the people. The president, as head of the executive, has thus greater leeway to organize the government in the way he/she wishes: this is particularly true in the USA. In some Latin American countries, on the other hand, the president has to an extent to take into account the desire of party leaders to play a part in the appointment of members of the executive. However, by and large, presidential governments are both constituted more independently from the parties and in particular from the parties in the legislature. They are also more hierarchical in character: the members of the government (typically known as 'secretaries') are responsible to the president for the department of which they are in charge (although in some cases the legislature can also censure them individually). They are not collectively involved in decision-making.

Governments are fashioned by their leaders. The twentieth century was characterized by the emergence of 'charismatic' rulers, including and perhaps above all in Communist countries, despite the fact that the Communist ideology is based on the notion that the economic 'substructure' is held to be paramount. 'Charismatic' or personalized leadership can also be found in liberal regimes, whether of the cabinet or of the presidential type. This has been the case not just of wartime leaders, such as Churchill or de Gaulle, but of rulers who attracted the imagination of whole populations, such as Kennedy.

4. The Duration of Governments

The duration of governments varies. The longest are those of the few remaining traditional regimes, in effect absolute monarchies, and those of some of the

more 'modern' dictatorships: Communist governments, their leaders in particular, often remained in power for over a decade; on the other hand, most other leaders are only in office for a few years. The other government members often stay for even shorter periods: the average duration of ministers or secretaries is in the region of three to four years, with a substantial proportion of them being truly transient and remaining in government for a year or less.

5. Career Patterns

The composition of governments also varies. Some of these, primarily where there is a cabinet system, include almost exclusively professional politicians, men and women who have been active in a political party, have then been elected to parliament and have joined the ranks of the executive after a few years on the 'backbenches.' Other government members are 'technicians,' more often drawn from the public sector than from the private sector: their career in politics tends to last a few years only and they return to other public or private jobs after their stint in government. Moves of this kind occur less frequently in cabinet systems than in presidential systems, where, as we noted, the head of the state has more freedom to pick and choose whom he or she wants to appoint; they also occur in many authoritarian governments, though, in these, military men are often side by side with civilian 'managers.'

Variations in career patterns are associated with differences in social background. In general, except where social democratic parties are frequently in power, as well as in the past Communist systems, men and women with a working class background are rare: lawyers, teachers, and managers form the bulk of the civilian members of governments. Only in the last decades of the twentieth century and in some countries, mainly Northern European, have women had more than a token share of governmental posts, especially in such key departments as those of foreign, economic, or internal affairs.

6. The Impact of Governments: An Unresolved Question

There is debate about the extent to which leaders and governments affect the countries which they rule. As their careers are often short, it is suggested that members of the higher civil service, together with the lobbies which gravitate around them, play a key part in decision making. As a matter of fact, it has not been possible so far to determine precisely the impact of leaders and members of governments even when they stayed in power many years: environmental factors, both internal and external to the country concerned, must be taken into account. Yet some leaders at least,

whether 'harsh,' such as Lenin or Stalin, or 'good,' such as Roosevelt or Churchill, had a major influence on the destinies of the countries which they ruled and indeed of the world. What can only be said is that there are massive variations in impact, as there are major variations in the characteristics of governments and in particular in their responsiveness, organization, duration, composition, and complexity.

Grammar: Functional Approaches

The term *functional* or *functionalist* has a meaning in linguistics distinct from the use of the term found in anthropology or philosophy. In linguistics, a func-

tional analysis is an analysis of linguistic structure that puts the primary emphasis on explanation in terms of factors outside the structural form, such as meaning or the function of language in discourse. Functional analysis is in contrast to *formal* analysis, which is an analysis of linguistic structure that puts the primary emphasis of explanation on principles defined purely in terms of structural form. The term *functionalist* has been applied to any school of grammatical analysis which argues for the primacy or centrality of functional explanations over formal explanations.

1. Introduction

Such a broad characterization of functionalism in linguistics, of course, requires further elaboration. We begin by illustrating the commonest types of functional explanations, and then turn to different schools of linguistic theory that call themselves functionalist.

2. Types of Functional Explanations

There are three types of functional explanations that usually are distinguished in the functionalist linguistic literature: processing, cognitive, and discourse or information structure explanations.

2.1 Processing Explanations

Processing explanations make reference to models of the production and comprehension of utterances. A processing explanation argues that some aspect of grammatical structure is due to limitations on the human ability to produce or comprehend the structure.

Processing explanations typically are employed to account for two sorts of linguistic facts. One is the relative frequency of a particular grammatical structure across the world's languages. For example, it has been observed that suffixes are on the whole more frequent than prefixes (or more complex alterations of word forms) in the world's languages. A processing explanation has been proposed for the suffixing preference. It is hypothesized that speakers process word stems before their inflections. Psycholinguistic experiments imply that the beginning of a word is most salient, hence the word stem should ideally occupy the initial position; the ends of words are the next most salient, hence inflections should ideally occupy the final position.

The second sort of phenomenon for which processing explanations are employed is to account for degrees of acceptability of a construction in a single language. For example, in English, subordinate clauses embedded in the middle of a clause are relatively less acceptable than subordinate clauses

embedded at the end of a clause: compare *I know the boy that owned the cat that caught your parakeet* to *The parakeet that the cat that the boy I know caught died*. This fact has been explained as a consequence of the difficulty in interpreting the latter sentence's center-embedded clauses. In fact, it is grammatical in English to move a relative clause from the middle of a clause to the end under certain circumstances: *A woman contacted me who I had shared an apartment with during my last year at college*.

Processing explanations have been proposed for constraints on certain types of syntactic structures, constraints on patterns of morphemes within words, and on sound patterns. The latter explanations typically are described in terms of ease of articulation or ease in discrimination (in speech perception). Processing explanations for syntax and morphology, especially in explaining differences in cross-linguistic frequency of word order and morpheme order, are particularly associated with the work of J. A. Hawkins (e.g. Hawkins 1994).

2.2 Cognitive Explanations

Cognitive explanations generally make reference to the conventional meaning of a word, inflection or syntactic construction (e.g. Bybee 1985, Tomasello 1998). A cognitive (semantic) explanation of a grammatical phenomenon essentially hypothesizes that some or all aspects of the analysis of the grammatical phenomenon make reference to conventional semantic properties. For example, some languages have plural inflections for all count nouns, while other languages restrict plural inflections to only nouns referring to animate beings, still others to only nouns referring to humans. This variation is built on a general ranking or hierarchy of nouns according to the semantic class of their referents: human < animate < inanimate. The description of the constraint on the occurrence of the plural inflection in each language, and the cross-linguistic pattern of constraints, requires reference to the semantic classes of entities denoted by the noun, described in terms of animacy.

Cognitive explanations, like processing explanations have been used to describe both grammatical constructions in particular languages and also patterns of cross-linguistic variation. The example of the animacy hierarchy in the preceding paragraph illustrates both sorts of explanations. It hypothesizes that the distribution of the plural inflection in any particular language will make reference to the semantic class of the entity denoted by the noun. It also hypothesizes that the cross-linguistic variation in the distribution of the plural inflection is subject to the hierarchical ranking of animacy categories given in the preceding paragraph. In recent cross-linguistic research, explanations of cross-linguistic patterns have been offered in which the patterns of occurrence of a

construction are mapped onto a single semantic or conceptual space applicable to all languages.

Some cognitively oriented functionalists make a stronger claim about the relationship between grammatical form and semantic function, namely that certain grammatical categories are better described in semantic terms. This hypothesis will be discussed below on the contribution of cognitive linguistics to functionalism.

2.3 Discourse (Information Structure) Explanations

Discourse explanations make reference to the organization and presentation of information in discourse, that is, the structuring of information for the purpose of communication. Such explanations are called discourse explanations by some functionalist, and information structure explanations by other functionalists. For example, the English active and passive voice constructions (*The car hit the tree* vs. *The tree was hit by the car*) both describe the same event and participants, but differ in which participant is encoded as the subject of the construction. It has been argued (based on naturally occurring examples) that the participant that is more topical is encoded as subject. Another example is the choice of construction in response to a question such as *Wasn't that incredible when Mary called the boss a pig?* One can respond with *Yeah, it really shocked me that she called him that*, but not with **Yeah, what really shocked me was that she called him that*. The unacceptable response uses the pseudocleft construction, and the pseudocleft construction is acceptable only if the information 'something really shocked me' is already in the hearer's consciousness. It is not in this case, and hence is unacceptable.

As with processing and cognitive explanations, discourse functional explanations have been offered both to explain restrictions on the acceptability of specific constructions in particular languages, and to explain the frequency of distribution of particular linguistic features across languages. Examples of the former were given in the preceding paragraph. An example of the latter is certain patterns of word order. In the overwhelming number of languages, the subject precedes the object in the most common order of elements in a clause. It has been proposed that the reason for this asymmetry is that the subject tends to be the topic, and the most common discourse pattern is for the topic to precede the 'comment,' or at least other less topical participants.

3. Schools of Functionalist Analysis

One of the most fundamental issues that divides schools of linguistic theory is: what is the relationship between linguistic form and linguistic function? The

relationship is not at all straightforward (Croft 1995). Also, depending on the position that a linguist takes on the relationship between form and function, certain additional hypotheses have to be made in order to accommodate linguistic facts. These hypotheses have to do with aspects of language not directly connected to the form-function relationship, such as the organization of grammatical knowledge in a speaker's mind, the nature of semantics, and the role of cross-linguistic evidence. Since these additional hypotheses are closely associated with various schools of functionalist analysis, they will be discussed here.

3.1 Functionalism and Formalism

Functionalist schools generally set themselves up as contrasting with the formalist approach, associated most strongly with N. Chomsky, but also advocated by other linguists who reject some of Chomsky's more specific claims about syntax. A purely formal explanation of a grammatical phenomenon makes reference exclusively to properties of grammatical form or structure. With respect to grammatical structure, a formal explanation of some pattern of sentence structure will make reference only to syntactic categories and structural relationships between the elements of a sentence, and not to the meaning of the words, inflections or constructions of that sentence, their discourse function, or their production and comprehension in language use. With respect to word structure, a formal explanation will make reference only to morphological categories and relations between roots and affixes, and not to aspects of the meaning and use of word forms. With respect to sound structure, a formal explanation will make reference only to the structure of the sound system independent of its articulatory and auditory realization.

This is not to say that formalist analyses have no place for the meaning and use of linguistic constructions. The formalist hypothesis is that there is a significant number of properties of grammatical form which can be explained in a purely formal way. The concept of a formal explanation is closely associated with the theoretical position that the organization of grammatical knowledge in a speaker's mind is divided into components which separate a linguistic form from its conventional meaning and use in discourse. A typical model describes grammatical knowledge as being compartmentalized into phonological, syntactic and semantic components. The phonological component is separated from its phonetic realization, and the syntactic component is separated from its semantic interpretation. Linguistic form is linked up to its phonetic realization or semantic interpretation, eventually: formal models have rules linking syntax to semantics and phonology to phonetics. The formalist hypothesis does however imply that linguistic form is organized in a purely formal way to a high enough

degree that it can be described best as existing in separate components. That is, the formal analysis of grammatical structure is self-contained relative to functional factors.

This is also not to say that formalists reject all explanations that make reference to functional factors. Formalism accepts that some, perhaps many, linguistic phenomena require reference to functional factors. However, formalists argue that there is a large body of linguistic phenomena, those which most linguists would consider to be central to grammatical structure, that can be analyzed without reference to any functional factors. Another way of describing this position is that the phonological and syntactic components represent a substantial core of a speaker's grammatical knowledge of a language.

Functionalism approaches to language challenge or reject the formalist model of the relationship between form and function to varying degrees. However, all functionalists accept that not all aspects of grammatical structure can be accounted for by meaning and use. There will always be some degree of arbitrariness in language structure, where arbitrariness is intended to mean not wholly explainable in terms of language function. The question is, how much arbitrariness is there in language structure, and to what extent does the arbitrary aspect of language structure form a self-contained system? Different functionalist schools give different answers to this question.

3.2 Autonomous Functionalism

The closest approach to formalism which calls itself functionalist can be called *autonomous functionalism*. Autonomous functionalism argues that the number of properties of grammatical form that are explainable solely in grammatical terms are considerably fewer than most formalist theories assume. In particular, the restrictions on the use of particular constructions are sought in functional properties, whether cognitive, processing or discourse-functional. To take a simplified example in the *There*-construction (as in *There is a bird in the bushes*), a noun phrase with an indefinite article (*a bird*) is acceptable but one with a definite article usually is not (compare) **There is the bird in the bushes*). A plausible explanation for this restriction is that the *There*-construction is used to introduce a new referent into the discourse, but definite noun phrases describe referents already known to both speaker and hearer. This would be an autonomous functionalist analysis of the restriction.

However, even in an autonomous functionalist approach, the rules governing the formation of the construction itself, such as the fact that *There* is the first element followed by a form of *be*, are considered to be purely formal. Autonomist functionalists focus their research efforts on accounting for as many of the

constraints on the construction as possible in terms of functional properties, while leaving the basic structure of the construction for formalist analysis. The autonomist functionalist research program is found in the work of Kuno (1987), Prince (1988), Ward, and their students and associates. Their explanations generally appeal to properties of information structure rather than semantic properties. Because they accept the basic structural analyses of formalist approaches, autonomous functionalists generally do not reject the view that linguistic knowledge in a speaker's mind is organized into components. Instead, they have proposed that there is another component, the information structure component, which should be included along with the syntactic and semantic components.

In fact, many functional analyses of specific constructions in more radically functionalist approaches to language are actually autonomous functionalist analyses, that is, they account for the restrictions on syntactic constructions in terms of the meaning and use in discourse of the construction. We may call these autonomous functional analyses in whatever sort of functionalist approach they are found in, that is, autonomist functionalist analyses of particular constructions are not incompatible with more radical functionalist approaches.

3.3 Mixed Formalism/Functionalism

Another sort of approach, not clearly identifiable with any particular school of linguistic theory, but sometimes called functional, challenges the hypothesis of a sharp separation between the use of formal or functional properties to describe grammatical constructions. In these theories, the description of both the structure and the constraints on a construction can mix formal and functional properties. Two schools, *Functional Grammar* of S. Dik and co-workers, and *Role and Reference Grammar* of R. Van Valin and co-workers, both use formal and functional properties (typically semantics, but also information structure) to describe the grammatical structure of sentences as well as the constraints on them. In addition, many grammatical descriptions of languages informally describe both syntactic and semantic properties of constructions without implying any sharp division between the two.

3.4 Typological Functionalism

As was noted above, cognitive, processing and discourse explanations have been offered for patterns of cross-linguistic variation as well as in the analysis of the grammars of individual languages. A school of linguistic theory known as typology has arisen which

focuses on cross-linguistic variation and its limits (see, for instance, Greenberg 1990, Comrie 1989, Givón 1979, Hawkins 1988, Croft 1990). Much cross-linguistic variation appears to be built on the base of general functional patterns, as illustrated above for cognitive, processing, and discourse explanations. This observation has led some typologists to argue that all cross-linguistically verified universals of language are susceptible to functional explanation in this way. This approach to analysis is called typological functionalism or the functional-typological approach.

Typological functionalism makes a stronger claim than the schools described in the preceding sections. The autonomous functionalist approach assumes that there still remains a significant amount of syntactic structure that can be described in terms of a self-contained set of rules (which are further assumed to be in part language-universal). The mixed formal-functional theories do not assume that formal principles governing syntactic structure are self-contained, but those theories allow for the possibility that there are formal properties of languages that are universal for all languages. The typological functionalist approach hypothesizes that any universal generalizations about linguistic structure are ultimately explained in functional terms.

The typological functionalist approach does not, in fact cannot, assume that the structure of a particular language's grammar is entirely explainable in functional terms. For instance, one example given above was that the occurrence of a plural inflection on nouns could be accounted for by the hierarchy human < animate < inanimate. The semantic hierarchy is universal, but each language applies the hierarchy to the distribution of the plural inflection in its own way, that is, one cannot predict what semantic class a language will extend (or restrict) its plural inflection to. That is, the exact class of nouns allowing a plural inflection is partly arbitrary, although it is partly explainable in terms of the semantic hierarchy: if the language allows plural inflection for animate nouns, it will allow plural inflection for human nouns. This sort of explanation of a linguistic phenomenon is sometimes described as motivation, in contrast to a set of rules that exhaustively predicts the forms that would be found.

A typological functionalist analysis must allow for some degree of arbitrariness in accounting for cross-linguistic patterns. If there were no arbitrariness, all languages would be alike in their grammatical structure; and they are not. But the typological functionalist approach hypothesizes that the arbitrary aspects of language structure are language-specific, and that any universal generalizations about linguistic structure are ultimately explained in functional terms.

An important element of typological functional explanations is the hypothesis of iconicity or iconic motivation, in which grammatical structure is hypoth-

esized to reflect semantic or conceptual structure to some degree. For example, the closer grammatical relationship between verb and object as opposed to verb and subject in many languages is attributed to the closer semantic relationship between states of affairs and the participants usually encoded as the object. Iconic motivation can be used to account for grammatical structure itself, not just constraints on grammatical structures. In this respect, typological functionalism represents a more radical functionalist approach than autonomous functionalism.

3.5 Cognitive Linguistics and Functionalism

Cognitive linguistics (e.g. Lakoff 1987, Langacker 1987, Talmy 2000) is a broad school of linguistic theory that is usually called functionalist. Cognitive linguistics, as its name indicates, focuses on cognitive (semantic) explanations for grammatical structure. Cognitive linguistics has contributed a number of ideas to other functionalist approaches that are relevant to assessing functional approaches.

Cognitive linguistics has proposed a model of grammatical knowledge, construction grammar, that offers an alternative to the formalist model in which form and function (semantics and information structure) are separated in distinct components. Construction grammar hypothesizes that knowledge of syntax involves the knowledge of individual constructions which combine formal properties (syntactic structures, morphological inflections) and functional ones (semantics and discourse function). For example, the ditransitive construction [X Verb Z Y], as in *Marilyn sent Gina a book*, specifies not only the syntactic structure of the construction but also the semantic relationships among the participants, such as the fact that Z comes to possess Y. Constructions are organized in a network of grammatical knowledge in a speaker's mind. More broadly, grammatical knowledge is organized as a system of signs or symbols, consisting of form (the signifier) and function (the signified). A model organizing grammatical knowledge in terms of constructions/symbols/signs allows for a direct statement of functional properties that are relevant to particular grammatical constructions and other grammatical units.

Cognitive linguistics argues that semantics involves conceptualization or construal of an experience by a speaker for the purposes of linguistic communication. For example, an English count noun can be used in a mass noun grammatical context, as in *There was a huge Buick there; just acres of car* (attested example). The noun *car*, normally denoting an individuable object, is construed to denote an unbounded quality (size). These and other examples indicate that the English count noun-mass noun distinction has at least some semantic basis. Cognitive linguists also accept that some alternative construals are conventionalized,

such as *chicken* (meat, mass noun) vs. *chicken* (live bird; count noun). Nevertheless, the conventionalized grammatical distinction conforms to the semantics of count noun vs. mass noun: a live bird is an individuable entity, while meat is a unbounded substance.
