The commentaries and digests follow the basic trends of the revealed, eternally valid *smṛti* texts. Even though the digests discuss the legal aspects of *dharma* in separate volumes, 'law' remains closely linked to other aspects of *dharma*: an adoption is still considered invalid if it is not accompanied by the *dattahoma*.

On the other hand, drawing on the entire body of *smṛti* literature as equally authoritative, the commentators and digest writers are able to fill in gaps in one *smṛti* by drawing on a different *smṛti*. With two exceptions, the *smṛti* texts tell us little about what happens to the inheritance of a father when he does not have any descendant beyond a great-grandson. The commentaries and digests appeal to all *smṛti* texts to establish complete, if rarely uniform, lists of heirs, from the son and other relatives, down to the king. The commentaries and digests do provide coherent, albeit different, systems of Hindu law.

Nowhere is that tendency expressed more clearly than in the contradictions referred to earlier. For the commentators, all *smṛti* texts are equally authoritative; there cannot be any contradictions, and it is their task to show this. They either present the rules as applicable under different circumstances, or they interpret one text literally and do not hesitate to force a meaning on the others, so that all texts are in perfect harmony. In the scholarly literature the often important and far-reaching difference between the interpretations put on the *smṛti* texts by the commentators are most often interpreted as attempts on the part of the latter to adapt the former to local circumstances and customs. Or, rather than being concerned with local customs, the commentators apply the same principles as their interpretations of *smṛti* texts in any other field of *dharma*: subtle grammatical explanations borrowed from Pāṇini's *Aṣṭādhyāyī* and other grammatical treatises, intricate rules of textual exegesis laid down in Jaimini's *Mīmāṃsāsūtras*, principles of logic contained in Gautama's *Nyāyasūtras*, etc. Each individual commentator brings his vast amount of traditional, panditic learning to bear on the *smṛti* texts, to mold them into one coherent system, to interpret them more correctly than his predecessors, with whom he does not hesitate to argue in the strongest possible terms.

Differently from the *smṛti* texts, which were revealed once for all through the intermediary of ancient *rishis*, the commentaries and digests were produced by human beings with whom it was possible to disagree as well as to agree.

3. Anglo-Hindu Law

In search of ways to govern Indians according to their own laws rather than by British Law, in 1772, under the impetus of the Governor of Bengal, Warren Hastings, the East India Company adopted the principle that 'in all suits regarding inheritance, marriage, caste and other religious usages or institutions, the laws of the Koran with respect to the Mohamedans and those of the Shaster with respect to the Gentoos shall invariably be adhered to.' The British administrators were familiar with Muslim law, but the law of 'the Shaster,' i.e., the *dharmaśāstras*, was totally unknown to them; in fact, at that time not a single Englishman had access to the language of the *dharmaśāstras*, Sanskrit. What followed, throughout the British period, is a series of remarkable attempts, on the one hand, to maintain the integrity of shastric law and, on the other hand, to interfere with it and abolish it whenever it came into conflict with basic principles of British justice.

In a first attempt to gain access to the sources of Hindu Law (1772), pandits were attached to the Anglo-Indian courts of law. The Court Pandit received the legal question via a translation from English or Bengali into Persian, and hence into Sanskrit. He consulted his law books, and made a decision, which was again translated, through Persian, into English. Besides being cumbersome and time-consuming, this procedure soon created uneasiness in British legal circles in India: distrust in the pandits and their decisions became a common topic in contemporary reports and correspondence. Even though the office of Court Pandits was not abolished until 1864, meanwhile some Englishmen decided that for them to get access to the sources of Hindu law, they needed to study Sanskrit. One of these early Orientalists was Sir William Jones, a judge in the Calcutta Supreme Court, who produced an English translation of the *Manusmṛti* (Jones 1794).

Even prior to Jones's translation, Hastings called to Calcutta a group of 11 pandits, to provide him with the code of Hindu law. While the pandits' composition, *Vivādārṇavasetu*, 'the bridge across the ocean of disputes,' was still going on, their work was translated into Persian, and from there into English by one of Hastings's protégés, Nathaniel Brassey Halhed. Halhed's book became known as *A Code of Gentoo Laws, or, Ordinations of the Pundits* (1776).

However, neither Halhed's *Code* nor Jones's *Institutes* proved to be helpful as law books in the Anglo-Indian courts of law. The former suffered much in the two successive translations (and is, in fact, very

different from the Sanskrit original); the latter displayed all the characteristics of an ancient *smṛti* text mentioned earlier: no answers to important legal questions, conflicting answers to the same questions, and so forth.

At that point the British turned away from the *smṛtis*, toward the commentaries which at least provided coherent legal systems and gave clear answers to questions raised in Court. On the other hand, each commentator's coherent legal system was, in varying degrees, different than that of any other commentator. Henry Thomas Colebrooke was first to introduce the concept of Schools of Hindu Law (Rocher 1972), a concept that was to dominate the history of Hindu law until the middle of the twentieth century. According to Colebrooke, there was one digest that was applicable in Bengal, and another commentary that was followed in the rest of India.

In 1810 he published a volume entitled *Two Treatises on the Hindu Law of Inheritance*, in which he translated *Jimūtavāhana's* digest *Dāyabhāga* (early twelfth century) as the text for Bengal, and the chapter on inheritance from the *Mitākṣarā*, a contemporaneous commentary on the *Yājñavalkyasmṛti*, as the text for India outside Bengal. In more recent years, as more commentaries and digests were translated, the 'Mitakshara School of Hindu law' was further subdivided into four subschools: the Benares, Mithila, Maharashtra or Bombay, and Dravida or Madras schools of Hindu law, each school and subschool administering Hindu law on the basis of its own Sanskrit text (or texts). The result was a pyramidal system in which the decision of any lower court could be appealed to the regional High Court, whose decisions were binding on the lower courts within its territory. The Judicial Committee of the Privy Council in London, the final court of appeal, made binding but different decisions depending on the region from where the appeal originated.

The basic difference between the two major Schools of Hindu law is that, in the *Mitākṣarā* school, any male individual born into a family, by his very birth acquires an unspecified right of ownership in joint family property. According to the *Dāyabhāga*, on the contrary, no one becomes the owner of any part of the family property before the time at which the right of the previous owner lapses, either by death or for any other reason that prevents him from exercising his obligations as the manager of the family property. This distinction inevitably had a profound impact on the lesser (*Mitākṣarā*) or greater (*Dāyabhāga*) power of the head of the family to manage the family property at his pleasure.

Notwithstanding these efforts on the part of the British to administer Hindu law to Hindus, and even though they continued to pay homage to the Sanskrit *dharmaśāstras*, at the same time they steered Hindu law in directions that were alien to the ancient *rishis* and the commentators.

First, based on the principle that 'we are here to administer law, not religion,' the Anglo-Indian courts drew the line between what they considered legal actions and the ritual activities that were an integral part of them in the Sanskrit texts: in Anglo-Hindu law, adoption became valid even without the performance of the *dattahoma*.

Second, since the commentaries and digests in each region became the principal sources of law, the Courts no longer considered it necessary to look for the correct meaning of the *smṛti* texts on which the commentaries were based; they relied invariably and solely on the commentators' interpretations, thereby reversing the original scale of authority between the human commentaries and the texts transmitted in the revealed *smṛtis*.

Third, even when Indians joined the Courts, the number of judges and advocates who knew Sanskrit remained small. All arguments and judgements were based on English translations. If one of the parties demonstrated that a translation was in error, the judges rejected that argument, and referred instead to precedents contained in the massive Indian Law Reports. From being based on texts, Hindu law now became a case law, and the law reports were interspersed with Latin phrases such as *stare decisis* and *communis error facit ius*.

Finally, there were traits of Hindu law that ran counter to basic British conceptions of law and justice. In many of these cases the judges overruled Hindu law on the basis of the principle of 'justice, equity, and good conscience.' When the sisters of a murderer claimed the inheritance of his victim, which in Hindu law their brother was entitled to because he was physically and mentally capable of performing the prescribed rituals (*śrāddha*) for the deceased, the case went through several appeals with opposite results, until the Privy Council rejected outright the murderer's right to inherit.

Conversely, Hindu law was expanded by the Courts' recognition of wills, which were unknown in the traditional system. In other cases, the British passed a number of Acts which overruled and abolished some existing practices of Hindu law. As the titles of the earliest Acts (*The Caste Disabilities Removal Act, 1850; The Hindu Widow's Remarriage Act, 1856; etc.*) indicate, they aimed at improving the living conditions of outcasts (a Hindu who renounced his religion or was excluded from his caste lost any right to property and inheritance) and women (when her husband died, his widow, however young she might be as a result of the common practice of child marriage, was not allowed ever to remarry).

4. Hindu Law in Independent India

In 1947 Hindu law as established by the British passed unchanged into the courts of Independent India.

Implementing article 44 of the Constitution: 'The State shall endeavour to secure for the citizens a uniform Civil Code throughout the territory of India,' was delayed. Even the more modest attempt at providing all Hindus in India with a uniform 'Hindu Code,' an idea that preceded Independence, failed. However, in 1955 the Indian Parliament enacted *The Hindu Marriage Act*, which applied not only to Hindus, but also to Buddhists, Jains, and Sikhs; in short to any Indian citizen 'who is not a Muslim, Christian, Parsi or Jew by religion' (art. 2 [1]). In 1956 *The Hindu Marriage Act* was followed by *The Hindu Succession Act*, *The Hindu Minority and Guardianship Act*, and *The Hindu Adoptions and Maintenance Act*. All four acts state, in almost identical terms, that:

Save as otherwise expressly provided in this Act,—

(a) any text, rule or interpretation of Hindu law or any custom or usage as part of that law in force immediately before the commencement of this Act shall cease to have effect with regard to any matter for which provision is made in this Act;

(b) any other law in force immediately before the commencement of the Act shall cease to have effect in so far as it is inconsistent with any of the provisions contained in this Act.

The impact of these modern Acts, overriding Hindu law as it had been practiced for a century and a half, is still a matter of dispute. The point is that, officially, they made large sections of traditional Hindu law obsolete. Any Hindu (in the broad sense) can legally marry any other Hindu, monogamous marriage becomes the rule of law, and so do annulment of marriage, divorce, and remarriage for women; succession to inheritance is made uniform, male and female heirs are treated equally; and women, who were accorded a limited estate in the past, now become full owners of their property and can dispose of it as they please.

There remains, however, an undetermined residue of Hindu law for which the Acts do not make any provision; in areas such as joint family law the Courts continue to administer Hindu law as it was prior to 1955 (Derrett 1963).

Hintze, Otto (1861–1940)

The Berlin historian Otto Hintze continues to fascinate those engaged in international historical research. In Germany, there was a particularly noticeable increase of interest in Hintze in the 1960s, in conjunction with an enduring resurgence of social historical schools. The rare combination of detailed investigation through decades of sources on the one hand and the elaborated approach of history's systematic contiguous disciplines on the other brought to light results which are still of great interest in modern research.

This is especially true for the comparative approach to political structural history, particularly that of the European states from the height of the Middle Ages to the nineteenth century. From an early stage, Hintze was at pains to incorporate the categories of political science and economics, constitutional law, and sociology into historiographical analysis, thus broadening the scope of the discipline. Despite modernization theory and more recent concepts of the comparative analysis of nation building, Hintze's advocacy of the comparative approach to constitutional and governmental history and the methodological initiatives taken in his works are still of great significance. Indeed, Hintze's approach remains indispensable to the investigation of the processes of state making.

Otto Hintze was born in the small Pomeranian town of Pyritz on August 27, 1861, as the son of a middle-

ranking civil servant. After studying for two years at the University of Greifswald, Hintze transferred to the Friedrich-Wilhelms-Universität of Berlin in 1880–1. There he studied, for example, under Johann Gustav Droysen, who was still in his final years of life. Hintze completed his doctoral studies in the spring of 1884 with a dissertation on medieval history (*König Wilhelm der Holländer. Ein Beitrag zur Geschichte des deutschen Interregnums*), supervised by the historian Julius von Weizsäcker. Gustav Schmoller, the economic and political scientist who was soon to have a considerable impact on Hintze, was not yet named as one of his academic teachers. Hintze followed his first rather narrow course of study in history with a second in legal and constitutional history (sciences of state). According to the records, this was a formative stage for Hintze, during which Schmoller introduced him to archival research on the Prussian administrative files. Even this, his very first research on unpublished source materials, was carried out in connection with early comparative projects. At the same time, it was Hintze's first practical preparation for his work on the *Acta Borussiae*, Gustav Schmoller's editing and research project on Prussian history in the eighteenth century in particular.

Hintze was engaged in this exhaustive project, which was based at the Prussian Academy of Sciences, in various functions over a period of decades. He was initially contracted in 1888 as a research fellow. In this capacity, he acquired an unparalleled command of the published and unpublished source material on the Brandenburg-Prussian state, its regions and provinces, classes and estates, before expanding the scope of his research to include the sixteenth and nineteenth centuries. He completed his postdoctoral thesis, a monograph on the history of the Prussian state economy (*The Prussian silk industry in the 18th century*), in 1895. In 1899 he was appointed professor at the University of Berlin, where—turning down several offers of chairs at other universities—he advanced to the status of full professor from 1900 to 1902–7, and continued to teach until prematurely given emeritus status in 1920. Besides his broad research, which had long since extended beyond the boundaries of Prussia, he owed this distinguished academic career to Gustav Schmoller's excellent contacts in political and administrative circles which is of vital importance in the view of the various animosities among contemporary historians.

The initial focus of Hintze's extensive writings was on constitutional and economic issues of Prussian history, culminating in 1901 in a lengthy monograph on the organization of the Prussian state administrative authorities around 1740. In this volume Hintze analyzed the making of the Prussian state, its development from a territorial state to a 'grand state.' He then reluctantly accepted an official commission to compile a comprehensive survey of the history of Brandenburg-Prussia. Several editions of this

work were published in 1915–16, leading to heated (interdenominational) controversies during World War I.

In the course of archival research spanning two decades, Hintze acquired an excellent grasp of the source material, establishing an empirical basis that enabled him, even in further-reaching investigations, to take concrete historical life into consideration, particularly that of more recent centuries. For Hintze, the exploration of Prussian history was never a limited end in itself, but a paradigm for the historical process *per se*. This does not mean to say that he took this historical example as a yardstick by which the development of other states was to be measured, however. By his own account, it was at an early stage of his career—during his studies of legal and constitutional history under Schmoller—that Hintze had identified a much broader area as his future field of research: general constitutional and administrative history, from the comparative perspective. Furthermore, in choosing his Prussian topics of inquiry, he had always considered their usefulness for the 'entirety of my academic plans and studies' (1892).

Long before the World War I, which marked a turning point in Hintze's life, he became engaged in other, broader fields of research. In the course of his dispute with the protagonist of the older German historical school of economics, Wilhelm Roscher, Hintze had presented his conception of a comparative approach to the analysis of world history as early as 1897. In contrast to Roscher, whom he accused of neglecting the fundamental social aspects of state structures, Hintze devised a procedure that integrated both social conditions and the effects of foreign policy and power politics into the analysis of the formation of political structures. Hintze's main concern was to identify the recurring patterns in the development of states by means of a typological and comparative procedure. 'In the social region, there is a tendency towards regulated organic development: the making of states follows this developmental trend to a certain extent, simultaneously regulating it, but is by no means dependent on it alone.' Hintze maintained that the implications of 'power interests' were not to be underestimated, that the establishment of a state was 'at least as dependent on its external position of power as on the preconditions of the particular social structure for domestic governmental activity,' and that the 'external conditions cannot fail to influence social development.' It was this 'political side' of the formation of political structures which Hintze felt was neglected in any typological theory of states which, following the Aristotelian example, merely tried to identify analogous sequences of state systems. Hintze considered the process of state making to be largely dependent on the 'interrelations of the states, on the forces prevailing amongst them, on the rise and fall of the neighbouring states,' i.e., on what Leopold von Ranke had called the 'great world relationships.' (see

Ranke, Leopold von (1795–1886)) Hintze considered power as a given category, which—like the phenomenon of state rivalries—he did not attempt to deduce in any further detail. For him, the central aim was to define and register ‘types conditioned by world history’: phenomena observed in groups of states that had maintained close political relations. In this sense, he explained afterwards, he understood state making to be a ‘general, regulative principle,’ thus implying that he did not intend strict rules to be postulated. It seems that in his early writings, Hintze still assumed a cautious primacy of foreign policy factors in the process of state making, but that—remarkable in the history of science—he turned away from this explanatory model over the course of his further research and analysis.

In a whole series of individual studies, whose scope was gradually to broaden, reaching the dimensions of world history in about 1930, Hintze applied and tested his typologically-based comparative approach. He developed what could be termed a spatial-typological procedure, which makes (European) historical development appear to be that of a bonded unit of regions. Above all, Hintze was keenly interested in the differentiation of a ‘core Europe’ (with a close genetic and spatial relationship to the Carolingian Empire) and a ring of ‘peripheral’ countries. He tested this spatial typological and structural historical differentiation at various junctures in his comparative studies of constitutional history—in his works on the history of the European estates, for example. It also becomes apparent in the comparison of continental western and central European absolutism on the one hand and the insular parliamentarianism of England on the other, a differentiation which has admittedly been called into question in recent Anglo-Saxon research. The ‘peripheral’ states of England, Sweden, Poland, and Hungary were of great interest to Hintze on account of their numerous structural parallels, especially where the ‘parliamentarian’ tradition was concerned.

Hintze set himself the aim of writing a comprehensive ‘general comparative constitutional and administrative history of the modern states, namely the Latin and Germanic peoples,’ but the manuscript was no longer published from around 1930 onwards. Central parts of this work were lost after Hintze’s death; the fragments that survived are currently being edited by an international team. New sources reveal that Hintze remained keenly interested in the ‘individuality’ of states and political processes. Of course, the historical legacy of Hintze’s work should not be allowed to conceal his innovative potential.

Otto Hintze sought to establish contact with the systematic contiguous disciplines at an early stage of his career, and not merely in reaction to the traumatic upheaval of political cultures subsequent to the 1914/1918 war. On the contrary, he had already begun to lose interest in the Prussian paradigm in the years

preceding the war. His openness to the more modern approaches taken by social history, psychology, and sociology became evident as early as 1900, in the mediating statement he made during the so-called Lamprecht dispute about the relationship of ‘the individualistic and the collectivist conception of history’ (1897). Hintze pointed to the significant contribution made to historiography by Comte and Spencer (see *Comte, Auguste (1798–1857)*; *Spencer, Herbert (1820–1903)*), both of whom he referred to in his lectures. For Hintze, individuality and collectivity constituted the two poles of historical insight, and he maintained that the methods of social psychology afforded great opportunities to go beyond Ranke. Admittedly, Hintze’s growing interest in the concepts of sociology characterizes him as an outsider among the historians of his time. Hintze’s great 1920s discussions on the theory and philosophy of history, not only with Weber (see *Weber, Max (1864–1920)*), but also with Oppenheimer, Sombart, and Troeltsch, as well as with the jurists Kelsen and Smend, merely marked the culmination of a continuous development in his work. This is demonstrated, for example, by Hintze’s discussion of Sombart’s *Modern Capitalism*, in which the Berlin historian also referred to Marx. The extent to which Hintze started from the assumption of a primary, autonomous concept of society is a matter of debate. While he regarded the state as the dominant factor, his later studies and the surviving fragments of manuscripts written prior to 1933 reveal marked changes and a broadening of approach—he now tended towards a concept of society which was not derived from the state alone. For Hintze, social and socioeconomic factors began to gain in causal-analytic significance; the same applies to the concept of class, though Hintze never approached Marxist conceptions with anything but a distant interest. It is thus also a matter of contention whether Hintze’s typological procedure, along with the principle of ‘clear abstraction’ (*anschauliche Abstraction*), *ipso facto* neglected the element of dynamics. Hintze’s procedure was related (or rather contiguous) to Weber’s conception of the ideal type (*Idealtypus*), though always referring to the central question of the individualities of historical developments. It should be noted that Georg Jellinek had made pertinent suggestions for a typological methodology as early as 1900 in his *Allgemeine Staatslehre (General Theory of State)*, and that Hintze was able to develop these ideas in his search for phenomena of ‘relative comparability’ (Kocka). In any case, Hintze saw his work as a necessary supplement to both the legacy of Ranke and modern sociology.

Hintze’s reception of Weber’s writings also predates 1914. Both the strength of his systematic interests and the positioning of methodological boundaries are evident in Hintze’s second unpublished magnum opus, which can only be reconstructed to some extent from lecture notes. After 1920, Hintze had intended to

publish this work as a 'general theory of state and society on a historical basis,' a continuation of and supplement to his general constitutional history. He had intended to paint a 'typical picture of the modern state in terms of its shared properties and developmental trends, its various historical stages and individual forms.' In this 'policy' of Hintze, which he evolved in his middle period, the primacy of the state and of the law was (still) very apparent. 'The state must be considered from the legal, the philosophical, and the historical perspective'—in this order. Social factors were suited and subordinated to this conception. In contrast to his classical studies of comparative constitutional history, in which industry and workers (or the labor movement) played at most a marginal role, Hintze integrated the social developments of the nineteenth century into his 'policy' by means of critical discussion of Marx and Lassalle. In so doing, Hintze was able to identify developments in the middle classes and nonmanual occupations that were to be examined in greater detail by later social historians.

All this makes Hintze still of interest to present-day historians. Of course, not all of his works are relevant today, as a brief glance at his political writings will show. However, his openness to the contributions of the social and political sciences—highly unusual among his contemporaries in the field—and the scope of his view, which finally extended beyond euro-centrism, mean that he remains an important, innovative figure in modern political structural history. Admittedly, the reconstruction of his *oeuvre* is essential to apply his approach in practical research also for further developing his theories, yet this is forever hindered by the fact that central works were never published and can only be substituted and inferred. After 1933 Otto Hintze, who had married the Jewish historian Hedwig Guggenhämer, became a *persona non grata* in Germany. He ordered that his personal papers should be destroyed after his death, which for the most part they were. Hintze died in his Berlin apartment on April 25, 1940, long since isolated from academic life.

Hippocampus and Related Structures

The hippocampus is part of the cortex of the forebrain in mammals and is closely linked to a restricted number of related cortical areas which are here collectively referred to as the parahippocampal region. This collection of cortical regions, which in humans is located in the most medial portion of the temporal lobe, is involved critically in learning and memory processes, in particular in long-term explicit memory. The hippocampus also has strong functional links with subcortical structures believed to play a role in the selection of appropriate behavior to favor either survival of the individual or of the species. In this

article, the wiring of the hippocampus and the parahippocampal region underlying these two proposed functions will be described, and experimental data that support the proposed functions will be summarized.

1. What is the Hippocampus and What are Related Structures?

The hippocampus is a macroscopically defined cortical structure which is present in the brains of all mammals. *Grosso modo*, its appearance looks alike in all species in that it is an enrolled continuation of the most medial rim of the cortical surface of the hemisphere. The cortices directly adjacent to the hippocampus, which are referred to collectively as the para (next-to) hippocampal region, are considered as the related structures. The particular arrangement of these different cortical structures can be appreciated easily in sections taken perpendicular to the long axis of the hippocampus (see Fig. 1).

The hippocampus and the parahippocampal region of different species are positioned differently in the brain, such that in species with a clearly developed temporal lobe, the hippocampus is positioned more ventrally and anteriorly (humans and monkeys) compared to the situation in, for example, the rat, where the hippocampus looks more like a c-shaped structure positioned in the caudal third of the hemisphere, such that its dorsal one-third has a marked spatial relation with the corpus callosum. However, these differences in position do not alter the major characteristics and the topological relations between the hippocampus and the parahippocampal structures (see Sects 2 and 3). Nor does it influence the fact that the most anterior/ventral portion of the hippocampus has a close spatial relationship with the amygdala (see *Amygdala (Amygdaloid Complex)*).

2. General Features of the Hippocampus/Parahippocampal Region and Species Differences

The hippocampus consists of three major subdivisions, which can be recognized easily in all species (see Fig. 1). The first field, the dentate gyrus, is a c-shaped, three-layered cortical structure which is characterized by a densely packed cell layer, mainly consisting of granular cells, i.e., cells with a round soma, and an apical dendritic tuft and no, or only sparse, basal dendrites. Enclosed in this c-shaped cortical blade is a polymorphic cell group generally referred to as the hilus of the dentate gyrus. The second subfield is the Ammon's Horn or Cornu Ammonis, generally abbreviated as CA-field. The CA-field is generally subdivided into CA1, CA2, and CA3. The third subdivision is the subiculum. Note that, according to some authors, a prosubiculum can be differentiated

from the subiculum proper. Also, readers may find texts in which reference is made to the subicular complex, consisting of (pro)subiculum, presubiculum, and parasubiculum. Based on connectional arguments, it is preferred to consider the presubiculum and parasubiculum as being functionally different from the subiculum (cf. Amaral and Witter 1995; and for a very detailed comparison between species the reader is referred to Stephan 1975).

The parahippocampal region, in contrast to the hippocampus, comprises cortical regions with more than three layers—generally, five or six layers are distinguished. In all species, the parahippocampal region comprises five different regions, the pre- and parasubiculum, the perirhinal and entorhinal cortices, and a fifth area which in primates is commonly referred to as the parahippocampal cortex. In nonprimates, the most likely homolog for the latter area is the so-called postrhinal cortex (cf. Burwell et al. 1995, Witter et al. 1989). The respective names of some of the areas that make up the parahippocampal region refer to the rhinal sulcus, which can be distinguished in all mammals. However, its particular features differ considerably between species. Whereas in rats it is a distinguishable fissure that runs along the rostrocaudal extent of the hemisphere, in humans it is only present in about 50 percent of the cases, as a shallow and short indentation in the most medio-anterior temporal lobe. It is of interest that the spatial relationships among the different fields of the parahippocampal region appear similar in, for example, mouse, rat, monkey, and human (see Fig. 2).

A remark is appropriate concerning the question of whether nonmammalian species do have a hippocampus and related structures. In reptiles, cortical areas have been described which resemble, both in terms of celltype as well as connectivity, the mammalian dentate gyrus and Ammon's Horn. Part of the olfactory-related cortex of reptiles may be considered homologous to the mammalian parahippocampal region (see Ten Donkelaar 1997 for further reading). Interestingly, there is some evidence that lesions of these structures in reptiles interfere with learning. With respect to birds, there is convincing evidence that a particular region in the forebrain, homologues to the reptilian cortex, is functionally important for spatial memory. This region is generally referred to as the hippocampus, but structurally it looks quite different from the mammalian hippocampus. Connection-wise, though, it is quite similar (see Clayton and Krebs 1995 for further details).

3. Wiring of the Hippocampus and Parahippocampal Region

Most detailed information about the connectivity of the system comes from anatomical tracing studies in

Figure 1

Three sections of the hippocampus and related parahippocampal structures cut perpendicular to the antero-posterior axis of the forebrain of the rat (upper left), the monkey (upper right), and the human (lower panel; modified after Scharfman et al. 2000, p. 11, reproduced by permission of the New York Academy of Sciences)

Figure 2

Two-dimensional representations of the parahippocampal region in the mouse, rat, monkey, and human, illustrating that in all four species this region comprises the same subdivisions but that their spatial arrangements and individual relative sizes differ between species. Note that the pre- and parasubiculum are not represented in these figures (from Burwell 2000, p. 29, reproduced by permission of the New York Academy of Sciences)

Figure 3

Summary diagram of connectivity of the hippocampus illustrating the two major communication pathways: 1, the cortico-hippocampal circuitry through the hippocampal region; 2, the fornix

the rat, although for some pathways, relevant detailed information is available for the monkey, and for the cat as well. The overall picture which emerges from all these studies is that this connectivity is rather conservative, such that a general non-species specific description may suffice. For further details, readers are referred to Witter et al. (1989, 2000a, 2000b), Amaral and Witter (1995), Burwell (2000), and Suzuki and Amaral (1994a, 1994b). The hippocampus has two major pathways through which it is connected to the rest of the brain. The first pathway makes use of the so-called cortico-parahippocampal-hippocampal circuit, and the second is formed by the fornix (see Fig. 3).

3.1 Cortico-Parahippocampal-Hippocampal Circuit

A striking feature of the cortico-parahippocampal-hippocampal circuit is that the hippocampus does not

have direct connections with the majority of the functionally different cortical regions. In contrast, this communication is mediated by way of the parahippocampal region. Of this region, the perirhinal and postrhinal/parahippocampal cortices maintain the highest number of cortico-cortical connections, including connections within all major sensory realms, such as visual, auditory, somatosensory, and gustatory ones. Also, massive connections exist with the other two major higher-order association domains, the parietal and prefrontal cortices, but connections with the motor cortex are less prevalent. The perirhinal and postrhinal/parahippocampal cortices, in turn, provide a major input to the superficial layers II and III of the entorhinal cortex, which are further reached by inputs from olfactory structures, the amygdala, and from the remaining two components of the parahippocampal region, i.e., the pre- and parasubiculum. Neurons in entorhinal layers II and III, which are the recipients of this wide variety of inputs, give rise to the major cortical input to the hippocampus, the so-called perforant pathway. This name is derived from the traditional descriptions by Ramon y Cajal (1911), who noted that fibers from the entorhinal cortex perforate the underlying white matter and the cortical lamina of the subiculum to gain access to the dentate gyrus molecular layer. In order to understand the potential functioning of the system, it is critical to point out that the perforant pathway projection harbors two different systems. Layer II cells distribute their axons to the dentate gyrus and CA3, whereas layer III cells send their axons to CA1 and the subiculum. In addition to this intriguing difference in target specificity, the terminal distributions of these two components of the perforant pathway are entirely different. Layer II cells give rise to a widespread projection to all dentate granular cells. In contrast, axons of layer III cells target only restricted groups of the available neurons in CA1 and the subiculum (see Sect. 5.1 for functional relevance; see also Fig. 3). This particular feature is of interest, since field CA1 and the subiculum constitute the major output structures of the hippocampus. Hippocampal output from these two hippocampal fields is distributed by way of projections back to the entorhinal cortex, from where ongoing output projections originate to a host of cortical and subcortical structures, including projections to perirhinal and parahippocampal/postrhinal cortices, prefrontal areas, amygdala, ventral striatum, and midline thalamus.

A further refinement has to be added to the overall organization of the connections between the parahippocampal region and the hippocampus. It has been established that the input-output system consists of at least two parallel pathways. One of the pathways carries inputs from the perirhinal cortex into and away from the hippocampus, whereas the second mediates transfer of information from and to the parahippocampal/postrhinal cortex. In view of the anatomical

organization outlined above, it has thus been suggested that in the hippocampus these two pathways converge at the level of the dentate gyrus and CA3, whereas they are kept more or less separate at the level of CA1 and the subiculum (cf. Witter et al. 2000b).

3.2 *The Fornix*

The fornix is a major fiber bundle which connects the hippocampus to the hypothalamus, in particular the mammillary bodies. On its way, the fornix also issues fibers to the septal complex, the ventral striatum, and the amygdala. As indicated above, the fornix is not a pure output pathway, since projections from the septal complex (see Sect. 5.2) to the hippocampus and in part to the entorhinal cortex travel by way of the fornix. In addition, the commissural connections between the left and right hippocampi also partially travel by way of the fornix. The hippocampal connection to the mammillary bodies is part of the traditionally described limbic or Papez circuit, which includes the mamillo-thalamic tract connecting the mammillary bodies with the anterior complex of the thalamus, which in turn project to large portions of the limbic cortex, including anterior- and posterior-cingulate cortex, and pre- and parasubiculum (see also *Cingulate Cortex* and *Limbic System*). All these structures, in turn, provide input to the hippocampus, either directly, or indirectly by way of the entorhinal cortex.

4. *The Hippocampus is not a Homogeneous Structure*

When one looks at the overall anatomical organization of the parahippocampal-hippocampal system, it appears that the hippocampus is rather homogeneous along its long axis. However, differences in numbers of neurons between the dorsal/posterior and ventral/anterior hippocampus have been reported, indicative for differences in the overall neuronal network. Moreover, in the rat and in the monkey, it has been established that the dorsal/posterior portion of the hippocampus receives its major cortical input from the more sensory-related or exteroceptive lateral and caudal portions of the entorhinal cortex, whereas the ventral/anterior hippocampus receives inputs from more medial parts of the entorhinal cortex, which most likely convey information that reflects the interoceptive status of the individual. In addition, direct reciprocal connections with the amygdala are limited to the ventral/anterior and intermediate levels of the hippocampus and are absent for the dorsal/posterior portion of the hippocampus (cf. Witter 1986). Behavioral data in support of this notion are the findings that in rats the dorsal hippocampus is critical for the initial learning and long-term memory of spatial

information, whereas the ventral hippocampus is not essential (cf. Moser and Moser 1998). Recently, brain imaging studies have revealed that in humans functional differences are also present between anterior and posterior halves of the hippocampus; however, the precise nature of these differences is still an issue for debate (Lepage et al. 1998, Schacter and Wagner 1999).

5. *Functions of the Hippocampus and Parahippocampal Region*

5.1 *Functions of the Cortico-Hippocampal System*

Ample clinical and experimental evidence supports the view that the hippocampus and parahippocampal structures are essential for memory processes, although the unique contributions of each of the different subfields are as yet incompletely understood (Scoville and Milner 1957, Squire 1992, Eichenbaum et al. 1994). The results of the behavioral studies, in particular, have provided insights into how each of the components of the hippocampal system contributes to memory processes. Instead of contributing in a unitary way to memory, it appears evident that individual structures make selective contributions. Such studies indicated that the hippocampal formation itself does not contribute critically to object recognition memory. Instead, it is the laterally positioned component of the parahippocampal region, the perirhinal cortex, that appears to be involved critically in this task (Murray et al. 2000). In contrast, the more posterior portions of the parahippocampal region, the parahippocampal cortex in primates or the postrhinal cortex in nonprimates, may be involved critically in spatial or topographical memory (Bohbot et al. 2000, Vann et al. 2000, cf. Witter et al. 2000b). Concerning the role of the entorhinal cortex, the results of lesion studies appear inconclusive; still, it is most likely that the entorhinal cortex operates cooperatively with the hippocampal formation, such that both structures process information in different, yet complementary ways. With respect to the hippocampal formation, it has been proposed that it plays a critical role in mediating memory for relevant relationships among conjunctions or associations unique to a particular episode (Eichenbaum et al. 1994).

5.2 *Functions of Hippocampus-Fornix Connectivity*

As indicated above, the fornix provides the hippocampus with another pathway, beside the cortical route, to communicate with a host of subcortical brain structures, including the mammillary bodies. Behavioral data indicate a clear functional dichotomy between the cortical versus the fornix route. However,

the role of the fornix pathway in learning and memory is as yet poorly understood. Lesions of the main target of the fornix, i.e., the mammillary complex in animals, do not result in marked memory deficits, although in Korsakoff's patients, which do show a marked anterograde as well as retrograde memory deficit, the mammillary bodies show a marked decrease in volume (cf. Aggleton and Brown 1999). In addition, there is convincing human evidence from patients with thalamic infarctions in favor of a role in memory processes of the connection from the mammillary complex to the anterior complex of the thalamus (van der Werf et al. 2000).

The fornix also mediates connectivity from the hippocampal-parahippocampal structures to the ventral striatum and the amygdala. In the ventral striatum, interactions may take place between hippocampal, amygdaloid, and prefrontal outputs, leading to the selection of appropriate behavioral strategies, for example, in learning paradigms (consult Groenewegen et al. 1999 for further reading). The functional relevance of the reciprocal connections between the amygdala and hippocampus, and for that matter also those between the amygdala and the parahippocampal region, is still poorly understood (Pitkanen et al. 2000, Stefanacci et al. 1996). It is assumed that amygdala inputs may provide the hippocampal system with a marker for relevance to a particular memory episode.

The connections to and from the septal complex of both the hippocampus and parahippocampal structures use the fornix as well as a number of other white matter pathways. Although much about these interactions has yet to be resolved, it is clear that the normal functioning of the hippocampal-parahippocampal-cortical interactions depends strongly on a functional septal complex. It is in particular the fact that the septal complex supplies the hippocampus and parahippocampal region with most of its cholinergic input, as well as the role of the septal complex in the synchronization of electrical activity which relates to its functional relevance (see Sect. 5.3).

5.3 Oscillatory Activity

The hippocampus shares with the entorhinal cortex the presence of strong rhythmical activity, in particular theta rhythm, which is coexpressed with trains of gamma waves during exploring behavior in the awake animal as well as during a particular sleep phase called Rapid Eye Movement (REM) sleep. Both structures also share the occurrence of so-called sharp waves, a high-frequency discharge which occurs predominantly during the alternating sleep phase, the so-called slow-wave sleep phase. Although the electrophysiological mechanisms underlying the occurrence of such oscillatory phenomena have been clarified to some point, the functional relevance, for example, in relation to learning, is still debated. There appears to be consensus though that the normal functioning of the

cortico-hippocampal learning system depends strongly on the normally occurring alternations between the theta and the sharp wave state (cf. Buzsaki 1996).

5.4 Clinical Relevance

The hippocampal-parahippocampal structures play an established role in learning and memory processes, which is supported by reports concerning pathological changes seen in diseases that are associated with learning and memory disorders such as Alzheimer's disease. However, other neurological/psychiatric disorders, such as epilepsy, schizophrenia, Huntington's, Parkinson's and Pick's disease are associated with pathological alterations in these regions as well. The most striking observation, however, is the specificity of the pathology in each of these diseases. In all except epilepsy and schizophrenia, the first pathological changes are seen in the anterolateral part of the entorhinal cortex, also called the transentorhinal cortex. However, in all these diseases, the layer showing the most dramatic alterations seems to be disease specific (Braak et al. 2000). In the case of epilepsy, the most striking initial pathology is observed in layer III of the medial entorhinal cortex (Schwarcz et al. 2000), whereas in the case of schizophrenia, the pathology appears to start in layer II throughout the entorhinal cortex (Arnold 2000). In all these disorders, the hippocampus becomes involved as well, leading to an overall dramatic reduction in neuronal numbers and/or connections.

M. P. Witter

Historical Archaeology

Historical archaeology is the concurrent study of material culture and documentary evidence. This article outlines the scope of the practice of historical archaeology, some of its principal features as a discipline, and some of the major research questions for which historical archaeologists seek answers.

In a strict sense, historical archaeology should begin with the discovery of writing, for it is from this time onwards that societies are able to express themselves both in the ways in which they fashion the world around them—their artifacts—and also through recorded self-expression: the written record. But in practice, these early literate periods have been left to classical archaeology, and historical archaeologists have defined their domain as the last 500 years. This half millennium saw the creation of extensive ‘world systems’ and, in particular, the colonization of the Americas, Africa, and parts of Asia by Europeans. This focus has given historical archaeology its particular character, and some have gone so far as to describe it as the archaeology of European colonial expansion. But more recently—as we shall see—these conventions have been challenged, opening up the possibility of a dynamic and expanding area of enquiry.

The practice of historical archaeology is rooted in the study of the European settlement of North America and, in particular, of the early seventeenth century colonial settlement in New England and the Chesapeake. Here, a rich heritage of material culture

has long been closely associated with a sense of national identity, best represented by the archaeology of Colonial Williamsburg, the eighteenth century capital of Virginia which has been preserved and reconstructed as an interpretation of daily life in America's early years (Colonial Williamsburg 2000). This focus has resulted in a rich narrative of early settlement, best represented by Ivor Noel Hume's excavation and interpretation of Martin's Hundred (Noel Hume 1983). Here, we see the carefully excavated traces of daily domestic life matched with an imperfect documentary record to reveal a far fuller narrative history than words alone could tell. Martin's Hundred is matched by numerous other studies that provide an ever-emerging picture of life in the early American colonies.

More recently, this emphasis on the settler and colonist has been balanced by the emergence of an archaeology of slavery. Archaeologists of slavery—whether working on former plantations in the south or on slave living sites in northern towns—have made the point that archaeology's claim to be the history of ordinary people must remain hollow if all dimensions of colonial life are not fully explored (Singleton 1995). In this area, historical archaeology has made notable gains in revealing domestic life on plantations and some of the aspects of identity, including the persistence of elements of African material culture in house design and personal artifacts, distinctive culinary practices, and patterns in composite material culture assemblages.

Historical archaeology in North America now extends well beyond this 'classic' focus and there is a variety of specialized subfields. These include the archaeology of western frontier settlements, battlefield archaeology, the archaeology of industrial sites, and urban archaeology. The practice of historical archaeology has also been strongly influenced by the professional field of cultural resource management, (CRM) as large State and federal projects have required numerous surveys and excavation projects ahead of development and urban renewal projects. CRM work has ranged from small studies of individual archaeological features to comprehensive surveys and extensive excavations in the face of freeway construction. Such work tends to be characterized by a heavy emphasis on fieldwork and recording, and less attention given to analysis, interpretation and historical synthesis, leading to a division between field-oriented archaeologists working in cultural resource management and archaeologists working in museums, universities, and other public institutions.

Despite a fondness for the self-image of a rugged fieldworker, uncluttered by intellectual pretensions, historical archaeology has reflected the major theoretical trends of the social sciences over the past half century (Hall 2000, Orser and Fagan 1995). Early work—such as Noel Hume's study of Martin's Hundred—was avowedly narrative. In this approach

(which has continued through to the present) the results of archaeological excavations serve to amplify and illustrate an incomplete documentary history, contributing to telling a story that is made richer by the tangible traces of the past. This empirical emphasis was challenged from several directions. Firstly, the 'New Archaeology' of the 1960s and 1970s sought law-like generalizations of human behavior through the evidence of material culture—an approach represented in Stanley South's search for standard patterns across archaeological sites (South 1977).

This approach was challenged by structuralism, best represented by James Deetz' widely read *In Small Things Forgotten* (1996). Here, material culture in its full breadth—from pipe-stems to houses—was organized as evidence of the human mind at work in creating systems of binary oppositions, together constituting 'world views.' Structuralism reassessed the principles of narrative history in seeking to show how European settlers 'became American' when they adopted an embedded mental template that determined how their world was arranged—the essence of cultural identity. But, in emphasizing the commonality of world views, structuralism lost a clear sense of cause and effect, and the processes of history unfolding. This prompted new interpretative approaches that turned to historical materialism for theoretical models. Well represented by Mark Leone's work in Maryland's Annapolis (1988), this approach has seen in the archaeological record the evidence for the emergence of merchant capitalism and social and economic control through the manipulation of material culture to create a false consciousness that disguises the true location of power. For example, Leone showed how garden design served to naturalize the authority of the new class of merchant capitalists in Annapolis, and how such naturalization extended to other categories of material culture, including musical instruments and ceramics.

More recently, the overwhelming association between historical archaeology and North America has been challenged by strong developments in other parts of the world. Each regional focus has tended to develop its own identity while remaining linked to the core concepts of this discipline. This is opening up the possibilities of a richer body of theory and of new areas of comparative study. One such area of development has been in Australia, where the archaeology of colonial settlement has gained increasing attention (Connah 1988). Here, studies have ranged from the historical archaeology of colonial buildings and early settler footholds on the continent to women's prisons in Tasmania. This has been matched by the development of historical archaeology in South Africa, where Dutch settlement in the mid-seventeenth century was followed by a century of British colonial settlement and a diverse material record (Hall 1993). Newer work in areas such as the Caribbean and in South America is adding a comparative richness to the field.

Despite these developments, though, historical archaeology still remains overwhelmingly the archaeology of European colonial expansion. Despite notable exceptions (for example, Johnson 1996), the archaeology of Europe itself in recent centuries still remains a separate field—'post-Medieval archaeology.' The archaeology of colonial contact—and the impact of European colonial expansion on the other side of colonial frontiers—remains largely unexplored. Claims for other forms of historical archaeology, for example the use of oral traditions as verbal sources (Andah 1990), remain largely unacknowledged. And the historical archaeologies of other large-scale, literate systems such as those of China or of Islamic expansion and settlement remain outside the scope of the field.

For some, historical archaeology is no more than a transition zone between preliterate periods, in which material culture is the only source of evidence, and documented history. But for others, historical archaeology has a distinctive character that makes it a discipline in its own right. There is some justification in this second point of view. Increasingly, historical archaeology has a distinctive set of methodologies and a suite of particular research questions of its own. Historical archaeology has its own professional journals, and its practitioners attend their own conferences. If this were the world of natural organisms, we could say that speciation is well advanced.

Historical archaeology shares with the rest of archaeology the basic methodologies of excavation. But although historical archaeologists often work with the precision of the prehistorian, teasing evidence from the slightest detail, they also often work to a larger scale. This is because the archaeological sites are large, with complex histories of deposition and disturbance which make the mechanical excavator a more appropriate research tool than the trowel. In addition, a large proportion of historical archaeological evidence is not beneath the ground. Standing buildings, field systems, roads and town layouts can reveal as much about the past as a conventional excavation. This brings historical archaeology close to fields such as ecology, cartography, architectural studies, and historical geography in its methodologies. Indeed, while retaining its ties with the time-honored skills of excavation, historical archaeology is quintessentially interdisciplinary in its search for, and analysis of, evidence.

Historical Change and Human Development

Human development refers to patterns of change and stability that characterize a person from birth to death. Many theories maintain that development is highly plastic, which means that it is not predetermined in its processes or outcomes. In fact, human development is highly responsive to social and historical change. This article examines how behavioral scientists interrelate history and biography: how the particularities of historical circumstance lead to unique patterns of development.

Historical data are also used to test general theories of the family, life course, and life span. This approach does not deny that historical forces operate in unique ways to shape development, but it does consider the generalizability of theories across historical settings. Accordingly, this article then examines how historical data are used to test general theories of behavior.

1. The Historical Time Frames of Human Development

Human development reflects mechanisms that operate in three historical time frames, each of which is studied from different disciplinary standpoints. First, human behavior reflects evolutionary mechanisms that operate across historical epochs covering many

millions of years. These mechanisms are studied by biologists, anthropologists, and evolutionary psychologists who share a set of Darwinian assumptions. Second, individual development reflects the unique influences of historical periods that are comparatively limited in their duration. For example, social historians and students of psychohistory examine how the organization and ideology of Medieval society led to specific biographical patterns. Finally, life-span psychologists and life course sociologists examine connections between human lives and the 'historical present,' which encompasses the historically specific circumstances of a person's life (e.g., the Great Depression or the 1970s).

1.1 Historical Epochs: Phylogeny, Ethology, and Evolution

One of the most influential (albeit erroneous) contributions to the study of human development has been the principle of recapitulation, which emerged in the late eighteenth and early nineteenth centuries. Although many nineteenth century biologists subscribed to recapitulation, its greatest proponent was Ernst Haeckel, whose biogenetic law maintained that ontogeny (the life history of the person) recapitulates phylogeny (the evolutionary history of the lineage leading to the person). That is, the morphological development of each person quickly repeats—indeed, is caused by—the adult forms of the evolutionary history that preceded it. For example, Haeckel argued that because 'the human egg is a simple cell, we may at once infer ... a unicellular ancestor of the human race resembling an Amoeba.' Similarly a later embryonic form in humans points to a 'primitive worm-like ancestral form which is related to the sea squirts or Ascidians ...' (quoted in Gottlieb 1992, pp. 29–30). Because this recapitulation takes place in the embryonic and juvenile stages of development, the further evolution of a species depends on terminal addition, the appending of new characteristics to 'the end of an unaltered ancestral ontogeny' (Gould 1977, p. 74).

The biogenetic law fails principally because there is no known mechanism that links the evolution of a lineage with the development of an individual. And yet this law is important for two reasons. First, even though it was commonly rejected in biological circles in the early twentieth century, various forms of psychological recapitulation continued to influence many developmentalists, including Baldwin, Freud, Hall, Piaget, and Preyer (Gould 1977). For example, the biogenetic law (as it addressed both morphological and behavioral development among its proponents) and Lamarckian biology influenced Freud in pervasive ways. Thus, Freud held that the psychoanalytic stages of development (e.g., the oral and anal stages) were recapitulations of the phylogenetic sexual stages of our remote ancestors (Sulloway 1979).

This influence also is illustrated clearly in *Totem and Taboo* (Freud [1913] 1962) and such later works as *Moses and Monotheism* ([1939] 1967). In these works, Freud elaborates his theory of psychosexual recapitulation—this time focused on the Oedipus complex—involving an early trauma, a defensive reaction, a latency period, and then the outbreak of a neurosis. This theory, he believed, characterized the history of the human species, the history of the Judeo-Christian tradition, and the life history of the individual.

In the history of the human species, following the Ice Age a horde of brothers killed and consumed their father because of their sexual desire for his wives. Later, the brothers atoned for this act by deifying the slain father, now represented by a totem, and by observing prohibitions against parricide and incest. This sequence of acts was probably repeated over the millennia and was traumatic; consequently, by way of Lamarckian inheritance (which posits that acquired characteristics can be transmitted to successive generations), the feelings that surrounded these events were passed to later generations and now reside deep in the memory of all people. That is, according to Freud, the Oedipus complex is an inherited psychological structure rooted in phylogeny.

The life history of the individual repeats this sequence. Childhood sexual traumas (either real or conjured from phylogenetic fantasies that often involve the Oedipus complex) are repressed and forgotten during a period of latency. Additional traumas or disappointments in adulthood can then lead to high levels of distress and often to a neurosis. Thus, mental disturbances in adulthood need not trace back to a trauma that is consciously experienced by people during their own childhood; all humans are born with inherited traumas that reside deep in the unconscious and that can compromise pathways of adult development. Unfortunately, Freud's theoretical edifice is flawed because of its strong and erroneous biological assumptions. Referring to Lamarckian biology, Freud himself remarked in *Moses*, 'If things are different, then we are unable to advance one step further on our way, either in psychoanalysis or in mass psychology.' (Freud [1939] 1967 p. 128, Sulloway 1979, see also *Freud, Sigmund (1856–1939)*).

Second, although the biogenetic law was a flawed attempt to link the evolutionary time frame with individual development, the link is still being pursued at the beginning of the twenty-first century, albeit in very different ways, including, for example, through ethology and life history theory. Ethology is the study of animal behavior, its causes, development, functions, and, importantly, its evolution. Developmentalists have drawn on ethological research to provide principles whose applicability to humans can then be assessed (Hinde 1982). This approach is vividly illustrated by Bowlby's attachment theory, which relies heavily on ethological research (e.g., animal im-

printing). In *Attachment and Loss* (1969–80), Bowlby explains that the attachment behavior of young children, which includes variations in proximity seeking to the primary caregiver, is an instinctual behavior observed in many birds and mammals because it facilitates survival (but see Belsky 1999). According to Bowlby, the attachment relationship in humans between child and primary caregiver leads to an ‘internal working model’ of felt security, which in turn has pervasive implications for one’s later relationships and psychological development (see *Attachment Theory: Psychological*).

Life-history theory refers to evolutionary explanations for the specific timing of biological events during the life course. Life-history theory assumes that natural selection has influenced when and how energy is allocated to growth, maintenance of the self, and reproduction so as to maximize reproductive output. Hence, life-history theory attempts to explain, for example the age of maturation, fertility rates and the spacing of children, menopause, senescence, and the length of the life span. For example, ‘disposable soma theory’ provides an evolutionary explanation for why people senesce (i.e., experience a decrease in bodily functions with increasing age). According to this theory, death from unavoidable causes (e.g., accidents, predation) in the course of evolution was inevitable and thus energy was diverted from attempts to live for exceedingly long periods to reproductive efforts earlier in the life span. Indeed, empirical evidence supports the proposition that the rate of senescence is directly related to the probability of death due to difficult-to-avoid causes. One of the major challenges to life-history theory, however, is its application beyond nonhuman species and primitive peoples. Many of its expectations refer to environments that were typical of the evolutionary past and so require further elaboration or restriction when applied to modern societies, especially societies that have experienced the demographic transition (Hill and Kaplan 1999; see also *Education and Learning: Lifespan Perspectives; Psychological Development: Ethological and Evolutionary Approaches*).

1.2 Historical Periods: Social History and Psychohistory

Compared to evolutionary epochs, historical periods are more limited in both time and place. Historical periods typically refer to intervals in history that represent relatively cohesive and distinct patterns of material living conditions, ideologies, norms, social organizations, and institutions.

Social history is often concerned with how these factors jointly shape biography, especially factors such as childhood socialization, school, work, and family. For example, many historians have studied how changing social circumstances have altered the mean-

ing of ‘childhood,’ ‘adolescence,’ and indeed the functions of the family before, during, and after the Early Modern Period, which is often defined in terms of the Industrial Revolution. Ariès’s path-setting *Centuries of Childhood* (1962) provided the impetus for many contemporary inquiries. According to Ariès, in medieval society (and much later among the lower classes), childhood and adolescence did not exist; rather, ‘as soon as the child could live without the constant solicitude of his mother, his nanny or his cradle-rocker, he belonged to adult society’ (p. 128).

Beginning in the sixteenth century, parents began to educate their children before they could enter the adult world. As educational systems developed, youth were taught in age-segregated settings according to curricula that were increasingly less concerned with vocational training than the medieval guilds had been. With this prolongation of education and segregation from the adult world, childhood and adolescence emerged as distinct age-graded identities. While *Centuries of Childhood* has been criticized in matters large and small, its basic analytic orientation—one that emphasizes the interconnectedness of work, school, family, and the phases of the life course—remains a point of departure for historians interested in human development (e.g., Kett 1977).

Psychohistory emphasizes the psychological development of the individual. Its primary focus is on the complex relationships between historically unique processes and the psychological functioning of individuals or, in some cases, mass psychology. Numerous biographies that utilize psychological data or theories have followed Freud’s early attempts. Most draw on some form of psychoanalytic theory, although there are notable exceptions (e.g., B. F. Skinner’s application of behavioral theory to his autobiography).

Erikson’s *Young Man Luther* ([1958] 1993) is often acknowledged as one of the great contributions to psychohistory. He focuses on the adolescent identity crisis because, according to his general theory of the life span, the resolution of this crisis ideally leads to the rejuvenation of the person and, potentially, to the rejuvenation of society. Erikson claimed that Luther’s crisis consisted of an intense Oedipus complex that prompted Luther to question the moral authority invested in father figures, be they his own father or the Pope. Both his father and the Catholic Church attempted to control Luther with a ‘negative external conscience’ since both had contributed significantly to his superego, which emphasized his inherently flawed nature: In the case of his father, Luther did not find support in his choice of occupations, and, in the case of the Church, he felt sinful and unworthy of his priesthood. According to Erikson, Luther’s uniquely strong sense of conscientiousness led to an affirmation of his inner voice as a valid instrument of both self-determination and religious belief, thereby justifying salvation based on faith rather than on obedience to an ecclesiastical (paternal) authority. ‘In laying the

foundation for a religiosity for the adult man,' Erikson argued, Luther 'displaced the attributes of his own hard-won adulthood; his renaissance of faith portrays a vigorous recovery of his own ego-initiative.' (Erikson [1958] 1993 p. 206).

Erikson's biographical approach is unusual for its reciprocal view of history and human development: historical forces clearly shaped Luther and yet, in resolving his identity crisis, Luther in turn shaped history. There are, however, several basic difficulties common to analyses such as Erikson's, including, for example, a lack of pertinent biographical information about the subject's childhood, difficulty establishing causal links between early and later events in a person's life, and identifying why one person—and not another among many people in similar circumstances—becomes a historically great figure (Runyan 1982; see also Erikson, *Erik Homburger (1902–94)*).

1.3 The 'Historical Present': The Life Span and Life Course

Social historians and psychohistorians emphasize common elements of context that people share in a historical period. Yet within historical periods, unique trends and events occur that differentiate age groups and even individuals within age groups. Life-span psychology and life course sociology represent two approaches to the historical present and development.

Life-span developmental psychology refers to a series of interrelated concepts and propositions that emphasize the complexity of development in historically changing contexts. According to this perspective, age-graded development is markedly influenced by existing sociocultural conditions and by social change. Indeed, development can be viewed as the interactions among age-graded, historical, and nonnormative (or idiosyncratic) influences (see Baltes et al. 1998). The life-span paradigm has been especially influential in charting connections between age trends in psychological phenomenon and historical time.

For example, Nesselroade and Baltes (1974) examined the relative contributions of age and history to the development of adolescent personality and ability between 1970 and 1972 in the USA. They reasoned that because youth are highly influenced by social circumstance and because personality reflects situational factors, trends in variables such as adolescent ego strength, independence, and ability may be explained by (a) unique historical experiences shared by young people born in the same year (a birth cohort effect) and (b) historical experiences that exert a similar influence across many age groups (a period effect). To examine these possibilities, they studied a sample of adolescents of diverse ages (ranging from 13 to 18) and, within age groups, adolescents from different birth cohorts (e.g., 15 year olds born in 1955, 1956, and 1957).

Empirical analyses reveal significant declines in self-rated ego strength and achievement and a significant increase in independence between 1970 and 1972, irrespective of age, which suggests that the development of adolescent personality and ability are less dependent on age than on historical setting. According to Nesselroade and Baltes, the observed effects may reflect several historical features that characterized the early 1970s and affected many adolescents (i.e., a period effect), including the tendency of youth to value moral, social, and political questioning (especially of the Vietnam war) rather than to value cognitive achievement, and the widespread decline in confidence in public and educational leadership. This research and related studies suggest that psychological development does not proceed as 'an orderly, sequential unfolding of universal, stage-like behavior patterns' (Nesselroade and Baltes 1974, p. 57), but rather is shaped in significant ways by historically based experiences (see also Schaie 1996, for notable cohort and period effects on adult cognitive development).

The life course refers to the sequence of age-graded roles that typically characterize development. These roles (e.g., student, worker, mother) bring with them expectations, opportunities, and limitations, all of which shape the contours of people's lives. This sequence of roles, their timing, and content are sensitive to immediate historical circumstances. Thus, the study of the life course typically begins with social changes and traces the implications of these changes to the developing person (see *Life Course in History*).

Drawing on data from a wide variety of sources, for example, Modell (1989) shows that the 'normative' sequence of roles often associated with the transition to adulthood—the completion of school, entry into work, marriage, and becoming a parent—became less common through the twentieth century. Modell juxtaposed his quantitative findings with the qualitative study of US cultural practices (dating, for example) to suggest that as youth were freed from the constraints of family and as they acquired financial resources of their own by wage labor, they increasingly became 'shapers of youth,' making choices about when and how they would enter adulthood. The aggregate of these choices creates a 'demonstration effect' for subsequent cohorts, until the next demonstration effect comes along to replace it.

The study of the life course owes much to Elder's watershed *Children of the Great Depression* ([1974] 1999), which integrated a focus on historical and social change with the study of the family and the social and psychological development of the person. A key analytic tool in Elder's research is the birth cohort (i.e., the year a person is born), which situates the person's development in the context of historical events. For example, Elder compared the lives of older children (ages 11–13 in the depths of the Depression) and younger children (ages 3–5 in the depths of the Depression) during and after this event. He further

distinguished between families who did and did not experience serious financial burdens because of economic downturn. Although the Depression led to similar changes in the deprived families of both cohorts—involving the division of labor, altered family roles, and social strains—its developmental effects varied by the age of the children. For example, children in the younger cohort from deprived families were more vulnerable to family strains and indeed were less likely to be hopeful, self-directed, or confident about their future than were their counterparts in families not adversely affected by the Depression. In contrast, the older boys from deprived families were likely to take active steps to help their families and themselves; these experiences in turn enhanced their social independence, which had lasting effects on their lives (see Elder et al. 1993).

Elder's research established a general analytic model that interrelates economic downturn and individual development. The basic model posits that economic stressors lead to marital tensions, which in turn have negative implications for parenting and children's well-being. Although the model was developed in the context of the Great Depression, it has proven useful in understanding other economic downturns (e.g., the Farm Crisis of the 1980s). Elder's research also established a series of analytic principles for the study of change and human development across historical circumstances. For example, the life-stage principle asserts that the influence of a historical event depends on the age at which the person experiences it. This principle is illustrated by the differences observed among the older and younger children of the Great Depression, but it has also been used, for example, to study the effects of military service, German reunification, and China's Cultural Revolution on people's lives.

2. Historical Data and Theories of Human Development

While the theories and empirical research discussed in the previous section emphasize how particular historical forces lead to specific patterns of development, some scientists use historical data to test general ideas about human behavior. This approach has yielded valuable insights, for example, about the factors that affect physical height (Fogel et al. 1983), human creativity (Simonton 1999), and the timing of puberty (Mitterauer 1993).

One of the landmark contributions in the use of historical data to test general psychological principles is Sulloway's *Born to Rebel* (1996). Sulloway developed an elaborate theory that interrelates birth order, family dynamics, and aspects of personality. For example, his theory predicts that later-borns are more likely to subscribe to radical ideas than first-borns. He tested

this and other expectations by drawing on a comprehensive database of 6,566 participants in famous scientific, religious, and political movements in history. A noteworthy feature of this research is the use of experts to rate the participants in these events in terms of their personality and social attitudes.

Drawing on these unique data, Sulloway found support for his theory. For example, the Copernican revolution and Darwin's theory of evolution by natural selection are both rated as radical scientific theories and in fact the leaders of both were likely to be later-borns, including Copernicus and Darwin themselves. (Alfred Russell Wallace, sometimes considered the co-originator of evolution by natural selection, was also a later-born.) In contrast, scientific breakthroughs of a technical nature are likely to be achieved by first-borns as found, for example, in the cases of Watson and Crick, the cofounders of the structure of DNA (as well as in the case of their chief rival, Linus Pauling, also a first-born). Sulloway's research is exemplary for its attempt to document person-by-situation interactions involving the historical context, such as birth order and the social implications of a scientific revolution.

3. Integrating History and Development

The preceding discussion suggests two directives for future research. First, accounts of human development will ideally incorporate explanatory factors from all three historical time frames. The case of attachment illustrates the potential of this approach. In terms of epochs, ethological research has contributed to an understanding of the instinctual basis of attachment behaviors. In terms of historical periods, the parent-child relationship is heavily conditioned by social institutions such as education, work, and family. And, in the historical present, parental loss or changes in the parent-child relationship are often precipitated by immediate circumstances of historical import. Indeed, attachment theory was inspired in part by the countless children left without parents after World War II.

Similarly, Sulloway's work on sibling strategies and family dynamics unites evolutionary theories about sibling competition with a consideration of historical practices (such as primogeniture), and finally with statistical patterns associated with individual development.

Second, interdisciplinary collaborations will benefit from the integration of diverse methods of inquiry. Many developmentalists rely on statistical analyses of data that were recently collected; these accounts typically emphasize how contextual and personal factors predict behavior. In contrast, many historians rely on the qualitative study of archival materials; these accounts typically emphasize the complex combinations of structural contingencies and cultural

meanings that shape biography. If developmentalists often ignore the interactionist, cultural stance of historians, historians are often skeptical as to whether their interests can be measured and subjected to statistical analyses. Yet a growing number of studies illustrate the value of integrating diverse methods, including, for example, Modell's (1989) study of the transition to adulthood and Elder's study of the Great Depression (Elder et al. 1993; for another example see Hareven 1982).

In short, as research on attachment and family dynamics illustrates, all three historical time frames come together to shape one's life, and thus render the study of human development an interdisciplinary task that encompasses diverse historical influences. And as research on the transition to adulthood and the Great Depression illustrates, the quantitative and qualitative methods of the behavioral sciences can be used in complementary ways to uncover these many historical influences as they shape development and the biography.

M. J. Shanahan

Historical Demography

Some of the central questions historical demographers are concerned with may be traced back to the writings of Thomas Robert Malthus. His influential thesis was that human beings are able to reproduce themselves 'in a geometrical ratio' while the capacity of the earth to produce subsistence increases 'only in an arithmetical ratio.' In the long run, therefore, population increase of the past must have been kept controlled either by the 'positive check' of higher mortality or by the 'preventive check' of abstinence or late marriage. However, it was not until the post-World War II period that historical demography was born as a separate discipline in historical science: in the 1950s concepts and techniques of modern demography were applied by French scholars to historical material. Its progress and achievements since then have changed our perceptions on the Malthusian and other questions.

1. A Social Science History

Historical demography is a social science history. It is distinguished from other branches of history by its explicit use of concepts and tools derived from a

discipline in social sciences, i.e., demography in this case. Its goal is to establish historical facts by applying such conceptual frameworks to historical sources, and its methodological novelty lies in quantification. The research results of historical demography as such, have often questioned the conventional pictures of past populations, thereby throwing doubts about assumptions many theories rest upon. The position of historical demography in social and behavioral sciences thus resembles that of New Economic History, but it should be realized that there are a few notable differences in emphasis between these two social science history fields. While the application of theoretically constructed econometric models is given prime importance in New Economic History, emphasis in historical demography has always been on measurement. Attempts to formulate models to explain historical facts have never been put aside, but more effort has been directed to the development of finer measures and the identification of patterns, temporal and cross-cultural, by using those quantitative measures.

2. Sources, Methods, and Impacts

The innovation in methodology often goes with the discovery of new data sources. In historical demography too, its birth was closely tied with the French scholars' application of family reconstitution method, a form of nominal linkage, to registers of baptism, burial, and marriage kept in Christian parish churches. Parish register demography, as one may call this type of research, is an attempt to reconstruct a demographic profile of the past based on a set of family histories reconstituted according to the rules set out by the demographer Louis Henry who turned to historical material to identify what he called 'natural fertility,' that is, fertility before the deliberate effort to reduce family size came to be practised.

Information that historical demography started supplying since then is a kind that they had always thought would only be available from modern vital records or sample surveys. Thanks to laborious works by historical demographers, demographers are now able to describe past populations in much the same vocabulary as for the present. However, there are a few drawbacks. In this kind of research, analysis ought to be restricted to persons whose burial dates are known, or who are known to have survived until their reproductive period was over. Since more people tended to leave the community with advancing age, it is very difficult to compute death probabilities across all the age groups, although a large enough sample, such as the one constructed by E. A. Wrigley and his associates at the Cambridge Group for the History of Population and Social Structure, does enable researchers to estimate age-specific patterns of mortality even from family reconstitution (Wrigley et al. 1997).

Furthermore, demographic research based on historical micro data has enabled the researchers to work with 'cohort' measures. Most demographic concepts, such as life table and marital fertility, are designed to portray the life events of a group of people who were born or married in the same period (termed 'cohort'), but usually it is not possible for present-day demographers to single-out people born in a particular period and to trace them to the moment they die. Instead of using cohort measures, they have to rely on 'period' rates to account for demographic events in a specified period, in which the behavior of one cohort is bound to be mixed with that of other cohorts. In this sense, historical micro data have given demographers an opportunity to work with methodologically ideal populations.

For historians, on the other hand, historical demography has offered them a different set of merits. First, population becomes tractable as 'population change' and can now be decomposed into demographic components such as births, deaths, and migrations. This in turn enables them to relate those demographic phenomena to changes in economic circumstances. For example, one of the results of the earliest family reconstitution studies in France showed us how changes in grain prices were correlated with those in births and deaths. Similarly, one may examine interrelationships between time series of demographic rates and real wages in detail.

Another impact historical demography has had is being felt in social history. Since parish register demography reconstructs families and their life events that occurred in familial contexts, it has offered social historians invariable insights into the demographic domain of family life. Marriage, for example, is no longer a subject tied only with legal and ecclesiastical concerns. Who married whom, at what age, with what age gap between spouses—all these questions can now be answered. In addition, information about pre-nuptial pregnancy, gender differentials in infant and child mortality, and other related topics, can shed light on the intimacy of family life in the past.

Also related, but somewhat different approaches, have been adopted by another group of social historians. Statistical studies of the family and household, launched by Peter Laslett at the Cambridge Group in the 1960s, have been conducted in close association with research in parish register demography (Laslett 1983, Laslett and Wall 1972). The research along this line strongly suggests that types of family system, whether or not a new household was formed on marriage, whether the presence of live-in servants in the household was frequent or not, the mean age at marriage, and the frequency of celibacy, were all closely interrelated.

These links with social history have led to the burgeoning of family and household studies in history. Topics studied thus far include servanthood, gender inequality within the household, care for the elderly,

widows and orphans, and the succession of headship and property. There are also issues that have enabled historians to get further into the inner domain of the individual. Abortion, infanticide, child neglect, and other means of family limitation embedded in traditional reproductive culture, are such issues.

However, source material being used in historical demography and its related research fields is not confined to the parish registers. In fact, there is a serious drawback in the use of parish registers as a source material. Since only people who registered baptism, marriage, and burial in a single community were recorded, it is impossible to reconstruct families who eventually left the community. Also impossible is to know how many people existed in that community at a particular point in time. All this implies that aggregative studies are extremely difficult to conduct, implying that the size of a settlement population, its birth and death rates, and in- and out-migration ratios can hardly be computed. Also difficult to conduct, for the reasons already mentioned, are mortality studies.

It is not surprising, therefore, that in many west European countries other micro data are being used. Especially useful are listings of households and population, most of which were one-off 'censuses' taken for various purposes. In other cultural regions, there are places where census-type records were regularly taken. In traditional Japan, for example, registers of village population were compiled by officials every year while in some parts of imperial China similar records were taken triennially. Such repetitive census-type data are useful not only for household analysis, but also for demographic studies since probabilities of entry or disappearance can be calculated at a regular interval, which, as monographs such as Smith (1977) and Lee and Campbell (1997) illustrate, allow researchers to draw demographic interpretations. One of the few shortcomings of such population registers is that it is very difficult to estimate the infant mortality rate since those born after the previous compilation, but died before the next, were not recorded at all.

3. Two Dimensions: Micro and Macro

Two broad areas of issues have been occupying a central place in the historiography of historical demography. One is the Malthusian models of positive and preventive checks, and the other the thesis of demographic transition. The former concerns pre-modern settings. The latter is about the transition processes from the pre-modern to the modern age, as Demeny (1972) put it: 'In traditional societies, fertility and mortality are high. In modern societies fertility and mortality are low. In between there is the demographic transition. In both fields of research, however, it is useful to distinguish micro-behavioral from macro-aggregative dimensions.'

3.1 Micro Demography

As noted in Sect. 2, parish register demography was born as a fertility-oriented research field. Malthus's notion of positive check posits that overpopulation tended to be checked by a rise in mortality, which postulates that reproductive behavior of couples was governed by the invariable 'passion between the sexes.' The classic theory of demographic transition assumes that pre-transition populations were under 'strong pressure on their members to reproduce,' and hence that marital fertility was uncontrolled and its level close to the physiological maximum. Both Louis Henry, who coined the term 'natural fertility,' and Ansley Coale, who developed a technique to measure a deviation from the natural, uncontrolled fertility pattern in the course of his own project on the European fertility decline, assumed that if the couple has no target size of family and is not concerned with the existing number of children (termed 'parity'), marital fertility is not controlled and hence its level must be invariably high. In other words, the decision made by a couple to end childbearing (termed 'stopping') is assumed to mark the onset of fertility limitation. Much effort, therefore, has been made to measure fertility levels and to identify patterns by examining age, parity, birth interval, and other factors associated with individual couples' reproductive behavior (see Coale and Watkins 1986).

However, according to a large body of empirical studies so far conducted the original assumptions about reproductive behavior prior to the demographic transition are no longer tenable (see Cleland and Wilson 1987, Friedlander et al. 1999). First, pre-transition of marital fertility was far more variable than previously imagined. Few populations exhibited levels comparable to that exemplified by the Hutterites, a small group of anabaptist settlers in north America, whose total marital fertility rate (TMFR, defined as the number of children a married woman would have within her reproductive period) stood as high as 11. In most cases, in fact, it was kept at moderate levels with their TMFR ranging from 6 to 9.

Second, it is confirmed that stopping behavior was never common among pre-modern populations. It should be noted, however, that some elite sub-populations, such as Catholic aristocrats in France and Italy and bourgeois families in Calvinist Geneva, exhibited a distinct stopping behavior, so that they can be regarded as forerunners of modern family limitation. Third, moreover, the couple's behavior to 'space' births at particular intervals, as contrasted with stopping, seems to have been more important in accounting for the moderate levels of marital fertility in traditional times. Unlike stopping, birth spacing could have been achieved either through deliberate means such as contraception, or through unconscious actions such as breastfeeding, and many research

results suggest that the role played by differences in feeding practices of the infant was unmistakable. Fourth, it is now widely recognized that in many instances marital fertility was rising, rather than falling, in the period immediately prior to the onset of modern fertility decline. This was the case in the UK and other European populations as well as in twentieth-century developing countries (Knodel 1988, Wrigley 1998). One of the factors suggested as having affected this rising tendency is a reduction in the level of breastfeeding, which was often associated with early phases of urbanization. Another is a decline in the incidence of stillbirths, which has recently been suggested for eighteenth-century England. The latter is a promising area of micro-demographic study, because even from family reconstitution, it is possible to investigate into the interplay between fertility and mortality measures at very early phases of life.

The conclusion that pre-transition fertility was not uncontrolled, be it consciously or unconsciously, demolishes the conventional divide between the modern and the pre-modern regime. Furthermore, findings from micro-demographic data analysis have made it difficult to see the demographic transition in a dichotomous framework. To what extent the transition was a behavioral revolution, still remains debatable.

3.2 Macro Demography

The concept 'reproduction' can also be applied to a population as a whole. It means the way in which the population replaces itself through natural processes of birth and death. The overall level of such replacement may be indicated by the total number of children that an average woman will have during her childbearing period. This is called the total fertility rate (TFR). Since it does not take mortality into account, the population's natural process should be measured in terms of both fertility and mortality such as life expectancy at birth (e_0). Thus one may describe historical populations by referring to the two, TFR and e_0 . According to Livi-Bacci (1997), for example, Paleolithic populations and the Russians in 1879 happened to roughly exhibit the same level of TFR, a little lower than 6.5 children per woman. But mortality was different. The life expectancy is estimated to have been at below 20 for the Paleolithic, whereas that for Russia was a little below 30. As a result, the difference in the rate of natural increase was considerable. It was only marginally above zero in the Paleolithic case whereas, more than 10,000 years later, the Russian population was growing at somewhat over 1 percent per annum.

This, however, should not be taken to imply that the driving force in population history was always mortality decline, with fertility remaining high throughout the long, long period before the modern age. Indeed,

over time both fertility and mortality may have exhibited substantial volatility. Neolithic settlers are supposed to have been characterized by fertility and mortality higher than Paleolithic hunters and gatherers, reflecting a combination of higher population density and lower mobility in the farming population. A much recent case in point is England from 1550 to 1800. Wrigley and Schofield (1981) have documented that from the late sixteenth century, when England's rate of natural increase stood at below 1 percent per annum, the country's TFR and e_0 simultaneously declined towards the late seventeenth century. From that period to the second half of the eighteenth century the two measures came back to a position of higher fertility and higher life expectancy again. This time, however, the speed of rise in fertility exceeded that in life expectancy, so that the country's population grew faster than 1 percent.

Since information from family reconstitution studies does not add up to macro, aggregate measures, complex and sophisticated estimation techniques, such as back projection, are needed to reconstruct the history of a past population at large. Judging from a few well-grounded back projection works, such as Wrigley and Schofield (1981) for England from the sixteenth to the nineteenth century and Weir (1994) and Bonneuil (1997) for eighteenth- and nineteenth-century France, first, there is now agreement that the role of nuptiality should be stressed in accounting for how overall fertility changed in pre-transition western Europe. The age at marriage was instrumental in adjusting the actual level of fertility in relation to changing economic circumstances. This what the classic Malthusian model of the preventive check predicted, thus suggesting that such a homeostatic mechanism was at work in the long- to medium-run time frame of the European past.

Second, this does not imply that mortality crises were not important. Short-term fluctuations in mortality were frequent in various regions in Europe, most of which were subsistence crises occasioned by crop failure. The frequency of famines, therefore, could account for the long-run level of death rates, but it should also be noted that changing levels of 'exposure' to viruses and other micro-organs were equally—sometimes more—responsible in determining that level of mortality in the past. The supposed link between mortality and the general standard of material life was thus less direct than often imagined (see papers in Bengtsson and Saito 2000).

It is true that during the period of fertility decline, neither nuptiality, nor mortality, could offset the declining trend of marital fertility and, hence, the corresponding rise in population. This, however, should not be taken to imply that economic growth, which accompanied this demographic transition in most cases, changed the whole relationship between the demographic variables. Neither industrialization, nor urbanization, was the crucial determinant of the

onset of fertility decline. Even the modern decline of mortality was not in close association with an increase in the general standard of living.

Finally, mention must be made to the role of migration. The basic demographic equation tells us that a population will change according to the addition of births and immigrants, and the subtraction of deaths and emigrants. In other words, without information about in- and out-migration it is impossible to account for any macro change. Migration, therefore, is as important a topic as nuptiality, fertility, and mortality in historical demography.

Unfortunately, however, as historical sources rarely recorded actual population movements, not much has been done on this important topic. The historiography reveals that the volumes of in- and out-migration, distance, pull and push mechanisms are issues relatively better covered thus far. Much less known is the demographic impact of such migration flows. Were death probabilities in areas migrants headed for, different from those in their native communities? Was their marriage and reproductive behavior altered by their geographical mobility? Or was even their parents' demographic decision-making affected by the prospect that their children would eventually leave for a place of, presumably, better opportunities? It is only in cases where no effect of these was substantial, that we do not need to know anything other than the rate of net migration (immigrants minus emigrants), which tended to be rather small. More specifically, any interpretation of results from family reconstitution studies rests upon the assumption that 'leavers' would behave just as 'stayers' did. All the demographic measures derived from this method only relate to the population of stayers, i.e., those born locally who continued to live in the their native community. The mean age at marriage, for example, could have differed between these two populations. Although it turns out that the difference was minimal in the case of English family reconstitution, the possible effects of migration on marriage as well as the other demographic variables can only be determined empirically (Wrigley et al. 1997, Chap. 5).

One of the few findings we have in this regard is about rural-to-urban migration. In a traditional setting the urban population was distinguished by a greater exposure to diseases and, hence, higher mortality than in the countryside. Obviously, even in such a mortality-dominant urban demography, the marriage market may also have been affected by the size of in-migration as well as that of labor demand. Moreover, the rural sector should not be considered demographically homogenous. There are European case studies suggesting that 'proto-industrial' villages exhibited an earlier age at marriage and higher fertility rates than farming villages. To what extent this was universal is debatable. What is certain, however, is that the destination and volume of each migration stream between the rural and urban sectors could

affect the overall rate of population change in a pre-industrial setting (de Vries 1984).

The picture becomes less clear for the period of modern fertility transition, which in many cases coincided with extremely large volumes of migration streams, both long- and short-distance movements. It is probably safe to suppose that rural-to-urban migration in this period also meant deterioration in the disease environment, while trans-oceanic migration to land-abundant settlements led to lower age at marriage and higher fertility. What is less clear is its influence on the population sending those migrants in the course of change. In the literature of demographic transition, migration, especially townward migration, tends to be regarded as having facilitated the decline of fertility. On the other hand, it is often noted that rural populations did not readily respond to changing economic and social circumstances by lowering their fertility. One suggested reason why it was still beneficial for peasant families to keep their fertility relatively high is the expanding prospects for the younger generation. When it was felt that they could emigrate and form their own households elsewhere, the older generation's immediate need for the limitation of fertility may have been reduced. In nineteenth-century Scotland, for example, people left when circumstances allowed, and the same set of factors accounting for the emigration forced stayers to postpone marriage. Once married, however, they were less pressurized to limit the family size (see Andersson and Morse 1993, Friedlander et al. 1999).

4. *The Demographic Landscape in Cross-Cultural Perspective*

At a more generalized level, historical demographers have developed a notion of homeostatic demographic regime. Many societies in the past had an ability to maintain equilibrium between their resources and the demographic characteristics. It is the ability to restore the original state of equilibrium, even if an external shock forces the system away from that position. When the ways in which this homeostasis is achieved are similar for a group of populations, it is probably appropriate to call that particular mode of inter-relationships between the demographic variables a 'demographic regime.' Given empirical evidence so far accumulated, therefore, we may see the traditional west European populations as characterized by a particular mode of demographic regime. In this regime, both fertility and mortality levels were relatively low, and the key to its adjusting mechanism was nuptiality acting to ensure the system to restore equilibrium.

Turning to the nuptiality patterns, John Hajnal in his influential articles has shown that in traditional Europe, west of the line from St Petersburg to Trieste,

the mean age at marriage was relatively high and celibacy not negligible, and that all this was closely tied with the nuclear family system and its associated principle of neo-localism (Hajnal 1965, 1983). In contrast, non-European countries exhibited comparatively low ages at marriage and very low proportions never married, suggesting that different demographic regimes were operating in other parts of the world.

Take China and Japan. According to in-depth regional studies in traditional periods, the level of life expectancy at birth (e_0) in northern China was 32, while it stood at 39 in central Japan (see Lee and Wang 1999 for China, Bideau et al. 1997, Chap. 8 and, Liu et al. 2001, Chap. 7 for Japan). Compared with the western European average, China's mortality was on the high side and Japan's was on the low side. On the other hand, TMFR in both countries fell between 6 and 6.5, unmistakably on the low side of the European standard.

The Chinese and Japanese results raise some interesting questions. First, it is clear that the much lower level of marital fertility did not reflect stopping behavior, but spacing, thus confirming much of what the work on Europe has suggested. What is not certain at this stage is whether the observed long birth interval was a mere reflection of low fecundity, or a product of deliberate actions. While the factors accounting for the former vary from breastfeeding to malnutrition, the latter raises further questions: to what extent abortion, infanticide, and child neglect were practised, which of the three was most responsible, and whether it was motivated by despair or guided by the notion of 'planning,' however, rudimentary it would have been. Second, the nuptiality pattern was undoubtedly different from that of western Europe. There was no neo-local principle working. Nor was the age at marriage functioning so as to adjust overall fertility to economic conditions in Asia. Rather, nuptiality appears to have been more closely related to mortality. Indeed, the female mean age at marriage was unmistakably higher in Japan than in China, reflecting the aforementioned difference in e_0 , although both countries seem to have shared the characteristics of universal marriage.

Third, however, if attention is turned to the status of females and family systems, we realize that there were some fundamental differences between China and Japan. For example, while no particular anomalies are observed from Japanese sex-specific life tables, the Chinese studies point out that there were persistent gender inequalities in mortality: the probability of girls dying between ages 1 and 5 was about 20 percent higher than that of boys, and such gender imbalance continued up to age 45. Clearly the status of girls and women was very different in traditional Chinese society. More specifically, it is the family system that differed. Predominant in Japan was the stem family system, under which the family household was vertically structured, and customs such as adoption, marriage, and remarriage were all for the family line to

perpetuate. In China, on the other hand, what was operating was the rules of joint family. Under that system the household was laterally structured and the composition tended to be perennially complex.

To conclude, historical demography as it now stands, is both interdisciplinary and comparative and has raised new questions of its own, as it has evolved over time as well as cross-culturally.

Historical Explanation, Theories of: Philosophical Aspects

There are three fairly distinct kinds of theory about the nature of historical explanations. First, there are reflections upon accounts people have given of basic processes of historical change which determine the general direction of history. These accounts are what J.-F. Lyotard calls 'the grand narratives' or 'meta-narratives' of history. In Western culture, these have generally been theories of historical progress and theories of cyclical change. Such theories have been proposed by theologians, political theorists, and philosophers, but seldom by professional historians, who are understandably wary of generalizations of such immense scope. In recent years both the truth and the point of such explanatory theories have been queried, and as a result such theories of world history are now seldom produced. Some historians still offer quite general explanatory interpretations of national and international history, but these too are often held to be partial, in both senses. For convenience historical explanations of this first kind will be referred to as 'general interpretations of historical change.' The closest thing to a theory about such explanations is the discussion by J.-F. Lyotard, so his writing will be used as a platform for some remarks about them.

Second, there are four carefully articulated theories of how historians should explain events. These are written by philosophers rather than historians. Some think historical explanations should be scientific, employing general laws. Some declare that history is not a scientific but a hermeneutic discipline looking for the meaning of events rather than their causes. A few favor comprehensive, many-layered structural history, noting how basic geographic and social structures

influence historical change. Finally, there are those who, in a postmodern vein, see history as no more than a form of literature, with historical events acquiring meaning from their place in a discourse. The philosophers who promote these theories of historical explanation would say they are describing historical practice, but in fact they are much less interested in analyzing historical practice than in promoting a form of explanation which they think very important in understanding history. For that reason these will be called 'prescriptive theories of historical explanation.'

The third kind of theory of historical explanation is a theory which claims to be descriptive and analytic, focusing on historical practice to discover the variety of historical explanations historians actually produce, and their criteria of acceptability. The task of this theory is to provide clear analysis of typical historical explanations, pointing out the logical standards which it seems they aim to satisfy.

The article will briefly describe each of these theories of historical explanation, and make one or two comments upon them.

1. General Interpretations of Historical Change

In the culture of Western Europe, there have been several grand theories of historical change. Christianity, more particularly the Bible, brought with it a theory of progress in history, of God establishing his kingdom on earth, first through his prophets, then through the Israelites, then through Jesus, and finally through the Church, until Christ returns in triumph. St. Augustine presented an immensely influential version of this story in *The City of God*. With the progress in science achieved by the application of reason in the seventeenth and eighteenth centuries, a secular theory of historical progress was created by Kant, Condorcet, and others, who saw reason and the methods of science driving human progress towards ever-increasing, this-worldly happiness. Hegel and Marx described the process of human progress as dialectical, contradictions being overcome by new stages of development, either in the advancement of reason, freedom, and self-consciousness in the case of Hegel, or in autonomy and prosperity, in the case of Marx. The optimism implicit in all these theories of progress was largely shattered by the experiences of the twentieth century, of hideous world wars, of vast economic depression, of rampant infectious diseases, of tyranny, greed, and madness defeating enlightenment in so many countries. As Lyotard puts it: Auschwitz invalidates the Hegelian assumption that the real is rational; Budapest 1956 invalidates the Marxist claim that what is communist is proletarian (Lyotard 1987, p. 162).

A few writers have argued that progress has indeed continued throughout the twentieth century. With the defeat of fascism and the disintegration of Soviet

communism, F. Fukuyama sees the emergence of liberal-democratic capitalism as the final stage of historical development, 'The End of History.' He says that it best satisfies the two driving forces in history, the desire for material prosperity and the desire for personal recognition. Tyrannies had to go, as tyrants showed no respect for the common people. In democracies everyone has a say, or at least a vote. It seems obvious, however, that if the vote is not enough to ensure the recognition and respect people desire, then history has not ended after all.

Lyotard has three main objections to the grand theories of historical progress mentioned above. The first has already been stated: all are contradicted by the horrors of the twentieth century. Second, Lyotard objects that these theories have constrained historical writing in an unacceptable way. Under the influence of such theories, historians have written particular histories as instances of the theory of progress they most favored. For example, they depicted political revolutions as steps towards political freedom, and scientific revolutions as evidence of the growth of reason. In this way Lyotard finds metanarratives oppressive, and prefers that people should write their narrative stories as they like (Lyotard 1984).

Finally, Lyotard says that 'all great historical upheavals' such as the French Revolution 'are formless and figureless in historical human nature' (Lyotard 1987, p. 174). The enthusiasm such an upheaval generates is sublime, he says, and incapable of true representation, although we like to suppose that all who participated were motivated by a desire for greater freedom. All that historians can truly describe, according to Lyotard, are individual human actions and responses, 'little narratives' of particular events.

A few comments on Lyotard's ideas seem called for. First, he is right to deny inevitable progress toward a more rational, free, self-conscious, prosperous, and autonomous society. Theories of progress all underestimate the desire and ability of powerful people to exploit others for their own gain. More realistic, it seems, are some cyclical theories of historical change. Aristotle and Polybius produced such theories which were revived during the Renaissance in the writing of Louis Le Roy and Jean Bodin in France, and of Machiavelli and later Vico in Italy. In Aristotle they found a doctrine of the natural succession of political structures from monarchy to aristocracy to democracy and back to monarchy again, each stage established to resolve injustices which had arisen in the previous one. From Polybius they came to see cycles in the growth, flourishing, and decay of states, some attributing decay to states overextending themselves, others seeing it as a result of moral failure among its leaders. However, as Bodin said, the causes of a state's collapse can be varied, including military conquest by its enemies (1965, p. 59). There is no general theory of historical change which is true without exception. Cyclical theories were popularized in the twentieth century by

Manuel Spengler's (1926–8) *The Decline of the West* and Toynbee's (1951–61) *A Study of History*.

Second, while metahistories may have been used to legitimate certain accounts of particular historical events, to the exclusion of others, some generalizations about the motivation for political revolutions and other events seem in order. The leaders of the French Revolution and the pamphlet writers who supported them did legitimate their attack on the monarchy by an appeal to reason, liberty, and human rights. Of course there were other, more self-interested motives at work as well, but that is not to deny the legitimation given to the revolutionary movement by these ideas. Rather than dismiss generalizations about the motives for revolutions and other large-scale events as all mistaken, historians should take care to qualify them so that they are fairly accurate. Generalizations are useful ways of summing up individual stories and describing social movements.

Finally, one of the chief objections to metahistorical explanations of historical change is something that Lyotard does not mention. They frequently assume that a whole series of events were all justified by the same ideals, when in fact this is false. For example, many political events and revolutions have been justified in the name of liberty and human rights, but the ideas of liberty and human rights were not always the same in every case. The rights and liberties sought in the English Revolution, the French Revolution, and the Russian Revolution, for example, differed significantly. Therefore, it is misleading to suggest that they were all legitimated by the same ideals.

This typically historicist objection to metahistory is important, but not entirely decisive. While different particular rights and liberties were sought at different times and places, all can still be called rights and liberties. Indeed, all drew upon traditions of thought about human reason and dignity found in classical and biblical writing, which were applied to the particular situations. It is wrong to suggest that these events all had precisely the same legitimation, but it is also wrong to deny that the values they appealed to were quite unrelated.

2. Prescriptive Theories of Historical Explanation

In the last section we considered some philosophical responses to theories of historical change, that is to theories which identified certain more or less constant sources of historical developments. These theories provided substantive explanations of history. We turn now to theories of historical explanation of a quite different kind. These are theories about the logical structure of explanations of historical events. They are not theories about what produces historical change, but theories about how historians should explain what has happened in the past. These theories are prescriptive, describing how their authors think historical

events should be explained. There are in fact many forms of explanation commonly used by historians, but these theories focus upon just those which their authors judge, for different reasons, to be the most important.

2.1 Theories of Scientific Explanation

In the nineteenth century both John Stuart Mill and the historian Henry Thomas Buckle argued that historians should try to explain historical events as scientists do, by discovering the laws of society which governed their occurrence. With these laws the occurrence of historical events could be deduced, given certain antecedent conditions, just as the occurrence of natural events can be deduced from the laws of nature.

When K. R. Popper came to propose a theory of historical explanation, he quoted Mill's theory with approval, but thought it could be made more precise. 'I suggest,' he wrote, 'that to give a causal explanation of a certain *specific event* means deducing a statement describing this event from two kinds of premises: from some *universal laws*, and from some singular or specific statements which we may call the *specific initial conditions*' (Popper 1961, p. 122). Popper went on to point out that the laws used by historians are familiar, everyday ones of no particular interest. He opposed those historicists who believe there are general laws of historical development; and he opposed those who claim that historical events are unique, and so have nothing general about them whatever. Those who present general laws of history, such as the Marxist theory that all history is of class struggle, are really offering interpretations, Popper said, describing those changes in history which interest them.

The philosopher who most clearly and forcefully presented a deductive model of historical explanation was C. G. Hempel, in his article 'The function of general laws in history.' Drawing upon the tradition of Mill, Popper, and others, he produced the following analysis: The explanation of an event of some specific kind *E*

consists of

- (1) a set of statements asserting the occurrence of certain events $C_1 \dots C_n$ at certain times and places,
 - (2) a set of universal hypotheses, such that
 - (a) the statements of both groups are reasonably well confirmed by empirical evidence,
 - (b) from the two groups of statements the sentence asserting the occurrence of event *E* can be logically deduced.
- (Hempel 1965, p. 232)

The letters *C* and *E* are intended to suggest cause and effect. The aim of historical explanations, he wrote, is that of 'showing that the event in question was not "a matter of chance," but was to be expected in view of certain antecedent or simultaneous conditions' (Hempel 1965, p. 235). He admitted that the

relevant laws are often difficult to formulate precisely, and that often the consequence of the initial conditions occurs only with a degree of probability (Hempel 1965, p. 237). Consequently he called the explanations offered in history incomplete 'explanation sketches' (Hempel 1965, p. 238).

Hempel's formulation of the deductive theory of explanation was subject to much discussion and criticism. The main objections were as follows:

(a) The model does not state conditions *sufficient* to produce a good explanation,

(i) because sometimes events which enable one to predict an outcome are not the events which caused it. For instance, from a sudden fall in a barometer one can predict a storm, but that event does not explain the occurrence of the storm, because the fall in the barometer was not necessary for the storm's occurrence.

(ii) Furthermore, for an explanation to be satisfactory, it must describe the kinds of cause which are of interest to the reader. If a man with a gastric ulcer is suffering from stomach pain after eating parsnips, a doctor would attribute the pain to his gastric ulcer, whereas his wife would attribute it to his eating parsnips. For the doctor, eating parsnips is normal, but having an ulcer is not, whereas the wife is familiar with the man's ulcer and picks out his eating parsnips as the event which made the difference. This objection assumes that the function of causal explanations is to explain a contrast between a given event and another expected, normal event, rather than to show why an event was predictable.

(b) The model does not state conditions *necessary* for a good explanation,

(i) because often all that is required to explain an event is to show that the event was more probable than a contrasting state, which might not be very probable at all. Consider the question: 'Why was the monarchy replaced by a republic in France in 1792?' This question could be asking: why was there a change in constitution and not just a change of government, why was the republic set up in 1792 and not earlier, and why was the establishment of a republic in France more likely than any other kind of constitution, such as a limited monarchy of the sort which resulted from the English Revolution?

(ii) Furthermore, many explanations in history are not intended to show that an event was very probable, or that it was more probable than a contrasting state. For instance, historians often want to know the reasons why people behaved as they did, reasons which may or may not have made their actions very probable.

There is some merit in Hempel's theory that historical explanations are meant to show events to have been very probable. Admittedly, some explanations have different aims. And certainly causal explanations must refer to events which were necessary for the occurrence of the event being explained. Never-

theless, some causal explanations are not contrastive, but are meant to explain what brought about a certain event by pointing out events and circumstances which made its occurrence very probable. However, this can very seldom be done by citing a single law relating cause and effect. Normally historical events are the product of several tendencies at work in a situation, and are explained as an outcome of those. Historians try to make the outcome appear as highly probable as possible, but often that is not very probable, just more probable than anything else in the circumstances.

2.2 Theories of Hermeneutic Explanation: Explaining the Meaning of Actions

While G. Vico and J. G. von Herder had written of the importance of understanding human cultures as complex, almost organic units, the theory of hermeneutic understanding, in opposition to scientific understanding, was first fully applied to history by W. Dilthey. The theory had its origin in the lectures on hermeneutics by F. Schleiermacher, whose biography Dilthey published early in his career (in 1871). Following Schleiermacher, Dilthey said that the way to understand human actions is by using empathy to imagine the experiences and thoughts which moved people to act as they did. We interpret what people do and say, he said, by drawing upon our own experiences of life to imagine what was going on in their minds to make them produce the expression which is being interpreted. After he had developed this psychological theory of understanding, Dilthey became interested in the meaning human actions have in furthering the aims of the social or cultural structures to which they contribute. He wrote:

To start with, the parts of a life have a meaning according to their relation to that life, its values and purposes, and according to the place they occupy in it. Furthermore, historical events become significant through being links in a system of interactions in which they co-operate with other parts to bring about values and purposes in the whole. (Dilthey 1961, p. 148)

The structures he mentions as being 'the simplest and most homogeneous' are 'education, economic life, law, politics, religions, social life, art, philosophy, science' (Dilthey 1961, p. 146). These different structures often express similar values and beliefs, and so are interconnected. These common ideas can create a common tendency in a particular culture for an age. People are constantly improving the structure and effectiveness of these organizations, and their actions can be interpreted as having such historical significance.

The main objection to Dilthey's theory of historical understanding was clearly stated, and addressed, by Gadamer in *Truth and Method* (1986). Dilthey had said that we understand other people's actions on the

basis of our general knowledge of life in the world. Gadamer pointed out that often the historian's world is remote from the world of the people being studied. Dilthey, he said, 'took no account whatsoever of the historical nature of experience' (Gadamer 1986, p. 212). Heidegger explained that understanding things is not something we do after we have apprehended them, but rather it is what we do *in* apprehending them, in reading a text or in recognizing a machine. And our interpretation of things is a function of our own historical nature (Gadamer 1986, pp. 230–2): 'that we study history only insofar as we are ourselves "historical" means that the historicalness of human There-being [*Dasein*] in its expectancy and its forgetting is the condition of our being able to represent the past' (Gadamer 1986, p. 232). Our understanding of what things mean is first of all provided by the traditions in which we have been raised (Gadamer 1986, p. 250).

Once the historicity of historical understanding is fully understood, the question of the objectivity of history becomes quite urgent. Is there any sense in which one's understanding of the past could be called 'objective'? Gadamer has a couple of things to say about this. First, he insists upon coherence as a condition of correct understanding: 'The movement of understanding is constantly from the whole to the part and back to the whole. Our task is to extend in concentric circles the unity of the understood meaning. The harmony of all the details with the whole is the criterion of correct understanding' (Gadamer 1986, p. 259). He remarks that when it is difficult to find a coherent interpretation, then we suspect that we are dealing with a world whose patterns of meaning we do not really understand. This leads to his second important point. Gadamer employs the concept of a 'horizon,' which he describes as 'the range of vision that includes everything that can be seen from a particular vantage point' (Gadamer 1986, p. 269). Historians occupy a particular vantage point in the history of the tradition which formed them. To *understand* a past event, they must do so from the point of view of those involved. They can find that historical horizon because they have learned of it from within their own tradition. Then when historians come to *report* their understanding of the past, they do so in terms of their present worldview. Gadamer explains: 'In the process of understanding there takes place a real fusing of horizons, which means that as the historical horizon is projected, it is simultaneously removed' (Gadamer 1986, p. 273). It is but a short step from Gadamer's account of historical understanding to postmodern theories, which describe history as a cultural construct, usually in narrative form, having no particular relation to the real events of the past whatever.

At the same time as German philosophers were reacting to attempts to make historical explanations scientific by developing theories of meaning, British

philosophers were pointing out that historical explanations are typically accounts of the reasons for which people acted as they did. R. G. Collingwood wrote as follows:

For science, the event is discovered by perceiving it, and the further search for its cause is conducted by assigning it to its class and determining the relation between that class and others. For history, the object to be discovered is not the mere event, but the thought expressed in it. To discover that thought is already to understand it. After the historian has ascertained the facts, there is no further process of inquiring into their causes. When he knows what happened, he already knows why it happened. (Collingwood 1961, p. 214)

Collingwood said that knowledge of past minds is arrived at by drawing inferences from observable facts, more particularly by forming and testing hypotheses about what people had in mind when acting as they did.

Collingwood's attack on scientific models of explanation and espousal of rational explanations was given fresh expression by W. H. Dray in his first book *Laws and Explanation in History* (1957). He criticized the 'covering-law models' of Popper and Hempel, and developed an account of rational explanation which was less idealistic and more logical than Collingwood's. He said that in deciding reasons for actions, historians relied on general knowledge of the form: 'When in a situation of type $C_1 \dots C_n$ the thing to do is x ' (Dray 1957, p. 132). Such statements, he said, were 'principles of action' which are universally known and respected. They explain actions by showing that the action was the rational thing to have done, in the circumstances.

Today we would give more respect to Collingwood's account of explanation than to this early statement of Dray's, because people's reasons for acting are not always universally appropriate. Indeed, even from the agent's point of view, they are sometimes not very rational at all. All that matters when explaining the reasons for an action is that they were the reasons for which the agent acted.

Hempel responded to Dray by arguing that reasons only explain actions if we know that people holding such reasons were likely to act on them (Hempel 1963). According to Dray, historical explanations should show that actions were reasonable responses to a situation. Hempel said they must always show that the action was to be expected in the circumstances. I think reasons can cause actions by inclining people to perform them, but they do not always make the actions appear either very rational or predictable.

2.3 Theories of Structural Explanation in History

There are two distinct kinds of structural explanation in history, both closely associated with the work of the French Annales school in the twentieth century.

2.3.1 Braudel's structural theory. The first kind of structural explanation is most famously exemplified by F. Braudel's large history, *The Mediterranean and the Mediterranean World in the Age of Philip II* (1972b). In it, Braudel explains the geographic and social structures in which observable actions occurred, and how those structures limited or promoted certain possibilities. He wrote:

when I think of the individual, I am always inclined to see him imprisoned within a destiny in which he himself has little hand, fixed in a landscape in which the infinite perspectives of the long term stretch into the distance both behind him and before. In historical analysis as I see it, rightly or wrongly, the long run always wins in the end ... it indubitably limits both the freedom of the individual and even the role of chance. (Braudel 1972b, p. 1244)

The constraints which Braudel had in mind were largely geographical and technological, but he included frameworks of belief as well (see Braudel 1972a, p. 18).

Braudel showed how geography and technology limited agricultural production and trade, and so the growth of wealth in the sixteenth century. The size of populations, and their vulnerability to famine and disease, also played a part. In addition to these slowly changing structures of geography and technology, Braudel also described cycles of economic and social change which occurred more frequently. These constituted processes of change within economic, social, and institutional structures which historians could model and describe in a theoretical way. He provided a careful analysis of the cycles of mercantile capitalism between the fourteenth and eighteenth centuries, which formed the background for the history of Philip II in the sixteenth century. As Braudel showed, these structures limited the possibilities of human action, as well as making the effects of certain events very probable. However, Braudel gave no systematic account of the relation between these two kinds of structures and the actions of individuals, which constituted the third level of historical description he identified.

2.3.2 Structures of meaning. The second kind of structural explanation favored by historians of the Annales school, such as Lucien Febvre, Marc Bloch, and more recently by Emmanuel Le Roy Ladurie and many others, is one which explains the meaning of an utterance, a gesture or a symbol by referring to a structure of meanings, a language, of which it is a part. Dilthey had anticipated this theory of meaning in some of his later writings, although he is best known for relating meaning to intention. This French structuralist theory of explanation emerged from work by Saussure in linguistics and Lévi-Strauss in anthropology, which explained the mean-

ing of one part of a language by referring to other parts to which it was systematically related. Historians found such patterns of meaning in social events. As Jonathan Culler has put it:

The cultural meaning of any particular act or object is determined by a whole system of constitutive rules [such as rules of a marriage ceremony or of football]—rules which do not so much regulate behaviour as create the possibility of particular forms of behaviour ... make it possible to marry, to score a goal, to write a poem, to be impolite. It is in this sense that a culture is composed of a set of symbolic systems. (Culler 1973, p. 22)

People are seldom aware of the rules governing the symbols they use, any more than they are aware of the rules of language, but the rules can be discovered by historians and anthropologists studying their behavior. The rules can be implicit or explicit. Historians prefer to study the explicit rules governing behavior, usually found in the discourse by which it is described, because then the meaning given to the behavior is truly historical, and not something merely inferred by the historian.

2.4 Theories of Narrative Explanation

Once historical explanations were thought to display the meaning of historical events, rather than just describe their causes, the way was open to view historical narratives as forms of explanation. This is precisely what Hayden White did in his seminal book *Metahistory* (1973). In the theoretical introduction to that book White describes 'explanation by emplotment,' 'explanation by formal argument,' and 'explanation by ideological implication.' A historical event which is merely listed in a chronicle, he said, has no particular meaning or significance. But once it is located in a story, it is given both meaning and significance, by being related to what preceded and followed it. Following Northrop Frye, White identified four forms of emplotment: Romance, Tragedy, Comedy, and Satire, each with its characteristic structure. Thus, for example, 'Romance is fundamentally a drama of self-identification symbolised by the hero's transcendence of the world of experience, his victory over it, and his final liberation from it.' (White 1973, p. 8). As well as telling stories of different kinds, he said, historians also describe the relations between events in the past in several different ways. Following Stephen C. Pepper, he identified four kinds of 'argument' about the nature of historical events. The Formist depicts them as unique; the Organicist sees particular events as parts of a whole; the Mechanist presents events as instances of general laws at work in history; and the Contextualist describes events as products of tendencies at work in their environment. Finally, narratives can represent certain ideological views of historical change, and give events meaning by locating them within one of those. Following Karl

Mannheim, White picks out four such ideologies: the Conservatives,' who see history as the evolution of existing structures; the Liberals,' who think that reason and goodwill will eventually see that certain ideals are attained; the Radicals,' who think utopian conditions should be achieved by revolutionary means; and finally the Anarchists,' who believe that an ideal state will be achieved by destroying existing structures and leaving people free to act on their own humanity. White found 'affinities' between these three groups of four. For example he said Romantic plots often employed a Formist presentation of events, and embodied an Anarchist ideology.

White correctly points out that explanations of these kinds can be viewed as interpretations. Interpretations are one of several more or less equally well justified accounts of a subject which give meaning and significance to its parts. White did not consider whether one interpretation could be better than another, but F. R. Ankersmit did in his book *Narrative Logic* (1983, Chap. 8), in which he declared that narrative interpretations should aim for maximum scope, not only in the number of events they describe but in the number they illuminate. This seems to be on the right track.

3. Descriptive Theories of Historical Explanation

Hayden White denied that his analysis of historical explanation was exhaustive, but it was far less prescriptive than previous theories, indicating a large range of ways in which historians could account for events in the past. An avowedly descriptive, analytic approach to historical explanations is that provided by McCullagh in *The Truth of History* (1998). McCullagh analyzes forms of explanation common in historical writing to discover both their structure and their conditions of acceptability. He contrasts explanations, which are answers to fairly specific questions guided by the preconceptions implicit in the question, and interpretations, which look for patterns among events with no particular preconception of what that pattern will be. The adequacy of explanations, on this account, is judged by how adequately they answer the questions they are addressing. The questions provide both the logical and conceptual parameters of the required explanation. The questions, he says, can ask *what* happened during a certain event, *how* a certain change took place, *who* a certain person was, *what* a text or symbol meant, *what* the structure of a society or institution was, as well as *why* a certain event occurred.

An interesting outcome of this approach is his analyses of causal explanations in history. McCullagh finds that causes are events which trigger causal powers, or tendencies, and he depicts causal explanations as setting out the active tendencies which, taken together, made probable the event being explained. A complete causal explanation, McCullagh says, will mention all the causes which directly

increased the probability of the outcome, and these could include both reasons for an action and circumstances which made such an action probable. It does not include all events necessary for the outcome, however, as these go back to the beginning of time.

At present there is some uncertainty as to whether the concept of a correct explanation is intelligible, and whether explanations always provide interpretations of the past. The answer depends largely upon our concepts of explanation and interpretation, and there is no doubt that these need further refining.

C. B. McCullagh

Historical Geography

Partly because of its richly diverse and spatially variable traditions, historical geography is not amenable to ready definition. While it is concerned with the study and reconstruction of past geographies and understanding processes of ecological and landscape change, its remit also includes the political, cultural, and economic interactions between past and present. Thus historical geography examines how our interpretations and representations of the past are constructed in contemporary circumstances and shaped by current needs. There are, however, significant differences between societies in the traditions of historical geography and the ways in which it is currently construed, researched, and taught. This article deals less with the history of historical geography than with certain of the prevailing trends in its current status as an academic project. A discussion of the nature of contemporary historical geography is followed by an assessment of three themes, which permit an elaboration of this general context. These are: interconnected historical geographies; differential historical geographies; and the past in the present.

1. The Nature of Historical Geography

Two overlapping perspectives long dominated traditional approaches to historical geography. First was an intensely academic concern, epitomized, for ex-

ample, through the work of H. C. Darby in Britain and Ralph Hall Brown in the USA, with the scholarly reconstruction of past geographies for their own sakes. The second, encapsulated, for instance, in the work of Andrew H. Clark in North America, emphasized vertical themes, the essentially spatial changes and continuities that occur through time and help explain the present. More recently, however, historical geography has been revitalized by the wider concern throughout the social sciences and humanities with the relativity of knowledge. Thus the fundamental assumption informing much current historical geography is that representations of the past are constructed in the present to serve the demands of contemporary societies. The content and methodology of this work, particularly in the anglophone world, also reflects the theoretical shifts in many of the social sciences away from the 'objectivist fallacy' of positivist models of research and knowledge production (Wishart 1997). Conceptualizing the past as a resource for the present also inevitably invokes notions of contestation as various groups compete for 'ownership' of the past. Consequently, much current work in historical geography acknowledges the situated nature of research and the political difficulties of reconciling contested interpretations of the past in multicultural societies.

While this work builds on historical geography's long-standing empirical focus on topics including industrialization, rural settlement and land ownership, agriculture and agrarian change, migration and population patterns, urbanization, and transport networks, it is also moving in new directions. Many contemporary historical geographers, informed by perspectives such as feminism, poststructuralism, antiracism, and postcolonialism, share concerns about questions of power and meaning with other researchers more readily located within the traditional systematics of cultural, economic, political, and social geography. The key themes evident in much recent historical geography include: a more overtly theorized exploration of the material, political, and symbolic dimensions of travel and exploration; imperialism and colonialism; nationhood and state formation; and ideas of nature and environmental change (Graham and Nash 1999, Nash 1999).

The exploration of the philosophy, content, and methodology of historical geography has itself a long tradition (Butlin 1993). This introspection has often been anxious, not least when faced with the positivistic revolution in geography in the late 1960s, a paradigm shift to which historical geography seemed ill equipped. The delineation of the boundaries between historical geography and geographical history has also occasioned much debate, often driven by a perceived need to stake out precise disciplinary territories. For example, Guelke (1997) and Donkin (1997) have expressed their fears at the deconstruction and potential disappearance of historical geography. To them it lacks an academic core, defined particularly through

the ways in which people relate to the earth. Nevertheless, much current historical geography is concerned less with the establishment of precise boundaries within geography, or between geography and history, than in engaging in the arguably more valuable task of creating a body of work that is both geographical and historical. In addition, concerns over the erosion of historical geography by other systematics within the subject, or its dilution through the influences of other disciplines, ignore the interdisciplinary and hybrid nature of both past and present historical geography. Where traditionally it drew on archaeology, economic and social history, ecology, and social theory, it now interacts with feminism, environmental history, post-colonialism, and cultural history.

Thus in his capacity as editor of the *Journal of Historical Geography*, Michael Heffernan (1997, p. 2) argues for an historical geography that is 'a haven of intelligent eclecticism.' He offers 'an alternative and more optimistic prospectus for the future' to those 'who worry that eclecticism breeds conceptual chaos and threatens the intellectual integrity of historical geography as an academic project.' Heffernan sees it as a hybrid discipline open to the widespread contemporary questioning of 'the conventional intellectual categories through which the modern world has been interpreted and conceptualized.'

While this eclecticism is undoubtedly reflected in a more cultural historical geography, that content should be no less concerned with the material shaping of places, spaces, landscapes, and lives, even if the need to ground historical geography in material contexts of power, politics, and economics is sometimes neglected. The past is a political resource and its control is fundamental to issues of hegemony and empowerment in societies. If historical geography is about the interplay between the past and the present, between symbolic and material worlds, it must also be open to the hard-edged realities that, for many people, 'history hurts.'

2. *Interconnected Historical Geographies*

Interconnectedness possesses at least three separate dimensions. First, the history of historical geography itself reflects complex webs of intellectual interconnections, which have produced different outcomes in different places. It is also true, however, that linguistic and intellectual parochialism often limits the potential of these interconnections. Second, historical geography possesses a lengthy tradition of locating regional studies within broader processes operating at macrospatial scales, and of paying attention to both the specificities of the local and their interaction with wider economic, cultural, and political domains and institutional structures. Finally, there are interconnections between places—for example, the modern networks of communication, transport, or trade that

connected Europe and its imperial sphere of influence—but also in the kinds of geographical discourses and practices that have structured the ways in which the relationships between places or regions are understood.

2.1 *Interconnections within Historical Geography*

Ogborn (1999, p. 99) argues that a key dimension to interconnectedness is that of showing how and why issues, ideas, and intellectual interactions ‘cross connect and reshape a kaleidoscopic interdisciplinary terrain.’ Thus cultural and material geographies combine, for example, to produce environmental histories that are also histories of power, colonialism, and imperialism (Wynn 1997). That historical geography is seeking to understand the social or cultural construction of spaces, knowledges, and powers also impacts on the discipline itself, which has been, and remains, a spatially variable process. The contents and methodologies of historical geographies vary both through time and across space, reflecting the current—if transient—trends defining the broader intellectual climates within which they are practiced. Consequently, the subject matter of contemporary historical geography in the anglophone world is dominated by the cultural turn in human geography and by the poststructuralist emphasis on situated knowledges. The early modern and modern periods are preferred to the medieval and the contingent to theories of a past shaped by cyclical processes of historical transformation of varying temporality. Marxian theories of world systems and modes of production that emerged from long-term cycles of history and their periodic crises (e.g., Wallerstein 1974–89) are deeply unfashionable in a discipline that has often embraced Foucault’s dictum that nothing is fundamental with uncritical enthusiasm.

The temporal and spatial variability in historical geography is nowhere better illustrated than in the contrasting perspectives on landscape, historical geography’s oldest and most enduring concept. For example, the evolution of British historical geography has, in many ways, been dominated by efforts to provide alternative directions to the source-driven methodology used by H. C. Darby in his systematic reconstruction of past landscapes. Although open to vertical themes and the cycles of history behind geography, Darby’s methodology invoked an empirical dependence on the inevitably elitist context of cartography and documents, and consequently excluded dimensions of power and culture in the societies and landscapes reclaimed. In some contrast, the French geographer, Paul Vidal de la Blache (1926), emphasized the significance of ordinary people and their environment: to him, the region was not simply a convenient framework, but rather a social reality

(Claval 1984). Vidal’s belief that landscape reflected a harmony between human life and the milieu in which it was lived was also fundamental to the work of the Berkeley geographer, Carl Sauer. For him, the richest source of evidence lay ‘in the material content of the cultural landscape,’ the ‘task of human geography [being] nothing less than comparative study of areally localized cultures’ (Conzen 1993, p. 28).

Vidalian ideas were also crucial to the *géohistoire* of the French *Annales* school, and its concerted attempt to map and explain the complex reality of human life by reference to local and regional studies. They also underpinned the geographical philosophy of Ireland’s most influential geographer, E. Estyn Evans, partly explaining why Irish historical geography evolved along a very different trajectory to that in Britain. This was one in which the meanings of historical place and landscape were seen as fundamental to a people’s genetic and cultural identity, albeit conceptualized in overtly more anthropogeographical terms than through the traits of polyvocality and hybridity that attend identity studies today. As in Sauer’s methodology, the critical evidence was that of the visible and material landscape. Similar ideas also influenced the study of landscape in North American, Scandinavian, and Australasian historical geographies, and clearly retain a contemporary resonance and vibrance, given the hybrid and multi stranded processes that link the discursive and material worlds, which constitute the raw resources of historical geography.

2.2 *Local Particularities and General Processes*

Historical geography has long been concerned with the processes of historical specificity and historical transformation across space and through time. The intellectual attraction of the ‘grand’ structuralist models lies in their identification of general power-related processes, which interact with the specificities of local place to produce an almost infinite chiaroscuro of individual outcomes and experiences. Historical geography becomes the product of this complex hybridity and polyvocality of places and peoples, while the contingent is reconciled—as societies seem to require—with temporal structures that create explanations of change, meanwhile observing a cultural and political need for continuity and social memory. The outcome is spatial and temporal diversity, which historical geography has long sought to reconcile with generality of process through a methodology of regionally based analysis.

This is perhaps most coherently encapsulated in a French *géohistoire* seeking to explain a country defined by diversity in which unity—as elsewhere in Europe—was achieved only by force, civil war, and the creation of ethnic nationalisms. Vidal de la Blache argued that it was this diversity—rooted in the physical en-

vironment—which paradoxically provides France with its identity. The country's unity evolves from a beneficent force of commonality, derived from the ways in which social life combines with—and transcends—its divisions through time. This relationship was encapsulated in the idea of the *pays* (literally an area with its own identity derived, not only from divisions of physical geography, but also from ethnic and linguistic divisions imposed on a region by its history) as the geographical mediation of synthesis and continuity, the product of human interaction with the environment over many centuries.

In his monumental (if unfinished) investigation of the identity of France, Fernand Braudel (1988–90) takes up the same theme. He sees a patchwork France, a jigsaw of regions and *pays* in which the vital thing for every community is to remain other from the next tiny *patrie*. But Braudel, recognizing a similar fragmentation elsewhere, was also critical of Vidal's exceptionalism: 'Yes, France is certainly diverse...it is a diversity which breaks up, divides, and sets one region against another.' But it is not an 'unparalleled' diversity: 'Germany, Italy, Britain, Spain, Poland can all lay claim to diversity' (Braudel 1988–90, p. 669). So too can smaller countries. Pursuing the same symbiosis of physical environment and human society, Evans (1981) believed that even fractious Ulster could seek unity in a diverse past to which all its present inhabitants might subscribe.

Although Braudel and Evans saw the natural world as providing the backdrop to this human diversity, both also recognized the decisive contribution of the economy and social intercourse. Moreover, diversity itself was more apparent because it often reflected what Braudel referred to as *l'histoire événementielle*, short-term episodic history or the history of events. Behind all that, however, lay *l'histoire structurelle*, the long-term changes of *la longue durée*, 'the slow speed of the secular trend, moving scarcely at all' (Braudel 1988–90, p. 678). The real essence of this European conceptualization of diversity lies in the ways in which these different histories, trajectories of time, and social change and geographical particularities have fused in varying ways to produce distinctive places and peoples.

The same theme of region and regionalism—albeit differently expressed and generally lacking the Marxian connotations of *géohistoire*—is also a fundamental feature of North American historical geography. Clark's immensely influential emphasis on historical change was expressed through a methodological approach that was 'explicitly historical, attentive to the economic basis of regions, devoted to field and archive, well integrated with professional history, analytically adventuresome, and book-oriented' (Conzen 1993, p. 61). The outcome, readily apparent in much historical geography in both the USA and Canada, was a heavily empirical emphasis on regional spatial patterns, which often conspicu-

ously failed to ask fundamental questions regarding broader social, political, and economic relationships (Wynn 1993).

2.3 Interconnections Between Places

This final dimension to interconnectedness refers both to the physical linkages between places, but also to the ways in which the relationships between places and regions are understood in geographical discourses and practices. It is concerned with the ways in which technological developments and their exploitation allowed particular countries to achieve at least a transient hegemony in the world system. Hugill (1993) argues that the postmedieval nations that developed and marketed new technologies best were the nations that rose to world power, revolutions in transport and communication technologies actually constituting the moments of transformation from one world economy to another. Globalization is not a recent process, the creation of European imperial empires effectively leading to the integration of large areas of the world into the emerging national space economies of Europe. These global networks and flows of information, capital, people, culture, plants, animals, and objects that linked the world in the past continue to rebound on its present, not least through the persistent patterns of disparity that mock the concept of global free trade.

If imperialism and colonialism were hierarchical, they also represented reciprocal networks of influence and power. European nationalism and the emerging nation-state system were framed within these imperial rivalries and later exported to the former empires. Thus the resistances to imperialism made anti-imperial citizens as well as imperial ones (Ogborn 1997). Moreover, a consideration of the connections between places also involves stressing the ways in which the historical geographies of colonial countries themselves were shaped by colonialism. The commonplace interpretation of the historical geography of colonialism as the imposition of the dominant logic of the colonial political and cultural economy unto non-Western time and territory, requires destabilization (Yeoh 1996). The difficulty in so doing, however, lies in the lack of knowledge about colonized groups, given the asymmetries of the historical record.

One final dimension to the ways in which the interconnections between places help shape geography concerns the linkages between geographical education and the making of citizens. Imperialism and colonialism also entailed political, intellectual and cultural, as well as material, domination. Historical geographers have extended the contention that imperial ideologies remain at the heart of modern Western culture to explore the linkages between the cultures of geography and imperialism. Thus 'knowledges of geography are themselves part of often complex geographies of knowledge' (Ogborn 1997, p. 416). Hence it can be

argued, for example, that both popular and formal geographical education in Britain and notions of Britishness were constructed in direct opposition to imaginative geographies of other places and peoples (Graham and Nash 1999).

3. Differential Historical Geographies

Inevitably, the previous discussion has already touched upon the general argument that despite the interconnected nature of world systems, the processes of social change through time, with which historical geographers are concerned, are still experienced differently by peoples in different social groups and places and articulated in different ways. Moreover, these dissimilar knowledges are articulated at a variety of scales ranging from the local to the global. The first dimension to this issue to be considered here concerns problems of social inclusion and exclusion. Second, however, it is also the case that knowledges themselves are rarely consistent and contemporary historical geography is itself internally differentiated or even contested between different ideological and methodological imperatives.

3.1 Social Inclusion and Exclusion

Narratives of the relationships between places are characteristically defined through processes that privilege particular accounts and peoples while marginalizing or excluding others. Contemporary historical geography recognizes that earlier generations did not sufficiently understand the privileging of Europe in their accounts and is aware of the need to avoid the naturalization of Western models of modernity and development. Again, Conzen (1993) identifies the 'startling silences,' including slavery, the African American experience, and the results of war, in American historical geography. The combined importance given to gender and racism in contemporary social and cultural theory helps explain the polyvocality and hybridity of contemporary historical geography. Just as racism ensured that colonized indigenous peoples were excluded from the narratives of empire, all human geography has traditionally privileged masculine discourses and conceptualized modernity in masculine, middle-class, urban, and Eurocentric terms (Nash 1999). Women—especially rural women—were equated with the authentic and premodern, while, in contrast, the modern was associated with a male-directed logic of rationalization, objectification, and developmental progress. Thus traditionally women have been largely invisible and misrepresented in historical geography, while men have 'monopolized the transmission of history' (Lowenthal 1998, p. 48).

However, it is important not to equate marginalization and exclusion with gender and race alone. A

contemporary historical geography has to be open to the nuances of multiple resistances, and to the enduring importance of class, ethnicity, and nationalism as criteria of identity. The implication of the past in the construction of identity narratives is but one example of the way in which historical geography has become a more pluralist and disputed enterprise since the beginning of the 1970s. There are many different modernities and many diverse dimensions to othering and otherness.

3.2 Historical Geography as a Contested Enterprise

As noted in the discussion regarding the interconnectedness of historical geographies, the result of differentiation may be knowledges that are internally inconsistent and contested between opposed ideological and methodological imperatives. Heffernan's 'intelligent eclecticism' does not preclude disputation, inevitably so because of the privileging of particular perspectives within the geographical discipline itself. If a methodologically diverse historical geography traditionally seemed eclectic, its focus on areal differentiation, modernist notions of development and progress along continuities from past to present, and its reliance on empirical, material evidence drawn from the landscape, did link it to many of the principal strands that defined the emergence of geography as a discipline.

In the 1960s, however, the positivist revolution seemed to have little to offer historical geography. Largely lacking the means to meaningfully quantify data and indulge in model building, its practitioners found little resonance in arguments that geography was a formal deductive science charged to describe and understand the real world. The important exception to this generalization was the reversal of historical geographers' traditional aversion to the urban realm, although this was expressed—as the prevailing *zeitgeist* demanded—through a commitment to the morphological and functional relationships of the historic city and to its modeling. Questions of power and social relationships remained peripheral as they had in the regional studies of the rural world.

Given historical geography's vulnerability to this paradigm shift, Harris's (1978) argument that an understanding of the synthesis of regions, places, and landscapes might come from the development of an historical mind that could encompass experience, memory, imagination, and reflection was a welcome harbinger of the revitalization of historical geography by the cultural turn in geography in the late 1980s and 1990s. It is still important, however, to be aware of the dangers of cultural exceptionalism in what remains a polyvocal enterprise. While the cultural theme was dominant in British historical geography and, if to a lesser extent, throughout the anglophone world for much of the 1990s, its content and methodologies do not define historical geography as a global enterprise,

or even describe the research of many historical geographers within the English-speaking world. The privileging of the cultural perspective at the expense of alternative methodologies and languages disguises the survival of enduring issues in historical geography—frontiers and borderlands, migration, settlement morphology, settlement—the city in particular—as an indicator of cyclical social change and social relations, placenames, and the making of the physical environment.

Again, despite its openness to previously disenfranchised peoples and their narratives, the cultural turn in historical geography is often neglectful of power and economy as they control material lives. To some extent, the denigration of the material world is a result of the extension of the source materials used in researching contemporary imaginative historical geographies to encompass a diverse range of written and artistic representations and texts—diaries, biographies, novels, poetry, and paintings. This otherwise welcome development has, however, led to a denigration of traditional sources of data such as the material physical and human landscape. Ironically, the contemporary emphasis on nuanced qualitative readings of texts and representations is paralleled by the previously unimaginable power of Geographical Information Systems and Remote Sensing methodologies to handle and manipulate huge repositories of statistical historical data.

Historical geography now possesses the technological means of far more effectively addressing its traditional responsibilities of reconstructing past environments, spatial analysis, and regional differentiation. Often, however, these tasks have largely been abandoned to a technologically proficient historical archaeology, which combines historical archival research with excavation and geophysical evidence of past societies in both terrestrial and maritime landscapes. More important, historical geography now also possesses the capacity, but has largely shirked the challenge, of producing and managing integrated masses of geographical information, which would substantially enhance understanding of social change through time but also elucidate the regional and local specificities that underpin the constructs of identity through which peoples project and comprehend their relationships with place. Intelligent eclecticism can encompass the deconstruction of the empirical and the abandonment of the objectivist fallacy, but must remain open to using far more elaborate means of processing of historical data, not least to avoid these being subverted by an apparently enhanced capacity for objectivism.

4. The Past in the Present

Finally, historical geography is also increasingly informed by the ways in which the past is remembered and represented in both formal or official senses and

within popular forms, and the implications, which these have for the present. It is in this respect that the past can be most clearly visualized as a domain of contested meanings, perhaps the most significant way in which contemporary historical geography differs from the archival, 'objective' reclamation of the past that characterized its previous existences. Interpretations of the past are seen as being context bound and power laden, an issue briefly explored here through a consideration of the functions of heritage (Graham et al. 2000).

4.1 Heritage and its Functions

The stories and places of contemporary heritage, and the ways in which they are told and described, often represent the most overt examples of the contemporary politics of the past in the present. Heritage is that part of the past selected in the present for contemporary purposes, be they economic, cultural, political, or social. If heritage knowledge is situated in particular social and intellectual circumstances, it is time-specific and thus its meaning(s) can be altered as texts are re-read in changing times, circumstances, and constructs of place and scale. Consequently, such knowledges are inevitably fields of contestation of meaning and function. As such, the past can be visualized as a resource but simultaneously, several times so. Clearly, it is an economic resource, one exploited everywhere as a primary component of strategies to promote tourism, economic development, and rural and urban regeneration. Heritage—variously defined—is the most important single resource for international tourism although the economic commodification of the past can so trivialize it that arguably the result may be the destruction of the heritage resource which is its *raison d'être*.

But heritage is also a knowledge, a cultural product, and a political resource and thus possesses crucial sociopolitical functions. In particular, the past validates the present by conveying an idea of timeless values and unbroken lineages and through restoring lost or subverted values (Lowenthal 1998). Hence there are archetypal national landscapes, which draw heavily on geographical imagery, memory, and myth. Continuously being transformed, these encapsulate distinct home places of 'imagined communities,' comprising people who are bound by cultural—and more explicitly—political networks, all set within a territorial framework that is defined through whichever traditions are currently acceptable, as much as by its geographical boundary. Such national traditions are narratives that are invented and imposed on space, their legitimacy couched in terms of their relationship to particular representations of the past. So important are these that peoples cut off from their past through migration or even by its destruction in war, often recreate it, or even 'recreate' what could—or should have been there—but never actually was. Inevitably,

therefore, the past as rendered through heritage also promotes the burdens of history, the atrocities, errors, and crimes of the past which are called upon to legitimate the atrocities of the present. Consequently heritage is always a duality—a resource of economic and cultural capital. This is less a dialectic than a continuous tension, these broad domains generally being in conflict with each other.

5. Conclusion

A hybrid and interdisciplinary historical geography has thus widened its interests alongside history itself. As historians increasingly explore popular forms of history today as well as cultural sources for the past, historical geographers have also extended what counts as source material in researching contemporary imaginative historical geographies. These include objects, practices, and discourses of popular culture as well as the past itself. If this makes historical geography more cultural, it should not make it any less concerned with the material shaping of places, spaces, landscapes, and lives, or with issues of empowerment and economy. These current intersections reflect the ways in which historical and cultural geography have overlapped in the past—in the study of landscape for example—just as they do in the present, whatever the labels academics chose to define their research interests. The opposition between an empirically grounded historical geography and a purely qualitative cultural geography is clearly reductive and redundant. Similarly, the contemporary emphasis on the ways in which the past features in the present does not make the work of historical geography any less concerned with happenings of history. Rather, historical geography is about the interplay between the past and the present, between symbolic and material worlds.

Historical Linguistics: Numerical Methods

1. Introduction

The main goal for numerical methods in historical linguistics has always been to answer the question of how closely two languages are related. Applied pairwise to languages, this can be used to reconstruct a tree

for a whole language family (lexicostatistics). More ambitious methods have additionally assigned dates to the splits within those trees (glottochronology). Recently the questions and methods have been extended to involve distant (hence controversial) relationships between languages, so the basic question becomes not just how closely two languages are related, but whether they are related at all. All methods in this area, no matter how sophisticated, rest on the simplest of observations: since languages change over time, two originally related languages gradually become less similar over time. This enables the linguist to infer something about diachrony from synchronic information only, particularly attractive in situations where little is known about the history. The methodological difficulties come in quantifying rates of change, measuring difference, and accounting for the myriad of factors that can interfere with so-called normal change processes (e.g., mutual influence between languages). The attractions of numerical methods in historical linguistics are the same as those attributed to quantitative methods in almost any discipline in the humanities or social sciences: speed, objectivity, replicability, and ability to handle large volumes of data efficiently.

2. Early Methods

The earliest precursor to a numerical method in historical linguistics is a statement made by Robert Gordon Latham (1850, p. 565, see also Hewes in Hymes 1960, p. 338): 'the average rate at which languages change is capable of being approximated' and 'the maximum difference, at a given period, between two or more languages is also capable of being approximated.' He never pursued this, and the next milestone in the development of numerical methods in historical linguistics was a statement by Sapir (1916, p. 76): 'The greater the degree of linguistic differentiation within a stock the greater is the period of time that must be assumed for the development of such differentiation.' Sapir's influence on later linguists was great, so even though he himself never followed this statement up by taking the basic steps of quantifying linguistic differentiation or rate of change, this can be seen as the genesis of the most widely known numerical method in historical linguistics, that of Swadesh (1950, and see below).

The first explicit numerical treatment of genetic proximity of languages was Kroeber and Chrétien (1937), following a method created by two anthropologists, Jan Czekanowski (1928) and Stanislaw Klimek (1935), for use in physical anthropology and ethnography. For each pair of languages, on a list of N features, calculate a (number of features shared by both languages), b (number of features in the first language but not the second), c (number

of features in the second language but not the first), and d (number of features in neither language). This produces a 2×2 contingency table, a well-studied mathematical entity enabling various forms of analysis. In particular, the quantity Nr^2 , where $r = (ad - bc) / \sqrt{(a+b)(c+d)(a+c)(b+d)}$, is χ^2 (one degree of freedom), enabling one to test the statistical significance of the relationship between the two languages. The values of r for all pairs of languages under consideration can become the input to various methods (e.g., hierarchical cluster analysis) for family tree reconstruction. The method is simple but not unproblematic (e.g., construction of the feature-list, difficulties with non-independence of features, interpretation of correlations especially if negative). (For fuller treatment and commentary, see Embleton 1986.)

The second numerical method in historical linguistics is Ross's root-retention model (1950). For N features and m languages, construct an $N \times m$ table in which a cell has a cross if that language exhibits that feature. The question of relationship of languages can then be recast as whether or not the crosses are distributed randomly in the table. For each pair of languages, calculate n_1 (number of features found in the first language is represented by the number of crosses in the first column), n_2 (number of features found in the second language is represented by the number of crosses in the second column), and r (number of features shared by both languages is represented by the number of rows with a cross in both columns). Then the probability for that pair of languages of obtaining the shared number of crosses or more is

$$\sum_{R=r}^N = \frac{\binom{n_1}{R} \binom{N-n_1}{n_2-R}}{\binom{N}{n_2}}$$

for which a normal approximation exists. These probabilities can be tested for significance, and could become the input for various family tree reconstruction methods. Interestingly, Ross's method can be shown to be mathematically equivalent under certain conditions to Kroeber and Chrétien's, and thus subject to the same problems. (For fuller treatment and commentary on this and the method in general, see Embleton 1986.) Although certain elements of these models recur today, both have largely been abandoned, although the problems encountered and lessons learned remain relevant.

Historically, the next method to evolve was Swadesh's, but given its centrality to the field and ongoing relevance, I will deal with that in a separate section. A final numerical method to consider is that of counterindications originated by Gleason (1959), later rediscovered by others. All topologically possible family trees for the languages in question are constructed, each is evaluated for how well it fits against a fixed list of features (every time the tree does not fit the distribution of that feature, a counterindication is

recorded), and the tree with the best score (even if not perfect) is chosen. This method is difficult to implement for two reasons. Even with modern high-speed computing and sophisticated algorithms, the number of topologically possible trees for even a moderately-sized language family quickly becomes unworkably large. The method is also highly vulnerable to the effect of borrowing across languages. A variant of Gleason's method, relying on hierarchical clustering and attempting to estimate branch lengths (i.e., used glottochronologically) is shown in Embleton (1986), along with fuller discussion of the method itself. Taylor et al. (2000), using recent advances and sophisticated techniques from computer science and biological cladistics, are developing a character-based (rather than distance-based) method for family-tree reconstruction with some similarities to Gleason's method. Despite difficulties with dealing with borrowing in realistic amounts, such methods are promising partly because they closely parallel the cognitive processes of skilled practitioners of traditional comparative-historical reconstruction techniques, while being more objective and simultaneously handling vast amounts of data.

3. Swadesh

By far the best known numerical method in historical linguistics is that introduced by Swadesh (e.g., 1950), actualizing Sapir's statement by regarding lexical replacement as analogous to radioactive decay. As with carbon-14 dating, dates could then be provided for branching points in the tree (glottochronology). Take a list of N meanings of supposed basic core vocabulary, found universally in all cultures, expressing basic noncultural concepts, expected to be more resistant to change and borrowing than other vocabulary items. Such a list, now known as a Swadesh list, contains such items as lower numerals, simple kinship terms, body parts, topographical terms, widespread flora and fauna, pronouns (personal, demonstrative, interrogative), verbs denoting basic actions, and naturally occurring noncultural phenomena. Assuming a constant rate of replacement, R , for words representing meanings on this list, one can calculate the time elapsed (time depth) since any pair of languages split using the formula

$$\frac{-1}{2R} = \ln \left(\frac{c}{N} \right)$$

where c is the number of cognates on the Swadesh-list between the two languages compared. By calculating time depths for all pairs of languages under consideration, we can construct a family tree with dates.

Swadesh's method was greeted with widespread enthusiasm and widely applied in the late 1950s, 1960s, and early 1970s, almost with a sense of euphoria about finally having an exact tool for obtaining insights into hitherto unknowable linguistic prehistory. The debate over Swadesh's method quickly became emotional, but regardless of the researcher's subjectivity, a common core of problems can be identified, sometimes with potential solutions.

Difficulties with particular meanings on the Swadesh-list.

(a) Some meanings cannot be translated into the target language. This is fairly rare, and best treated as missing data, reducing N accordingly.

(b) Sometimes there are multiple possible translations in the target language for a meaning on the list. Different researchers might make different but equally valid choices from the range of possibilities ('multiple synonymy'). Solutions include always counting only the most frequent possible translation, choosing at random, always choosing to maximize the cognate count, always choosing to minimize the cognate count, or various fractional scoring systems.

Difficulties with cognacy judgments (remember one is not necessarily dealing with languages where the history, and hence cognacy are well known).

(a) Due to accumulated sound change, cognates may not be recognizable, causing us to overestimate time depth.

(b) Chance similarities may be wrongly interpreted as cognates, causing us to underestimate time depth. In practice, one might hope that this and the preceding cancel out.

(c) Sometimes only one part of a word is cognate to a word in another language ('partial cognation'); how should one score this? Solutions include always counting this as positive, always counting this as negative, or various fractional scoring systems.

Problems with the universality of R , which was shown to vary over time, between languages, and according to meaning. R had been estimated from languages with written historical records as about 14 percent per millennium for the standard 100-word Swadesh-list and about 19 percent per millennium for the standard 200-word Swadesh-list. Not only might the very fact that these languages are written bias the rate (one might expect less replacement in a language with a lengthy written history), but 11 of the 13 pairs used to establish the rate were Indo-European (representing only three of its branches).

Problems with the family tree (Stammbaum) model, generally centering around the splits not being clean (thus giving any precise date is artificial and meaningless). Languages are often in close physical proximity even after they split, mutually influencing one another; tendencies in the two languages predating the split may come to fruition only afterwards. Both these interfere with the model, but are more properly problems with the family tree model, and Swadesh's

adoption of it, rather than problems with Swadesh's method itself.

Borrowings between languages (related or unrelated) can alter replacement rates quite substantially. For some languages, even the Swadesh-list contains a high amount of borrowed vocabulary.

For various reasons (see Embleton 1986 and elsewhere), the use of Swadesh-style lexicostatistics and glottochronology waned by the mid-1970s, although applications lingered on in several language areas, and the methods continued to be refined by applied mathematicians.

4. Sankoff

Most refinements introduced by applied mathematicians involved adding further parameters to the basic Swadesh model. For example, parameters were added to account for drift and for 'chance recurrent cognation' (i.e., when a word was replaced twice, such that the original word was restored), replacement rates were allowed to vary from meaning to meaning, a very crude allowance was made for borrowing, and there was talk of allowing the rates to vary from language to language and from time to time. (Further details, along with some models, can be found in Embleton 1986.) Some of these are useful refinements (e.g., allowing replacement and borrowing rates to vary over time, between languages, and between meanings), but these are very much a mathematician's way of solving the problem, producing quite elegant solutions. But in the real world in which the linguist works, all those parameters have to be estimated—and this is surprisingly difficult even for well studied languages for which we actually have both long and extensive written records. It is also the case that an extraordinary amount of data is required to estimate so many parameters, and this is most often simply impossible. So these elegant theoretical solutions have very little practical import.

However, the single most important development was the incorporation of a geographical dimension into the family tree, thus allowing for borrowing to be largely dealt with. The basic insight here is due to Sankoff (1972), with correction and further refinement by Embleton (see 1986 for the most comprehensive treatment). The resulting set of differential equations required to reconstruct the tree and estimate the branch lengths is complicated, reflecting the increased power of the method (equations are given in Embleton 1986 and elsewhere). The parameters required all have some reasonable chance of being estimated, even for lesser studied families; these are a similarity measure for each language pair, replacement rates for each language, borrowing rates between each language pair (not necessarily symmetric), and knowledge of which languages are in contact with one another.

5. Starostin

Largely independently of the work described above, research on numerical methods in historical linguistics was proceeding in the Soviet Union (later Russia, still later 'in diaspora'). Unlike the impetus for Swadesh's work, which was largely to aid in providing histories and trees for relatively little studied language families (e.g., Amerindian), much of this work gained its impetus from questions of more distant linguistic relationship. This had its effect on the development of the methods, because it was crucial that the methods be able to produce useful results even at much greater time depths, where Swadesh's method typically has difficulty distinguishing the signal (cognacy, true genetic relationship) from the noise (chance resemblance, contact relationship).

Historically the first advance here was due to Dolgopolsky (1986), who capitalized on the fact that different meanings change at different rates. He compiled a list of the 15 most stable meanings, based on examination of 140 languages. One can then calculate the probability of fortuitous coincidence of the words representing those 15 most stable meanings for any language pair; if the probability is significantly less than that expected by mere chance, this can be taken as evidence of relationship. This method is most striking in its extreme simplicity, but can also be related to some more complex and ongoing work, largely carried out in eastern Europe, founded on the observation that several characteristics of a word (e.g., length, number of meanings, age) are intercorrelated with its frequency. Words of more recent origin tend to be less frequent, longer, and have fewer meanings, whereas older words tend to be more frequent, shorter, and have more meanings. The age-frequency relationship in particular is being extensively researched, as there may be a small hard core of ancient short vocabulary which may reveal distant relationships, and may even be able to be harnessed into a lexicostatistical or even glottochronological method.

Another advance has been made by Sergei Starostin, with work first published in the 1980s and continuing to the present, known as root glottochronology or etymostatistics (see Starostin 1999). Compared to standard Swadesh-style glottochronology, the main innovation is the observation that while glottochronology regards any change (however small) in a word's meaning as a loss of that word from that meaning, root glottochronology does not. Thus while standard glottochronology sees English *dog* and German *Hund* in the meaning 'dog' as noncognate, root glottochronology notices the existence of the English word *hound*; this more conservative approach to the maintenance of a language's root stock enables one to work better at greater time depths. Starostin's method also gives more accurate results for known cases where the time depths are more shallow (standard glottochronology tends to give dates which are too recent).

Root glottochronology takes a text, containing a given set of words in the parent language, and then measures the number of these words still extant (in any derivative, with any semantic shift) in the daughter language. It proceeds only with detailed comparative-historical and etymological analysis (eliminating look-alikes and loans), and also can be repeated for more than one text (hence a different set of words), giving greater precision and potentially some estimate of error (see Starostin 1999 for formulas and more detailed explanation).

6. Ringe

Various linguists have used probabilistic methods to assess similarity between vocabularies of two different languages, usually focusing on phonological similarities (an early example is Ross 1950). The basic question is whether the observed degree of similarity between the two vocabularies is greater than what could be expected based on chance. Although the problem is conceptually simple, it quickly becomes mathematically intractable even between just two languages, as one has to wrestle with different phoneme distributions, different phoneme frequencies, how to measure phonetic distance between different phone(me)s, different phonotactic structures, and lengths of roots, quite apart from the questions (familiar from glottochronology) of how much semantic latitude to allow between the words compared. The most recent and sophisticated treatment of this problem is by Ringe (e.g., 1998 and references therein), who attempts to account for many of the above issues, albeit with simplifying assumptions. This research remains active, yet without consensus as to its utility, partly because of the degree of the simplifying assumptions, but also partly because it has mostly been applied in the realm of long-distance relationships, where the emotions over the results can sometimes cloud the objectivity with which the method is viewed.

7. Future Directions

Research in numerical methods in historical linguistics is gradually reentering the mainstream after several decades on the sidelines. The most active areas of current research are improvements to the basic Swadesh model, exploration of the age–frequency relationship, root glottochronology, computer-implemented tree reconstruction using methods borrowed from biological cladistics, and Ringe’s probabilistic methods. The degree of mathematical, statistical, or computational expertise required is extremely high, which is likely to prevent the majority of historical linguists from ever mastering the methods, and consequently render them unable to do more than use results produced by others or participate in research

teams where others control the methods. There seems to be a growing realization, however, that numerical methods, while not providing any magic solutions to any long-standing problems, can make a useful contribution as one of the tools that we use to explore our linguistic history and prehistory.

Historical Linguistics: Overview

Historical linguistics is the study of language through time, and involves the consideration of changes from some earlier stage towards the present; the construction of earlier, unattested states; and the determination and depiction of relatedness among languages and language groups. Although the main focus of twentieth-century linguistics was synchronic, there is currently increasing interest in historical linguistics, both from linguistic theory and cognate historical disciplines, notably archaeology and genetics.

1. The Scope of Historical Linguistics

Historical linguistics involves the study of languages as they change through time. It includes tracing developments from an earlier stage of a language to a later one: for instance, English 'silly' meant 'blessed' at the time of Chaucer; Latin sentences often had the word order Subject Object Verb, as in *Helena Marcum amat* 'Helena loves Marcus,' whereas its daughter language French typically has Subject Verb Object, as in *Hélène aime Marc*; and many Old English noun and verb endings with final nasal consonants, like *-an*, *-um*, *-on*, dropped gradually about 1,000 years ago. Historical linguists are interested in when, how, and ultimately why changes of this sort happened.

However, this diachronic perspective also operates in the opposite direction, encouraging historical linguists to look back from present-day or recorded languages to earlier, unattested stages in an attempt to reconstruct unrecorded features and characteristics. This may involve filling in gaps in the historical record, for instance in hypothesizing the form a word might have taken in Old English or in Latin, although that word does not actually appear in any surviving manuscript. At greater time depths, features of unattested, hypothetical ancestral languages, like Proto-Indo-European, the probable source of most languages of modern Europe and northern India, may also be reconstructed. Work of this kind also explicitly or implicitly involves consideration of language classification: reconstruction necessarily includes the hypothesis and testing of linguistic family groups, which are taken to be demonstrably descended from a single common source. At present, it is uncontroversial to say that English, French, and Latin are all related, as members of the Indo-European family; but it would be more controversial to contend, as some historical linguists do, that these languages are in turn related to Semitic languages like Arabic, Akkadian, and Hebrew; or that Chinese is related to Chechen and other Caucasian languages.

In this article, the development of historical linguistics will first be considered briefly, and its place within

modern linguistics assessed. Then the two subdisciplines of language change, and linguistic classification and reconstruction, will be examined in turn, with the emphasis on outlining currently lively and productive areas of research. In the final section, some trends common to change and reconstruction will be identified, with their implications for future work in historical linguistics.

2. Historical Linguistics Within Linguistics

In the heyday of traditional work in the late nineteenth century, historical-comparative linguistics was linguistic theory. Its focus and methodology were in line with the strongly historicizing tendency of the day, and with the development of parallel sciences such as geology and evolutionary biology, so that although the foundations for language comparison and study had been laid considerably earlier, the discipline advanced rapidly and attracted considerable scholarly attention in this period (see Davies 1998). The cornerstones of the discipline were set with the classification and reconstruction of Indo-European in particular, and the Comparative Method on which such reconstructions are based (see Fox 1995) is still the foremost tool of the reconstructionist's trade, although many of the specific results obtained have been modified, as knowledge of language change has deepened and developed, and more data have become available. The Comparative Method requires sets of cognate forms in descendant languages: these will be similar in form and meaning, and will show regular, recurrent correspondences of particular sounds across the group of languages compared. We can then hypothesize that these have been derived historically from a single most plausible common source, by the operation of generally regular sound changes. Thus, given English *father*, Irish *athair*, Latin *pater* and Greek *pater*, alongside a large number of similar comparands which equally lack an initial consonant in Irish, and have English /f/ corresponding to Latin /p/, it seems reasonable to hypothesise Proto-Indo-European **pátér*. It is also possible to set out the contexts in which particular sound changes have operated in the daughter languages, and therefore to begin to identify the factors in the surrounding sounds which may have led to these developments (see *Linguistics: Comparative Method*).

Although many of these methodological and theoretical assumptions still hold good in historical linguistics today, the twentieth century has seen a radical shift in perspective in linguistics as a whole. The development of structuralism led to a move away from the study of individual languages and families, and towards identifying language universals, those aspects of human language which recur regardless of genetic linguistic affiliation. Consequently, the historical linguistic concentration on variation as a key to linguistic

relatedness gave way to attempts to identify theoretical limits on variation. Finally, whereas most earlier work had concentrated on vocabulary and phonology, the 'Chomskyan revolution' of the 1960s centered attention on syntax.

However, these rapid and far-reaching changes have not led to the demise of historical linguistics; although it is true that historical work became less of a core part of linguistics for some years in the mid-twentieth century, it is now again one of the liveliest areas of the discipline. This is for three main reasons. First, advances in linguistic theory, while typically based on synchronic study and data, often allow the sources of change to be identified and explained in a way which was not previously possible: much nineteenth-century work, although allowing individual elements to be plausibly reconstructed, was piecemeal and did not trace related changes to a common cause. Explanation comes center stage in modern linguistic work. Second historical data provide an additional means of testing and refining these linguistic theories, which may benefit from a demonstration that they can analyze and incorporate language change. Finally, related disciplines like genetics and archaeology may not always find developments in linguistic theory *per se* particularly useful or enlightening; on the other hand, interactions of data and hypotheses from these areas with those of historical linguistics are promising. All these areas will be considered, with respect to both change and reconstruction, in the following sections.

3. Areas of Debate in Language Change

3.1 Phonology

Much early work on sound change was based on the assumption of relative ease of articulation: that is, it is presumed to be more straightforward for a speaker to utter two similar adjacent sounds, or indeed to make them identical, than to produce a sequence of sounds which require major vocal tract movements between the two. This explanation for the extremely common sound change of assimilation, as seen in Latin *somnum* → Italian *sonno*, was put forward in the last century. However, advances in phonetic technology has allowed historical linguists to pinpoint more accurately the types of sound sequences which are likely to cause such problems, and the advent of experimental phonology has allowed these hypotheses to be tested, not only from the point of view of the speaker's production problems, but also taking the hearer's perception difficulties into account (see *Phonetics: Articulatory*). One of the pioneers in this area, John Ohala (1993), has suggested that certain sound changes like dissimilation, which increases the difference between close or adjacent sounds in the stream of speech, may be provoked by the hearer's

expectations. Thus, a hearer receiving the Proto-Quechumaran word */t'ant'a/ 'bread' might erroneously have assumed that the speaker has produced two ejective [t']s close together by assimilating a second, nonejective stop to the first truly ejective one. Undoing this perceived but not real mistake by the speaker produces the modern Quechua form /t'anta/. Advances in phonological theory may also be relevant here, for instance in helping us understand what it means for sounds a and b to be closer in their constituent features than sounds b and c; or in showing that the apparently disparate environments triggering a particular sound change in fact form a unified class in terms of some deep principle of phonology. In this respect it is encouraging that, while certain phonological theories current in the 1980s, such as Government Phonology and some forms of Declarative Phonology, explicitly ruled historical processes out of their remit, Optimality Theory, a currently popular model which has been developing since the early 1990s, already includes a considerable body of work addressing problems of both change and variation.

3.2 Morphology and Syntax

Morphology has often been left out of historical linguistics as a separate domain of enquiry, being seen as simply an interface: phonological changes, like the loss of final unstressed syllables, may have morphological consequences if case or tense markers are lost, and this in turn may have a knock-on effect on the syntax, changing or fixing word order. However, morphology has more recently been the focus of attempts within Natural Morphology (Wurzel 1989) to identify those features which are favored universally, for instance in terms of ease of production, perception, or acquisition, and the factors underlying that naturalness, as well as assessing why in many cases these universally natural morphological features are subordinated to language-specific requirements which may reduce naturalness. Morphological change is also one component of grammaticalization, the extremely common process whereby independent words become grammatical markers, as in German *Drittel* 'third' and *Viertel* 'quarter,' formed from the numerals *drei* 'three' and *vier* 'four' plus a reduced form of *Teil* 'part'; or the famous French negative *ne ... pas*, where *pas* is derived from Latin *passum* 'a step,' and became an integral part of the negative construction in earlier French, perhaps via gradual bleaching of reinforcing constructions meaning 'I won't go a step.' Grammaticalization has become a major focus of research in linguistic theory (see Hopper and Traugott 1993), introducing many students and researchers to issues in linguistic change (see *Grammaticalization*).

In syntax, historical work has become enormously more sophisticated over the last 30 years, reflecting the

newly ascendant status of syntax in synchronic work and in linguistic theory. Work at first may have been hampered by lack of knowledge of the range of syntactic changes, and uncertainty over quite fundamental questions, such as whether syntactic change can be seen as essentially regular in the same way as many sound changes. These issues are now being addressed by major cross-linguistic surveys (see Harris and Campbell 1995). On a more theoretical level, Lightfoot (1991, 1999) uses historical data and current models of syntactic theory in a mutually informing way, attempting to show that children learn syntax in the way they do because of particular factors in their innate, universal grammar, but that certain superficial changes in syntactic structures may also cause them to learn differently, setting up new structures which will form the basis for subsequent development in their language.

3.3 Semantics

Developments in linguistic theory may also increase understanding of semantic change, which has long been seen as a domain where description is the highest achievable goal. Earlier approaches have attempted to classify changes, but seeing developments as, for instance, extensions, or restrictions of meaning does not necessarily explain why these occur, and linguists have tended to fall back on the old adage that 'every word has its own history.' Developments in pragmatics and in cognitive linguistics may improve prospects here. For instance, Traugott (1982) suggests that many words develop from an external to an internal, subjective sense: thus, English *feel* begins as descriptive of some characteristic external to the speaker, in *It felt soft*, but comes to signal internal states, in *I feel miserable*. Sweetser (1990, p. 2) suggests that linguists must crucially adopt 'a cognitively based theory which takes not the objective "real world," but human perception and understanding of the world to be the basis for the structure of human language': this approach allows recurring semantic changes, such as those involving mind-as-body metaphors of the *grasp*, *cast light on*, and *see* type, to be unified.

3.4 Variation and Change

One of the most productive recent developments in historical linguistics has been the recognition of a connection between variation and change, and the development of sociohistorical research (see *Sociolinguistics*). First, this substantially increases the database of changes available for study, since changes in progress can now be considered alongside the more traditional category of change from earlier, written data to the present day. However, for spoken, colloquial data to be accepted, it is necessary to delimit

and define what constitutes a change in progress, requiring new quantitative techniques for identifying and measuring ongoing change. Innovations, which may provide the seeds of future developments, must now be distinguished from changes, and innovators from early adopters, the speakers who begin to use a new variant and spread it to their own social group (see Milroy 1992, Labov 1994).

This sociohistorical work has also directed attention away in part from internal, systemic factors and towards external factors in the search for explanations for change. Internal factors may belong to the language system itself, or to some other level of the grammar, or involve the innate language faculty which many linguists see as unique to humans; such factors have typically been favored by theoretical linguists in their attempts to explain change. However, socio-linguistic work places great emphasis on the social characteristics of speaker and interlocutor, including age, sex, and social class, and on characteristics of the interaction itself, such as level of formality and topic of exchange. This in turn encourages focus, not only on interaction between speakers, but between varieties and languages. The consequences of language contact have therefore become vitally important in recent historical linguistics, with increasing interest in contact phenomena like borrowing and convergence; the development of pidgins and creoles; and socio-linguistically determined language breakdown and loss in language death (Bickerton 1981, Thomason and Kaufman 1988, Dorian 1989). These are no longer being seen as peripheral and uncommon, but as a central part of language change and germane to a greater understanding of language itself (see *Language Contact*; *Areal linguistics*; *Pidgin and Creole Languages*; *Language Obsolescence*).

4. Areas of Debate in Reconstruction and Classification

4.1 Typology and Reconstruction

In the closely related subfields of classification and reconstruction, matters have advanced considerably since the various nineteenth-century attempts to write a fable in Proto-Indo-European. There is still much interest in what is reconstructed: the reliability and realism of reconstructed systems remain open questions, as does the issue of whether syntax can be reconstructed using the same methods as phonology, or whether early, unattested areas such as word order are beyond recovery (Lass 1997). Innovations in phonological reconstruction continue to occur: for instance, the 'new look' of Proto-Indo-European proposes a set of ejectives alongside the more traditional voiceless and voiced stops, on the basis that the resulting system would be more common cross-

linguistically, even though the alleged ejectives have disappeared, largely without trace, in the daughter languages. This opens a wider debate over the roles of typology and uniformitarianism in reconstruction (see *Linguistic Typology*): that is, to what extent should reconstructions be driven by generalizations that hold for modern-day languages? Is it more important to reconstruct a proto-form or proto-system which accords with the comparative evidence from its daughters, but which might appear skewed when compared with other attested systems, or to produce a balanced, typologically normal system although considerable changes may be required to derive the daughter forms?

4.2 Classification and Methodology

However, classification has recently threatened to overtake reconstruction as the main focus of interest in this area, and here the questions are primarily methodological. The Comparative Method (see *Linguistics: Comparative Method*), with its concentration on regular, repeated correspondences and its incorporation, at least for many practitioners, of reconstruction as a test of the family groups proposed, has been challenged by Greenberg's much simpler method of multilateral comparison, based on straightforward surface inspection of word-lists from many languages. Family groups are then proposed on the basis of etymologies drawn from these lists: forms within an etymology are similar to an extent in form and meaning, but the similarities need not be recurrent, and reconstruction is not necessarily undertaken. These families tend to be considerably larger (and hence potentially older) than those conventionally reconstructed using the Comparative Method. For instance, Greenberg (1987) uses multilateral comparison to propose only three language families for the Americas, including Amerind, a phylum or superfamily containing more than 1,000 languages. Even more controversial connections are drawn by other practitioners of multilateral comparison, for instance between the Sino-Tibetan and Caucasian languages; and there have even been attempts to produce universal etymologies, including forms from all or most language superfamilies, which might suggest forms of Proto-World, the alleged first language of mankind (see Ruhlen 1994).

4.3 Connections with Archaeology and Genetics

Multilateral comparison remains extremely controversial. Its apparent ease of use may be deceptive, not compensating for problems of reliability of data, and potential laxness of the criteria governing what counts as a phonetic or semantic match. Many historical

linguists are reluctant to accept the method or its results, and therefore doubt whether language groupings above the traditional family level, and beyond a time threshold of perhaps 5,000–8,000 years, can be conclusively established.

Long-range comparativists are, consequently, increasingly turning to data from outside linguistics itself in an attempt to validate their work, and exploration of the potential for historical linguistics and related disciplines like archaeology and genetics to produce mutually informing and enforcing data is becoming central. For instance, Greenberg et al. (1986) cite genetic and archaeological data which seem to favour a three-way migration of peoples into the Americas, mirroring Greenberg's tripartite classification of New World linguistic groups. Cavalli-Sforza et al. (1994), in work which caught the popular scientific imagination, analyzed genetic data from 142 indigenous populations worldwide, and argued that the resulting population tree closely matched a linguistic family tree including controversial linguistic phyla.

However, these correlations are themselves problematic. The lack of a one-to-one correspondence between language and archaeological culture means interpretation is all important, and increases the need for data from the fields under comparison to stand independently and to be subject to rigorous validation within their own areas before cross-disciplinary conclusions are drawn. In genetics, in particular, advances in the data-types which can be considered may produce a range of possible population histories rather than a single definitive answer: thus, Cavalli-Sforza et al.'s (1994) picture of the Americas, based on classical analysis of proteins, does not agree with the genetic groupings derived from more recent analysis of mitochondrial DNA and Y chromosomes; these will therefore produce population trees which need not match a particular linguistic tree.

Connections of historical linguistics with genetics and archaeology are also relevant beyond the domain of long-range comparison and influences move in both directions. For instance, Dixon (1997) applies the biological model of punctuated equilibrium to language, arguing that Comparative Method and the associated family tree model may be relevant only to periods of concentrated change and expansion in the histories of language families. At intervening periods of relative equilibrium, language contact and gradual diffusion of features would determine the course of language change. Geneticists and archaeologists are also increasingly seeking a historical linguistic methodology which is truly independent and repeatable, and which might transcend arguments among its practitioners, for comparison with their own data: the development of quantitative techniques of language comparison therefore remains a pressing goal within historical linguistics (see *Historical Linguistics: Numerical Methods*).

4.4 The Evolution of Language

If our attempts to reconstruct might be blocked beyond a certain time-depth on methodological grounds, some progress might be made by starting from the other end: that is, by considering the origin of language in our species. This is a topic which logically belongs with historical linguistics, at least from a nonspecialist point-of-view, but which has traditionally been excluded from the field, being famously banned by the Société de Linguistique de Paris in the 1860s. However, some rehabilitation has taken place during the 1990s, with increasing interchanges of ideas between historical linguists, computational linguists, primatologists, neurobiologists, and psychologists; Hurford, Studdert-Kennedy and Knight (1998), for instance, includes contributions on the possible emergence of phonology and syntax, with some use of computer simulations to show how learning of these new structures might have taken place, as well as work invoking more social and anthropological considerations to explain the rise of human language. Again, this is by definition interdisciplinary research, which raises questions fundamental to historical linguistics (such as how the, probably simple, initial constructions of early language developed into the modern range of variants), and to linguistics in general (such as the limits which might be set on what aspects of language are innately specified and which might be learned, this in turn depending in part on whether the underlying systems responsible for language evolved by natural selection or are in some way maladaptive).

5. Common Trends in Reconstruction and Change

In the sections above, change and reconstruction have been presented separately for convenience. However, these areas are not truly independent, and some common themes can be discerned which may be important for the future of historical linguistics in general.

First, it must be emphasized that change and reconstruction influence one another. For instance, if an early text or unknown language is deciphered, the database usable for drawing conclusions about changes is increased, but the same data may also confirm or refute the results of work on reconstruction.

Second, both subdisciplines need to become reconciled to the development and use of quantitative, computational approaches, and of tools. Work of this kind is probably more advanced in change, where techniques derived from sociolinguistics are already well established in some domains. The need is more pressing, and the issues involved more controversial, in classification.

Finally, it is encouraging to note that historical linguistics is becoming a major focus of research

within linguistics. This means that historical linguists in turn must be willing to work with synchronically-based theories, and to consider what cognate disciplines like genetics and archaeology might require, as well as what they can provide.

A. McMahon

Historical Sociology

In 1844, Auguste Comte's *Lecture on the Positivist Outlook* (*Discours sur l'esprit positif*) proposed the name 'sociology' for the general science of humanity. In Comte's vital vision, the hierarchy of sciences proceeded from mathematics at the base through astronomy, physics, chemistry, and biology to sociology at the summit. The maturing of basic sciences, he declared, now made it possible to construct the capstone science, sociology. In that defining moment for the sociological discipline, Comte's conception of sociology included history, in fact consisted largely of analyzing the development of humanity through historical stages. From that point onward, however, professional history and professional sociology moved in very different directions.

As the historical discipline organized later in the nineteenth century, professional historians came to specialize in particular times and places, for example, modern Latin America or ancient China. This specialization built up clusters of expertise in the sources, languages, and institutions peculiar to different time-place settings, which in turn promoted collective research programs, debate among experts, education of newcomers, and exclusion of nonprofessionals from the historical guild. It also made syntheses of all human history in a Comtean style less attractive to ordinary historians.

Meanwhile, sociologists divided up their own specialties mostly by structures and processes—families, religions, industrialization, crime, and so on—and drew their evidence chiefly from observation of the countries they currently lived in. Sociologists' historical essays divided among broad evolutionary and stage schemes, scattered examples illustrating general arguments, and sketchy prologues to studies of contemporary social phenomena. From these contrasting bases of intellectual organization sprang a number of mutual misunderstandings between historians and sociologists, including the sociologists' common presumption that sociology is an explanatory, generalizing science and history a descriptive, particularizing science fated to provide raw material for sociologists' generalizations. Historians returned the compliment by complaining that the present studied by sociologists

was itself a narrow historical moment with no claim to universal significance, and that to pluck examples from history without thorough knowledge of the relevant sources, languages, and institutions courted intellectual disaster.

Despite increasing separation between the disciplines, to be sure, occasional thinkers since Comte have ventured into grand syntheses that do not obviously belong to a single discipline. The ideas and accomplishments of Karl Marx and Max Weber transcend any single discipline. Grand syntheses addressing major historical questions have continued to appear in the twentieth century, with inquiries by Barrington Moore, Jr., Norbert Elias, Immanuel Wallerstein, and William H. McNeill overflowing disciplinary containers. Such works belong to the common heritage of history and the social sciences rather than to the narrower field of historical sociology.

The idea of a distinct enterprise called historical sociology only formed during the twentieth century, as sociologists themselves began to distinguish sharply between evidence coming from direct observation of the present and from indirect observation of the past. Historical sociologists sought to connect the two through serious investigation of other settings than the ones they lived in. During the twentieth century, historical sociology has differentiated into four rather different pursuits. We might call them *social criticism*, *pattern identification*, *scope extension*, and *process analysis*. All are legitimate, effective forms of sociological analysis. They differ substantially, however, in aims, procedures, and results.

Historical social criticism reconstructs the past on the way to informing human choices in the present and future. It rests on the plausible assumptions that history contains a record of human successes and failures in dealing with problems persisting into the present; that if long-term trends exist, their causes are likely to continue; and that recent history limits what will happen next. Thus sociologists have created competing accounts of capitalism's development as liberation, as oppression, or as something in between. Similarly, sociologists of the family review its history as a means of criticizing current trends and charting alternative futures.

Although the description and criticism of contemporary social conditions preoccupied many nineteenth century sociologists, a large share of nineteenth century sociology consisted of historical social criticism—attempts to make better sense of current dilemmas and general directions of human development by situating the present in long, large social processes. Landmarks of nineteenth century social thought such as Karl Marx's *Capital*, Max Weber's *Economy and Society*, or Ferdinand Tönnies' *Gemeinschaft und Gesellschaft* embedded critiques of contemporary social life in vast historical syntheses. The tradition continues into our own time, as sociologists in the

varied styles of Göran Therborn, Theda Skocpol, Jürgen Habermas, and Orlando Patterson contribute to current social criticism by reworking history. At its best, historical social criticism helps people act wisely and effectively in the present by displaying possible futures and paths to them.

Historical social criticism overlaps with historical pattern identification, which it helped bring into being as a sociological specialty. Pattern identification searches for recurrent structures and sequences across time and space. Before World War II pattern identification often involved natural histories for large social aggregates, for example, Pitirim Sorokin's claim that each civilization passes through Ideational, Idealistic, and Sensate phases. (Sorokin's analyses edged over into social criticism as he argued that western civilization had reached the last, corrupt stage of sensate culture, and that only spiritual renewal could save the West.) Pattern identification also took the form of natural histories for wars, revolutions, social movements, and other smaller-scale phenomena.

After World War II, ideas of development and modernization sometimes followed the natural history model, but pattern-identifying historical sociologists generally moved toward the study of processes within countries or regions such as secularization, industrialization, revolution, democratization, and population growth. Pattern identifiers usually seek to discover necessary and sufficient conditions for large, recurrent social transformations and/or to establish general sequences within those transformations. Much pattern identification consists of lining up comparable cases to determine whether they conform to the proposed pattern. Thus students of state formation as different in approach as Reinhard Bendix, Michael Mann, and Bernard Silberman collect historical evidence on central bureaucracies in multiple countries to see whether state bureaucratization regularly occurs in the course of economic expansion. At its best, historical pattern identification facilitates recognition of recurrent social processes with sufficient accuracy to permit intervention or anticipatory action.

Scope extension applies techniques, models, or generalizations that sociologists have developed in studies of contemporary social life to historical situations. Demographers, for example, have often verified or refined models of fertility change developed initially to explain differences or short-range shifts in contemporary populations by examining longer runs of historical experience. Similarly, network analysts have sometimes extended ideas and techniques from the study of connections within currently observable populations to the reconstruction of changing connections within historical populations. Scope extension to historical cases can remain quite ahistorical or even antihistorical if the analyst disregards the time-space contexts of the social processes under investigation. But it also offers grounds for extensive collaboration between historians and sociologists,

as well as for adaptation of sociological ideas by historians. Historians have, for example, conducted valuable investigations of social mobility in past times, examining evidence and time spans rarely available to their sociological cousins.

Within disciplinary history, in fact, the special fields of social history, family history, demographic history, and economic history have grown up as interfaces with the social sciences, including sociology (Zunz 1985). In these fields, some work actually consists of sociological scope extension or its equivalent in relation to economics and political science. More takes up questions of general concern to historians by means of models, theories, or techniques grounded in social science, for example, using collective biography to trace changes in composition of the English gentry (Stone and Fawtier Stone 1984).

Scope extension has a mirror-image version. It consists of using historical evidence to challenge widespread suppositions of contemporary sociological analysis. The historical work of Viviana Zelizer offers an excellent case in point. Although her later writings about the social meanings of money balance between scope extension and process analysis, her treatments of life insurance and valuation of children in the United States during the nineteenth and twentieth centuries demonstrate that economic transactions commonly portrayed as operating independently of culture—or even to the detriment of culture—actually rest on extensive, changing webs of shared understanding. It took extensive cultural work, for example, to make the insuring of human lives acceptable to Americans. At its best, scope extension accomplishes two distinct objectives: it corrects historical misconceptions as it broadens the domain of social scientific knowledge.

Process analysis examines how social interactions impinge on each other in space and time. Instead of considering space and time as additional variables, it presumes that space-time connections define social processes, and that social processes operate differently as a function of their placement in space and time. Sociologists studying urbanization, for example, have long sought to identify recurrent sequences and geographic arrangements of urban growth (pattern identification) and to determine whether explanations of urban growth that work reasonably well in contemporary capitalist countries also apply in non-capitalist history (scope extension). But they have also tried to determine how, why, and under what conditions large cities host highly differentiated occupations (process analysis). Although theorists have sometimes drawn their ideas on the subject from biological ecology or from the comparison of contemporary populations, this sort of process analysis is intrinsically historical. The analyst has no choice but to locate the processes under examination in time and space, then to ask how time and space affect them. Process analysts typically deny the premise of pattern

identifiers: that large structures and processes repeat themselves in essentially the same form across history. Process analysts search instead for explanations of variation.

A bold example comes from Janet Abu-Lughod's study (1989) of the thirteenth century world system. Reacting to Immanuel Wallerstein's claim that under European capitalist auspices the first economic world system formed during the fifteenth century and has prevailed ever since, Abu-Lughod examined connections among such far-flung cities as Baghdad, Calicut, Canton, and Malacca three centuries earlier. She offered evidence of an active trading system, connected by both land and sea, of which Europe was then a peripheral appendage. Although Abu-Lughod's analysis centers on the same sorts of mechanisms—generation of interaction by trade in high value-for-bulk commodities—as Wallerstein's, it resets the questions. Abu-Lughod forces us to ask how and why a vast Asian-centered world system declined and a European-dominated system arose in its place. At its best, process analysis identifies causal mechanisms of broad scope as well as conditions that affect activation, interaction, and outcomes of those mechanisms (Hedström and Swedberg 1998).

Social criticism, pattern identification, scope extension, and process analysis take somewhat different approaches to historical evidence. Social criticism relies almost entirely on selective use of existing historical accounts, often privileging earlier social criticism and social thought. Thus Jürgen Habermas' *Theory of Communicative Action* reinterprets modern western history (especially that of Germany) via critiques of Karl Marx, Max Weber, Emile Durkheim, Talcott Parsons, and other thinkers, arriving at proposals for a critical theory to serve human liberation. In a more obviously historical vein, Manuel Castells' *The Information Age* reviews changing information systems and identities in the world at large during the later twentieth century in order to identify choices and challenges facing today's humanity. Castells' sources include statistical compilations and his own observations, but beyond general theory and the immediate past they center on works by historians and historical sociologists.

By and large, pattern identifiers draw their evidence from historians' syntheses, extracting comparable elements from the detail. In effect, they apply a uniform questionnaire to distinct historical episodes. Robert Wuthnow's *Communities of Discourse* (1989) asks how ideological innovations take root by comparing the Protestant Reformation, the European Enlightenment, and the formation of Marxist socialism. His implicit questionnaire's broadest headings concern environmental conditions (e.g., pace of economic growth), institutional contexts (e.g., extent of division within ruling elites), and action sequences (e.g., communication of new ideologies to broad audiences). Wuthnow draws evidence under these headings from

wide reading of relevant histories, refashioning the evidence to establish uniformities, for example, the regular emergence not of a unitary belief but of competing ideologies, from which a political selection process singles out one or a few for predominance. Such implicit questionnaires discipline inquiry, but they also run two serious risks: of treating as equivalent events, institutions, and social relations that actually differ fundamentally, and of ignoring the causal connections of events, institutions, and social relations within their actual historical settings.

Among historians, authors of textbooks and of grand narratives often proceed in a manner superficially resembling that of sociology's pattern identifiers; they incorporate other historians' detailed studies into large syntheses. Historians' syntheses, however, typically hang together not through the detection of similar elements in distinct episodes but through the establishment of connections *among* episodes. Historians' connections arise in different ways: from evolution of political or economic systems, from the impact of leaders, from transformation of the dominant culture, or perhaps from critical events such as creation of the first Chinese empires or the Russian revolutions of 1917. But on the whole historical synthesizers, unlike their sociological cousins, insist on connections in space and time.

Within historical sociology, extensions of scope often employ procedures and sources resembling those of historical researchers. Historians make a rough distinction between *primary* and *secondary* sources. If the historical processes under study directly generated the sources, they qualify as primary; administrative correspondence, triumphal arches, artisans' tools, and contemporary portraits can all serve as primary sources. Secondary sources include later efforts to reconstruct what happened, especially efforts by other historians. The distinction must remain blurred, since chronicles, autobiographies, ambassadors' dispatches to their home countries, newspaper accounts, and similar sources occupy a middle ground.

Sociological scope extenders characteristically become familiar with the character of primary sources in their chosen historical eras even when their own analyses rely chiefly on secondary work by specialist historians. Thus historical demographers have frequently compiled and analyzed registers of births, deaths, and marriages for themselves in search of clues concerning determinants of changes in fertility, mortality, or nuptiality (Willigan and Lynch 1982). As historical demography illustrates, sociologists working with a recognized body of historical sources are more likely than their historical brethren to center their analyses on models, methods, or arguments drawn directly from contemporary studies of ostensibly similar phenomena.

Not all sociological scope extenders, however, apply formal models to the past. In common with their cousins in anthropology, for example, sociologists

with historical orientations have often engaged in retrospective ethnography, taking the questions and procedures of local community studies back in time. In a pioneering work of historical sociology, *English Villagers of the Thirteenth Century* (1941), George Caspar Homans reconstructed the organization of different sorts of villages much as contemporary observers of communities were reconstructing the organization of villages in the Americas, Europe, and elsewhere. Homans substituted historical records for the interviews and first hand observation of community ethnographers. Don Kalb (1997) has adopted retrospective ethnography to follow transformations of class, family structure, and politics in industrial North Brabant during the nineteenth and twentieth centuries. Both Homans and Kalb made simultaneous contributions to sociologists' and historians' treatments of their subject matters.

Of our four varieties of historical sociology, process analyses engage sociologists most directly in thinking about history as history, that is, as the embedding of human action in time and space. Here the distinction between primary and secondary sources begins to dissolve, and the sources rarely come ready made. Reconstructing processes by which science changes, for example, engages historical sociologists of science in looking simultaneously at organizational settings, individual biographies, interpersonal networks, contested bodies of thought, and connections among all of them. No simple exportation of contemporary models into the past will accomplish that sort of synthesis.

Process analysts concentrate on connections among events, which means that, whether explicitly or implicitly, they typically construct matrices having multiple dimensions: time, place, type of event, form of connection, and so on. Wherever they find their historical evidence, then, process analysts snip, splice, paste, and rearrange it extensively. John Markoff's *Abolition of Feudalism*, a case in point, recasts local statements of grievances from the France of 1789 into regional and class distributions of demands, then integrates a vast catalog of peasant actions into an analysis of popular mobilization as a dynamic process during the early Revolution. Similarly, Roberto Franzosi pursues a search for causes of industrial conflict by threading his way among aggregate Italian strike data between 1950 and 1980, increasingly refined econometric models, and close examination of shifts in institutional and political settings. In both cases, the analysts ended up showing that when and where political processes occurred significantly affected *how* they occurred, and what results they produced.

As sociology and history now operate, relatively little flow occurs between sociologists' historical social criticism and adjacent fields of historical endeavor. The same is generally true of historical pattern identification. Neither endeavor attracts much attention from historians. Nor do sociologists respond readily to historians' efforts along similar lines. More

ideas flow in both directions across the boundaries of scope extension, but the chief effect of collaboration between sociologists and historians at that interface has been to create a series of specialized subdisciplines: historical demography, demographic history, and their equivalents. As a result, sociologists and historians at large remain woefully ignorant of each other's sources, methods, models, ideas, and discoveries.

In the zone of process analysis, however, we find intense interaction between historians and sociologists. We also find sharp disagreement. Questions of epistemology, ontology, and method align practitioners with competing answers to such questions as 'What is an event?', 'Can we detect causes in history?', 'Do all social processes result from individual choices?', and 'Do organizations really exist?' Debates over such issues roil current discussions of state formation, population change, revolution, capitalist development, and other large processes (see, e.g., Abbott 1994, 1998, Bates et al. 1998, Hamilton 1996, McDonald 1996, Steinmetz 1999). That is as it should be; where relations among historical researchers run harmoniously, we should fear that they have worked out a comfortable but ultimately fruitless division of labor. We can take some satisfaction from noticing that the deep epistemological, ontological, and methodological divisions of our time do not pit historians against sociologists, but cut across the once-forbidding frontier between history and sociology.

Historicism

1. Origin and Meaning of the Term

The term ‘historicism’ comes from the German Historismus, and first appeared in German as far back as the closing years of the eighteenth century. It was only imported into other European languages—French, Italian, English, Spanish, and so on—much later, from the 1930s. In German the term is to be found (albeit only occasionally) in writers such as Novalis and Friedrich Schlegel, and in the nineteenth century, in spite of having an uncertain definition, it came to be used quite widely, assuming a wide variety of meanings, most of them negative. On the whole it was used to refer to the conception of history and society worked out by the German historical school—in its writings on law and (especially) on the economy. Thus for example Carl Menger entitled one of his works ‘Die Irrtümer des Historismus,’ to criticize the reduction of economic theory to economic history, or at least the confusion of the two at the hands of the historical school of economics (see *Political Economy, History of*). A few decades later, Edmund Husserl, in his essay on ‘Die Philosophie als strenge Wissenschaft’ (1911), argued that naturalism and historicism were two parallel forms of thought which reduced philosophy to a Weltanschauung. Even when the word was used more neutrally—as occurred in the early years of the twentieth century, in writers like Ernst Troeltsch or Friedrich Meinecke or, in Italy, Benedetto Croce—its connotation was by no means univocal. It is no accident, therefore, that it was used mainly to refer to movements and theoretical approaches belonging to the preceding centuries.

This use of the word primarily to refer to the past explains why it was employed to refer to different things: (a) the conception of history present in the German historical school; (b) the positions of (often widely differing) writers such as Wilhelm Dilthey, Georg Simmel, Ernst Troeltsch, Friedrich Meinecke, and (to some extent) Max Weber; (c) the conception of history found in Hegel or Marx (this is the use Popper makes of the term); and (d) (a usage confined to Italy) a speculative tradition going back to Vico and Hegel, and leading up to Benedetto Croce. Up until the years between the wars, there were no writers who described themselves as 'historicist,' and up until that time, the word had rather negative connotations. The first attempt to provide a thoroughgoing overhaul and redefinition of historicism as a historical movement was Friedrich Meinecke's *Entstehung des Historismus* (1936, trans. *Historicism*, London 1972), a work which, however, produced more criticism than consensus (see *Historiography and Historical Thought: Modern History (Since the Eighteenth Century)*).

2. Historicism and the Historical School

There is no doubt, however, that historicism is not just a historiographical tendency—even though it has certainly had widespread influence on historians—for it is primarily a general conception of reality, or at least of Man and the human world, a conception whose roots are to be found in late eighteenth-century German culture. (The inclusion of Vico as a historicist is a retrospective operation, and one that is highly controversial.) Historicism in fact emerged in close connection with that reaction against French culture that started to make its voice heard clearly with Johann Gottfried Herder. In *Auch eine Philosophie der Geschichte zur Bildung der Menschheit* (1774), Herder argued against views of history which saw it as the progress of humanity out of a savage state towards civilization, but espoused a developmental perspective which maintained there was an analogy between the life of humankind and the life of an individual. According to Herder the various epochs that came after one another—seen as paralleling the gradual passage from childhood to youth and then virile manhood—correspond to the succession of peoples. Each historical epoch was said to bear the imprint of the national character of a particular people, which was destined, in the same way as humanity as a whole, to run through a life cycle. Herder linked up this organicist perspective with the idea that history was the working out of the design of Providence. Thus each people was seen as carrying out an indispensable task in the history of humanity, imparting in the process the mark of its peculiar nature—its 'spirit'. The idea of 'a people's spirit' (*Volkgeist*) therefore came to mean the essence of a particular people, the

fundamental traits which underlay and united all the forms that people took in the course of its development.

It was precisely this idea which was taken up by the historical school. Whereas Hegelian philosophy of history developed Herder's providential perspective, and tried to show the essential rationality of history, demonstrating that underneath the apparently accidental succession of events was the development of spirit, Friedrich Carl von Savigny interpreted law as the individual creation of a particular people—thus rejecting the natural law tradition. In a similar way, Wilhelm Roscher and other exponents of the historical school among economists saw economic life as the expression of a particular people, and thus a pattern which could not be understood independently from other aspects of that people. Most influentially of all, Leopold von Ranke gave a theoretical framework to romantic historicism in a series of works—from *Geschichten der romanischen und germanischen Völker von 1494 bis 1535* (1824) to his unfinished *Weltgeschichte* (1881–5). Rather than seeing each people as having an essence, Ranke saw each epoch as possessing its own individual character. He believed each age was characterized by dominant 'ideal' tendencies, and that the people who lived in a particular age were shaped by these tendencies. He denied that it was possible to interpret the succession of epochs as having any teleological development, and denied that earlier ages could be seen as laying the way for later ones, or later ones the necessary outcomes of earlier epochs. Each epoch has its own value, and is, as Ranke put it, in an immediate relationship with God. The divine presence in history did not imply, therefore (as Hegel believed) that there was a 'progressive' evolution from one age to another.

A common thread in Romantic historicism was the belief that all knowledge about Man, society and the state must be historically based. Historicism thus put forward an alternative approach to that which had become dominant in the second half of the eighteenth century—exemplified in writers such as Montesquieu or Adam Smith—which took modern natural science as the pattern to follow. Its epistemological model not only implied that historical knowledge was different from knowledge of natural phenomena, but also insisted on the need to bring all disciplines studying Man back to a historical basis. This meant that knowledge of this kind was inevitably 'partial', for it took objects—economic life, say, or law, or the organization of the state—which could only be abstractly isolated from the historical process. Only historical knowledge could lead to understanding of the historical process, it was claimed, or understanding of any epoch in its totality. And only historical knowledge could reveal the deep underlying meaning of events and of the relationship between them. The historicism of the historical school thus remained faithful to the organicist framework it inherited from

Herder. Indeed, it ensured that a shadow of divinity fell upon history—since it was only God who could give a sense to humanity's journey.

3. Modern Historicism

In the last two decades of the nineteenth century a decisive turn took place in historicism. There was an encounter with the neo-Kantian movement and it was felt that what were called the 'sciences of the spirit' or 'sciences of culture' needed to be given an epistemological foundation. This turn started with Dilthey's *Einleitung in die Geisteswissenschaften* (1883). Dilthey positioned himself in the tradition of the historical school, but he abandoned its organicist assumptions. Still more importantly, he rejected any attempt to use history as the basis for a metaphysical perspective which saw history as containing a *deus ex machina*—whether this consisted of a transcendent will (as in Christian ideas) or an immanent one (as in Hegel). Dilthey tried to apply the kind of critique that Kant had made of natural science to the sciences of the spirit. He therefore thought it was necessary to supplement the critique of pure reason with a 'critique of historical reason'—a critique which would 'provide foundations' for the disciplines concerned with Man, society and the state. However, this enlargement of the critical enterprise demanded a shift in approach, according to Dilthey, to permit a non-metaphysical analysis of the historical world.

A kind of historicism thus began to emerge which was different from, and in many ways opposed to, that of the Romantic period. This new historicism was active in two fields—in epistemology and methodology, and in analysis of the structure of the historical world. In both fields work was produced which was often very diverse. Dilthey was more tied than were other new historicist writers to the historical school, and he saw knowledge of history as part of the *Geisteswissenschaften* (seen as including psychology and the various social sciences as well as history). He thus tried to identify what it was about knowledge of this kind that made it different from knowledge in the natural sciences. He saw the natural and human sciences as differing both in their object and in their method. Whereas natural sciences took as their object phenomena which belonged to a world outside human beings, and were rooted in external experience, in the sciences of the spirit the knowing subject and the object belonged to the same world; knowledge thus came from the lived experience knowing subjects had of their own inner states. Dilthey took up Droysen's idea that historical knowledge was 'understanding' (*Verstehen*) rather than explanation (the kind of knowledge which could be achieved in the natural sciences). Other writers, however, such as Wilhelm Windelband and his pupil Heinrich Rickert, who were more directly influenced by the neo-Kantian

movement, took up Ranke's idea that history is a search for individual identities (the identity of an age) and transposed it into the theory that history was a kind of knowledge oriented towards the individual—as against natural science, which is the search for general laws. Still others, such as Simmel, focused on the social sciences and especially sociology, and posed a problem which was analogous to Kant's problem regarding how nature was possible—asking how society was possible.

These various positions are related to different approaches to the structure of the world of history. Dilthey developed the critique of 'historical reason' into a historical critique of reason, and thus came to a theory of historicity which later influenced Martin Heidegger's *Sein und Zeit*. The historical world—that is to say, systems of culture, systems of social organization, historical epochs—was seen by Dilthey as the outcome of a process whereby life was objectified (became 'objective spirit'). Yet life as an attribute specific to human beings was itself a process which evolved in time. Man is thus a historical being, and his life is historically conditioned by the tendencies of a particular epoch. This led Dilthey to deny that there could be any absolute values—a position which was quite different from that of Windelband and Rickert, who took the neo-Kantian movement in the direction of a theory of values. Dilthey's denial of the possibility of absolute values was echoed on the other hand by Simmel, who produced a psychological interpretation of the Kantian *a priori* and asserted that knowledge was just as relative as other forms of life. After 1910 Simmel came to espouse an immanent-type philosophy of life, founded on the dialectic between life, 'more-life' and 'more-than-life.'

In the period between the two world wars, German historicism again changed track and returned to the metaphysical perspectives of Romantic historicism. The work of Oswald Spengler, published just after the First World War, stressed the radically relativistic implications of historicism, and portrayed history as the terrain in which heterogeneous cultures played themselves out—each one carrying its own set of values, which were peculiar only to the people living within the particular culture in question. Spengler was influenced by Goethe and Nietzsche: from Goethe he adopted the idea of the opposition between the 'world of nature' and 'the world of history,' and also the analogy between cultures and organisms, and he drew on Nietzsche to make a distinction between culture and civilization (*Zivilisation*), with civilization being seen as the inevitable decline of any culture (see *Civilization, Concept and History of*). Troeltsch and Meinecke opposed the relativism of Spengler and tried to re-assert the absolute nature of values from within the historical process itself. Troeltsch advocated a 'material' philosophy of history that would create a 'cultural synthesis' between the various national components of European civilization. Meinecke went

back to Ranke's work and investigated the relationship between the structure of the historical process and God. For both writers, the fact that values were situated in history did not imply that they could not be transcendent, and thus escape becoming outmoded by the course of historical development or becoming.

4. *Beyond Historicism*

In the first two decades of the twentieth century Max Weber took another path, going 'beyond historicism' as Wolfgang Mommsen put it (see *Weber, Max (1864–1920)*). Weber broke decisively with Romantic historicism, took up Menger's critique of the historical school in economics and rejected the organicist assumptions of so much historicism. Weber did not draw on Dilthey—who was still linked to the historical school—but rather on Rickert's distinction between historical knowledge and natural science. For Weber, however, historical knowledge consisted of a set of disciplines that needed not only the explanation of historical phenomena but also what he called nomological knowledge. The focus on individual phenomena therefore in no way meant that general concepts and laws could not be used: these are, indeed, essential if events and the relations between events are to be explained. These general concepts and laws differed from those of natural science in that they took the form of ideal-types. However it was they that made up the basis of 'pure' economics and sociology—these being seen as generalizing disciplines which tended to distinguish them from historical research proper. Weber's position was similar to, but more rigorous than, Simmel's. Both wished to restore the relationship with the social sciences which the emphasis on the individual nature of historical phenomena (the inheritance of Romantic historicism) seemed to imply was impossible.

Weber also broke with Rickert's theory of values on another terrain—that of the interpretation of the status of values. Rickert had sought to ground historical knowledge in universal values, which were transcendent and independent of the course of history. For Weber, on the other hand, values were the criteria for choosing from the infinite range of empirical data—and thus a criterion whereby a historical object was constituted. Far from being absolute, therefore, values possessed a validity that coincided with the possibility of their finding concrete form in human action. Weber also denied that values were organized in systems, as Rickert believed, for values are multiple, as are the spheres of values. Between the various value spheres, and between individual values within each sphere, there was 'collision' of values. This is true even within the sphere of ethics, which is dominated by the split between ethics of intention or conviction (*Gesinnungsethik*) and ethics of responsibility (*Verantwortungsethik*). Given that there is a plurality of conflicting values, Weber argued

that people have to choose; and choosing certain values inevitably means rejecting others. For Weber, history was thus the stage on which people positioned themselves vis-à-vis values, adopting certain values as criteria in their own action, thus putting them into effect.

5. *Historicism outside German culture*

Like that of Troeltsch and Meinecke, Weber's thought was cast in the framework of modern historicism. This was not the case for Croce, who was in intellectual dialogue with Hegel's philosophy of history—although he also put forward a 'reform' of the Hegelian dialectic. Croce denied the existence of a nature existing outside spirit—so even ideas are included in spirit. So reality as a whole was identified with spirit—and this, in turn, was identified with history. In epistemological terms, knowledge was seen as historical knowledge. The sciences (whether abstract sciences such as mathematics or political economy, or empirical sciences, such as the natural sciences) were denied any cognitive validity: Croce argued they simply had an 'economic' function. Croce termed his thought 'absolute historicism'—that is to say, it asserted the thoroughly historical character of reality and knowledge as a whole. Croce's thought was absolute in another, perhaps deeper, sense. For Croce saw history as the 'unfolding' of a first principle, spirit, which becomes real by moving from one to another of its eternal forms—whether art, logic, economic activity or ethical action. He saw individuals as—at best—simple instruments of these processes. History for Croce was about spirit, not about individuals, even though it did deal with individual's 'works'.

Croce worked out the principles of his 'absolute historicism' in the years following the late 1920s—so at a time when modern German historicism had virtually come to an end. The distance between the two types of historicism became clear in the debate which followed publication of Meinecke's *Entstehung des Historismus*. This debate made it clear that Croce and the German historicists thought of historicism in different terms, and also had differing interpretations of the history of historicism. Croce saw his historicism as opposing not only the 'abstract rationalism' of Enlightenment culture, but also the irrationalism which he saw as being present in the historical school, and also in Meinecke. Meinecke saw historicism as originating in the passage from the natural law tradition to Romantic thought, and thought of its greatest triumphs as being the works of Goethe and Ranke. Croce, in contrast, was critical of Ranke's approach to history, which he saw as being unproblematic, and he imagined a direct line of inheritance running from Hegel to his 'absolute historicism' (although the genealogy was complicated by Vico—the national progenitor).

In this same period, historicism (especially German historicism) started to spread to the Latin and the English-speaking countries. This produced some significant accounts and re-statements, e.g., at the hands of José Ortega y Gasset in Spain, or Raymond Aron in France. Croce's historicism (although not fully distinguished from Dilthey's) found an echo in Britain, in Robin G. Collingwood's work. However, by this time, historicism was almost at an end. In 1944 Karl Popper (see *Popper, Karl Raimund* (1902–94)) published a book with the significant title, *The Poverty of Historicism*, which took up the criticisms which neo-positivists (particularly Otto Neurath) had made of the traditional distinction between historical knowledge and natural science. After the war historicism was subjected to head-on attack from various sides (e.g., in the critiques of Leo Strauss and Karl Löwith). In the second half of the twentieth century it has been rare for writers to admit to describe their philosophical positions as 'historicist', even though some have taken up themes and forms of analysis which are similar.

6. From Historicism to 'Historical' Social Science

At the same time as its influence in philosophy was declining, historicism became important again for historians, especially in Germany. Central was the reference to Max Weber and his insistence on the need to link historical research and the social sciences, and on the need for history to employ concepts and theories developed by the social sciences. Instead of making the traditional distinction (and contraposition) between historical disciplines and the natural sciences, or that between historical understanding and 'systematic' knowledge of society, Weber favored a strong link between the latter two kinds of knowledge; this approach was taken up by historians such as Hans-Ulrich Wehler, Jürgen Kocka, Wolfgang J. Mommsen and others. In a 1969 essay Wehler proposed a definition of history as 'historical social science' and argued that history ought to be seen as one of the social sciences, yet at the same time have its specificity recognized. He thus emphasized historiography's affinity to economics, sociology or political science, in so far as it necessarily drew on theories, and took most of them from other social sciences.

One of the consequences of this current of thought was that it opened the way for a return to Marxism: not Marxism as a general theory of history, but as a set of theories which could be tested in the interpretation of specific historical processes. In other words, Marxist concepts were used in a 'Weberian' fashion, as ideal types. Theories thus had a purely functional value and could not guarantee the validity of research. This brought out the problem (stressed especially by Kocka) of how to check the findings which theoretically guided research led to, and the related problem of

how the validity of theories could be assessed. Kocka's solution was that it is not theories which legitimize findings, but rather findings which demonstrate the heuristic efficaciousness of theories.

These works left aside many of historicism's classic problems, and rejected many of its methodological stances, such as its opposition between explanation and understanding. Their aim was to show that historical writing had its scientificity, albeit scientificity of a special, 'sui generis' kind. They had nothing in common with the revival of Dilthey in hermeneutics championed by Hans-Georg Gadamer. And they were firmly opposed to the notion of history as 'narrative,' proposed by Hayden White and many other American scholars (in work that, not surprisingly, also often embraced a hermeneutic perspective) (see *History: Theories and Methods; Bourgeoisie/Middle Classes, History of*). Nonetheless, this did not stop writers like Jörn Rüsen recognizing the narrative character of historical writing, and seeing this as the feature which marks history out from other social sciences. But Rüsen does not deny either the need for theories nor the scientific character of historical research: on the contrary, he aims to show that the narrative structure of historiography is perfectly compatible with the use of general theories, and does not absolve historians from the duty to empirically check the results of their research.

Historicism has thus not so much been extended as 'superseded.' For not only does 'historical social science' reject Ranke's ideal that the historian should be purely 'objective'. It goes so far as to claim that history can and should be critical (or 'emancipating' in Habermas' terms): that is to say, critical vis-à-vis traditional history-writing and its methodological principles, including the separation between history of ideas and social history, but also critical towards traditional historiographical interpretations of Germany's past. This has led to a significant shift in attitudes towards the Enlightenment (see *Enlightenment*). As we have seen, historicism was born partly out of polemic with Enlightenment culture, which it considered anti-historical. In contrast, Horst Walter Blanke has recently tried to link 'historical social science' up to Enlightenment historiography and the Enlightenment conception of history. This marks a sharp break with the traditional conceptions and categories of historicism—especially (but not exclusively) those of Romantic historicism. Thus, historicism did not only decline as a general philosophical approach, but also as a paradigm of historical research and writing.

Historiography and Historical Thought: Christian Tradition

Ever since the beginnings of orderly reflections on the topic of history in Christianity and the first literary attempts to write history (by the author of *The Gospel According to St. Luke*, c. 81–96 AD, cf. Luke 1, 1–4 and Eusebius of Caesarea, c. 264–340 AD, *Ecclesiastical History*), four basic problems have been characteristic of all such attempts. Their uninterrupted

significance from the ancient world up to the present allows development of a history of problem areas of Christian historical thought. All Christian historical thought and also all Christian historiography can be characterized by basic decisions concerning the following four problem areas: (a) the classification as a specific inside or outside perspective on Christianity (Sect. 1); (b) the respective understanding of the position of one's interpretation on a range between historical and theological standards (Sect. 2); (c) specific mechanisms of selection (Sect. 3), and (d) a small number of models by which the past is reconstructed see (Sect. 4).

1. The Problem of Inside Perspective and Outside Perspective

A Christian understanding of history describes Christianity from an inside perspective; but in many cases such descriptions can, to some extent be regarded as outside perspectives. This is because, together with an outside perspective on Christianity, e.g., by non-Christians, there are also outside perspectives of Christian minorities on Christian majorities, and vice versa. Such perspectives have a special forming influence on the understanding of history: The *Ecclesiastical History* by Theodoret of Kyrrhos (c. 393–466 AD), one of the most definitive works of Christian historians of the second generation after Eusebius, regards historical developments as formed by the debates between orthodox church ('orthodoxy') and apostate heresy. The *Ecclesiastical History* by his contemporary Philostorgius (c. 368–425 AD) has the same perspective, however with the opposite judgment: the theological tradition of the Alexandrine presbyter Arius (c. 260–336 AD), which has influenced theological thought mainly in Great Britain up to the present, is regarded as true orthodoxy by Philostorgius but as apostate heresy by Theodoret. Besides these, there have always existed more or less critical descriptions from an outside perspective by non-Christians (e.g., by the Roman historian Ammianus Marcellinus, c. 330–395 AD, in the heyday of Christian historiography in late antiquity) in which Christian historians were tackled implicitly or explicitly.

It was only in modern Europe that Christian historians have made determined attempts towards a reduction of inside-perspective elements in Christian historiography. This is, of course, mainly with respect to the narrow horizon of thought formed according to the self-awareness of the three Christian denominations that arose in Central Europe after the religious wars of the sixteenth and seventeenth centuries (the Religious Peace of Augsburg 1555 and the Peace of Westphalia 1648). At the beginning of the modern era, reflecting denominational antagonism, the Lutheran, Reformed, and Roman Catholic interpretations of

history entered into competition. The protagonist of the overcoming of this denominational approach to the history of Christianity was Gottfried Arnold (1666–1707; Professor of History in Giessen 1697–1698). He tried to write a ‘*unpartheiische*,’ which is a non-denominational church history. In the twentieth century, following the institutionalization of the ecumenical movement, which has tried to overcome the denominational splittings of the sixteenth century, the call for a general ‘ecumenical church history’ (Ernst Benz) arose. In a widespread late twentieth-century attempt to conceptualize the alternatives, ‘church history’ as opposed to ‘history of Christianity’ has been used. ‘Church history’ describes a perspective orientated towards the Christian denominations, and ‘history of Christianity’ describes a trans-denominational perspective.

2. Christian Interpretation of History—Historical and Theological Standards

A Christian interpretation of history experiences a tension between historiography (or history) on the one hand and Christian theology on the other. This tension has existed from the very beginning in so far as theology (which in this context means the theory of the Christian faith) naturally favors certain theoretical options when reconstructing a history, for example, its assumption of a god acting in history, which other interpretations of history may hold but are by no means bound to hold. Such specific theoretical options always have methodical consequences; this is what the religious philosopher Ernst Troeltsch (1865–1923) showed in his clear analysis and what has been called ‘historical or dogmatic method’ (Troeltsch 1922, pp. 729–753). But one must not overestimate the ‘theological’ elements of Christian interpretations of history before the modern era: from the fourth century they had as a matter of course been orientated towards the literal and methodical standards of the interpretation of history of their respective times. This theoretical background was broken only very partially by specific religious or theological concepts. The first author of an ecclesiastical history, Eusebius of Caesarea, already followed the forms and standards of the historiography of his time in his historical writing, as can be seen in the prologue (Eusebius, *historia ecclesiastica* I 1,3f). Consequently, his account leaves out central questions of a theological interpretation of history. Because pagan ancient historiography very rarely explicitly treated the difficult relation between divine acting in history through fate (*θεοτεῖχη/theoteiche* or *fatum*) and human freedom, Eusebius, too, never picked out the exact relation between man’s freedom and God’s acting in history as a central theme.

The fundamental problem of the relation between an interpretation of history according to modern

standards on the one hand and specific theological premises on the other hand intensified in modern Europe. In the course of the modern secularization of historical thought, under the premise of *etsi Deus non daretur* (God is not necessary), new determinants of history (such as fate, chance, reasons of state, and ethics) were established in place of the Christian approach to a history regarded as being under the law of God. In consequence, the problem of how—under these conditions—a theological view of history was possible, increased. Most Christian interpretations of history after the Enlightenment have, however, tried to take up the problem, often through a religious or theological interpretation of the philosophical framework of the historiographic theory. The Berlin theologian Friedrich Schleiermacher (1768–1834) for example made the following point in his notes of the years 1796–1799: ‘*Die Historie ist immer religiös und die Religion muß ihrer Natur nach historisch sein*’ (‘history is always religious and religion must be historical by nature,’ Schleiermacher 1984, p. 25). At the same time the possibility of a Christian interpretation of the world, which was lost during the period of Enlightenment, was meant to be restored by means of such a religious charging up of history.

3. The Mechanisms of Selection of Christian Interpretation of History

All interpretation of history and, furthermore, all historical writing, is characterized by acts of selection from a huge amount of material. Within the framework of a Christian interpretation of history, first the basic choice of subject must be made: to date, it has been heavily disputed whether a Christian interpretation of history merely ought to deal with certain fields of general history such as Christianity, the history of certain denominations or ecclesiastical groups, or a particular history formed in a particular way by a transcendental power (‘*Heilsgeschichte*’, ‘salvation history’), or whether a Christian interpretation of history ought rather to come up with a distinctive Christian perspective on history as a whole called ‘world history’ since the end of the eighteenth century. The controversies over whether the chosen ideological perspective necessarily leads to a concentration on an ecclesiastical history, or on a history of Christianity, or alternatively on the wider framework of a universal history, has always been an issue in Christian historical writing.

The first Christian author of a historical monograph, Eusebius, chose to concentrate on an ecclesiastical history without any detailed consideration of the political history of his time. A universal history, now lost, was presented by the Greek presbyter Philippus of Side less than a hundred years later, before AD 439. The Christian interpretation of history

that has had the strongest influence up to the modern era, and which was fundamental in the middle ages, was written by the North-African theologian Augustine (AD 354–430). It takes the perspective of a universal history: after the city of Rome had been captured by the Goths in AD 410, both pagan and Christian interpretations of history, which until then had their focus in the Empire, broke down because of the obvious collapse of the Roman Empire. As a consequence, the bishop was bound to develop his own distinctive concept of a universal history which would be able to convey a new sense of history. Augustine presented it with his work *De Civitate Dei*, 'The City of God' (AD 413–426; for details see Sect. 4).

While the Middle Ages mainly expressed concepts of universal history based on Augustine's, e.g., by Otto of Freising (c. 1112–1158), the traditional Christian universal—historical interpretation broke down during the Enlightenment. Theological categories, such as 'God's revelation' or 'God's acting', which had been systematic premises of the Christian interpretation of a universal history, and had consequently formed a unity of transcendental and earthly reality, became problematic. After the attempts of the nineteenth century to recreate such a concept of unity on a new basis, and thus to once more present a Christian interpretation of a universal history (in very different ways by Schleiermacher, Hegel, and Ranke), the twentieth century progressively withdrew from such theological interpretations of history. Christian interpretation and presentation of history in the twentieth century were more or less confined to the specific context of Christianity and church, even if the theoretical basis was sometimes broader. That was the systematic reason for the modern criticism of concepts which attempted to create a close correlation between the history of human development and God's acts of salvation, by way of 'salvation history', the theological interpretation of certain incidents.

Along with the fundamental question of whether a Christian interpretation of history must be understood universally, or be restricted to a history of Christian institutions, there are other mechanisms of selection taken from general historiography which are of importance to a Christian interpretation of history. Historians of the ancient world and the middle ages used, as important mechanisms of selection, the questions of the meaning of an incident, of its benefit for future generations, or of its documentation in the respective privileged sources, and so forth. The bias thus created is obvious. However, in general, the critical sense with which historians before the modern era treated their own modes of selection is underestimated. Such reflections were usually made in the prologue of historiographical works.

The vehement calling into question of traditional mechanisms of selection in the general history of the twentieth century (see e.g., the criticism of any

historical interest with a biased concept of histories of ideas or politics, the criticism of the concentration on Europe, and of the neglect of feminist research) reached the historiography of Christian denominations with a certain delay; its consequences on a general Christian historical awareness only gradually become apparent.

4. The Basic Models of a Christian Interpretation of History

Christian conceptions of history up to the modern era usually have reconstructed it on the basis of a small number of comparatively simple models. Eusebius describes the history of the church according to a model of a process of constant 'advances,' something which is in strict contrast to the historiography of his times with its stress on cyclic processes and the decadence of traditional Roman values. The history of his own religion teleologically leads to the Christian empire of Constantine. Augustine breaks with Eusebius' model of a progress with his concept of two cities (*civitates*) wandering through the ages. He differentiates between the *civitas Dei*, the 'citizenry of God' as an earthly community of the heavenly citizens, and the *civitas diaboli*, 'the citizenry of the devil.' Of course, the Roman state and the community of those who do not live under God and towards him are not identical in the sense of the state as such being the *civitas diaboli*. But Augustine takes up the traditions of radical Christian criticism of the state, and with his anthropologically based historiographic model gives a clear analysis of the social deficiencies of his time. The European Reformation breaks with this conception. It mainly follows the models of decadence developed by the medieval church reformers, which can also be found with humanistic authors: the promising beginnings of the first Christians had decayed in a middle period which are only now brought to light again. This conception was monumental, and had a strong anti-Catholic impetus in the so-called 'Magdeburger Zenturien'—a team effort by protestant theologians (Basel 1559–1574) led by the strict Lutheran Matthias Flacius Illyricus (1520–1575), which has been known under that name since the eighteenth century, and which has remained a fragment. Along with a comparatively simple modeling, the work is characterized by the use of an enormous number of sources. Cardinal Caesar Baronius (1538–1607) reacted to this challenge with his *Annales Ecclesiastici*. But this catholic reply, in terms of method only, mirrored the protestant work, and it tried to answer the reproach of having broken with the truth with a proof of uninterrupted continuity from the age of the early Christian church.

The model of decadence gained special influence (e.g., in Goethe's work); Arnold applied as a basis—despite his programmatic orientation towards an

impartial standpoint. Arnold explained the history of Christianity according to a model of progressive decadence, beginning after the pure earliest church. Despite his persistent interest in counterevidence to official protestant ecclesiastical historiography, he held to his conception of decadence, and to a structural principle of the denominational history of Christianity. Such simple basic models for the reconstruction of the history of Christianity were by no means, or first, only questioned by the European Enlightenment. Augustine's criticism of Eusebius' conception of progress in *De Civitate Dei* is an example, because it was motivated by an empirical diagnosis of society and by critical work on biblical texts. Humanist historians of the Reformation must also be mentioned, particularly Philipp Melanchthon (1497–1560) and Johannes Sleidanus (1505–1556). In his short world history, and in a work on contemporary history entitled *Denkwürdigkeiten, Betreffend Staat und Religion Unter Kaiser Karl V*, strict models of decadence are missing. Sleidanus always endeavored to describe religious changes with regard to imperial power and state power; he can be regarded as one of the progenitors of a strong orientation towards political history.

Along with the orientation towards simple conceptions of progress or decadence, the history of Christian historiography, and the Christian awareness of history, has called into question over-simplified models up to the present. In Ranke's formula, for example, each epoch is immediate to God; divisions into periods are good indicators for the respective underlying models. In this respect, denominational Christian interpretation of history tends to differ from the standards of general history; protestant conceptions for example speak of a 'period of Reformation' as a threshold between the middle ages and the modern era.

The four basic problems outlined above have characterized Christian concepts of history from its beginnings, and they show that the crucial changes in Christian interpretation of history, caused by the increasing influence of the methodical standards of modern historiography and finally by the victory of historicism, must not be overlooked in theology, either. The victory of historicism has had a significant consequence on academic theology as a whole, because the historicization of all theological disciplines was demanded (among others by Troeltsch), and was partially carried out. It is equally clear and almost undisputed that the general 'crisis of historicism' also had an impact on theological form of Christian interpretation of history, something which had already been diagnosed by contemporary church historians like Karl Heussi (1877–1961). Mainly in continental Protestant theology, this general crisis was accompanied by a theological criticism of general historicism. This development is now called an 'anti-historical revolution' (Graf 1988, pp. 377–405), a term which points to its consequences: the removal of

church history as a leading subject of academic theology.

In the twentieth century there was an interesting revitalization of apocalyptic thought on a large scale, the relation of which to the 'crisis of historicism' is not immediately clear. This form of Christian theology, which goes back to a movement in Hellenistic Judaism, and which had already left deep marks on certain biblical texts, is characterized by a distinctive awareness of history. The present time is interpreted as the 'last age,' and forms part of a certain fixed scheme of the course of history, whilst there is no historical interest in the identification of certain 'signs of the times.' In the ancient world, the formation of a Christian awareness of history was accompanied by a drastic loss of meaning of apocalyptic elements for Christianity. The eruptive revival of apocalyptic trends in the middle ages, the early modern era, and the present has in most cases been accompanied by a protest against Christian interpretations of history orientated towards the standards of the respective time.

5. Current Problems and Questions of Christian Interpretation of History

The systematization of current schools of Christian interpretation of history meets with the difficulty of the actual presence of pluralism (Nowak 1997, pp. 3–12), perceived a 'new confusion.' Such concepts are present in the institutional fields of denominational church history as well as independent of these. The Christian inside perspective, considered to embody prejudice in some accounts, presents a challenge to other approaches to the problems of Christian historicism; they have not, however, discarded it. This shows the limited significance of the presently popular alternatives of a 'church history' and a 'history of Christianity.' In both cases, attempts to take an outside perspective are, more or less admittedly, wrapped in an inside perspective.

Within the horizon of the standards of history at the beginning of the third millennium on the one hand, and of Christian theology on the other, almost all schools have tried to achieve careful de-theologization. This, however, is rarely picked out as a central theme. It is only very occasionally that a decidedly theological contribution to the general discussion on history is demanded (Herms 1997, pp. 305–30); a 'resort to pragmatism' can be noted (Nowak 1997, p. 12). Even if some historians still demand a concept of universal history in Christian terms as regards the selection of subject matter, most publications actually present contributions to a discipline of general history. That such presentations are in most cases characterized by the leading assumptions of universal history (and theology) is obvious to any sensitive examination; but

it is only rarely admitted or made explicit. The presently vigorous call for an approach to church history, or history of Christianity, as historical-cultural studies also implies certain universal-historical structures in the shape of an '*histoire totale*'.

The critical calling into question of historiographical mechanisms of selection and of modeling, which mainly arose in the twentieth century, has increasingly been accepted by the institutionalized Christian interpretation of history. But it is very rare that it is understood as one of the consequences of fundamental decisions made in the course of the European Reformation movement which have created a high level of ideology-critical potential.

These four basic problems of Christian interpretations of history cannot be solved by means of isolated special theological hermeneutics. They call for an original contribution to the general discussion of history and of the interpretation of history. This is especially true in view of the latest developments in 'writing history in the postmodern era': can the concept of a literal sense as the regulatory concept of the process of interpretation really be given up in the course of the deconstruction of its own narrative? does not a Christian interpretation of history which does away with the 'grand narratives', and the 'master processes' dissolve itself? is the notion of 'God's acting' dispensable in a Christian interpretation of history? Here, a new and interesting challenge is put to the long-neglected field of a theory of Christian interpretation of history. It is possible that a theoretically renewed, clear-cut, Christian interpretation of history helps to preserve in a positive sense two functions of the Christian interpretation of history under the conditions of the postmodern era: the function of forming society, and the function of critically analyzing society. But with all this, the traditional objections to a simplistically designed history of salvation remain important.

C. Markschies

Historiography and Historical Thought: Classical Period (especially Greece and Rome)

Historiography, the rational reconstruction of the past in the medium of a prose that claims to literary quality, was developed in Greece during the fifth century BC. Its emergence reflects the peculiar intellectual and political developments of this age. The high cultures of Egypt and Mesopotamia had known lists of rulers, their foundations, festivals, and wars that represented the official version according to which the monarch inevitably would crush enemies. There was no need and no chance to develop a conception of the past in which the course of events would be ascribed to the contending efforts of multiple actors, the result of which was unpredictable and thus needed to be reconstructed and narrated in each case. The historical books of the Old Testament, in a certain sense, took account of the contingency of human affairs but at the same time attributed the outcome of events to God's intervention.

1. The Origins of Greek Historiography

After the development of literacy during the eighth century BC, Greek commemoration of a distant past had materialized in the epic tradition (Homer, Hesiod). Its combination of 'historical' and 'mythical' elements became subject to criticism in an age when Ionian sixth century philosophy (as represented by the Milesians Thales, and Anaximander) had attempted at a 'scientific' explanation of the physical world and of human society. About 500 BC Hecataeus of Miletus tried to reconstruct the genealogical facts out of the mythological traditions. He wrote a pioneering work of geography which reflected the expansion of the geographical and historical horizon of the Greeks as a result of their colonization (since c. 750 BC). This

included their expansion on the shores of the Mediterranean and Black Seas, their voyages of discoveries, and the information that the Eastern Greeks (as subjects of the vast Persian Empire) had acquired about parts of Asia. Historiography, in a narrower sense, developed out of the experience of the Persian Wars. However, the realization that the great victories of the Greeks in 490 and 480–479 BC had been achieved, so to speak, against all probability apparently developed only with a certain distance to the events themselves.

Herodotus (c. 485—after 425 BC; a widely-traveled native of Halicarnassus in Asia Minor) opened his account of the Persian Wars with the statement that he wanted to present the results of his research (*historie*) in order to commemorate the deeds of both Greek and Barbarians and to establish the cause of their conflict. *Historie* is a general term for a rational inquiry. It was only later (especially with Aristotle's *Poetics*) that it became the label for the literary genre which Herodotus had created. Herodotus pointed out that his study was the work of an individual and that he felt obliged to an impartial approach. Greek historiography was developed by free intellectuals and did not start as officially committed accounts. Apparently, especially exiles like Herodotus—and later *inter alia* Thucydides, Xenophon or Polybius—were able to take on the position of an (at least, subjective) neutral observer. Herodotus did not only provide the first work of an *histoire événementielle* based on stories which might have been generated two generations before his own time; he also continued the tradition of geographical and ethnographical accounts by incorporating digressions on the various peoples (from the Egyptians to the Scythians) under Persian control. Here he relied on local traditions and autopsy and sometimes reported stories, the authenticity of which he himself doubted.

Herodotus' younger contemporary Thucydides of Athens (c. 460—c. 400 BC) created a quite different model of historiography. He deliberately distanced himself from Herodotus (though without naming him) since he thought Herodotus to have shown too much confidence in his sources. Thucydides' statements on his methodological principles are (with the notable exception of Polybius) almost without parallel in ancient historiography. He chose as his subject the Peloponnesian War between Athens and Sparta and their respective allies (431–404 BC; Thucydides' account, however, is incomplete and breaks off at 411 BC). According to his own words he had started to take notices already with the outbreak of the war since he had anticipated the unprecedented dimensions of this war which affected the whole Greek world. Later, he used his time in exile (the consequence of his defeat as an Athenian general in 424) to collect all available facts by interrogating protagonists and eyewitnesses of both sides. Being confident that he was able to reconstruct the objective course of events he did not

name his sources or quote varying, or even conflicting, versions by different witnesses but digested all information into an authoritative account of 'how it had really happened' (an aside of his which was later to be taken up by Ranke). He wanted to differentiate the long-term causes, which led to a climate of mutual distrust between the two powers, from the immediate occasions, which made them take military action. War and civil war were seen by Thucydides as revealing the *condition humaine*, love of power, ambition, greed, and fear as constituents of people's invariable nature; thus the thoroughgoing analysis of human action should provide insights of everlasting value.

Already Herodotus had incorporated some speeches into his narrative in order to explain the motives behind the decisions of protagonists but Thucydides went much further by systematically using this stylistic device based on the techniques of rhetoric that were taught by contemporary Sophists. As Thucydides explained, his methodical principle was 'to make the speakers say, what, in my opinion, was called for by each situation while keeping as closely as possible to the general sense of the words that were actually used.' Those speeches served to present opposing arguments (in pairs of speeches ascribed to antagonists) and to discuss the political, moral, and juridical implications of certain decisions or to express the self-image of a society (especially in the 'Funeral Speech' attributed to Pericles). The unity of style, the high level of abstraction, the implicit cross-references, and the shortness of the speeches point out that they were primarily a medium to carry the historian's interpretation. Since Thucydides, the inclusion of more or less fictitious speeches was a standard feature of ancient historiography. Thucydides made two exceptions to his principle of writing a strictly contemporary history. He gave an account of the development of early Greek history in order to prove that due to the level of its material culture, a war of such dimensions like the Peloponnesian War would have been impossible. That was a sort of conjectural history based on theories of societal development and on the interpretation of cultural survivals. He also gave a selective description of the 50-year period between the end of the Persian Wars and the outbreak of the Peloponnesian War in which he stressed the rise of Athenian power and the distrust it fostered with the Spartans. This account also served to bridge the gap between Herodotus' narrative and his own.

Thucydides' model of historiography differed from the Herodotean one by eliminating the features of cultural history and ethnographical discourse. But both corresponded with respect to concentrating on large-scale wars, which involved great parts of the Greek world, and with regard to treating matters of constitutional history and internal politics of the states concerned only insofar as they were relevant for the course of events. Their different attitudes to the period

of time that could be reconstructed by drawing on oral traditions notwithstanding, they both primarily relied on oral sources. As a rule, down to the Christian historians of Late Antiquity ancient historiographers did not consult documentary evidence systematically like inscriptions or state papers in archives and did not engage seriously in 'antiquarian' research on constitutional, legal, and religious institutions. That is why they could not think of replacing the narratives of former historians by a new account based on other better sources. Thus Thucydides was a continuator of Herodotus, Xenophon, and other fourth century historians who started their Greek histories at the point where Thucydides' narrative had broken off. Historians who wanted to treat former times again, cannibalized (often in combination with harsh criticism) the accounts of their predecessors.

2. The Variety of Greek Historiographical Production

Thucydides had shaped the trend-setting model of military and political history that was followed by a great number of Greek writers including the historians of Sicily. However, his successors, embellished the rhetorical elements or amplified scenes with emotive appeals to readers. Throughout antiquity, Herodotus enjoyed a dubious reputation as being at the same time the father of history but also a narrator of fabulous stories (in Cicero's famous phrase). The broader Herodotean approach, however, was not totally outdone; it was taken up again by the historians of Alexander the Great and survived in later works with strong geographical and ethnographical interests like that of Posidonius (c. 135–c. 50 BC) and in the specialized geographical works from Eratosthenes (third century BC) to Strabo (Augustan age).

Besides the mainstream of military and political history, a number of specialized historical genres developed since the late fifth and during the fourth centuries. These included: universal history (Ephoros of Cyme, fourth century BC, whose—later lost—work was used by Diodorus Siculus, first century BC); foundation histories, local chronicles, and constitutional histories (e.g., on Athens); cultural histories (Dicaearchus, pupil of Aristotle, late fourth century BC); biographies (late fifth century BC sketches later to be used by Plutarch, c. 45–c. 120 AD; and Xenophon's life of the Spartan king Agesilaus II, fourth century BC).

During the Hellenistic Age, an enormous number of historical works of various kinds have been produced by nearly a thousand historians known to us by name. This tremendous increase of historical production reflected the political reorganization of the Mediterranean world by the establishment of the vast Hellenistic empires (and later the rise of Rome to a world power). It was fostered by the patronage of Hellenistic

monarchs and the establishment of libraries and scholarly institutions, especially in Alexandria and Pergamum. Almost all of this extremely rich production has, however, got lost and is only known from quotations and references in later works. For example, the various reports on Alexander's campaigns by court historiographers, officials, and generals only emerge with the compilation of Diodorus; comprehensive accounts of Alexander's history based on the works of his companions date from the second and third centuries AD (Arrian and Curtius Rufus).

Polybius (c. 200–c. 120 BC) is the only Hellenistic historian of whose historical work a substantial amount has survived. Polybius, a military of the Achaean Confederacy (on the Peloponnese) was one of 1,000 leading Achaeans who were deported to Italy after 167 BC. He came into close contact with prominent figures of the Roman nobility, especially Scipio Aemilianus (the destroyer of Carthage). The subject of his historical work was Rome's rise to world dominion in the time from the Punic Wars to the destruction of the Macedonian state (167 BC). Polybius calls it a 'pragmatic history'; it focuses on political and military actions and is especially based on eye-witness reports and first-hand knowledge of the theaters of war. His intentions and explicit methodological reflections (combined with polemic against several former historians) imply a conscious return to the Thucydidean model of historiography. But Polybius understood Rome's military success as having depended on its uniquely stable, and at the same time flexible, political system. In order to explain this point to his Greek readers he incorporated a description of the Roman constitution and military system and thus gave a systematical treatment of institutions otherwise not to be found in ancient historiography. (His analysis of Rome's 'mixed constitution' should become one of the most important subjects in the reception of ancient political theory since the Renaissance.)

3. Roman Republican Historiography

Roman history was first made the subject of historiographical works by Greek authors like the Sicilian Timaeus of Tauromenium (c. 350–c. 260 BC) and other Greek writers who were especially interested in the stories about the foundation of Rome. Latin literature only developed since the mid-third century BC as a product of the reception of Greek culture. Certain records of the past, however, had been preserved since early times: public documents like laws, decrees of the senate and international treaties, and family records of the aristocracy. And there were the *annales* kept by the pontiffs in which the names of consuls (the eponymous magistrates) were listed, triumphs and religious prodigies were noted, and some

miscellaneous information was collected. About 200 BC, the senator Fabius Pictor provided the first history of Rome written by a Roman yet in Greek. Drawing on the models of Hellenistic historiography Fabius Pictor covered the time from the founding of the city until 200 BC. He probably gave elaborate accounts of the early, and of the contemporary periods and only a sketchy one of the time in between, a proportion that should become typical of many later writers. He was followed by other historiographers writing in Greek until the mid-second century. The older Cato (234–149 BC) was presumably the first to write a historical work in Latin. His *Origines* applied the interest in foundation history not only to the earliest history of Rome but also to the emergence of the cities in Italy and paid particular attention to the unification of Italy. His treatment of political history focused on the justification of his own policy and thus provided the model for the *ex parte* tendency of Roman contemporary historiography. Roman historiography was ethnocentric and it was the product of the leisure-time activity of senators. Their intentions were to demonstrate Rome's cultural equality with the Greeks, to justify her domination over the Mediterranean world, to praise the wisdom and success of the ruling aristocracy, and to take sides with respect to contemporary conflicts. From the late second century onwards, a number of Latin historiographical works were composed which followed in their structure the pontifical *annales* (which were published in a full version in 120 BC) and gave a year-by-year account from the origins of the city. They apparently embellished their descriptions of the early republic and especially the 'Struggle of the Orders' between patricians and plebeians by projecting back features of the internal conflicts that had become almost endemic since the tribunate of Tiberius Gracchus (133 BC). Some historians seem to have taken into account certain results of serious antiquarian research, others had no scruples and they invented 'documents.' (It was the Greek author Dionysius of Halicarnassus who, living in Augustan Rome, showed the greatest interest in evidence of antiquarian nature.) All these Latin 'annalistic' works (as well as the earlier historiographical attempts previously mentioned) are only indirectly known. They were used by Livy (c. 59 BC–AD 17) who was the first Roman historian without a record of political and military experience of his own. His history covered the time from the foundation of the city to 9 BC. Out of his 142 books, only 35, which reach down to 167 BC (with *lacunae*) have survived. Livy often struggled with the contradictory accounts of his predecessors and the quality of his own descriptions obviously depends on the quality of the sources available to him. He did not invent his own versions of the course of events but his work shows the problematic nature of a history totally made on the basis of other, often overtly partisan, historical works that were mostly accepted at face value.

The Thucydidean model of contemporary history was imitated by Sallust (86–35 BC) who after the failure of his political career wrote monographs on the conspiracy of Catiline (63 BC) and on the Roman Wars against the Numidian king Jugurtha (111–106 BC). He interpreted the political crisis of the Late Republic as the consequence of a moral decline following from the abandonment of traditional values. (No other contemporary work on the Late Republic has survived; a comprehensive account of this period is only available in works by later authors such as Appian, second century, and Cassius Dio, third century, who both wrote in Greek.)

4. Roman Imperial Historiography

Writing contemporary history might become a dangerous job under the Emperors as the fate of the historian Cremutius Cordus demonstrates. Under the reign of Tiberius (in AD 25) he was indicted for *lese majesty* because of the republican sympathies he had shown in his work on the Civil War period (he committed suicide; his work was burnt). The short sketch by his contemporary Velleius Paterculus, a former military, covered Roman history from the very beginnings to his own days in only two books and culminated in the panegyric of the emperor Tiberius.

The historiography of Tacitus (AD c. 55–c. 120) reflects a new climate of intellectual freedom during the reigns of Nerva and Trajan in comparison to the experience with the tyrannical régime of Domitian (under whom Tacitus had started his public career). His (only partly preserved) works, the *Histories* and the *Annals*, cover the time from AD 69–96 and AD 14–68, respectively. Tacitus kept the annalistic form and he paid special attention to the proceedings of the senate. But the form was often at odds with the contents of the works since the policies of the rulers could not easily be fitted to a chronological scheme that had been adequate for a senatorial régime with yearly changing consuls at the head. Tacitus showed certain nostalgia for republican liberty without indulging into illusions about a return to a republican constitution. Though claiming to write *sine ira et studio* his personal judgments on rulers (especially the gloomy picture of Tiberius) should serve to uphold the mirror of an honest ruler and his comments on senatorial proceedings reflected his standards for dignified behavior under a monarchy. Tacitus' work with its stress on the psychology of emperors and senators marks the final point of Latin senatorial historiography. (However, later there was an annalistic history of Rome from the beginnings to AD 229 written in Greek by the senator Cassius Dio.)

Apart from short summaries of Roman history, during the second century serious historiography gave way to imperial biographies. Suetonius (AD c. 70–c. 140, secretary for the library and subsequently for the imperial correspondence under Hadrian) gave the life

of 12 rulers from Caesar to Domitian. They were arranged in a more topical than strictly chronological manner and drew on archival materials as well as traditions stemming from court gossip. Modeled on Suetonius but of a highly fictitious character (with numerous references to imaginary sources) was the *Historia Augusta*, a series of biographies of emperors for the time from Hadrian (AD 117–138) to the accession of Diocletian (AD 285) which was probably produced in the late fourth century by one or more anonymous writers who took on the names of bogus authors.

5. *The Impact of Christianity*

The religious tensions of Late Antiquity due to the rise of Christianity did only partly affect pagan historiography which continued to concentrate on short summaries of Roman history. The general restraint from religious polemic holds also true for the work of Ammianus Marcellinus (c. 330–395), a Greek from Syrian Antioch and former military. His history, written in Latin, is otherwise a great exception since he embarked on a continuation of Tacitus that treated the time from Nerva's accession to the throne (96) to the emperor Valens' disastrous battle of Adrianople against the Goths in 378 (only the exhaustive parts on the years from 353 onwards have survived).

Christian authors did not enter into a competition with pagan ones on the traditional fields of political and military historiography but they developed models of historical writing that should become the most important innovations until Renaissance times. Since the third century they compiled chronicles of universal history which synchronized the data of biblical, Greek, and Roman history. The chronicle—in Greek—by Eusebius (c. 260–339, bishop of Caesarea, adviser, and later biographer of Constantine the Great), its Latin translation and continuation (until 378) by Hieronymus and several successor works provided the model for a view of world history since the creation. Eusebius, again, created with his *Church History* a new historiographical genre not only with concern to the subject, the history of the Christian 'nation,' but in formal respects as well by his dispensing with speeches, his giving bibliographical surveys, and his verbatim quoting from letters, official documents, and other sources. The awareness that their theological approach might make their accounts challengeable led Eusebius and later *inter alia* Socrates and Sozomenus (both early fifth century) to prove thus the accuracy of their factual reports.

6. *Concluding Remarks*

Given the complexity and variety of ancient historiography it is almost impossible to summarize its impact on the later Western tradition, especially since the Renaissance, in a few sentences. The most im-

portant legacy of Greek historians was the development of a critical attitude to the past, the invention of methods that made it possible to discern between facts and fiction. The shortcomings of their attempts in view of modern eyes should not obscure this unique contribution to the development of the Western mind. The adoption of historiography by the Romans provided the model for constructing the past in the shape of national history. The Christian writers invented ecclesiastical historiography as a subject of its own and a model for universal chronicles and histories starting from the creation. Since the Renaissance, Thucydides and Tacitus were taken as the masters of political history, Polybius as the model military historian. With the growing interest in Oriental cultures Herodotus gained a new reputation as a cultural historian. Ancient historiography, which had covered republican city-states as well as world monarchies, was as a whole considered as teaching political and moral lessons of everlasting value (and thus was also of great importance for political theory). The tradition that historiography and antiquarian studies were two quite different subjects survived until the late eighteenth century. There were a vast number of commentaries on ancient texts, collections of inscriptions and coins, learned dissertations on the constitutional, legal, military, and religious institutions of the ancient world but nobody thought of replacing the ancient historiographical works by writing anew narrative histories of antiquity. Gibbon was one of the first to do this and to integrate the results of antiquarian research but he still avoided the period covered comprehensively by ancient historiography and thus started his own narrative only with the second century AD. The doubts on the reliability of ancient historiography, especially of the Roman annalistic tradition, that had been developed in learned dissertations since the seventeenth century led only in the early nineteenth century, starting with Niebuhr, to compose a modern historiography of antiquity based on source criticism and systematic researches on the monumental remains of the ancient world.

Historiography and Historical Thought: Current Trends

1. Introduction: Dominance of Social Science Models of History around 1970

The years 1970–2000 have seen important reorientations in historical thought and historical writing. These changes are closely related to fundamental transformations in the conditions of modern life.

Briefly comparing the intellectual and historiographical situation in the year 1970 with that of 2000, we can distinguish certain dominant trends then and now. In neither case, however, is it possible to reduce historical thought to simple common denominators. There are no paradigms in the Kuhnian sense that determine historiographical practice but a great plurality of outlooks that are perhaps even more numerous now than they were then. Nevertheless, in 1970 most historians were still convinced that history was a science, albeit a social science, engaged in recreating a real past as it had actually occurred. Today this confidence in the objectivity of science, including historical inquiry, has come under severe attack, as have the notions still dominant in the early 1970s of a coherent process of history. To be certain, faith in objective truth, in historical inquiry, and confidence in history as the ongoing development of civilization had been undermined as early as the second half of the nineteenth century, e.g., by Jacob

Burckhardt and Friedrich Nietzsche, and even in the United States, which remained a citadel of belief in science and progress, by leading historians such as Carl Becker and Charles Beard in the 1930s.

Historical science, as it was generally understood in the Western world around 1970, viewed history as a social science. It replaced an earlier orientation sometimes labeled 'historism' (which had been dominant in much of the nineteenth and well into the twentieth century), that had argued that history as a *Geistes-* or *Kulturwissenschaft* required a logic of inquiry different from that of the hard sciences, namely one which takes into account the elements of meaning and intention in human life which cannot be reduced to abstract generalizations. These conceptions of historical study that viewed history as a special sort of *Geisteswissenschaft* were increasingly replaced in the twentieth century by conceptions of history as a 'social science.' The new social science orientations went in several directions discussed below, but they shared certain assumptions. They criticized the older historiography for narrating a history of events, primarily political, focusing on leading personalities in positions of power, and called for a history that proceeded analytically, seeking to examine the social context in which events occurred. While the older historiography relied heavily on philology as a tool for the examination and understanding of texts to fathom human intentions, the new history turned to the neighboring social sciences, sociology, economics, and psychology, and in France also geography, which analyzed social structures and processes and stressed the interdisciplinary nature of historical studies. They strove for a history that was more comprehensive than that of the conventional narrative political historiography. They also wanted to include broader segments of the population into the historical accounts.

But it was only after 1945 that forms of social science history emerged as a dominant model for historical studies. Again it is difficult to reduce social science-oriented history to a common denominator; it ranged from the studies of the material and biological bases of historical life in the French *Annales* in the 1960s, to the new historical demography in France and Great Britain, to quantitative urban history and electoral behavior in the United States, to the formulation of quantifiable models of economic cycles in the United States, Great Britain, and France, to a 'historical social science' in West Germany strongly influenced by Max Weber. Nevertheless, despite their differences, they all agreed that history had more kinship to the social sciences than to the humanities. This assumed, as the earlier social science-oriented history had also done, that there was a real historical past that constituted the object of historical studies. It sought to make historical method conform to the methodologies of other social sciences. Hence, it generally preferred different kinds of sources than did the older historiography; for example, hard economic

and demographic data. This made Geoffrey Barraclough comment in a survey written in the 1970s for UNESCO on trends in recent historical studies that:

the search for quantity is beyond all doubt the most powerful of the new trends in history, the factor above all others which distinguishes historical attitudes in the 1970s from historical attitudes in the 1930s (Barraclough 1978, p. 39).

These historians tended to sacrifice individual human beings to structures and processes thus largely ignoring the individuals who compose history.

A key to almost all forms of social science history, with the possible exception of many of the historians in the *Annales* tradition, was the notion of history as an ongoing directional process. This was true of the various advocates of history as an empirical, analytical social science as it was for the different shades of Marxists and for the German school of 'Historical Social Science.' A broadly shared concept was that of modernization. It went back to nineteenth-century positivism and assumed that history, or at least the history of the modern Western world, was marked by an ongoing process towards greater scientific enlightenment followed by technological progress and by the concomitant development of a 'modern' society. While most forms of social science history tended to downgrade political history, the German school of 'historical social science' (Wehler, Kocka) sought to locate politics in the context of social structures and processes to understand how it was possible for National Socialism to gain power in Germany.

2. Challenges to Social Science Approaches to History: Postmodernism

This widely held confidence in social science and modernization was radically challenged in the 1970s and 1980s, most vocally by postmodernist philosophers and literary critics, but more quietly also by historians, particularly cultural historians. While it is difficult to reduce these critics to a common denominator, they agree in repudiating two assumptions that they consider to be central to the modern historical outlook. The first concerns the belief in the coherence and continuity of world history, the invention of a 'master' or 'metanarrative' (Lyotard) which sees history as an onward development to the modern Western world with its promise of enlightenment, emancipation, and well-being for the world as a whole. Practitioners of the established historiography, critics charged, had overlooked the close relationship between Western progress and imperialism abroad and the consolidation of power relations based on race, gender, and class at home taken for granted in their view of history. But history, they argued, had no coherence, thus eliminating the possibility of a grand narrative and opening the way to innumerable separate histories.

Closely related to this critical view was the rejection of the possibility of objective historical inquiry into the past. According to Peter Novick the idea and ideal of objectivity lay at the very center of the historical profession as it was constituted with its 'commitment to the reality of the past, and to truth as correspondence to that reality' and consequently 'the separation of history and fiction' (1988, pp. 3–4). This commitment, Hayden White noted, rests on the 'illusion that there is a past out there that is directly reflected in the texts' (1987, p. 209). Postmodernists according to Keith Jenkins seek to free modern historical consciousness from the notion that behind appearances there lies a solid, foundational, real world. 'In fact history now appears to be just one more foundationless, positioned expression in a world of foundationless, positioned expressions' (Jenkins 1997, p. 6).

For the postmodernists history consists of texts that are linguistic constructs with no direct relation to reality. It is language that creates reality. Jacques Derrida went further in denying that there is anything beyond the text (*il n'y a pas de hors-texte*) (see Megill 1985, p. 266). Moreover, for Derrida the text has no stable signification, but is open to an infinity of significations because there is no Archimedean point from which a clear meaning can be assigned. The text, moreover, according to Foucault is seen not only independently of its relation to the external world, but also independently of its author. Derrida criticized what he considered to be the 'logocentrism' of the classical Western philosophic tradition since Socrates that rested on the error that reality could be reduced to rational concepts, ignoring that these concepts reflected systems of domination. The idea that reality was not given but was constructed through language was further developed in feminist theory. Gender, for Joan Scott, is not found as such in nature but is socially constructed through language, texts, and cultural symbols that reflect or challenge power relationships. Thus the deconstruction of language is a necessary tool for revealing and dismantling these unequal power relationships.

All this leads to epistemological relativism. Perhaps the most influential proponent of such relativism as it relates to historiography has been White, who argued that historical thought is 'the captive of the linguistic mode in which it seeks to grasp the outline of objects inhabiting its field of perception' (1973, p. xi). Consequently it is not the purportedly objective investigations of the historian into a real subject matter which lead to knowledge about history but rather the knowledge at which the historian arrives is conditioned by the linguistic mode in which she/he operates. Professional historiography for White generates no more objective knowledge of the past than does speculative philosophy of history or the historical novel. Any attempt to go beyond the facts to a coherent narrative is a 'poetic act' so that the 'best

grounds for choosing one perspective on history rather than another are aesthetic or moral rather than epistemological' (1973, p. xii). 'Viewed simply as verbal artifacts,' he notes, 'histories and novels are indistinguishable from one another' (1978, p. 122). Similarly, 'the opposition between myth and history ... is as problematical as it is untenable' (1978, p. 83).

This negation of a distinction between history and fiction is at the core of the French literary critic Roland Barthes's essay—*Le Discours de l'histoire* (*Discourse of History*). For Ankersmit, while 'science was the alpha and omega of the modernists' (1995, p. 166), for postmodernism 'the metaphorical dimension of historiography is more powerful than the literal or factual dimensions ... criticizing metaphors is indeed an activity which is just as pointless as it is tasteless. Only metaphors "refute" metaphors' (p. 180). Hence research is irrelevant because 'the "real past" does not enter into historiography except rhetorically' (Jenkins 1995, p. 18).

3. *The Turn to Cultural History and the Return to Narrative*

Few practicing historians would agree with Barthes, Derrida, White, Ankersmit, or Jenkins that there are no criteria of objectivity. They would continue to hold that historical works in contrast to historical novels must proceed from research that requires standards of objectivity shared by the scholarly community. Postmodernism had reflected a general mood that was shared by many historians. Part of this mood was a general skepticism regarding the nature and quality of modern civilization and its science; the recognition that the historical science of the West, whether in its historicist or its social science form, had legitimized relationships of power in which a middle and upper-class elite had been privileged at the expense of the broad masses of the population, including women, and of the nonWestern world. Thus, by the 1970s the old scientific ethos of the social science historians was shaken. In 1979 in a now famous article, *The Revival of Narrative*, Lawrence Stone noted that in the 1970s a change had occurred in the way history was viewed and written. The belief, central to social science history, that 'a coherent scientific explanation of change in the past' (1979, p. 19) was possible, was widely rejected. In its place there emerged an interest in the most varied aspects of human existence, accompanied by the conviction that 'the culture of the group, and even the will of the individual, are at least as important causal agents of change as the impersonal forces of material output and demographic growth' (p. 9). Yet, although Stone emphatically rejected the illusion of 'coherent scientific explanation,' he nowhere suggested that historical narrative should surrender its claim to rational inquiry and realistic reconstruction.

4. *The Impact of Cultural Marxism on the Writing of History*

The new directions which historical studies took must be understood within the context of the political climate of the 1960s and after, such as the emergence of a women's movement, the rise of ethnic consciousness, the struggle for racial equality, anti-colonialism, and environmentalism which all pointed at the inadequacies of the social and economic order of an industrialized, modernizing Western world and the social science which served it. The transformations within Marxist theory and historiography provide important indicators for the change of attitude among historians. Marxism itself was in a deep crisis as indicated in the Soviet power block by the suppression of the Prague Spring and by the rejection of Marxist orthodoxy in the West.

But the significance of a non-dogmatic Marxism on historical thought in Western Europe as well as in Japan, India, and Latin America should not be underestimated. Marxism–Leninism was of little significance there as compared to Western forms of Marxism informed by Antonio Gramsci, Georg Lukács, and the Critical Theory of the Frankfurt School. Western Marxism preserved the idea of class conflict, the role of domination as a major force in social relations, but gave up the idea of a necessary development to a classless society.

The reorientation of Marxism began in the 1920s and involved an examination of the traditional economic interpretation of history. Gramsci's writings in Mussolini's prisons in the 1920s and 30s, which became known in the West only in the 1960s, explained the defeat of the communist workers movement in Italy in terms which involved factors insufficiently developed in traditional Marxist philosophies of history. For him the strength of capitalism rested ultimately not exclusively on its economic strength but on its cultural hegemony over the working classes. Lukács already in 1923 had seen in the section on 'The Fetishism of Commodities' in *Capital* the core of Karl Marx' critique of economic conceptions of capitalism. The empiricism that dominated scientific and social science thought in his opinion failed to understand the broader context of society and culture. A similar note was pursued in the 1930s and 1940s by the 'critical theorists' of the Frankfurt School (Horkheimer, Adorno, Marcuse) who, proceeding from a critique of capitalism that they argued had turned culture into an industry in the service of economic ends, strove for a science which went beyond quantifiable data to the qualitative aspects of society and culture. They nevertheless gave up Lukács' historical optimism.

Perhaps no book had as great an impact on the reorientation of social history, at least in the English-speaking world but also beyond, as E. P. Thompson's *The Making of the English Working Class* (1963).

Thompson maintained the concept of class and the notion that 'the class experience is largely determined by the productive relations into which men are born—or enter involuntarily' (p. 9). But he stressed that class must be seen not as 'structure,' or even 'category' but as something which in fact happens in human relationships (p. 9). The English working class was thus not primarily the product of economic forces, as it had been in the *Communist Manifesto* or in structuralist, functionalist sociology, but an active agent, coming from a specific cultural tradition, which made itself as much as it was made. Hence, his reliance on qualitative elements that make up a culture such as literature, art, folklore, and symbolism. Moreover, Thompson emphatically rejected the orthodox Marxist notion that sees the past as a step to the future.

Yet Thompson's historiographical approach soon came under attack from cultural Marxists who argued that he had not broken sufficiently with classical Marxist notions of class. Even if he saw class in terms of culture, they charged, this culture still focused on an industrial working class in which those not directly linked to the industrial work process played little of a role. The *History Workshop: A Journal of Socialist Historians*, founded in 1976 in Great Britain—which in 1982 changed its subtitle to *A Journal of Socialist and Feminist Historians* and in 1995 dropped the subtitle altogether—tried to overcome this by expanding the concept of work in a changing society and including women in the family and the workplace.

From the perspectives of much post colonialist history of the 1980s and 1990s, such as put forward by Latin American *Dependencia* Theory or Indian Subaltern Studies, Marxism operated with a concept of historical development, akin to that of capitalist writing, for which modernization was understood as Westernization. Edward Said in *Orientalism* (1978) argued that Western scholarship had invented an Arab culture that rested not on historical knowledge but on preconceptions, pitting an enlightened West against a backward Muslim East which needed to be Westernized. Postcolonialist writings integrating feminist, psychoanalytical, and Marxist theories argued that categories of class, ethnicity, and gender must be seen in their interaction. They held that a Marxist conception of class conflict misses the analysis of power to which Foucault had pointed as an infinitely complex network of micro powers that permeate every aspect of social life and culture.

5. From Macro- to Microhistory

While few social historians could be identified as postmodernists or Marxists, certain central ideas of postmodernism and of cultural Marxism impacted a great deal of writing in social history which increasingly moved in the direction of cultural history. The idea of the unity or direction of history gave way to the

concentration on small units, on the local and the marginal.

While this same orientation destroyed the credibility of orthodox Marxism, the Marxist commitment to the oppressed, even if oppression was now understood differently, occupied a great deal of the new culturally oriented social history whose subjects were most often 'the lives and feelings and behaviour of the poor and obscure rather than the great and powerful' (Stone 1979, p. 19). Anthropology and semiotics replaced sociology and economics as the key auxiliary sciences of social history. But anthropology underwent a sea change. While classical anthropology, e.g., that of Bronislaw Malinowski in the 1920s and 1930s, had tended to a static analysis of 'primitive' and 'timeless' societies, anthropologists had now become increasingly historical in outlook, recognizing that all, even the most 'primitive' cultures, evolve and that modern societies as well are proper subjects of anthropological study.

At the same time, historians increasingly turned to an interpretative, cultural anthropology. As the cultural anthropologist, Clifford Geertz, phrased it:

Believing with Max Weber that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of laws but an interpretive one in search of meaning (Geertz 1973, p. 5).

In Germany, this anthropological turn in the 1980s took the form of *Alltagsgeschichte*, which sought to reconstruct the experiences and emotions of common people (Hans Medick, Alf Lüdtke, Lutz Niethammer) in earlier preindustrial as well as in modern industrial times. In Italy, historians (Carlo Ginzburg, Eduardo Grendi, Carlo Poni, Giovanni Levi) around the journal *Quaderni Storici*, began in a series of books and articles to give a firm theoretical foundation to a microhistory (*microstoria*) which reduces historical research to identifiable individuals and from these creates a history from which the net of relationships of these individuals would emerge. In place of the thousands of quantifiable data on which the older social history constructed a history of mentalities, the microhistorians wanted to recapture a fuller picture of individual experiences using transcripts and inquisitorial records in which the voices of the subjects were recorded. Outside of Italy, Emmanuel Le Roy Ladurie in *Montaillou* (1975) used such records to recapture the lives and emotions of individual villagers in a fourteenth-century village while Natalie Davis in *The Return of Martin Guerre* (1983), using judicial records, focused on gender in sixteenth-century rural France.

Nevertheless, the new orientations toward microhistory did not necessarily mean a break with the social sciences. Foucault had rejected the idea that theories can be verified because in his view the standards of verification came from a social scientific discipline which represented institutions of power;

Geertz had argued that any attempt to approach a historical subject matter with theoretically oriented questions distorts this subject and has to be replaced by 'thick description' which immerses itself untheoretically into an alien world. This, in effect, invalidated traditional forms of historical inquiry. But neither Ginzburg nor Levi were willing to go so far. For them, *microstoria* does not reject the empirical social sciences *in toto*, but stresses the methodological need for testing their constructs against existing reality on a small scale. Levi's concern in *L'eredità immateriale: Carriere di un esorsista nel Piemonte del Seicento* (1983) (*Inheriting Power: The Story of an Exorcist*) is social scientific insofar as he wishes to test established hypotheses on a local level. His central concern is patterns of power relationships in the village. In studying land purchases, Levi questions the extent to which impersonal market forces and the development of the modern state machinery determine these power relationships and argues that the decisive element in the understanding of the peasant world is 'the preservation or transmission of intangible or symbolic goods: power and prestige' (back cover of English paperback edition). Here Levi was much closer to Pierre Bourdieu's conception of 'symbolic capital' than to Geertz' 'thick description.'

The gap between social and cultural history began to close markedly in the 1980s and 1990s. On the one hand, there were important works in microhistory emphasizing anthropological aspects of culture (Medick, David Sabean). Despite the reservations these historians expressed in regard to the systematic social sciences, they relied heavily in their work on economic and demographic data and made use of computer analyses. On the other hand, historians coming from a social science orientation recognized the significant role of the cultural dimension in society. The work that the German school of 'Historical Social Science' had undertaken in the social analysis of politics now increasingly gave consideration to the interaction of society and culture. An example of this is the major comparative project on the nineteenth-century European bourgeoisie (*Bürgertum*), headed by Jürgen Kocka, which defined the latter as much in terms of culture and education as in terms of economic status. The journal *Geschichte und Gesellschaft* became an important forum for the presentation and discussion of these tendencies.

The economic analysis of class also began to play a decreasing role in the study of the revolutionary movements since the eighteenth century. By the 1970s not only the economic interpretations of the French Revolution by Marxists such as those of Georges Lefebvre and Albert Soboul, but also of their non-Marxist critics such as Alfred Cobban and George Taylor, were replaced by new viewpoints (Régine Robin, François Furet, Lynn Hunt) which placed greater stress on culture and language. As Lynn Hunt explained in the introduction to her *Politics, Culture,*

and Class in the French Revolution (1984), this work conceived in 1976 began as 'a social history of Revolutionary politics' but 'increasingly turned into a cultural analysis in which the political structures ... became but one part of the story' (p. xi).

Linguistic analysis plays an important role in William Sewell's analysis of the 1848 Revolution in France, in Gareth Stedman-Jones' study of British Chartism, and Thomas Childress' examination of electoral propaganda in the Weimar Republic. None of them, however, would share Foucault's radical position that 'reality does not exist, that only language exists' (quoted in Berman 1988, p. 183). Rather, they would agree with Carroll Smith-Rosenberg that 'while linguistic differences structure society, social differences structure language' (Spiegel 1990, p. 84).

6. The Transformation of Political History

With the move to the social sciences in the 1950s and 1960s and to the cultural sciences since the 1970s, the significance of political history has been downgraded. Various forms of social science history, as early as the *Annales* before 1945, reacted against the focus on political history in conventional historiography. Moreover, the new cultural history that sought to move away from conceptions of centralized power also consciously neglected the state. Yet this led to a certain blindness regarding the realities of the present world. The rapid changes in international relations since the collapse of communism in 1989–1991 have made the significance of politics for society and culture apparent. Recent historical theory with its emphasis on the pluralism of historical narratives has assigned the process of modernization and globalization to the sphere of macronarratives that it rejects. But one cannot escape the reality of processes of modernization, however complex and varied they may be, as significant aspects of modern historical development.

The history of politics, of international relations, of peace and war, and the study of political regimes in the twentieth century continued to occupy an important place in the historiography of the last third of the twentieth century, notwithstanding the new emphases on cultural history. And political history continued to work closely with documentary sources.

Nevertheless, as seen above in recent histories of the French Revolution, greater emphasis was given to cultural factors and to language. Something similar has happened in the studies of the Holocaust. Earlier studies had seen the destruction of the Jews as a vast and complex administrative process, as Raoul Hilberg had described it in *The Destruction of European Jews* (1961), carried out from their desks by bureaucrats like Adolf Eichmann acting on orders from above. The long debate between the 'Intentionalists' and 'Functionalists' centered on the question whether the genocide had its roots in the conscious decisions of the

Nazi leadership or developed without a clear plan in the course of the war. Both approaches failed to deal concretely with the Holocaust as it involved perpetrators and victims on the local level. More recent studies such as Christopher Browning's *Ordinary Men: Police Reserve Battalion 101 and the Final Solution in Poland* (1993) have sought to study the killing through the concrete participation of individual perpetrators.

7. Conclusion

The concerted attack on ideas of objectivity and historical method on the part of postmodernist critics has by no means resulted in the abandonment of serious historical study based on research into the sources. Although the borderline between scholarship and literature has become more fluid, as for example in Simon Schama's *Dead Certainties: Unwarranted Speculations* (1991) which points at the tremendous problems in telling a truthful history, few historians, whether in the areas of political, social, or cultural history, would abandon the commitment to honestly reconstructing the past. At the same time, the confidence of nineteenth-century professional historians in the possibility of telling definitely *wie es eigentlich gewesen* has yielded to the recognition that the same sources and the same set of events lend themselves to a variety of interpretations, but that these interpretations do not necessarily disprove one another but cast different perspectives on a subject. The years 1970–2000 have seen the collapse of illusions dear to modern historical thought until then: the linear progression of Western history and the accumulation of historical knowledge. The scope of historical study has been expanded immensely. The concentration on centers of political power and macroeconomic and macrosocial processes has been supplemented by a new interest in many aspects of life and culture which previously had not entered the imagination of historians, or at least of professional historians, and which require special research strategies. These two scales, the macro and the micro, by no means exclude each other, and in fact, as we have indicated, political and social historians have become increasingly aware of the role of culture, and cultural historians have become aware of the social and political context in which collective human existence takes place.

Historiography and Historical Thought: East Asia

1. Features of East Asian Historiography

The art of recalling the past has developed very differently in Europe and East Asia. Whereas, since the time of Herodotus and Thucydides, Western

historiography has been centered on histories written by individuals for individuals, since ancient times East Asian historiography has developed a historical culture pivoting on public historiography. The distinctive characteristic of East Asian historiography could be described as publicly sponsored history, a tradition that continues today as a *basso continuo*.

'East Asia' as a historic-cultural concept, comprises present-day China, Japan, Korea, and Vietnam, where history developed around China, which overwhelmed the peripheral countries with its physical size, and political and cultural ascendancy. This historic East Asia has been termed 'the Chinese world order' or a system of international relations with China at the center. The system reached Korea and Vietnam in the early Han period (202 BC–9 AD), and Japan in the first century AD.

This Sino-centric system also formed the common cultural heritage of East Asia: the classical Chinese language, and Chinese writing system; the Confucian social and familial order; Buddhism through Chinese translations; the legal and administrative systems, and the art of historiography. The peripheral states of the East Asian world might also be called Sino-graphic cultures, in the sense that they used classical Chinese as a common language, which is, in a sense, comparable with the use of Latin in mediaeval and early modern Europe.

2. Role and Purpose of Historiography

For the most part, the task of historiographical compilation in East Asia was traditionally a state-run project. The 'official history' produced by that compilation, along with materials collected for the purpose, constituted the core of East Asian historiography. It could be said that historiography was the primary cultural undertaking in East Asia. This is in contrast to the cultures of Europe, India, and Islam, where the concentration of cultural power has not been fixed in history.

For 2,000 years, Chinese historiography centered on the 'official history' compiled by each successive dynasty as a state enterprise. Later generations positioned the *Shiji* (*The Records of the Grand Historian*) by Si-ma Qian (145 – ca. 86 BC) as the first official history and since then, 24 official histories have been compiled. A characteristic of these official histories is that they have an encyclopedic tinge; that is, the body of the work originated by Si-ma Qian brought an entire culture, its politics, economics, society, culture, technology, etc., into one unified structure. History was written as a means of comprehensively describing such a world system.

Historiography in East Asia is perhaps equivalent to such 'primary cultural undertakings' as Biblical commentary and the *Corpus Iuris Iustianianus* in the

West, the *Laws of Manu* in India, and the *Koran* in the Muslim world.

The purpose of writing history in East Asia was based on the Chinese philosophical premise that historical facts were the only certain and immutable reality. Chinese metaphysics was not premised on a revealed religion based on the existence of a unique, almighty God, like Judaism, Christianity, and Islam. Rather, it took the world as an ever-changing phenomenon, as presented in the *Yijing* (*The Book of Changes*). Therefore, it sought immutable reality in history, because human beings could not alter that which had already happened. This belief took history as its axis in Chinese civilization.

This culture of history later spread throughout East Asia in tandem with Confucianism, creating a common historical culture throughout East Asia. The proclamation of this philosophy may be found in Confucius' statement that, 'All the empty words I want to write down are neither so clear nor so startling as seeing their meaning in action' (*Shihji*).

The Chinese had developed their own way of creating an immutable past. In China and Korea, it was standard practice that, once the state's historical compilation bureau had completed compiling the official history of the previous dynasty, the bureau destroyed all the sources it had collected. This was to prevent the revision or rewriting of the official history, for once it was published by the government, the history itself took on the character of a sacred text. The most certain way to endow the official history with the imprimatur of authority was to destroy the sources on which it had been based. During the Korean Chosŏn dynasty (1392–1910), for example, the source materials were burned after use. When that was done, the account embodied in the official histories became the facts of history.

In this fashion, East Asian cultures preserved the ideal that history was the sole immutable basis for human judgment. The biographies that comprise over half the material in the official histories maintained this tradition of objective narration in their own way. In the biographies, as in other sections of the official history, they first set forth what they believed to be 'fact,' and following that, the historians added their own evaluation. This vast corpus of biographies forces us to consider why the historians believed the biography to be a necessary part of a history. It is because in a culture that lacks a unitary supreme being, the records of the lives of eminent individuals are the only true sacred texts.

3. Historical Objectivity

The tradition was maintained of seeking objectivity in historical narration in the lives of the historians who wrote it even more than the narration itself. We can

find an episode that presents the historian as a lofty figure in the life of a fifteenth-century Korean historian.

It is recorded that in 1431, as the compilation of the *T'aejong sillok* (the *Veritable Records of King T'aejong*) was nearing completion, his successor King Sejong (1418–1450) asked the compilers to show him their work in advance. 'In the previous dynasty, every monarch personally reviewed the veritable records of his predecessor; but King T'aejong did not review the Veritable Records of King T'aejo.' Sejong's senior ministers replied that, 'If Your Majesty were to review [the work in progress], later monarchs would surely revise [the historians' work]. Then, [future] historians would suspect that the monarch might look at the draft, and they would inevitably fail to record the facts completely. Then, how would we transmit [facts] faithfully for the future?'

In traditional East Asia, the role of the past was to serve as a normative history. This forms an interesting contrast to Western historical practices, where it evolved as a cognitive discipline. That is, in the West, the historian found his *raison d'être* in rewriting the past. The discipline of history developed as a competition among the interpretations and approaches of different historians.

'History' in modern East Asia is generally parsed with the two-character compound Chinese word *lishi* (Japanese, *rekishi*; Korean, *yoksa*), but until the middle of the nineteenth century it was expressed in the single-character term *shi* (Japanese, *shi*; Korean, *sa*). This word *shi* itself originally denoted the historian himself, and only later, by analogy, did it come to refer to the product of the historian's craft, the written work of history itself. This is particularly important when we note that in the languages of Europe, it was precisely the reverse: The word 'historian' was formed to refer to the maker of the written 'history.'

It is a notable characteristic of historical consciousness in East Asia that it tends to focus far more on the attitude of the historian, than on actual works of history themselves.

4. Development of East Asian Historiography

4.1 China

In China, Sima Qian substantially established the tradition of Chinese historiography by inventing his own format for compilation. He succeeded his father as the grand historian of the Han emperor, and with his access to court archives, he completed the *Shiji* (The *Record of the Grand Historian*) in 130 volumes. It covers a history of three thousands years from the (legendary) Huang-di dynasty to his own period, and covers China and Central and South Asia. The format consists of five sections: 'Benji,' or imperial annals (12 volumes); 'Biao,' a chronology of the successive

dynasties (10 volumes); 'Shu,' treatises on economy, technology, astronomy, etc., (eight volumes); 'Shi-jia,' annals of feudal states and nobles (30 volumes); and 'Liezhuàn,' biographies of famous persons and foreign peoples (70 volumes). Sima's format is encyclopedic in nature, systematizing the world in a single, unified structure; his historiographical format dominated East Asian historiography until the mid-nineteenth century.

Ban Gu (32–92 BC) followed Sima Qian's work, but limited himself to the history of a single dynasty, which he completed as the *Hanshu* (History of the [former] Han dynasty). His practice, that each Chinese dynasty compiled the history of its predecessor, became standard for all of the following official histories. It was in the Tang dynasty (618–906) that historical culture truly flourished, as history became an independent subject in the Chinese classification of learning. Historians were closely linked with governmental bureaucracy and their team method of compilation started in this period and continued until the twentieth century.

A new format for compiling historiography was proposed by Sima Guang (1019–1086) in his 294-volume *Zizhi tongjian* (The *Comprehensive Mirror for Aid in Government*) in 1084. It was an extensive historiography that employed the method of chronological order to help readers find certain historical events through dynasties. It covers sixteen dynasties of 1,362 years and includes information from dynastic histories, chronicles, biographies, novels, etc. It is necessary to refer here also to the Hanxue (the Han School), the development of which established historical study based on textual criticism of historical documents in the Qing dynasty. Qian Daxin (1728–1804) was one of the great figures among them, whose *Nianershi kaoyi* (Verification of the text of the 22 histories) was an examination of characters and language, dates and places, genealogies and institutions in the text of the 22 official histories.

4.2 Japan

The idea of official history spread from China to the other East Asian countries that compiled their own official histories, modeled on the Chinese format and written in classical Chinese, not in their native languages.

The first Japanese state historiography was the *Nihon shoki* (The *Chronicle of Japan*, 720) compiled by Prince Toneri, and modeled after the Chinese format. It covers the period from the Age of Gods to the end of the reign of Empress Jitô (686–697), arranged in chronological order, in annalistic form. Toneri used history as a forum to establish Japanese national identity and consciousness. This is in marked contrast to the *Kojiki* (Record of Ancient Matters, 712) by Ôno Yasumaro, which was also a historiography based on a transcription of oral tradition.

This tradition continued until the late nineteenth century. The *Honchō tsugan* (*Comprehensive Mirror of Japan*, 1644–1670), compiled by Hayashi Razan and his son Hayashi Gahō, was also in the same line of official history sponsored by the Tokugawa shogunate, and the *Dai Nihonshi* (*the History of Great Japan*, compiled 1657–1906) was compiled under the support of the Mito clan.

Apart from the historiographical tradition, it is important to add such auxiliary sciences as bibliography, classics, textual criticism, and philology, which had developed in Japan to the same levels as in the West by the nineteenth century. These originated, in Japanese tradition, from the *Chronicle of Japan* (720), of handing down variant texts or conflicting readings and traditions intact to posterity. In this important respect, China differed markedly from Japan. In China, history was transmitted as an authentic, authoritative text, which admitted no variant. This difference is richly illustrated by the work of Hanawa Hokiichi (1746–1821). His *Gunsho ruijū* (*Classified collection of Japanese classics and documents*), begun in 1779 and still in progress, first appeared in 1819, with 1,270 titles in 530 volumes; another 2,103 titles in 1,150 volumes appeared in 1822. The objective was not to establish the authoritative text and obliterate the others, but to make available all the variant texts, which later generations might judge. This collection compares favorably with such European endeavours as the *Monumenta Germaniae Historica*, the *Rerum Italicarum Scriptores*, etc.

The Meiji government, established in 1868, which was responsible for the restoration of the emperor as the focus of sovereignty, and led the subsequent modernization of Japan, also continued the tradition of ‘official histories,’ founding the Office for the Compilation of National History. The aim here was to create an official history of Japan, but for various reasons the objective was amended to that of compiling historical documents, and the original idea of compiling a national history was abandoned. The work of the Office continues today in its successor, the Historiographical Institute, now part of Tokyo University. Moreover, virtually every prefecture, district, and locality in Japan, even down to the level of individual villages, continues the tradition of official history at the local level today, compiling local historical sources, and publishing local histories. Similarly, many individual government bureaus, as well as corporations, universities, and other corporate entities, regularly commission their own histories, extending the model of ‘official history’ to the private realm.

4.3 Korea

It was around the fourth century that Korea founded its historiographical tradition, though the epoch-making historiography did not appear until the twelfth

century. Kim Pu-sik (1075–1151) compiled the *Samguk sagi* (*History of the Three Kingdoms*) in 1145, the oldest extant history of Korea, covering from antiquity to the decline of unified Silla in 935. It follows the format of Sima Quan’s official history as is shown by the name *sagi* (the Korean pronunciation of *Shiji*), and he intended to provide moral lessons for posterity. Iryōn (1206–1289), a high-rank Korean Buddhist monk, compiled the *Samguk yusa* (*Memorabilia of the three Kingdoms*) in 1281, which is the only extant history of Korea before the Chosōn dynasty (1392–1910), together with the *Samguk sagi*. This work is unique in the sense that he wrote it privately, including myths, tales, and social issues, and even refers to the sources he used.

So Kō-jōng (1420–1488), compiled the *Tongguk t’onggam* (*Comprehensive Mirror of Korea*) as a Korean official history in 1485, modeled on Sima Guang’s *Zizhi tongjian*. It covers the period from ancient times to the end of the Koryō dynasty in 1392. This work was compiled under the influence of neo-Confucianism, and reflects the moralistic purpose of praising good and condemning evil. An Chōng-bok (1712–1791) likewise published his *Tongsa kangmok* (*Outline of Korean History*), 20 volumes, in 1778, a chronological treatment of Korean history from Tan’gun, the legendary founder of Korea to the decline of Koryō in 1392.

4.4 Vietnam

In Vietnam, just as in Japan and Korea, some official histories were published including *Dai Viet Su Ky Toan Thu* (*Complete Book of the Records of Vietnam*) in 1479, which is based on the style of the *Zizhi tongjian* of Sima Guang.

5. Historiology in East Asia

The study of historical theory in East Asia began with Liu Zhiji’s *Shitong* (*Comprehensive Historiography*), written in China in the eighth century (708). It was the first thorough treatise in Chinese—or any other language, for that matter—on historical criticism, which also constituted a history of Chinese historians and a theory of historiography, and deals with such questions as selection and criticism of historical materials, historical objectivity, judgment in history, historical causality, etc. The work was a constant reference for Chinese historians until the nineteenth century, and gave rise to the meta-historical tradition in Chinese historiography.

Liu’s theory of history was further developed by Zheng Qiao (1104–?1162) in his *Tongzhi* (*Comprehensive Monographs*, 200 volumes). In the introduction to the *Tongzhi*, he proposed his core idea of ‘synthesis’ and ‘inter-relatedness and causality,’ through which he argued the importance of the continuity of his-

torical development. Based on this theory he completed the voluminous *Tongzhi*, including the 'Twenty Summaries,' his noteworthy encyclopedic chapters.

Zhang Xuecheng (1738–1801) wrote his *Wenshi tongyi* (*General Survey of Literature and History*), a work on the theory and history of historiography (only published in 1920, long after his death). The first chapter starts with 'The Six Classics are all history,' in which he expressed his philosophy of history, that the very idea of the Sacred (*tao*) can only be known through men's actions (*shi*), which are recorded in the *Six Classics*.

It is thought provoking to realize how few works of historical criticism were written outside China, in comparison with the voluminous amounts of historical works. It signifies that traditional East Asian historiography was normative in nature, in the sense that it required little discussion of the nature of history. It is also necessary to refer to the fact that there were relatively few works of metaphysical interpretation of the course of history—save perhaps Wang Fuzhi's (1619–1692) discussion of historical logic and historical tendency in work published only after his death. East Asians valued detailed precision in history, rather than the philosophical interpretations that were developed in Europe. Some exceptions, informed by Buddhism, were found in medieval Japan. Jien (1155–1225), a prominent Japanese Buddhist cleric, wrote his self-deprecatingly titled *Gukanshō* (*Notes of the Views of a Fool*, 1220), in which he proposed his philosophy of history with the term *dōri*, an idea of historical inevitability, through which he explained historical processes in terms of the state of development and proposed his own periodization. Similarly, a century later Kitabatake Chikafusa proposed in his *Jinnō Shōtōki* (*Chronicle of the True Descent of the Divine Sovereigns*, 1339) that Japan is a land founded by the gods and maintained by the blessings of an unbroken lineage of divinely descended emperors.

6. The Rise of Modern Historiography in East Asia

Western concepts of 'civilization and enlightenment' were introduced systematically to East Asia beginning in the mid-nineteenth century had a transformative effect on notions of history and historiography as well. The movement toward 'modern' and 'scientific' history in East Asia began with a variety of intellectual experiments among Japanese scholars in the 1870s and 1880s. As Korean and Chinese intellectuals ventured to Japan toward the end of the nineteenth century, 'modern' Western notions and methods of historical inquiry and explanation gradually filtered across the entire East Asian region.

It is worth special mention that Western cultures and technologies including historiography were

introduced through translations of European and American works into Japanese. Japanese intellectuals created their own neologisms to translate Western terms by combining two or three Chinese characters together. Those newly invented terms in Chinese characters were later exported to China and Korea, and in consequence, East Asian scholars now share most academic terms in the liberal arts and sciences.

The very fact that such translations were feasible, and successfully received, demonstrates the stage that Japanese historiography had achieved. By introducing Western historiography through translation, rather than keeping it as the preserve of a few language specialists, Western history and historiography were transformed into common intellectual property for all East Asian historians, and, in particular, made accessible to those who worked on their national histories.

As far as historiography is concerned, there already existed a traditional Japanese historiography, and the auxiliary sciences made possible the introduction and importation of Western historiography. Native pioneers in the introduction of Western historiography, historians like Shigeno Yasutsugu (1827–1910) and Kume Kunitake (1839–1931), were initially trained in *Kōshōgaku* tradition (Chinese, *kaozhengxue*: textual criticism, which originated from the so-called 'Han School' in the Qing period), and were thus well prepared to accept the empirical methods of Leopold von Ranke. They were particularly receptive to his notions of a rigorously critical approach to sources and the avoidance of value judgments, when his student Ludwig Riess, who was invited to Tokyo Imperial University as a professor of history in 1887, introduced Ranke's ideas to Japan.

The acquisition and acceptance of European historical theory was started by Japanese translations of leading contemporary European works on historical method and theory, such as those by J. G. Droysen, E. Bernheim and C. V. Langlois and C. Seignobos. Under the strong influence of Bernheim, Tsuboi Kumezō published his *Shigaku kenkyūhō* (*Methods of Historical Research*, 1903) in Japan, and Liang Qichao (1873–1929) published the *Zhongguo lishi yanjiufa* (*Methods of Chinese Historical Research*, 1922) in China.

'To study history' in traditional East Asia had meant 'to become conversant with the official Chinese histories,' and the introduction of Western ideas of historiography opened new horizons for students of history, who began to inquire, 'what are the historical facts,' in the sense of going beyond the historical narrative to examine the underlying facts themselves. It was an indication of the opening of modern historical scholarship in East Asia, in which the introduction of Western learning played an important role.

A typical example of this consciousness is found in Shigeno Yasutsugu, nicknamed 'Doctor Obliteration.'

Applying the European historical method to Japanese history, he re-examined the *Taiheiki* (*Chronicle of the Great Peace*, 1370–1371), and proved that the fourteenth-century military commander Kojima Takanori never existed.

In China, Gu Jiegang (1893–1980) was one of the most eminent figures, whose *Gushibian* (*Critiques of Ancient History*, seven volumes, 1926–1941) contributed greatly to the modernization of Chinese historiography by taking a finely honed critical scalpel to the world of ancient Chinese legend, which had long been accepted as fact. His school was named ‘ancient doubters.’ His method was rooted in the Qing dynasty (1644–1911) school of ancient doubters; however, it was at the same time backed with the new European historical method.

Yi Pyŏng-do (1896–1989) was the first Korean historian to have received training in the modern historical method. He stressed critical and objective methods of treating historical sources in his *Han’guk-sa taegwan* (*Grand Survey of Korean History*, 1963).

With the introduction of Western culture to Japan, history became re-institutionalized from the mid-nineteenth century onwards, from the governmental section to the newly established Imperial University. However, it should not be forgotten that the introduction of Western historiography reduced East Asian historiography from its former position as a state enterprise to merely a single academic field within the university. Individual historians started to have their own ‘specialty’ in order to survive in this new ‘university’ setting, and in order to distinguish themselves from eminent amateur historians, their researches were published as monographs in the newly established historical journals.

On the one hand, in the West, the ‘professionalization’ of historical research resulting in the establishment of history as an independent university academic field was a great achievement for this institutionally neglected discipline. In East Asia, on the other hand, the introduction of modern Western historical research heralded the end of the prestigious traditional East Asian historiography, which had aimed at a comprehensive description of the entire world. Since then, the subsequent evolution of East Asian historiography has developed largely along the lines of ‘modern’ historiography, in the same basic methodological and theoretical terms as the rest of the ‘advanced’ world.

7. Development of Modern Historiography

Since modern historiography was introduced to East Asia, its development varied according to the situation in each country.

In China, along with Gu Jiegang’s ancient doubters, newly discovered archaeological results urged a new

perspective of ancient history on Chinese historians. In particular, the discovery of oracle-bone inscriptions laid the foundations for the new Chinese ancient history led by such historians as Luo Zhenyu (1866–1940) and Wang Guowei (1877–1927). These new works were later synthesized with Marxist materialism by Guo Moruo (1892–1978). His *Zongguo gudai shehui yanjiu* (*Study of Ancient Chinese Society*, 1930) is the first Marxist work on ancient Chinese society. Thereafter, especially with the establishment of the People’s Republic of China in 1949, Marxism became dominant among Chinese historians. Traditional historiographical achievements were mostly replaced by reverse interpretations, a trend which was highlighted in the period of the Cultural Revolution (1966–1976). After the 1990s, the worldwide information revolution and the introduction of the latest historical methods of social history are changing Chinese historiography, opening it to the rest of the world.

In Japan, soon after the introduction of modern European historiography, the emperor-centered state promulgated a new political orthodoxy, and began to restrict intellectual freedom, especially in the study of ancient Japanese history. Since the 1930s, social and economic history began to apply the Marxist framework to Japanese history, mostly to the study of Japanese capitalism. After World War II, Marxism emerged as the dominant historiographical school, and it was only in the 1970s that Japanese historians began to accept the idea of social history as their latest historical method from France, Germany, and England. Since the late 1980s, many Marxist historians quietly shifted from socioeconomic history to social history.

8. Metamorphoses of Public History

Currently, in East Asia, the aura of official history still floats on the surface of peoples’ collective historiographical consciousness. The past is still seen as the trustworthiest ‘mirror on mankind.’ What is being sought from official historiography is not ‘a’ history, but ‘the’ history, the reliability of which, people undoubtedly believe, is guaranteed by public editorship.

In China, 24 official dynastic histories have been published and the tradition of public history continues to the present day. The *Qingshigao* (*Draft of the History of the Qing Dynasty*) was completed in 1927, and was finally published in Beijing in 1977. This applies to local history too; the publication of prefectural histories sponsored by local governments began in the Ming dynasty (1368–1644), and continues even in contemporary China.

In Japan, this idea is seen in school history textbooks and local histories. The Japanese Ministry of Edu-

cation vets all school textbooks, the idea of which seems a reincarnation of official history as far as history textbooks are concerned. Japanese schools teach students 'what' rather than 'why.' They cram students' heads with a fixed course of history – Japanese history, world history, whatever – without much attempt to have students recognize that there are differing viewpoints. Forty-two Japanese prefectures out of 47 have compiled their own prefectural histories – some of which have been compiled two or three times over the last 120 years – and there is hardly a city, town, or village anywhere in Japan that has not done likewise. These local histories are premised on the traditional historiographical notion that there is a historical truth that is embodied in authoritative narratives.

Korea also continued to chronicle an official history and this tradition is alive in present-day South Korea. The 25-volume *History of the Republic of Korea*, whose publication was completed in 1979 by the National History Compilation Committee (established in 1948), is a state-produced history of the homeland.

Since the late nineteenth century, the practice of history has undergone professionalization and specialization on a worldwide scale, and East Asia too has been drawn into this whirlpool. Since then the style of historiographical practice in East Asia has, in most respects, been the same as that in Western countries. The work of the historian, as an individual, is to write many research papers and books. However, many historians, as far as historians working on their national history are concerned, are also at the same time involved in publicly sponsored historiography; countless university-based Japanese historians, for example, serve on the editorial boards of local and prefectural history projects. We can thus observe the continuing 'coexistence' rather than 'conflict' of the two differing traditions of historical study.

To put it another way, East Asian historians simultaneously inhabit two worlds of historiography, one a world of Rankean (or traditional East Asian) factual objectivity and another world of post-Rankean interpretations 'varied and opposing voices.'

Historiography and Historical Thought: Indigenous Cultures in the Americas

1. Terminology

History is information handed down from generation to generation. Since information can be inherited in the form of natural objects as well as by culture itself, a basic distinction needs to be drawn between natural history and the history of civilization. The way people develop consciousness of their history is by taking information from their natural environment, their cultural artifacts, and their memory, which is then collectively conceptualized by means of interpreting, reconsidering, and agreeing on its meaning. Historical concepts resulting from this always reflect the people's experience of their natural environment as well as their specific cultural achievements. In exceptional cases a historical concept can be limited to the individual. However, historical research is more concerned with collective concepts, since it is characteristic of human societies that mainly those dominant concepts are handed down. Thus each society cultivates a particular historical concept, which again needs to be handed down in order to become and remain effective. All cultures are alike in inheriting their historical concepts in the form of oral (stories and myths) and figural traditions (monuments). In addition to this, civilizations often use writing (books and inscriptions) as the preferred means for handing down historical concepts to future generations.

2. America

The only people of pre-colonial America to develop a fully functioning writing system were the Lowland Maya. They used the written records to maintain knowledge of a wide thematic range and thus stored and conserved an enormous amount of cultural

information from which they formed their own distinctive historical concept. Rather incomplete writing systems (picture-writing) were characteristic of their northern and western neighbors—that is in historical order the Epi-Olmecs, the Zapotecs, the Mixtecs, and the Aztecs. Taken together, these cultures form the core of the cultural area Mesoamerica, characterized by similar, and in many respects uniform, conceptions of history, and therefore can be treated to all purposes of this article as a unit.

On their first contacts with indigenous peoples of the Americas, the European conquerors came across various forms of picture writing that was used to note down historical events. This even occurred in some areas of North America, predominantly in the eastern woodlands and on the plains and prairies west of the Mississippi. South America was in this respect quite the reverse, even though pictorial representations in painting (Moche, Nasca), weaving (Paracas, Nasca), and rock engraving (Nasca) were highly elaborated.

The description in Sect. 3 is mainly restricted to Mesoamerica, which is distinguished from all other cultural areas by its emergent writing systems.

3. *Components of Mesoamerican History*

The Mesoamerican *Weltbild* shows three basic components, inasmuch as the world is conceived of as consisting in discrete and ordered entities, often arranged in cycles. Connections and explanations of meaning beyond the historical facts make use of analogy, i.e., interpreting something that is identical or similar in form to be also identical in substance or related in a causal way. Another method is the reification of originally mental constructs and their material (picture-written) form of expression. This is particularly significant if information is handed down over a long time and cannot be clarified independently from written or pictorial sources. These and other methods of interpretation were operating in historical traditions, which is why they contain to a great extent patterns, topics, and stereotypes extraneous to the historical facts.

Mesoamerican cultures have also developed methods of dating. A cyclical and public calendar based on the solar year of 365 days, in addition to a ritual 260-day almanac for private and personal use that is likewise cyclical and parallels the solar calendar, are the foremost methods of dating historical events. The Lowland Maya included in their historical writing the calculation of temporary celestial phenomena like the lunar, Venus and Mars cycles, and observed the positions of planets in constellations of fixed stars; comparable to the Zodiacs of the Mediterranean cultures. They even managed the complex arithmetic of interrelations between some of these celestial cycles. Yet they accomplished only the arithmetic calculation

of it, but never presented a geometrical model of the world's system corresponding to the Ptolemaic and Copernican models.

4. *Historical Topics*

By means of chronology Mesoamerican people created histories (theogonies and myths) of anthropomorphic and theriomorphic deities. This is conveyed in detail particularly for the Aztecs through the *Legend of the Suns* (Lehmann 1938) and the famous calendar stone. Mesoamerican people believed in the existence of four or five successive world ages, each with duration of a few thousand years. Each age is quite distinct with different creatures inhabiting a world, which is then destroyed in cataclysm by water, fire, and air (wind)—the reader may note the analogy to the ancient Greek theory of the elements. A new creation marks the beginning of each world age. Not even the contemporary world age of the Aztecs around 1500 was considered to be of unlimited duration. Within the chronological framework of this age man appears relatively late, and more detailed chronological units (years, year bundles of 52 years) apply to his history. Yet Mesoamerican people connect themselves occasionally, and in a speculative way with the world of their deities anteceding the human epoch. This holds especially true for the ruling dynasties of the Maya who very often consider themselves to be descendants of the gods of preceding world ages (Palenque). Such a Mayan world age lasts exactly 1,872,000 days, which is about 5000 years. The duration of the world ages in Central Mexico is not exactly known, since their chronology is technically less developed. The interrelation of the people with their pantheon becomes, furthermore, apparent in the tutelary deities of each tribal group. These are commonly organized in city-states during Postclassic times: Quetzalcoatl for the Toltecs (capital: Tollan) around AD 900–1100 and for the Chololtecs (capital: Cholula) around AD 1000–1500, Tohil for the Quiché (capital: Utatlán) around AD 1000–1500, and Huitzilopochtli for the Aztecs (capital: Mexico) around AD 1350–1500. In this manner origin-related, trans-historical interrelations take form in a similar way as they are known for the civilizations in the Old World (Sumer, Ancient Egypt, Babylon, Jewish culture of the Old Testament).

Tribes with their leaders, the ruling dynasties arising from them during the process of getting sedentary and their tutelary deities are the main actors of Mesoamerican history. Rulers are described with their most important *rites de passage* (birth, inauguration, marriage, procreation of offspring, death), martial triumphs, and—to a lesser extent—civilizing deeds (introduction of cultivated plants or technical skills). There exists the idea among Mesoamerican tribes that they originated from a distinct place, which is the tree

of Apoala for the Mixtecs, the Seven Caves or the island of Aztlan in the center of a lake for the Central Mexicans and the Totonacs; and this origin is placed in an apparently rather historical not very remote time; according to the Aztec main tradition this happened in the year AD 1064. In some areas, the version of an origin in an even more historical setting, namely the city of Tollan can be encountered (Cakchiquel). This Tollan was the capital of the famous Toltecs, who were actually a historical people, admired for their skills and accomplishments. Migration myths, apart from being descriptions of historical events, which are to a certain extent factual—as far as can be concluded from language history and geography—seem to have functioned as a means of political legitimization. The successfully migrating and thus surviving tribal group legitimizes its right to rule over the traversed territories and the cities within, or at least to exert indirect political control in case the areas in question are too distant for factual dominance. After settling down, topics such as marriage alliances, conspiracies, insidious martial acts, and heroic self-sacrifice appear in the form of historical episodes. It is in these later times, when major wars between the different Mesoamerican polities become a subject of history. In Central Mexico it is learned that the Mexicans throw off the yoke of Tepanec rule by Azcapotzalco and gain completely independent status, prestige and property of lands. In the Southern Maya Lowlands the city-states of Calakmul and Tikal are at war with each other for hegemony of the region; and the Guatemalan Highlands are the scene of frequent warfare between the Mam, Quiché, and Cakchiquel. Since the range of historical accounts rarely transgresses the own polity and is immediate neighbors and never exceeds the limits of the Mesoamerican core area, 'world history' from the precolonial Indian perspective is very limited. Nevertheless this compares, albeit on a more narrow basis, with antique and medieval concepts of the world in Near Eastern and European cultures. No statements revealing knowledge or speculation about countries and peoples beyond this horizon can be found, even though archaeological investigations indicate external contacts in the form of trade relations with peoples far outside Mesoamerica, namely with the North American Southwest, with Panama, and with Ecuador. This seemingly odd and willful limitation of the historical horizon is characteristic for many early states and for most chiefdoms worldwide.

It is men who predominate the historical records as well as the actual political scene, and these are generally members of the nobility as all Mesoamerican societies were ranked. The historical records give special emphasis to particularly successful individuals: such as to ruler '8 Deer Tiger Claw' among the Mixtecs or to the rulers 'Pakal' of Palenque and 'Kakupakal' of Chichén Itzá among the Lowland Maya. In addition to politically active members of the ruling nobility,

historical records of the Maya and the Aztec convey a few names of artists (painters, sculptors, poets, and performing artists), thus demonstrating to some extent interest in cultural and art history.

Taking into account that political history is predominantly the subject of men, the reader's attention must be drawn to the occasional significance of women among the Lowland Maya, especially in the city-states of Palenque and Yaxchilán around AD 600/700. These women presumably never equaled men in rank, but gained prominence in their patrilineal societies only in order to substitute for a male heir and to uphold dynastic continuity. It remains unclear whether this role involved real implementation of power or whether it was confined to representational duties, although—in keeping with ethnological theory of gender studies—a rather representative and symbolic function is suggested. Apart from this, noble women appear as objects in marriage alliances that serve to enlarge the ruling territory and become instruments of political provocation (loot, rape, and sacrificial death).

5. *Indian Reflections on History*

It is impossible to give a definite description of historical thinking among the Mesoamerican Indians, since no explicit statements related to this can be found in the historical sources. It is, however, manifest that man is controlled and directed by deities to whom, he for his part, is compelled to pay tribute in the form of prayers, offerings, and cult (there are 18 major monthly feasts per year) in order to maintain and ensure the world's existence. This is most evident in the Aztec's dogmatic obligation of invigorating the sun on its course with sacrificed human hearts. This compulsion to human sacrifice led to those sacrificial excesses that were later witnessed by the Spanish conquerors. Prior to the conquest, several Indian philosophers had already criticized and perceived the practice of human sacrifice as incorrect by expressing their desire for the idealized Toltec times (around AD 1000) to return, when people sacrificed flowers and animals instead of human beings.

The general Mesoamerican outlook on life is pessimistic and fatalistic, which manifests itself especially in the divinatory rituals of the Maya, Zapotec, and Aztecs where negative prophecies are outnumbered by the indifferent or positive ones. The collective fatalistic behavior of the colonial Yucatec Maya and—two centuries later—of the Itzá concerning their own political fate might serve as an example of this common way of thinking. However, it needs to be taken into account that the Yucatec case could well be the result of traumatic experiences during the Spanish conquest; since only colonial sources give information on this topic, it is difficult to decide, whether fatalism is a traditional or an adopted behavior. Human life is

considered to be hard and fateful (like in Old Jewish faith), controlled by deities, and improvement can only be gained by religious manipulation. Consolatory is hence the Aztec concept of the otherworld, where sweet paradise awaits those who endure dangerous labor and hardship on earth, favoring warriors and childbearing women. Yet we lack a theologically differentiated comprehension of the Aztec idea of an afterlife, since this is not further described in the historical accounts. The Lowland Maya left more written and pictorial documents regarding this topic, although these have not been systematically analyzed thus far.

Rarely, reflections on antecedent cultures can be found among the descriptive historical traditions of the Central Mexican Aztecs. The major city Teotihuacan, which had been abandoned prior to Aztec times, is taken by myth as the place of origin of the gods. Earlier cultures are remembered by conserving their artifacts and imitating their products. The idealization of such a past culture—the Toltecs—has been mentioned earlier.

6. Traditions and Sources

The numerous monuments from lasting material (stone), although not yet completely understood, are an important source for historical thinking. They date back as far as 1000 BC: Beginning with sculptures portraying Olmec rulers and slabs illustrating Zapotec conquests (so called *danzantes*). The first real inscriptions date from the first two centuries of the Christian era, called the Epi-Olmec period. Especially noteworthy is the stela from La Mojarra, although its long inscription presumably representing the Proto-Zoquean language of the Isthmus region is not fully deciphered yet.

Vase paintings of the Maya with their pictorial and partially narrative depictions and hieroglyphic explanations are one of the chief sources for reconstructing the Mesoamerican classic from AD 300–800 AD. These vessels show painted scenes from royal palaces, royal visits, payment of tribute, or the hunting of deer and birds. All illustrations do probably depict scenes from the otherworld. Since daily life can be assumed to have served as the *calque* for the concept of this otherworld, it is possible to reverse this relation in deducing every-day life of the Maya from the vase paintings. Vase paintings have been similarly exploited for reconstructing daily life of the South-American culture of Moche, which was contemporaneous but unrelated to the Maya.

Further sources of historical records are manuscripts with historical contents, which—due to their fragility—generally do not date back too far. About a dozen precolonial manuscripts and perhaps a hundred copies and extracts compiled during early colonial times have been preserved. Most are of Central

Mexican (*Codex Huitzilopochtli*) and Mixtec (*Codex Nuttall*) origin.

Christian missionaries introduced the writing with the Latin alphabet in the early colonial times (AD 1520–1650). Written documents of this type are especially numerous in Central Mexico. Basically European in form, and to some extent even in content, the object of these written sources is almost completely related to the colonial situation (lawsuits dealing with inheritances, properties, and privileges). The writings obviously connect pre-Spanish traditions of picture writing with oral traditions and form a new integrated genre. In the Guatemalan highlands (*Popol Vuh*, *Annals of the Cakchiquels*), as well as with the Yucatec Maya (Books of *Chilam Balam*) these sources are not only less numerous but show less European influence. From other Mesoamerican regions only a few historical documents have been preserved, written in the Spanish language by Spaniards who drew on remembered information and interviews. Thus Gonzalo Fernández de Oviedo y Valdés reported on the Nicarao who lived at the southern periphery of Mesoamerica; the Franciscan missionary Juan de Torquemada conveyed comparable traditions of the Pipil; and the accounts of the Mixtecs by Francisco de Burgoa were comprehensive but a little concise.

A major European element in sources, which have been written in the indigenous languages but with Latin letters, is the synthesis regarding world history and natural history. This synthesis can be noted, for instance, in a general chronology drawn from the uncoordinated lists recording royal succession in individual Indian city-states as presented by the *Annals of Quauhtitlan* and the works of Domingo Chimalpahin. As suggested by its subdivision into 12 books, the topics, and the illustrations, the *Historia General* of the Franciscan friar Bernardino de Sahagún obviously resembles medieval European natural history and its antique origins (Pliny the Elder).

7. Problems of Research

Without explanations from the creators themselves, it remains difficult to understand form and symbolism of the great range of historical objects and sources, even though researchers have presented seemingly comprehensive and highly sophisticated interpretations (in particular Eduard Seler around 1924–5). Hieroglyphic captions of Mayan vase paintings, which have been subject to serious research since the 1980s, are—although seemingly well understood—overly standardized (e.g., ‘this is the beaker for cacao belonging to X’) and, therefore, still meager in cultural content and fuzzy in context. Most inscriptions that designate singular objects like ‘earring’ or ‘[sack full of] beans’ are short and do neither contribute to a differentiated understanding of the depicted scene, since they only name the object, nor do they help much in a broader

comprehension of local history, since they only mention the owner or receiver of said object.

Although theoretically achievable, the decipherment of pictorial and hieroglyphic writing systems (Zapotecs, Epi-Olmecs, Maya, Mixtecs, Aztecs, Tetzocans) has not been completed yet and not all documents have been thoroughly studied. The research strategy regarding these documents assumes a uniform paradigm underlying all different regional forms of pictorial and syllabic writing (Maya, Mixtec, Aztec, Tetzocan, etc.). Nevertheless, painstaking and detailed analysis of each document, as well as methodological reasoning in decipherment and interpretation are required. Investigation should strategically begin with thematical complexes that are especially revealing because their cultural contexts are well understood, such as burials at major archaeological sites containing inscribed goods.

Texts from early colonial times (until about 1650) that have been written down in the indigenous languages by means of the Latin alphabet are easier to approach, although they are still not very well understood either. Most of these documents originated with the Aztecs, some of them with the Yucatec and Highland Maya, while there are only very few from other language groups and regions. Whereas the more technical problems of translation can be met by increasing language competence, the main problem of ethnohistory (the technical term for the discipline of history that analyses sources in the writing-systems and languages of the people studied) is to grasp concepts and metaphors, etc. from the *Weltbild* of the Indians. These are then interpreted in terms of European historical thinking, and their authenticity elucidated with regard to events that have actually come to pass.

Devoting more time to research of chronological problems is most likely rewarding, since Mesoamerican chronology is not only of high accuracy but also omnipresent in historical records. For the time of the Maya Classic from AD 300–900 there is not a single year without several exactly datable historical accounts. Not close by region but by time, Central Mexican historiography from approximately AD 600 until the Spanish conquest is structured with about the same amount of dates. However, due to the calendrical system, Central Mexican dates are chronologically ambiguous, since they recur every 52 years. The interrelations of dates in the different calendar systems (of Mixtec and Aztec and between Aztec and Lowland Maya), and the comparison of dates with chronological reconstructions in archaeology, and the absolute dating by way of historical astronomy, making use of permanent celestial phenomena, some day will render it possible to compile a wide-ranging historical chronological chart for the Mesoamerican core area.

Because of Mesoamerica's high civilizing and political complexity as well as its dynamics, the analysis of overarching political systems and their changes is a

very important field of research. A great amount of effort has already gone into acquiring knowledge on the Post-classic times in Central Mexico, Oaxaca, and Northern-Yucatan; the Lowland Maya Classic is currently subject to politico-historical analysis (Nikolai Grube and Simon Martin). No historical events can be reconstructed for the Formative Period, in which the later Mesoamerican states emerged, since it lacks sizable written records. Yet the abundant archaeological findings of this period, including monumental sculpture and buildings, serve for assessing general theories on the emergence of the state. Such theories have made use of the respective Indian cultures, mostly Aztec and Inca, since Adolph Bandelier (1880) classified the Aztecs within the scope of an evolutionary scheme, followed over 100 years later by Stefan Breuer's (1990) more sophisticated analysis. American cultures are particularly relevant for this kind of research because it is assumed that they developed independently of Old World civilizations.

8. *Survey of Other American Regions*

With its politically tight organization and its technical achievements (metallurgy, road system) the South American cultural area of the Central Andes, which was last dominated by the Incas, can be perceived as superior to Mesoamerica. The study of historical concepts is nevertheless here rendered more difficult due to a lack of pre-colonial written records. All records of Indian history originated in early colonial times, are based on oral traditions and the system of knotted cords (*quipu*) only, and have been written mostly by Spaniards (Juan de Betanzos, 1551) or mestizos (Garcilaso de la Vega). They thus show the categories and forms of the European conception of history. This holds true also for writings that are sometimes considered as 'ancient Indian' such as the preciously illustrated *Nueva Corónica y Buen Gobierno* of Guaman Poma de Ayala, which is formally European in its illustrations and text, even though with mainly Indian contents. The anonymous historical drama *Ollantay* is according to its form and subject rather similar to a baroque theater play from Europe than being an expression for Indian thinking, albeit written in a stylistically pure form of *Quechua*, the language of the Inca empire, which makes it appear very Indian. The general assertion alone that something like an 'Andean Historical Concept' exists is not helpful. If more substantial information on the Indian historical concept of this cultural area is to be revealed, progress can be achieved only by concentrating on less spectacular administrative sources (*visitas*) and by diagnostic separation of European and ancient Indian components in all sources. It should also content itself with subjects of manageable size in respect to thematical scope and regional breadth, before proceeding to generalizations.

In conception and structure similar to the Mesoamerican historical tradition are the eighteenth- and nineteenth-century historical traditions of the Lenape (Algonkin language family) and the Indians of the Great Plains in North America. The Lenape (*Walam Olum*, the authenticity is controversial) and other related groups, e.g., Creek, cultivated an oral and possibly picture-written tradition of the tribe's migrations led by certain chiefs; while the Plains Indians depicted individual events from the group's daily life following the year's seasons (*Winter Count*).

Historiography and Historical Thought: Islamic Tradition

'Islamic historiography' is a useful but somewhat misleading term commonly applied to the historical writing produced in the predominantly Muslim societies of Asia and Africa between the rise of Islam (post-622 CE) and the mid-nineteenth century. In contrast, history written after that point may have a distinctive regional or cultural orientation, but increasingly it falls within the post-Enlightenment historiographic discourse established and dominated by Western Europe. The term is useful because it allows us to discern the degree to which the enormous historical literature produced within Muslim-dominated societies and polities embodies an unbroken (albeit complex and constantly changing) tradition of debate over the meaning and interpretation of the past. It is misleading insofar as it beguiles us into thinking that this literature was produced entirely by Muslims, or that it is exclusively grounded in Islamic doctrine and focused on religious issues. In fact non-Muslims produced important works (admittedly a small proportion of the total) within the 'Islamic' historiographic tradition. More importantly, much historical writing by Muslims focuses on decidedly nonsacred topics and presents these topics in a manner that owes little to Islamic religious concepts and concerns.

1. History as a Form of Knowledge and a Profession

Quite apart from the ambiguity of the term, Islamic historiography represents an intriguing paradox. Historical works were produced in great profusion from at least the mid-eighth century on, and it is evident from the number and distribution of manuscripts that these works were widely read. Technical terms for historical writing emerged very early and remained in constant use thereafter: *ta'rikh* (literally 'dating,' hence 'chronicle'), *akhbar* ('recitals of events'), and less commonly, *sirah* ('biography'). '*Ta'rikh*,' the most common term, referred not only to chronologically organized works but to historical writing of every kind, including alphabetically arranged biographical dictionaries. However, even though historical writing permeated medieval Islamic culture and was universally seen as a distinct form of knowledge and literary practice, it never achieved the status of a 'science' (Arabic, '*ilm*')—i.e., it never became a formal

subject of study and training in the scholarly curriculum. Within the normative classification of knowledge constructed by medieval Islamic culture, history remained always on the margins of scholarship and literature. For religious specialists it was ancillary to the core disciplines of legal studies (*fiqh*), Prophetic tradition (*hadith*), and Qur'anic exegesis (*tafsir*). Secular writers might well regard history as *magister vitae*, a trove of practical wisdom, but only rarely did they regard it as the foundation for a systematic investigation of politics and society. Even in the humble roles of handmaid and schoolmaster, however, history still generated many works of great literary and methodological sophistication. The political (and occasionally social and economic) analyses of the best Muslim historians yield nothing to their counterparts in the ancient, medieval, and Renaissance West. All this suggests that history played a much more fundamental role in defining Islamic self-understanding than that culture's spokesmen knew how to articulate. History showed Muslims how God was working his purposes out in the deeds and sufferings of the community of believers; in particular, it measured the fidelity (or lack thereof) of the believers to the revelation brought by Muhammad. History challenged Muslims to measure their progress on the path to salvation or perdition as the inevitable Day of Judgment approached.

Historians were in effect self-taught amateurs, bureaucrats, or religious scholars who composed *ta'rikh* in their spare time. They learned how to do it not through formal study with established masters, but simply by reading the works of other historians and adapting the forms and approaches of these writings to their own purposes. Some histories were written at the behest of rulers anxious that their deeds be properly memorialized for future generations, but even these do not represent a true professionalization of history. We do find official court historiographers under the Ottomans between the sixteenth and mid-nineteenth centuries, but for the most part the job was handed over on an *ad hoc* basis to any member of the ruler's entourage who was thought to possess sufficient political acumen and literary skill.

Two outstanding scholars did attempt to make history into a generally recognized formal science, but in spite of their great prestige and influence, neither achieved his goal. The Qur'anic exegete, jurist, and historian Abu Ja'far al-Tabari (838–923) tried to demonstrate in his *Chronicle of Prophets and Kings* (*Ta'rikh al-rusul wa'l-muluk*) that historical reports could be deployed according to the rigorous criteria applied to *hadith* (the dicta ascribed to the Prophet). However, very few followed him down that path, even though his reconstruction both of pre-Islamic history and of Islam's first two centuries provided an authoritative framework for almost all later chroniclers. Far from adopting al-Tabari's strict method, most of his successors simply condensed and paraphrased his work. Five centuries later, the North African Ibn

Khaldun (1332–1406)—a gifted legal scholar and logician as well as a historian—argued in his famous *Muqaddimah* that history was the science of society and as such ought to be treated as a branch of philosophy. Again, his argument did not suffice to move historiography up to that exalted status, in spite of the substantial circulation and influence that his work enjoyed.

2. The Producers of Historical Knowledge

As we have seen in Sect. 1, history was written (and read) by highly literate men with some time on their hands. Given the social and educational structures of medieval Muslim societies, that means it was written chiefly by chancery secretaries and religious scholars (Arabic, '*ulama*'). It is tempting to describe these two groups in terms of well-defined ideal types and thus to posit opposing historical perspectives of palace and mosque. In reality these perspectives overlapped in complex and constantly changing ways.

Throughout Islamic times the '*ulama*' were given state appointments as judges or mosque officials, though it is true that many of the most prestigious scholars prized their independence and refused to accept such positions. But after the mid-eleventh century, even the independent-minded found it difficult to refuse professorships in the burgeoning religious colleges (*madrasahs*) that were endowed and to some degree controlled by the rulers and their senior military commanders. However scrupulous they might be, scholars could hardly avoid some entanglement with the princely courts. Quite apart from questions of material interest, most also had a profound fear of social disorder—as a popular dictum had it, one night of anarchy was worse than sixty years of tyranny. Thus they seldom challenged or even questioned the underlying political order of their societies, however severely they might criticize particular rulers.

On the other hand, their relations with the princely courts were always ambivalent. They knew that rulers came and went like the clouds. They might collaborate with the regime in power but rarely identified themselves closely with it. Their job was to embody Islamic beliefs and values in their own lives and to propagate these within society at large. Religious scholars came from a wide range of social backgrounds and interacted constantly with the urban population. They indeed derived much of their prestige (the only solid basis of their social influence) from their accessibility to all.

As historians, then, the religious scholars were the spokesmen for the community and its concerns. As such, they stood not so much against the princely courts as apart from them. They naturally placed the rulers and their doings at center stage in their historical writing, since the rulers were the heads of the Muslim

community within the territories they ruled—responsible not only for defense, public order, and justice, but also for ensuring that Islamic religious practices and moral norms were maintained. Without a Muslim ruler, however incompetent or corrupt, an authentic Islamic way of life was impossible. However, they did not regard rulers as the sole guardians of these matters. On the contrary, scholar-historians asserted the indispensable role of their own class by recording the lives and words of eminent men of religion in countless biographical dictionaries.

In contrast to the religious scholars, chancery secretaries were men of the regime, who shared and indeed articulated its perspectives on rulership and society. The middle and upper ranks especially tended to live in a world apart from the people they governed. Their lives and fortunes were held at the whim of an autocrat, whose purposes and moods were of far greater importance to them than the life of the larger society outside the palace walls. In spite of their narrow focus, the secretaries often took a surprisingly critical view of the regimes they served. They typically judged them in accordance with the political traditions of pre-Islamic Iran, though these were often blended with specifically Islamic values. Iranian political tradition emphasized the crucial obligation of the ruler to uphold justice within his realms. In practice that meant respect for established social hierarchies, equitable taxation, enforcing right religion, and mastery of the army. The chancery secretaries might well be sincere Muslims, but for them the ruler and his senior officials were the sole actors who really counted. Hence their historical writing was strongly focused on the court and on the struggle for power. The best historians provide searching analyses of this struggle, to be sure, but with a few notable exceptions they portray it as the affair of a few score individuals, not of broad social groups and forces.

3. *The Problem of Origins, 622–825 CE*

Islamic historiography was born in obscurity. The earliest historical texts that we now have only acquired their present form in the late eighth century. For earlier stages of development we are reduced to inference or, more accurately, speculation. We can at least be sure that Islamic historical writing emerged within Arabophone Muslim circles, for the most primitive elements in this literature are couched in archaic Arabic and reflect almost exclusively the internal concerns of the Muslim community. Islamic historiography emerged out of the triumph and trauma of the seventh century: the sudden rise of a new religion among the peoples of Arabia, the vast conquests which they made under the banner of that religion, the profound changes which religion and empire wreaked on their traditional culture and socio-political organization, and the bitter civil strife which

rent a unified community of believers into hostile sects and factions. To make sense of these tremendous events, early Muslims had to devise some way of recalling, ordering, and interpreting them.

By the early eighth century they had come to believe that the Qur'an held the key to the underlying meaning of these events. The Qur'an (the collection of the revelations received by Muhammad between his call to prophethood ca. 610 and his death in 632) is far from a historical record of the earliest Muslim community. It alludes to a few crucial events which formed that community but does not narrate them. Rather, it places Islam within the long sequence of prophetic messages through which God has repeatedly called his creatures back to obedience. In the Qur'an, Muslims could see how a prophet had been sent to every people, bearing the promise of salvation for those who believed and the threat of damnation for those who refused. Most peoples rejected their prophets and suffered destruction for their obduracy. In contrast, a very few (most notably the Jews and Christians) did accept their prophets and prospered so long as they adhered to the messages these prophets had brought them. Over time, however, even these believing peoples tended to fall away, and God called them to repentance by periodic chastisement and humiliation. Through this repeated pattern the Qur'an laid down a paradigm which could explain the course of historical events. This paradigm contained three elements: the covenant offered by God to his people, the ever-present threat that this covenant might be betrayed by its recipients, and the desperate hope for redemption even after betrayal. In the circumstances of the seventh and eighth centuries, the Qur'anic paradigm of Covenant–Betrayal–Redemption was very compelling indeed.

Paradigms do not create literary genres. To recount the things that had befallen them, the early Muslims developed short prose narratives (Arabic, *akhbar*, singular, *khabar*) focused on discrete events. The earliest historical narratives about the seventh-century conquests and the internal struggles within the community of believers sprang up in a spontaneous, uncontrolled manner. They represented the contradictory memories and claims of innumerable tribal spokesmen and sectarian advocates, not a master narrative propounded by official spokesmen of the caliphal court. They were originally (and perhaps remained for some decades) oral accounts, and changed constantly as they were told and retold. Moreover, highly partisan narratives inevitably provoked counter-narratives. With a very few exceptions, it is no longer possible to recover the primitive form of any of these early narratives. That was no doubt the case even by the early 700s.

The earliest methodical effort to identify and collect the most reliable (i.e., religiously and politically acceptable) of these floating, infinitely plastic narratives took place around 700 under the aegis of the Umayyad caliphs. But the Umayyads could impose no

monopoly on the process of collection and redaction; indeed their version of Islam's first century was nearly obliterated when they were overthrown by the Abbasids in 749–50 and subjected to a systematic *damnatio memoriae*. Between 750 and 830 a group of scholars with informal ties to the Abbasid court did generate a stable corpus of historical narratives. This corpus represents what we now regard as the 'mainstream' version of early Islamic history. But competing versions produced by rivals and opponents of the Abbasids survive, albeit in fragmentary or masked form. However obscure the realities of early Islamic history may be, the historical debate of the late eighth and early ninth centuries is very well known.

The narratives collected, redacted, or (sometimes) created in the early Abbasid period were usually gathered in 'monographs' devoted to a single event (typically a battle) or category of information (e.g., lists of provincial governors). However, this period also witnessed the first major syntheses. Ibn Ishaq (d. 767) produced his famous biography of the Prophet Muhammad, the oldest complete work of Islamic historiography to reach us, and the following decades saw a host of works on the early conquests, the first caliphs, etc. Structurally, these syntheses are compilations of discrete narratives (*akhbar*), not continuous integrated narratives. On the other hand, the editors shaped their compilations in accordance with a conscious (though usually unstated) design and agenda. Mid-range syntheses of this kind dominated Islamic historiography down to the late ninth century, and they never ceased to be produced altogether.

The early Abbasid period also witnessed a plethora of efforts to develop a reliable absolute chronology, though the first essays in this direction seem to have been made under the later Umayyads. Chronographers naturally used the *hijri* calendar, traditionally instituted in 642. But of course events that had occurred before 642 had to be backdated, while the precise dates for a host of later events could only be guessed at. Nevertheless, Muslim historians quickly came to feel that precise dating was an essential element of their craft; the effort to pin things down and put them in the correct chronological order became a permanent characteristic of Islamic historical practice. By the 850s at latest, we begin to see chronicles of the kind long familiar in Byzantine historiography—viz., a year-by-year calendar of significant events (usually recounted in very summary fashion), beginning at a fixed point and coming down to the present. In the Byzantine tradition, that fixed starting point was typically the Creation, while early Muslim historians favored the Hijra (622 CE). The annalistic structure of the chronicle was a rigid but useful way of ordering events, and by the eleventh century it had become by far the most widely used format in Arabic-language historiography.

The early ninth century witnessed the appearance of one last genre of synthetic historiography, the bio-

graphical dictionary. The first major work of this class was the *Great Book of Generations* (*Kitab al-tabaqat al-kabir*) of Ibn Sa'd (d. 845). His goal was to compile concise biographies of all those persons who had transmitted Islamic religious knowledge from generation to generation, beginning with the Prophet himself. These biographies seldom provided a detailed account of the events of a person's life, let alone any effort to probe his personality. Rather, they aimed at evaluating his religious standing and his reliability as a scholar. Ibn Sa'd had clearly addressed a deeply felt need, for succeeding centuries (including the twentieth) saw a profusion of such works. In addition to countless dictionaries dedicated exclusively to religious scholars, there were dictionaries dealing with poets, men of letters, mystics, physicians, bureaucrats, and ultimately all those (including numerous women) who had earned a place within the cultural memory of Islam.

By the last quarter of the ninth century Muslim historians produced a series of grand syntheses, which claimed as their subject matter all of Islamic history, or even the history of the world since the Creation. Among many remarkable works, pride of place undoubtedly belongs to al-Tabari's massive *Chronicle of Prophets and Kings*, a work still in progress at his death in 923 (see Sect. 1). Apart from its methodological rigor, al-Tabari's compilation is distinguished by its vast scale, its meticulous attention to biblical and Iranian (though not Roman) history, and its inclusion of conflicting perspectives on the critical events of Islam's first 250 years. Al-Tabari was a somewhat controversial figure in his own time, but his authority among later generations was immense. Most of his successors were content simply to abridge and condense his account of early Islamic history, but from him they did learn to place Islam within God's plan of creation and salvation by linking it to the religions and empires which had preceded it.

4. The Mature Tradition, 950–1800

By the time al-Tabari died, the Covenant–Betrayal–Redemption paradigm that had shaped historical discourse throughout the eighth and ninth centuries seemed only remotely connected to the new crises confronting the Islamic world. Historians now had to grapple with the collapse of the unitary caliphate and the rise of a host of warlord-dominated regimes throughout the Islamic lands—in short, the political disintegration of the community of believers. Moreover, the religious conflicts which had arisen in Islam's first two centuries could no longer be healed; indeed, by the mid-tenth century what had been fluid if bitterly contested allegiances were transmuted into rigidly defined sectarian divisions. Political and religious fragmentation were unwelcome facts, but facts they incontrovertibly were, and they deeply shaped the historical writing of the following centuries.

First of all, the new environment provoked a change in subject matter. In striking contrast to al-Tabari and his predecessors, historians began to focus on recent and contemporary events rather than the community's early history. Likewise, they increasingly framed their work in local and regional rather than universal terms; their subject was more often the history of Isfahan or Damascus than of the Islamic world as a whole. This emphasis on recent and local events encouraged historians to adopt dynastic history as a framework for their narratives, for dynasties (and the warlords who created them) were the most visible political reality in their world. The turn to dynastic history was linked to new interpretive concerns. For historians observing the rise and fall of the warlord states, the central problem was not a ruler's role in the grand drama of salvation, but rather the reasons for the success or failure of his regime.

Within this new historiographic culture, universal history—i.e., history which claimed to include the whole Islamic world since the time of the Prophet, or even the Creation—continued to be written. But even the finest work of this genre, the *Complete History* (*al-Kamil fi al-ta'rikh*) of Ibn al-Athir (1160–1234), is strongly inflected by the distinctive concerns of its era. Within its strict annalistic framework is imbedded a quite visible sequence of dynastic histories. It covers all the lands of Islam with remarkable balance and detail, but it does so by examining each region *seriatim* as it surveys the events of each year. Finally, its primary focus is the mundane political process and the pragmatic lessons that can be inferred from that process.

Two other universal histories of great originality are equally products of their time and place. The *Comprehensive Chronicles* (*Jami' al-tawarikh*) composed under the supervision of the vizier Rashid al-Din (d. 1310) is a work which symbolizes the aspirations to universal rule of the Mongol rulers for whom it was written, for it deals with the history of every people about whom Rashid al-Din could obtain any information. Even the usually despised and neglected Franks are included within his vast tableau. It is an irreplaceable encyclopedia of the historical knowledge available to Iranian scholars in the early fourteenth century. Finally, the *Book of Examples* (*Kitab al-'Ibar*) of Ibn Khaldun (1332–1406) is distinguished not only by its famous introductory volume (*al-Muqaddimah*) but by its analytic survey of peoples and cultures and its author's grasp of the socioeconomic structures which shaped events.

Apart from these shifts in subject matter and emphasis, the mid-tenth century witnessed the bifurcation of historical writing into two linguistic branches. Arabic (the traditional language of Islamic scholarship) was now joined by Persian, the language spoken at the emerging princely courts of Iran and Muslim Central Asia. Arabic continued to be used throughout the Iranian cultural zone (which came to

include Central Asia, Anatolia, and much of South Asia) for the religious sciences, but Persian rapidly supplanted it in other arenas: secular and religious poetry, government administration, didactic prose, and history. The use of Persian was more than a linguistic phenomenon, for Persian historiography quickly developed distinctive characteristics of its own—e.g., a preference for lengthy continuous narratives, an explicit appeal to the political precepts and institutions of ancient Iran, a certain vagueness or carelessness about chronology. By the eleventh century Arabic and Persian historiography clearly embodied two distinct traditions, each developing in its own way. This picture was further complicated by the emergence of Turkish as a vehicle of literary expression in the late fifteenth century. From that point down to the mid-nineteenth century Turkish-language works were composed throughout the Middle East—no surprise, since the political and military elites from the Nile to northwest India were overwhelmingly of Turkish origin during that period. However, the main centers of Turkish literature were located in predominantly Turkish-speaking areas—i.e., Uzbek-dominated Central Asia and the core Ottoman lands in Anatolia and the eastern Balkans. In spite of some specific characteristics of its own and many works of outstanding quality, Turkish historiography tended to model itself upon the Persian tradition, and in some regions the two languages coexisted on almost an equal basis as vehicles of literary expression.

5. The Transition from Islamic to European Models, 1800–2000

By 1800 the Muslim peoples of Asia and North Africa faced severe military and economic challenges from Europe. However, most Muslim polities (with the important exceptions of the Mogul Empire in India and the sultanates of Java) still retained their political independence, and the deep-rooted societal and cultural structures of the Islamic lands seemed intact. By 1900, however, almost every Muslim state had been swallowed up or made a client regime, and Muslim societies were enmeshed in massive, uncontrollable transformation on every level.

Change on such a scale inevitably compelled the creation of a radically new historiography, though the process was slow and complex. Works of great merit continued to be produced within the existing traditions throughout the first half of the nineteenth century. Indeed, excellent historical scholarship of a decidedly traditional cast was being written well into the twentieth century. Nineteenth-century historians were fully cognizant of the new world they inhabited, but for many decades traditional historiographic forms and approaches seemed adequate to the task. By the 1870s that was no longer the case. First, existing models of historical writing simply did not possess the analytic

tools that were needed to address the profound cultural and ideological problems created by the European challenge. For this purpose a new historiography was essential. No less important, by this time many Muslim intellectuals had studied in Europe or with European teachers, and they felt the powerful allure of Enlightenment and post-Enlightenment thought. To them it was self-evident that European military and economic power was grounded in the power of European ideas. Just as Muslim armies needed to adopt European weapons and tactics, so Muslim intellectuals had to appropriate European concepts and methods of inquiry.

European ideas and literary models were easier to perceive than to internalize, and the later nineteenth century witnessed a difficult struggle by Muslim intellectuals and scholars to develop new ways of writing history. Most late nineteenth-century historiography is thus a hybrid product. The point is illustrated by two major works, both marked by broad scope, critical use of documents, and awareness of European scholarship. Ahmet Cevdet Pasa's history of the Ottoman Empire (12 Vols., 1855–84) adheres to the traditional chronicle form, while 'Ali Mubarak's historical geography of Egypt (20 Vols., 1886–88) is modeled on a classic work by the fifteenth-century Cairene scholar al-Maqrizi (d. 1442). A model for historiography in a modern (i.e., European) style was provided by the *History of Islamic Civilization* (*Ta'rikh al-tamaddun al-islami*, 5 Vols., 1902–6) of Jurji Zaydan, a Syrian Christian novelist and man of letters. For both political and cultural reasons, however, Zaydan had no immediate imitators, and only after World War I did Middle Eastern historiography begin to internalize contemporary European modes of research and presentation. This shift was first visible in works dealing with modern history, but by the end of the 1930s the same trend had taken hold for studies of early and medieval Islamic times. The 'Europeanization' of historiography affected not only research methods and literary structure, but also the kinds of questions that Muslim scholars asked about their past. Even where (for a wide range of scholarly, political, and religious reasons) they rejected the specific analyses and interpretations of Middle Eastern and Islamic history asserted by European historians, they could not ignore the problems to which these scholars had called attention.

This transformation coincided with the professionalization of history after World War I—a sharp departure from traditional practice in the Islamic world. This process began with the establishment of European-style universities in Cairo and Istanbul just before the war, along with the creation of officially sponsored societies for historical research. Simultaneously, history was enlisted in the struggles for national independence and cultural autonomy of the interwar and postwar periods. Finally, by World War I a few Muslim scholars were taking advanced degrees from

the leading universities in Europe, and their numbers increased greatly in the following decades. The prestige and authority that these foreign-trained scholars enjoyed when they returned home in effect imposed a new model of historical thought and writing on their students.

Cross-cultural influence in historiography has not flowed in a single direction, however. Even in the 1920s and 1930s, a few Muslim scholars published their work in Western languages, and since the 1950s this trend has grown enormously. A growing number of scholars from Islamic Asia and Africa have not only taken their advanced degrees in Europe and North America, but have also been appointed to many of the most prestigious teaching posts there. This situation has begun to create a real dialogue among a plurality of theoretical and cultural perspectives. The history of the Islamic world is increasingly in the hands of its own scholars—the natural state of things, perhaps, but one which was hardly the case in the nineteenth and twentieth centuries.

Historiography and Historical Thought: Jewish Tradition

1. Biblical Traditions of History Writing

Together with the historical traditions of ancient Greece the Hebrew Bible contains the oldest corpus of historical writings. While not all of the various books which entered the Jewish biblical canon reveal a strong sense of history, quite a few—such as Samuel, Kings, and Chronicles—are primarily historical accounts. In contrast to the Greek historians, the authors and editors of the Bible were interested not in recording history but in giving a theological sense to history. The numerous biblical passages which command the Jews to remember (*zakhor*) do not imply a special interest in history itself but express a definition of the Jews as a historical people held together first and foremost by its will to observe its historically revealed laws and to remember its common history. God is described in terms of His historical deeds. He is the 'God of the fathers' and 'Your God who brought you out of the Land of Egypt.'

With the canonization of the Hebrew Bible in the second century CE (Christian Era) Jewish historical writing undertakes a clear shift. The first century CE produces the last major Jewish historical writings for about 15 centuries. In a historical work, of which only two out of five parts survived, Philo of Alexandria describes the persecution of Egyptian Jews by the Roman governor Flaccus and the delegation of Alexandrian Jews (including himself) to the emperor Caligula. The most important historian in this period is Flavius Josephus, whose account of the Jewish War against Rome in 66–73 CE was written a few years later in Roman exile and—together with his *Antiquities*—stands in the tradition of Roman rather than Jewish historiography.

2. Historical Thought in Rabbinic Literature and Medieval Sources

There is hardly a more telling symptom for the decline of Jewish historical writing than the fact that Josephus' histories fell into oblivion among the Jews during the Talmudic period. The same holds true for many historical accounts which did not enter the Jewish Biblical canon, such as the Books of the Maccabees, which describe the rise of the Hasmoneans against Hellenism. Preserved by non-Jews, they were re-discovered by Jews only in the sixteenth century. During the Middle Ages the history of the Second Temple period—beyond the Biblical accounts themselves—was known among Jews in rather distorted versions of the original accounts, such as the *Book of Antiochus* and the tenth-century *Book of Yossipon* (believed to be Josephus' original account), both produced in southern Italy.

The Talmud, which was to become the single most important source for Rabbinic Judaism over the centuries, is unhistorical in its nature. Although this vast corpus contains quite a few passages of historical value, its editors reveal no special interest in the chronology of events. Thus, rabbis of different centuries are made to engage in conversations, and biblical events are often presented out of their chronological order.

Medieval Jewish historical thought is framed by the memory of the biblical past on the one hand and by the longing for a messianic future on the other hand. The time span between a golden past and an ideal future is usually interpreted with clear reference to the biblical course of events. Biblical place names like Ashkenaz and Sefarad designate European countries, Christianity is Edom, and Islam is Yishmael. Vicious rulers are called Haman, like the archetypal biblical villain from the Book of Esther, and saviors are termed Mordechai after the hero of the same story. Messianic expectations led to concrete calculations about the End of the Days, and contemporary tragedies were often seen as the birthpangs of the Messianic Age.

Altogether, traditional Jewish historical thought as expressed in Rabbinic literature and medieval sources reveals at least a partly cyclical understanding of time. Every year when celebrating Passover observant Jews remember the exodus from Egypt, and during three annual days of fasting they mourn the destruction of Jerusalem. Each rescue from persecution is regarded a new Purim (in commemoration of the Book of Esther). Every Sabbath morning a weekly portion of the Pentateuch is read in the synagogue, thus reviving sequentially each year the historical accounts of the Five Books of Moses.

The most prominent genre of historical writing during the Middle Ages was the chronologies, which often tried to establish a reliable 'chain of tradition' (*shalshet hakabbala*) from Moses through the leading Rabbis of the Mishna and Talmud and up to the

authors' own time and place. They constituted a refutation of the anti-Talmudic challenge made by the Karaite sect and at the same time underlined the importance of the local Jewish community in which they were produced. Examples of this genre are the *Letter of R. Sherira b. Hanina* from the academy at Pumbedita in Babylonia, who in the late tenth century responded to scholars from Kairouan, and the twelfth-century *Sefer Hakabbala* (Book of Tradition) of the Spanish scholar Abraham ibn Daud. A stronger emphasis on contemporary events can be seen in the detailed accounts of the Crusade massacres concerning the cruelties which befell the Jewish communities of the Rhineland in the eleventh and twelfth centuries.

Among the most popular sources reflecting medieval and early modern Jewish historical thought in Central Europe were Memor Books, which contain collections of prayers together with a necrology of distinguished persons, and recorded local martyrs and persecutions. The oldest known Memor Book is from Mainz and dates back to 1296. A few hundred Memor Books are extant, mainly from seventeenth-century rural communities in southern Germany.

3. Sixteenth-century Jewish Historiography as a Response to Catastrophe

The sixteenth century saw a sudden upsurge of Jewish historical writing with the publication of 10 important historical works, more than all of those known to us from the Middle Ages. Quantitatively as well as qualitatively the development was significant, with a new interest in history itself, as Yosef Hayim Yerushalmi demonstrated in his seminal study *Zakhor* (1989). Writers like Yosef ha-Kohen, Abraham Zacuto, and Samuel Usque wrote in the wake of the expulsion of Jews from Spain and Portugal (1492 and 1497), which affected not only their own lives but also completed the wave of expulsions of Jews from Western Europe. The new search for explanation is apparent in their writings, perhaps most pointedly in Solomon ibn Verga's *Shevet Yehuda* (The Staff of Judah, 1554), but also in the historical oeuvre of the only Ashkenazic author of this group, David Gans from Prague. His *Tsemah David* (Offspring of David, 1592) contains the most precise account of Jewish and world history undertaken by a Jewish author until that time.

The Italian Jew, Azaria de' Rossi, who completed his *Me'or Enayim* (A Light to the Eyes, 1573–5) at about the same time, has the merit of recovering ancient sources that had been lost to Jewish tradition because they did not enter the biblical canon. Among them are works by Philo of Alexandria and the apocryphal *Letter of Aristeas*. For the first time the historical interest of Jewish writers did not concentrate on the biblical past or speculations about the messianic future but dealt with the concrete history of the Jews

during recent centuries and in their own time. These authors also showed a genuine interest in the histories of other nations. The impact of their work on later Jewish historiography was, however, minimal. It was only as a result of the encounter with academic scholarship in the early nineteenth century that modern Jewish history writing developed.

4. The Beginnings of Modern Jewish Scholarship and Critical Historiography in the Nineteenth Century

The beginnings of modern Jewish scholarship can be dated to the small circle of Jewish university students from Berlin who founded the *Verein für Cultur und Wissenschaft der Juden* in 1819. Leopold Zunz, the leading spirit of this group and the dominant figure in the field which would become known as *Wissenschaft des Judentums*, published in 1818 a systematic agenda for modern Jewish research under the title '*Etwas ueber die rabbinische Literatur*' (On Rabbinic Literature). The study of history, which had been marginal in the works of eighteenth-century Jewish enlighteners (*maskilim*), now became a central pillar of Jewish scholarly enterprise. From the beginning, a certain apologetic character was inherent in many attempts at reclaiming the Jewish past. As Immanuel Wolf, a founding member of the *Verein* expressed it: 'Scientific knowledge of Judaism must decide on the merits and demerits of the Jews, their fitness or unfitness to be given the same status and respect as other citizens.'

In a more direct way, the scholarly studies of Leopold Zunz served as instruments to achieve emancipation for German Jews. Like Wolf, Zunz believed that 'the equality of the Jews in customs and life will follow from the equality of *Wissenschaft des Judentums*'. In his *Gottesdienstliche Vorträge der Juden, historisch entwickelt* (1832), he documented the long tradition of Jewish sermonic literature, thus rebutting the Prussian government's dismissal of German synagogue sermons as innovations in Jewish liturgy. Five years later, in his study on Jewish surnames, *Die Namen der Juden*, Zunz proved the ancient origin of many 'non-Jewish' names among Jews and thus reverted to a decree which forbade the use of Christian first names among Jews.

It would, however, not do justice to the enormous enterprise of nineteenth-century *Wissenschaft des Judentums* to view it predominantly under the aspect of apologetics, as did later critics, especially Zionists, most prominently Gershom Scholem. Another important motif for the pioneers of Jewish historiography was to retrieve the lost treasures of the past for a rapidly assimilating Jewish community as a means of strengthening their particular identity as modern Jews. As Yosef Hayim Yerushalmi writes, 'History becomes what it had never been before—the faith of fallen Jews' (1989, p. 86). Finally, the purely scholarly

interest in the Jewish past at a time in which history writing and reading became one of the most popular intellectual endeavors should not be disregarded.

There was no bridge between those first scholarly accounts of Jewish history and earlier Jewish writing. It was through the non-Jewish world that historiography entered Jewish writing. Consequently, it was not a Jew, but a Protestant French author in Dutch exile, Jacques Basnage, who wrote the first multi-volume postbiblical Jewish history. He characterized his *Histoire du peuple Juif depuis Jésus Christ jusqu'à présent*... (1706–11, rev. edn., 1716–21) in his subtitle as a continuation of Josephus, and there was indeed some truth to this statement. To be sure, his account would in no way measure up to modern scholarly standards, and was still full of missionary intentions, but it was nevertheless the first serious attempt to write a comprehensive postbiblical Jewish history.

5. Political Agendas and the Writing of Jewish History

The first Jewish writer to embark on such an endeavor was Isaak Markus Jost, a member of the *Verein für Cultur und Wissenschaft der Juden* and one of the pioneers of *Wissenschaft des Judentums*. The modern secular education he received as a student at Berlin and Goettingen is visible in his attempt to present a sober and objective view of Jewish history in his nine-volume *Geschichte der Israeliten seit der Zeit der Maccabäer bis auf unsere Tage* (1820–28). Jost's work is clearly centered on the German-Jewish experience and draws a picture of Judaism as a religion which has lost all its original national characteristics. Depicting modern Jews as a purely religious community was part of the larger German-Jewish struggle for Emancipation. The title of his later work, the three-volume *Geschichte des Judentums und seiner Sekten* reveals the urge to present Judaism as a religion analogous to Christianity.

When Heinrich Graetz wrote his 11-volume *Geschichte der Juden von den ältesten Zeiten bis auf die Gegenwart*—the most popular such history ever written—one generation later (1853–76), he deviated from the early works of *Wissenschaft des Judentums* representatives in his stronger emphasis on the existence of a Jewish people and by a more passionate presentation. Although he was later claimed as a proto-Zionist writer, it is important to note that his definition of the Jewish nation is that of a community held together by an essentially religious idea. Like Jost, for whom modern Jewish history begins with the enlightened Prussian monarch Frederick the Great, Graetz located the beginnings of Jewish modernity in Germany, with the appearance of the philosopher Moses Mendelssohn and the Berlin Jewish Enlightenment.

It was not until the late nineteenth century that a clear break from the earlier Germanocentric view of Jewish history and from the strong emphasis upon a 'history of suffering and scholarship' (Graetz) appeared in the work of the Russian-Jewish historian Simon Dubnow. His 10-volume *World History of the Jewish People* was written in Russian but published first in German translation (1925–29). Motivated partly by his own political agenda—he was the founder of the autonomist Jewish movement which represented Jewish diaspora nationalism in eastern Europe—his version of Jewish history centered on institutions of Jewish life in the diaspora, most notably the *kehilla*, the semi-autonomous Jewish community.

Dubnow was also among the founders of the YIVO Institute for Jewish Research—an institution established in Berlin and Vilnius in 1925 to systematically research the Jewish past and present in Eastern Europe and other Ashkenazic communities. In contrast to the traditional German dominance of nineteenth-century *Wissenschaft des Judentums* and to Hebrew-language Zionist scholarship, the YIVO deliberately presented its research in Yiddish, the language spoken by the Jewish masses of Eastern Europe.

From the end of the nineteenth century, Jewish historiography was increasingly influenced by new subdisciplines of *Wissenschaft des Judentums*, such as ethnography, sociology, and demography. The *Gesellschaft fuer Juedische Volkskunde*, a society of Jewish folkloristics founded in 1898 and led by the Hamburg rabbi Max Grunwald, played a pioneering role in the scholarly research of Jewish folk traditions around the globe. Its journal, the *Mitteilungen fuer Juedische Volkskunde*, published the most important findings in the field for almost three decades (1898–1929). In Russia, an expedition to the traditional communities of the Ukraine led by the playwright and folklorist An-Ski from 1912 to 1915 was the culmination of a long search for the remnants of rural Jewish life.

Jewish demographers created their own institutional framework when they established an Office for Statistics among the Jews in Berlin, which from 1904 published its own journal and was closely related to the burgeoning interest in Jewish sociology best expressed in the pioneering works of Arthur Ruppin. Most of these endeavors were clearly related to the 'Jewish Renaissance' propounded by the emerging Zionist movement. Zionist scholars reacted against what they alleged to be the orientation of nineteenth-century Jewish scholars exclusively to the Jewish past and broadened their interest to include contemporary issues within their research.

After the establishment of the Hebrew University in 1925, scholars with a Zionist outlook formed a vaguely connected group of Jewish historians, sometimes referred to as the 'Jerusalem School,' emphasizing the centrality of Palestine in the course of Jewish history. Their most outspoken representative was the later

Israeli minister of education Benzion Dinur (Dünaburg), who in 1935 helped to establish the most important Hebrew-language historical journal, *Zion* (an earlier series of the journal had been aborted), together with the first professor of Jewish history at the Hebrew University in Jerusalem, German-born Yitshak (Fritz) Baer.

From the very early works of Zionist historiography, usually written by Zionist activists who were not professional historians (such as Nahum Sokolov and Adolf Böhm), a teleological view of history leading to the return to the Jewish homeland is clearly visible. At the same time, the Jewish past in the Land of Israel is placed in the center of interest at the expense of diaspora history. In contrast to most historians, Benzion Dinur thus commences the period of exile not with the destruction of the Second Temple in the first century CE but much later, with the Muslim conquest of Jerusalem in the seventh century CE. In a similar vein, he concludes the period of diaspora domination as early as 1700, when a group of pious Jews from Eastern Europe made their way to Palestine. In his *History of Zionism, 1600–1918* (1919) Nahum Sokolov anachronistically dates the Zionist movement back to the seventeenth century.

While Dubnow's conception of Jewish history represented a corporate view of Jewish diaspora life and the Jerusalem School emphasized the centrality of Palestine, the last historian who attempted a single-handed multi-volume universal Jewish history, Salo Wittmayer Baron, stood for a more positive approach to individuals' diaspora experience. His 16-volume *A Social and Religious History of the Jews* (1952–76) reaches only the year 1650. His more affirmative view of the diaspora was certainly influenced by his own experience of spending most of his life in the United States, where he was appointed in 1930 as the first professor of Jewish history at a Western university, Columbia University in New York.

Jewish historiography has thus to a large extent been determined by the political context, the geographical situation, and the ideological and religious outlook of the respective historians. Since all these factors differed considerably in the Jewish world, the outcome was a highly diverse array of Jewish historical writing – even though, at least up until the second half of the twentieth century, most of those who undertook to write Jewish history were themselves Jews. The destruction of European Jewry, the establishment of the State of Israel, and the flourishing of Jewish studies in the United States led to an entirely new situation for Jewish historiography after World War II.

6. Twentieth-century Trends

With the exception of Baron no single historian embarked on a monumental Jewish history project in the tradition of Jost, Graetz, and Dubnow in the course of the twentieth century. There were a few

attempts to publish Jewish world histories as collective enterprises, as early as the ambitious plan developed by Ismar Elbogen of the Berlin *Hochschule für die Wissenschaft des Judentums* in the late 1920s; these, however, fell victim to the economic and political crisis of the early 1930s. More successful, but for financial reasons also never completed, was a multi-volume project initiated by scholars of the Hebrew University.

After World War II Jewish history became more and more a field for specialists who would concentrate on limited areas and periods. This tendency toward specialization was also the result of an increasing professionalization and acceptance of the subject as a distinct field to be taught at university level, with new centers emerging in Israel and the United States. Until the 1960s, the teaching of Jewish history in the US had been restricted to a handful of universities and a few institutions with a strong emphasis on Jewish education, such as rabbinical seminaries and Jewish teachers' colleges or the Jewish-sponsored Brandeis University. With the establishment of new Israeli universities the singular role of the Hebrew University in Israel diminished, while a true explosion in the field of Jewish studies enabled a similar diversification at American universities beginning in the 1970s. European institutes of higher learning followed to a more modest degree in the 1980s and 1990s. By 2000, Jewish history had become a highly specialized and diversified field represented at almost every major institution of higher learning in the United States and many European countries.

This development led to a more complex picture of Jewish historiography. The personalities and political programs of individual historians and the formations of more or less clearly defined schools no longer dominate the professional scene. Zionist historians who had fought an ideological battle over Jewish history, mostly against their non-Zionist Jewish colleagues, up to the 1930s were essentially left without opponents as a result of the Holocaust and the destruction of alternative Jewish options, such as diaspora nationalism and Bundist socialism. In the State of Israel, apologetical historiography (now mainly directed against Arab and British versions of the history of Palestine) did not entirely disappear but was more and more balanced by the emergence of a younger generation of historians, by whom the existence of the Jewish state was already taken for granted. This resulted in a gradual break with long-accepted notions rather than an intellectual revolution as more and more historians and sociologists of a new postwar generation attacked the older schools of Zionist historiography in the 1980s and 1990s.

While mainly questioning issues of Israeli history or prehistory, such as the role of the Zionist leadership in Palestine with respect to attempts at the rescue of European Jewry in World War II, and the accepted notions surrounding the first Arab–Israeli War in 1948–49, the views of the so-called 'New Historians'

also challenge more general Zionist notions of Jewish history. In a highly politicized context the two sides of the 'Israeli Historians' Debate' stand not only for different views on Jewish or Israeli history but mark also different paths for Israel's political future. In contrast to Israeli historiography, which has been dominated by a classical left-liberal Zionist intellectual establishment, the 'new' historians and sociologists often represent a post-Zionist stance and as such constitute a major challenge to the master narrative of Jewish and Zionist history.

In the last decade of the twentieth century, Jewish historiography moved from its early Germanocentric and later Eurocentric emphases to a stronger integration of widely neglected communities. In particular, the histories of Jews in the Muslim world have slowly been integrated into the general picture. This is partly the result of the emergence, mainly in Israel, of historians of oriental background, but also of the establishment of a few academic positions concentrating on Sephardic Jewry at American universities. It was in the United States, where the history of Jewish women emerged as a subfield of gender studies, with significant publications in the 1990s about Jewish women in Imperial Germany and in the United States, and a historical encyclopedia of Jewish women. New trends among general historians, including post-modern ideologies, have also left their imprint on Jewish historiography.

Europe, too, witnessed a revival of Jewish historical scholarship in the 1990s. The larger Jewish communities of Western Europe, France and Britain, emerged as new centers of Jewish scholarship, although most of the historical studies there deal with their respective national Jewish histories. Central and East European institutions relating to the Jewish past were destroyed by the Nazi onslaught, together with those who participated in them. Ironically, the Nazis entered into much more systematic Jewish historical research than non-Jewish scholars had done in the Imperial and Weimar periods; they established research institutes for Jewish history in Munich, Frankfurt, and Berlin. Studies undertaken there, however, were preoccupied not with Jewish history *per se*, but with the so-called 'Jewish Question' and sought to justify Nazi discrimination and persecution against the Jews from a pseudo-scholarly perspective.

It is interesting to note, though, that some of the research begun there—especially on the Court Jews and on Sephardic Jews in Hamburg—was published with only slight alterations in the 1950s. More modern Jewish historical research in Germany developed as a result of the establishment of the first Jewish Studies institutes and of the emergence, starting in the 1960s, of a new interest in German-Jewish history among modern German historians. While Jewish history is mainly written by Jewish historians and for a Jewish public both in prewar Europe and in today's Israel and America, the postwar European situation is different.

With only small Jewish communities, research is mainly undertaken by non-Jewish scholars, and mainly read by non-Jews.

7. Major Issues in Modern Jewish Historiography

Perhaps even more than scholars of other particular histories Jewish historians have been divided by a set of fundamental questions. First of all, there is the question of whether Jewish history exists at all or whether the history of Jews merely constitutes a chapter within the histories of the nations among whom they lived. If Jewish history exists in a broader sense, the question arises whether it is the history of a people or a purely religious history—or whether at some point the national history turned into a religious history. Finally, an additional problem of Jewish history is its theological interpretation by some modern Jewish and non-Jewish thinkers, which makes Jewish history appear as though it escapes the regular laws of history. This last argument is strengthened by the conspicuous role of antisemitism throughout the centuries and the claim of the uniqueness of the Holocaust which brought about the near destruction of European Jewry.

The doubt whether Jewish history exists *per se* seems rather superfluous in an age of expanding programs in Jewish history and within the framework of an article discussing the rich tradition of Jewish history writing. Nevertheless, one can still find this opinion among some modern historians. It is based partly on the Christian theological notion that active Jewish history came to an end with the early stages of Christianity, and partly on the secular claim that Jews lack a clearly defined political history based on a common territory. In the nineteenth century such a belief was inherent in the theological characterization of ancient Judaism as 'late Judaism,' while on the other side of the spectrum of historical outlook Marxist historians denied a separate course of Jewish history on the basis that Jews not only lacked a territory of their own but also a division into classes of society in the modern period. Nowadays, the questioning of the existence of a Jewish history throughout the ages is less explicit. More indirectly, however, such a view can be detected in the almost exclusive interest of many historians in the histories of the Jews in their respective societies. Thus, German Jewry or French Jewry are often seen as isolated entities, as part of German or French history, but without any connection to the developments of other Jewish communities. On the other hand, there has been a contrary tendency among some Zionist historians to neglect the respective contexts of Jewish histories and view them only through a national Jewish perspective.

If we accept the notion that Jewish history exists as such and is stretched over numerous centuries and

over five different continents, the question remains whether it is primarily a national or a religious history. The pioneers of Jewish historiography in nineteenth-century Germany often preferred to depict Jewish history in terms of the development of a religious idea (the purest form of monotheism) and its bearers. This concept was in line with the demands of Emancipation that Jews integrate into European societies as citizens who only differed in their religious creed. Thus, the notion of a Jewish people was characterized as an ancient idea long left behind. With diaspora nationalists like Simon Dubnow and the emerging Zionist school the national element was restored to Jewish historiography. Both schools emphasized that Jews never ceased to constitute a nation even if they lacked their own territory. Dubnow went so far to stress that a nation which had overcome the need for its own territory constituted the highest and most sophisticated form of nationalism. Zionists, on the other hand, emphasized the unbroken longing for return to the Land of Israel and the use of the Hebrew language over the centuries.

A final peculiarity of Jewish history is the theological weight it enjoyed especially in a Christian context. In medieval and early modern Europe Jews often constituted the only non-Christian minority. The traditional position Jews enjoyed in Christian Europe was a mixture of protection and discrimination. Jews served as the classical 'other,' being protected because they bore testimony to Jesus Christ while at the same time discriminated against as Christ-killers and as unbelievers. On the basis of this peculiar role, many Christian authors of postbiblical Jewish history regarded this particular history as outside the course of 'regular' history. They claimed accordingly that it should be judged by theological rather than historical criteria. On the Jewish side, the most prominent proponent of a Jewish '*Sonderweg*' theory, albeit with a different background, was the philosopher Franz Rosenzweig, a student of Friedrich Meinecke, who stressed in his main work *The Star of Redemption* (1921) that general rules of history do not apply to Jewish history. More recently, the discussion of the uniqueness of the Holocaust has brought the question of a peculiar course of Jewish history to a different level. In this view, it is not Jewish history that is incomparable to other histories, but rather the persecution of the Jews which culminated in the attempt of their total annihilation.

In his programmatic and provocative essay, 'Ghetto and emancipation' (1928), the historian Salo Baron fiercely objected to what he called a 'lachrymose version of Jewish history.' At the beginning of the twenty-first century, and half a century after the greatest tragedy of the Jewish people, numerous voices once again express their reservations against a one-sided picture of Jewish history reduced to a history of persecution. While they stress the importance of research on antisemitism and the Holocaust, they also

warn not to read Jewish history backwards starting from its most tragic chapter.

Historiography and Historical Thought: Modern History (Since the Eighteenth Century)

1. Reorientation of Historical Thought in the Eighteenth Century: The Emergence of a Secular Outlook

There is good reason for beginning this article on Western historical thought and historical writing in the modern age with the eighteenth century. The Western tradition is much older, going back at least to the Hellenic Age. There is much continuity between the older traditions, particularly those of the humanistic historiography of the Renaissance and historical writing in the eighteenth century. Yet there are also profound changes in the conceptions of history and of historical knowledge and in the institutional context in which history is written that mark a sharp break with previous periods.

Henri Berr and Lucien Febvre in the article 'History' in the first edition of the *Encyclopedia of the Social*

Sciences in 1932 identified two characteristics of the modern conception of history as basic to the modern historical outlook and practice: the commitment to establishing the 'truth' and to placing historical accounts within 'universal history.' A third is the transformation of historical studies into a professional discipline. The older ancient and humanistic historiography, they argued, saw history as a form of rhetoric in the service of politics and morality and as an art form. 'History as it is conceived today,' they noted, 'may blossom into art, may be crowned with philosophy; but it is primarily and necessarily the solid establishment of facts' (Berr, p. 358), however difficult this may be.

This formulation presupposes a sharp distinction between history as literature and as a scientific discipline, even if its approach to science takes into account the elements of contingency and particularity that distinguish history from the generalizing natural sciences; but it assumes that historical accounts based on a solid factual basis narrate a coherent development that reflects historical reality.

There is a good deal to be said for this description of the transformation which historical studies underwent in the eighteenth and particularly in the nineteenth century; but especially from the perspective of the late 1990s it seems one-sided and incomplete.

On two levels, historical thought and historiographical practice in the eighteenth century moved toward greater historical realism. On the one hand, an increasingly secular outlook insisted on the exclusion of the supernatural and held that historical explanation must not violate a common understanding of natural reality. This secular approach was relatively new in the eighteenth century. On the other hand, it coexisted often with a residual religiosity, as it still did even in the nineteenth century with a conception of a hidden divine plan, as in Leopold von Ranke's trust in the 'hand of God' (1973, p. 138), or in a less hidden form in G. W. F. Hegel's dialectic. Thus Enlightenment historians such as J. C. Gatterer and A. L. Schloetzer did not challenge the biblical chronology or the biblical account, although for the post biblical period, or for the non-Hebraic ancient peoples, they insisted on an approach in accord with natural reality.

Apart from the great works of synthesis in the eighteenth century, David Hume, Montesquieu, Voltaire, Edward Gibbon, G. T. Raynal, and Adam Ferguson, there exists a tradition of erudition that introduced standards of source criticism, which went back to the humanist scholarship of the Renaissance and Reformation and to the erudition of seventeenth-century historical scholarship. The belief that great philosophic works of synthesis are not enough and that scholarly history cannot be written until the authenticity and veracity of the sources on which it rests have been established expressed itself in the great methodical collection of sources begun in the seventeenth century with the Jesuit *Acta Sanctorum*,

published after 1643, to provide a firm basis for ecclesiastical history, and with Ludovico Muratori's efforts in the *Scriptores rerum italicarum* (1723–51) to lay the foundation for an Italian national history. The German scholars at the universities, first J. L. Mosheim and J. S. Semler at Halle and then J. A. Ernesti and J. O. Michaelis at Göttingen, established a tradition of historical exegesis that laid the foundations for historical hermeneutics and the new discipline of historical philology which emerged in the latter part of the eighteenth century and became the key elements of the critical method of B. G. Niebuhr and Ranke in the nineteenth century.

A key concept of eighteenth-century thought was the linear character of history. History was no longer understood as a cumulation of events but as a continuous story possessing inner coherence. Reinhart Koselleck has suggested that between 1750 and 1850 the concept 'history' (*Geschichte*) replaced that of 'histories' (*Geschichten*). Each of the great historical works of the eighteenth century followed a continuous, coherent story whether in Gibbon's *Decline and Fall of the Roman Empire*, Hume's *History of England*, or Voltaire's *Essai sur les mœurs*.

Yet the conception of world history that arose with the Enlightenment constituted not only an extension of the historical outlook but at the same time also a narrowing. And this conception dominated almost all of Western historical thought and historical writing until well into the second half of the twentieth century. The history of the world was identified with the history of civilization and the latter rather narrowly with that of the West. Two variations emerged in the conception of what constituted world history, one identified with Condorcet, centering around an idea of progress on a world scale, the other identified with Herder, which stressed the diversity of peoples and cultures. Yet on closer examination, these two conceptions shared many characteristics, specifically in their stress on development.

The Enlightenment has too many aspects to permit one to reduce it to a simple formula. Two ideas were central to it, but neither was free of contradictions. The first assumed the essential equality of all human beings in all cultures; the second maintained that only human beings who had attained a high degree of culture and education deserved to be free and equal citizens. The latter view distinguished between societies that were in the vanguard of civilization, understood as Western civilization, and less-developed peoples. If G. W. Leibniz and Voltaire had still regarded China as a civilization equal and possibly superior to that of the West, Christoph Meiners considered the yellow peoples as inferior to Europeans, and the Blacks as barely different from animals. The notion emerged of a distinctive Western civilization with roots in classical Greece. J. J. Winckelmann's rediscovery of Greek art in 1764 contributed to an idealization of Greek standards of beauty and personal

culture which were adopted as models for a modern culture distinguishing the West from other cultures and giving it its superior standing. Meiners' scientific racism represented an extreme position, but the idea of the unique position of the West and the relative inferiority of all non-Western cultures and peoples became a central assumption in Western historical consciousness.

2. Nineteenth-century Conceptions of History and Historical Science: Between Romantic Historism and Scientistic Positivism

This outlook was dominant well into the twentieth century. It reflected the changes that had taken place in the world in political and military strength, economic power, and scientific and technological development. The two divergent historical outlooks in the first half of the nineteenth century, one represented by Hegel's dialectical philosophy of history, the other by Ranke's historism, shared this outlook despite their philosophic differences. Hegel's perception of the world as an ongoing dialectical process by which, through progressive contradictions, the absolute mind, reason, fulfills itself and takes on concrete forms in the institutional life of the modern European world, and specifically in the Prussian political and social order after the French Revolution and Napoleon, reflects its origins in specifically German political and philosophical traditions. But it has parallels in less involuted intellectual currents of thought outside of Germany, from Turgot, Condorcet, and Thomas Paine in the late eighteenth century to Henri de Saint Simon, Auguste Comte, J. S. Mill, Thomas H. Buckle, Herbert Spencer, and Benedetto Croce in the nineteenth century. For all of them world history is the history of the European world, a world which for some may include the United States but for all excludes the Slavic peoples. For Hegel only the West has a history. China, India, and Persia may have been the earliest civilizations but they have remained stagnant.

According to Hegel, Black Africans are incapable of cultural creativity. Karl Marx with his conception of static Asiatic modes of production took over much of Hegel's conception of the inferiority of non-Western societies and he and Friedrich Engels used this to justify Western imperialism as the only way to bring the non-Western world into the realm of modern civilization.

Theoretically Ranke's conception of the historical world represented the antithesis of Hegel's. Ranke rejected the idea of progress as well as the schematization of historical development as it occurred in Hegel's philosophy of history. History for him deals with the particular and the contingent and avoids generalizations and determinism. In fact, however, Ranke saw history as a linear process at the culmination of which stood the post-Napoleonic Western and Central Euro-

pean world. Ranke proclaimed that 'every age is equally immediate to God' (1973, p. 52), but at the same time denied that China or India had a true history. Except for his early work on the Serbs, his writings deal with the countries he defined early as the Latin and Germanic. His incomplete *World History* is a history of the West.

Whatever the philosophical and political differences, nineteenth-century thinkers as well as the educated public generally turned to history as the key to understanding things human that replaced traditional philosophy. The charges, often repeated, that the eighteenth century, particularly the Enlightenment, ignored history, generalized, and moralized, and did not recognize individuality and uniqueness of historical contexts is disproved when we look at the great historical works of the eighteenth century which we have already mentioned. Despite the impact of romanticism in the first part of the nineteenth century, with its stress on imagination and poetry, a cult of science dominated historical study and writing, which was not necessarily in conflict with a romantic outlook.

This search for a scientific approach to history took two different directions: one that has frequently been called positivism, the other historism, neither of which can easily be reduced to a common denominator.

The first of these orientations took the natural sciences as its model. Building on Turgot and Condorcet, Auguste Comte sought to formulate laws of development by which societies moved from simpler to more complex forms of organization. The driving force was the transformation of knowledge from theological and then metaphysical stages to positive science that would provide the means for the scientific organization of society. But positivism remained largely grand theory with little empirical application to historical inquiry. More significant was Karl Marx's approach to history. Marx saw the driving force of history in the lawful development of economic forces, which constituted the basis of historical transformation, and the revolt of this basis against the social, political, and intellectual superstructure. In the course of this conflict the contradictions within the social order, which involved inequality, would be overcome in a classless society. Marx thus intended to replace Hegel's idealist dialectic with a materialistic one.

If positivism both in its Comtean and in its Marxist form in its search for a scientific history envisaged a utopia at the end of history, the main currents of historical scholarship sought to avoid a speculative approach to history but nevertheless did not free themselves from metaphysical and even theological presuppositions which they refused to acknowledge. Ranke may perhaps serve as the most influential representative of this orientation. He too was committed to a strictly scientific approach to history. For him, however, this approach must recognize that general laws have no application to history that deals

with the particular and the contingent. For him the task of the historian was to recapture the past as 'it actually was' (*wie es eigentlich gewesen*), free of any bias, requiring the application of philological methods to the critical analysis of the sources as F. A. Wolf and Niebuhr had applied them. But for him history was more than the reconstruction of the past. It involved interpretation and synthesis, as it did for J. G. Droysen. Ranke was convinced that the particular event contained the general, and that the general became apparent to the researcher who immersed himself in the sources, because—and here we return from the realm of strict science to that of metaphysics—the historian can observe the general tendencies that manifest themselves in history, tendencies which do not represent God's direct intervention in the world, but nevertheless reflected divine purpose.

3. Professionalization of Historical Studies

The stress on the scientific character of historical studies led to the formation of a professional discipline of history. Professionalization was not restricted to history but was part of a process in which scholarly studies in all fields, in the liberal arts as well as the natural sciences, were institutionalized at centers of higher learning, primarily the universities and research institutes. The German model was imitated elsewhere, relatively early in France with the introduction of the German seminar method at the *Ecole Pratique des Hautes Etudes* in Paris in 1868 and in the United States with the introduction of a research oriented graduate program at The Johns Hopkins University in Baltimore in the 1870s leading to a Ph.D. With some delay the German model was adopted in Japan, Great Britain, the Netherlands, Italy, Spain, Russia, Scandinavia, Greece, Romania, Latin America, and elsewhere, each time, it must be stressed, with major modifications that reflected different scholarly traditions. Thus, the sharp distinction between the cultural and the natural sciences which dominated German thought played less of a role elsewhere.

A basic tenet of professional historians was the total objectivity or what Ranke called the 'impartiality' of the historian. In fact, however, the new discipline was highly politicized everywhere. This intensified interest in archival research went hand in hand with the wave of nationalism that gripped all Western countries and also modernizing non-Western countries such as Japan. The broad cosmopolitan view of many historians in the eighteenth century gave way to a new focus on national history. Ranke still wrote the histories of a variety of European states, Serbia, England, France, Prussia, and also the Reformation in Germany, and the Papacy. Later historians, who took him as a model for their own scholarship, in most cases concentrated on their own nation.

However, the development of modern historical scholarship was not a German monopoly. The opening of archives and the collection of documents, primarily those of the Middle Ages, became a prerequisite for scholarly national history. In Paris the *Ecole des Chartes* was founded in 1821 to train scholars in the critical use of documents. Muratori's collection of Italian documents in the eighteenth century has already been mentioned; this was followed by the *Monumenta Germaniae historica* launched in Germany in 1819 and by similar undertakings in France, Great Britain, Spain, Poland, Bohemia, Greece, and elsewhere.

The Rankean belief that immersion into the sources guarantees an impartial view of the interrelation among historical events turned out to be an illusion, something which was openly recognized by the scholars of the Prussian school such as Heinrich von Sybel, J. G. Droysen, and Heinrich von Treitschke who frankly saw historical scholarship as a tool for the legitimation and propagation of the German national cause under Hohenzollern rule. Moreover, the process by which scholars were recruited guaranteed a high degree of homogeneity in social composition and political outlook.

Professionalization was to guarantee objectivity, but also to provide a scientific or scholarly discourse distinct from that of literature. Ranke had stressed the scientific character of history, but at the same time he also recognized that history combines science with art. The great prestige which history enjoyed everywhere in the nineteenth century—a number of the leading French statesmen from François Guizot to Alexis de Tocqueville, Alphonse de Lamartine, Adolphe Thiers, and Jean Jaurès were important historians—rested on the literary quality of their histories. History could not escape being literature, and imaginative literature at that. In fact there existed a close parallel between the great histories written by professional historians and the great realistic novels of the nineteenth century—Stendhal, Honoré de Balzac, Charles Dickens, Gustave Flaubert, Gottfried Keller, Gustav Freytag, Ivan S. Turgenev, Fyodor Dostoyevski, and even Thomas Mann's *Buddenbrooks* (1902). They all constructed a plot that followed a temporal line and involved individual subjects as agents. And the great historians of the century, Jules Michelet, Denis Fustel de Coulanges, Thomas B. Macaulay, and Theodor Mommsen, who in 1902 received the Nobel Prize for literature, were read as great literature, as was Ranke himself. Michelet is a striking example of the crossing of borders between critical scholarship and imaginative literature, the exhaustive mining of the archives for the purpose of creating a national memory and identity.

But the role professionalization played in nineteenth-century historical writing should not be overestimated as it often has been. A great deal of history did not follow the dominant paradigm of narrative

national history such as three of the most important and lasting works of the mid-century, Fustel de Coulanges's *La Cité antique* (The Ancient City), de Tocqueville's *L'Ancien régime et la Révolution Française* (The Old Regime and the French Revolution), and Jacob Burckhardt's *Die Kultur der Renaissance in Italien* (The Civilization of the Renaissance in Italy). Moreover, many leading writers of history such as Thomas Carlyle, Macaulay, John Green, George Bancroft, Lamartine, Louis Blanc, and, of course Tocqueville, were not professional historians.

The great literary histories of the eighteenth century, for example, those of Hume, Gibbon, and Voltaire, were intended to entertain, educate, and edify a broad educated public. Professional historians wrote often for specialists. But in fact the division between literary and professional history and their audiences was not as deep as it may appear. Certainly Hume, Gibbon, and also William Robertson were serious scholars and the great professional historians of the nineteenth century, such as Ranke, Fustel de Coulanges, Theodor Mommsen, and Lord Acton were read avidly by a broad public for whom history had become the key science replacing philosophy as a guide to understanding the human world.

4. Twentieth-century Reorientations of Historical Thought and Scholarship: The Turn to the Social Sciences

Outside the discipline proper, critical methods were applied to many areas: the history of religion (F. D. Strauss, Ernest Renan), the history of law, the history of literature and art, and other fields. While the historians proper neglected the study of society and economics, an important group of economic historians, the so-called 'Historical School of National Economy' in Germany (Bruno Hildebrand, Karl Knies, Wilhelm Roscher, and Gustav Schmoller) pursued a middle course between an empirical approach, seeking generalizations of economic behavior and development, reminiscent of positivism, and an intense regard for the particular historical setting of culture and society in which economic behavior occurred, which reflected historicist principles.

The late nineteenth and the turn to the twentieth century witnessed profound reexaminations of the historical outlook that had been dominant until then. On the one hand, there was a continued, even a heightened faith in science, technology, and the progress of Western civilization which largely survived the trauma of World War I. On the other hand, there was an increasing sense of discomfort with the quality of modern civilization. Darwinism, or rather Social Darwinism, played a fundamental role in both of these outlooks. The world was seen as a struggle for the survival of the fittest that could forecast the pro-

gressive victory of the white races over the rest of the world, which for Oswald Spengler was a desperate struggle for survival. At the turn to the twentieth century, some Europeans and Americans foresaw progress in terms of growing tolerance and democracy, while others preached racism and ultra nationalism.

As far as historical thought was concerned, both Burckhardt and Friedrich Nietzsche voiced their discomfort with a modern industrial society with its concomitant social and cultural aspects, a mass civilization moving to commercialism and democracy, and extended this dismay to a critique of the modern faith in science. Nietzsche, Wilhelm Dilthey, Henri Bergson, and Georges Sorel in differing ways called for a restoration of the vital against the mechanical aspects of life and culture. Established patterns of historical scholarship, as practiced by the historical profession, were called into question simultaneously at the end of the nineteenth century from Russia and Poland to North America. Generally, however, the critics of the historical profession did not criticize the latter because it was too scientific but rather because it was insufficiently so and had not taken into consideration the tremendous changes in modern society and civilization in an industrial and democratic age.

The most spectacular confrontation with the established profession occurred in Germany with the so-called *Methodenstreit*, occasioned by the publication of the first volume of Karl Lamprecht's *Deutsche Geschichte* in 1891. Lamprecht criticized his colleagues for their narrow focus on the state and their neglect of broader cultural and social aspects of history. He also accused them of working with an outdated concept of science and historical science that restricted itself to events and personalities rather than taking into consideration the structural context of historical change. The German professoriate, reflecting the peculiar semi autocratic character of the Prussian German state, vociferously rejected Lamprecht's initiative and saw in it a threat to the established social and political order. Lamprecht's attempt to formulate laws of historical development was rejected internationally but his call for a broadening of historical perspective to encompass society, economics, and culture was generally welcomed outside of Germany. Historians in Russia (Paul Vinogradoff, Vasiliev Kliuchevskii, Paul Miljukov), Romania (Nikolae Iorga), Poland (Jan Bujak, Frantczek Rutkowski), Norway (Halvdan Koht), Belgium (Henri Pirenne), as well as the circle around the journal *Revue de synthèse historique* founded by the philosopher Henri Berr in 1900 as a forum for an international discussion, and the American 'New Historians' (F. J. Turner, J. H. Robinson, Charles Beard, Carl Becker, H. E. Barnes) called for an expansion of the scope of history and a closer cooperation with the empirical social sciences.

Two variations of a social science approach to history need to be mentioned. The first is Max Weber's historical sociology that moves between the historicist

emphasis on the recognition of the uniqueness of cultures and a historical social science working with clearly defined concepts and a rigorous logic of inquiry. Weber's conception of social causation and historical development was in some ways indebted to Marx, but unlike Marx emphasized the interrelation between culture, including religion, and economics, and placed much greater weight on contingency. Weber recognized that societies constituted meaningful relationships that required an interpretive sociology but avoided the sharp distinction that idealistic philosophers such as Wilhelm Windelband, Heinrich Rickert, and Wilhelm Dilthey made between the generalizing natural sciences and the cultural sciences (*Geisteswissenschaften*) that favored empathetic understanding (*Verstehen*).

A second approach to a history taking into account the social sciences was offered by the so-called 'Annales school.' It is difficult to reduce the *Annales* to a common denominator. The journal by this name, launched in France in 1929 by Lucien Febvre and Marc Bloch with the support of Henri Pirenne, continued initiatives begun early in the century in Henri Berr's already mentioned *Revue de synthèse historique*. A similar project was initiated in Poland in the journal *Roczniki Dziejow Społecznych i Gospodarczych*, the editors of which, Rutkowski and Bujak, were in close contact with the *Annales*. In the place of the concentration of the established historiography on events and great personalities, the *Annales* explored impersonal forces and structures.

The 'human geography' of Vidal de la Blache played an important role in the early works of Lucien Febvre and Marc Bloch. Human history had to be understood in the concrete context of space and time. But unlike the German Friedrich Ratzel, who saw soil and race (*Volk*) as determining factors in history, Paul Vidal de la Blache, as did Febvre, Bloch, and Fernand Braudel later, recognized the role which human agency and culture played in the formation of the geographic setting. The historians of the *Annales* attempted to pursue a 'total history,' generally limited to a restricted region, in which all aspects, geographic, economic, political, religious, and demographic, were to be included. Quite consciously the dividing line between the established disciplines were overcome and in the *Maison des Sciences de l'Homme*, opened in Paris in 1968, economists, sociologists, anthropologists, linguists, psychoanalysts, and literary critics were housed with history as the integrating science.

In other ways too, the *Annales* represented a radical break with older historical conceptions. The nation no longer represented the basic unit of history; it was replaced by the region or by a broad comparative approach that extended beyond Europe (Braudel, Pierre Vilar). The concept of a linear time, so basic to all forms of nineteenth century historical thought, and with it the idea of progress, were abandoned and a historical epoch viewed in its own terms, not as part of

a historical process. Burckhardt had already done something similar in 1860 in *Die Kultur der Renaissance in Italien*, and had worked with a very broad concept of culture, as had also Jan Huizinga in *Herfsttij der Middeleeuwen* (1919), but unlike the *Annales* historians they focused heavily on elites. In contrast the *Annales* dealt with the population at large, but ran the danger that at times their history became impersonal and void of concrete human beings.

In retrospect, the racist historiography of German National Socialism of the period 1933–1945, although it built on widespread Social Darwinist ideas and ultra nationalism, remained an interlude, which even in Germany had limited influence. The Marxism-Leninism of the Soviet Union and its dependent states in its dogmatic forms, in many ways a perversion of Marxism, similarly represents an interlude. As early as 1956, historians in Poland and Hungary, and until the freeze after the Soviet occupation in Czechoslovakia, and even in the Soviet Union (Aaron Gurevich), participated in the broader historical discussions of the international community.

5. New Orientations after 1945: The Turn to a Cultural Dimension

A subsequent article will deal with trends in historical thought and study in the second half of the twentieth century. The victory of the Allies in World War II and the dominance of the United States in the postwar world revived older beliefs in progress and science. The 1950s and 1960s witnessed a turn to the quantitative social sciences in historical studies.

The years since the late 1960s have seen a re-orientation in historical outlook in the Western world generally, including to a lesser extent also Eastern Europe and Russia. The conflicts of the 1960s, the racial confrontation in the United States, the Vietnam War, the student revolts throughout Europe and North America, and the suppression of the Prague spring all contributed to a reorientation as did the fundamental technological changes which resulted in the transformation of an industrial society concentrated on production into an economy based on information technology, in which consumption and services play a key role and the old socioeconomic classes gave way to new ones. The confidence in science and economic growth was severely tested as a new generation became increasingly conscious of ecological concerns and called for the emancipation of subordinated segments of the population such as women and ethnic minorities at home and the peoples of the former colonies abroad. The very quality of the modern Western world, including its science, came under attack. All of this had consequences for historical studies after the 1960s.

Historiography and Historical Thought: South Asia

This article addresses two interlinked subject matters, the history of South Asia to which scholars from all over the world have contributed, and historiographical developments in the region of South Asia itself. It briefly covers the historical tradition in pre-modern times and primarily focuses on developments since World War II.

1. Historiography of Ancient India

1.1 Historical Traditions in Ancient India

Compared to classical Europe, ancient India was rather deficient in historical traditions. The Hindu mythological texts called the *Puranas* (circa first to fourteenth century) contained genealogical lists of Indian dynasties. These lists, by way of narrating the achievements of the kings, also recorded rudimentary information about wars, conquests, and the rise and fall of empires. A very small number of works chronicle the history of individual kings and dynasties. Of these, the most famous is Kalhana's *Rajatarangini* (Stein 1900), a history of the Kashmir princes. Incidentally, the author recognized one historical principle, namely, that the historian must try to be unbiased in his/her judgment, 'like a judge.'

The Buddhists and Jains developed a tradition of sacred history, especially hagiographies centered on the life-stories of their founders. Some of the stories concerning the Buddha, like the account of his death (*Mahaparinivvana-sutta*, Bongard-Levin 1986) bear the stamp of authenticity.

1.2 European Scholarship on Ancient India

In the nineteenth century, European scholars like Pargiter tried to reconstruct the dynastic history of ancient India using the Puranic lists, inscriptions, coins, archaeological remains, and foreign accounts of India like those of Alexander's historians and the Chinese Buddhist pilgrims. European Orientalists also tried to reconstruct the religious and social history of India, using religious texts and the *smritis*, normative

writings laying down the rules by which the Brahminical Hindu was expected to live in matters both ritualistic and secular (like inheritance and punishment for crimes). They also undertook the massive task of publishing critical editions of religious texts which laid the foundation for serious work on religious, cultural, and social history. A large number of German, French, and East European scholars have contributed to this enterprise.

1.3 *Historiography of Ancient India: The Indian Contribution*

A large body of Indian scholars started research on ancient Indian history following the lead of the European scholars. Their work was heavily focused on archaeological evidence, especially the study of inscriptions. The archaeological work, by Europeans and Indians, helped move back the known beginning of civilization in South Asia to about 3000 BC through the discovery of the Indus valley civilization. The work of the Indian Indologists also reflected the new-found nationalistic pride in the glories of ancient India. Some of it focused on traditions of democratic/oligarchic politics and developed statecraft to challenge the notion that these were European imports into India. However, the central concern of the earlier work was with the meticulous reconstruction of dynastic history, especially the correct chronology. Some scholars like R. K. Mukherji and R. C. Majumdar did research on the history of Indian cultural influence in south-east Asia and invented the now discarded notion of Greater India.

1.4 'Orientalism': A Controversy

Edward Said's *Orientalism* (1995), which projects the view that western scholarship on Asia projected the notion of an inferior 'other' of Europe and thus reflected the new relationships of power generated by imperialism, has had a seminal influence on the historical work on South Asia (since 1980) even though Said's primary point of reference was the Middle East. The controversy generated by this work has drawn attention to the many strands of Orientalist studies in the West and to the fact that French and German studies of South Asia do not project any unquestioned superiority. For ancient India, the controversy has led to more research on western historiography than to any reorientation in exploration of substantive themes.

1.5 *Indology after World War II*

The post-World War II historiography of ancient India has moved away from these earlier preoccupa-

tions and, under the influence of Marxism as well as anthropology, concerned itself with discovering structures like feudalism and patterns of large-scale social change over time. The writings of D. D. Kasambi (1965), R. S. Sharma (1990), Romila Thapar et al. (1990) are prime examples of this initiative. The multi-volume *History and Culture of the Indian People* edited by R. C. Majumdar (1951–1969) reflects a more traditional approach, while Louis Dumont's *Homo Hierarchicus* (1972) applies Levi-Strauss' structural analysis to the study of the caste system.

2. *Historiography of the Indo-Islamic Period*

The thirteenth century saw Turkish and Afghan dynasties and tribes, Muslims by faith, firmly established as rulers in many parts of India. The sultanate based in Delhi, where there was a succession of dynasties, became the seat of a pan-Indian empire with fluctuating boundaries. These dynasties were succeeded by the Mughals or Timurids in the sixteenth century and their effective rule lasted until the late eighteenth century. This long period, marked by the encounter between the older Indian civilization and the religion and culture of Central Asia's Islamic peoples, has been the subject matter of a rich historical literature.

2.1 *The Medieval Persian Chronicles*

India's central Asian invaders brought with them a rich tradition of historiography. This literature, written mostly in Persian, is known as *tarikhs*, a term, translated as annals. The *tarikhs* are narratives of dynastic successions, wars and conquests. Some of the writers had leanings towards Islamic fundamentalism and hence were inclined to present the wars of the Muslim invaders and Hindu dynasts as *jihad* or 'holy' wars. These accounts were later used by some British writers to project the Indo-Islamic era as an age of Muslim tyranny. This perception informed the ideology of India's proto-nationalism, which saw the struggle of the Rajput clans and other Hindu chiefs to retain their territories as the Hindu struggle for independence. However, chronicles provide ample evidence of a pragmatic bent in the policies of the Muslim kings, anxious not to alienate their Hindu subjects. The historians at the court of the third Mughal emperor Akbar, project his policy of peace with all, which was not to the liking of the more orthodox elements at his court. One component of the historical literature of the period is the memoirs written by the emperors, Babar and Jahangir and by Babar's daughter, Gulbadan. These sensitively written accounts offer a portrait of the age and the family life of the Mughals.

2.2 Regional Histories

The Indo-Islamic era also produced a rich and varied body of historical writings written in the regional languages. Best known among these are the Marathi *bakhars*, modeled on the Persian *tarikhs*, the chronicles of the Ahom kings of Assam, known as *buranjis*, and the *Madla Panji* retained in Orissan temples which recorded the annals of the local dynasties. Besides these, the Vaishnavas in Bengal produced a body of hagiographical literature celebrating the lives of their founder, Chaitanya and other pioneers of the movement. All these products of the period have been later used to reconstruct the history of the period.

2.3 Colonial and Post-colonial Historiography of the Indo-Islamic Era

The earliest 'modern' historical writings on the Indo-Islamic era go back to the nineteenth century. Works like Orme's *History of Indostan* are amateur efforts focused on the political history of the period. The famous collection of selected source material, translations from the Persian chronicles, Eliot and Dawson's *History of India as told by her own Historians* (1981), contain introductions which are essentially historical statements. One of the compiler's stated objects was to prove how very inferior 'Muslim rule' was compared to its British counterpart. In general histories of India, written by administrator-scholars like Vincent Smith (1981) the same concern to prove the superiority of British rule is less obviously present. It only appears as a view of Indian history which projects a long-term proneness towards political unification that finally succeeds only under the British. Such works contain an implicit evaluation of moral and material welfare of the people in pre-British times. The twentieth-century economic historian W. H. Moreland (1920) undertook a comparison between India at the death of emperor Akbar with conditions in the nineteenth century. Serious academic research on the Indo-Islamic era, based on the study of the chronicles as well as documentary evidence like the *akhbars* or newsletters of the Mughal period, belong to the twentieth century. It produced magnificent works of scholarship like Sir Jadunath Sarkar's multi-volume histories of Aurangzeb and the later Mughals focused on political narratives. There were other studies dealing with the religious policies of the Mughals and art and architecture of the period. The burgeoning nationalist consciousness sought to emphasize the syncretist traditions of the Indo-Islamic era, implying that the conflict between communities was a product of British rule.

Since World War II, a major development in this field of study resulted from the work of a group of scholars based at Aligarh. Irfan Habib's *Agrarian System of Mughal India* (2000), drawing upon a wide

range of source material, was hailed as a path-breaking contribution to the study of agrarian history. The research of the Aligarh 'school' uses the methods of modern historiography and has drawn upon a vast quantity of new material. While some of the scholars subscribe to Marxist theories of history, the impact of Marxism is not very obvious in their work.

In recent years some Western historians have projected the view that the Mughal empire, like all its predecessors in India, was a 'segmentary state' under a thin veneer of centralization. This has led to a controversy with some of the Aligarh historians.

3. Historiography of the Colonial Era

3.1 Colonial Historiography under Colonial Rule

British historians writing in the colonial era produced a large body of works which recorded the history of the conquest, the wars with indigenous powers, and histories of the local powers like the Marathas, Sikhs, and Mysore with whom they had to contend for power. These histories are in the purely narrative mode, supplemented by ethnographic accounts of various elements in Indian society. They are informed by a simple assumption regarding the legitimacy and naturalness of the British conquest. One of the pioneers in the field, James Mill (Mill and Wilson 1997), writing in the early decades of the nineteenth century, first projected a clear notion of cultural and racial superiority, significantly absent from earlier British writings on India.

British writings in the latter half of the nineteenth and early decades of the twentieth century often assumed a defensive posture in response to the growing nationalist criticism of their rule, especially the charge that the colonial nexus had induced a drainage of resources from India, thus steadily impoverishing the country. British historians challenged this view and instead projected a picture of economic transformation and development as a result of colonial rule. This controversy has not yet died out. The British historiography of colonial rule before World War II almost entirely focused on the activities of the government. A number of studies dealt with individual viceroys. Some twentieth-century works briefly refer to the burgeoning nationalist movement (one historian described it under the heading 'Political Sentiment') but with one exception they dismissed it as a phenomenon not to be taken seriously until the very eve of the transfer of power. However, the British colonial historiography increasingly adopted the methods of modern research with its emphasis on 'objective' analysis of records. But since the records in question were for the most part products of the colonial government, the resulting research inevitably reflected the built-in bias of the documents, a bias which the

historian generally shared. Indian historians, excepting those writing on economic history, rarely ventured into comments on the history of British rule. Exceptions to this pattern were the publicists writing on the rising of 1857 (one of whom described it as India's First War of Independence) and authors who considered British rule to be beneficial for India. The strong ideological and political undertone manifest in the historiography of the colonial era has assumed more subtle forms in the post-colonial period.

3.2 *Historiography of Modern India after Decolonisation*

Since the transfer of power in 1947, attention has shifted from the working of the British administration to the structure and dynamics of indigenous politics, though a number of monographs on the political history of the Raj, as well as its administrative and constitutional initiatives, were written during this period. Indian historians now came to be deeply concerned with the history of the Indian nationalist movement and its social-cultural origins. A group of historians approached the subject from the overt perspective of nationalism; others were influenced by Marxist class analysis and saw Indian nationalism as an expression of colonial bourgeois aspirations. A group of British historians centered at Cambridge explored the close relationship between British administrative and colonial initiatives on the one hand, and the structure and dynamics of indigenous politics on the other. The competition between those who were admitted to a share in power by the colonial ruler and those who were not was seen to be the central feature of indigenous politics. Nationalism itself was perceived to be a strategy reflecting the aspirations of the 'have-nots.' This view was questioned by Indian historians who saw the thesis as a continuation of the old colonialist perception dismissing nationalism as a conspiracy of the self-seeking few. However, the thesis was directly, or indirectly, questioned outside India as well. A group of historians under the leadership of Professor Low of the Australian National University recognized the reality of Indian nationalism and proceeded to unravel its local and class roots. American scholars brought to the subject the insights of social sciences, especially sociology and anthropology. There were considerable developments in economic history, using economic theory as well as statistical methods. The new techniques were used to tackle the old questions regarding the negative or positive impact of colonialism. The debate, as noted, remains inconclusive. The inadequacy of statistical evidence is one reason for this state. It should be noted here that Indian historical research has now become an international enterprise to which the Japanese, Russian, and continental scholars have made significant contributions.

One major new development in the subject is centered on the series of publications entitled *Subaltern Studies* (Guha et al. 1988). Borrowing the concept of the Subaltern from the Italian Marxist, Gramsci, the contributors to this series have focused on the history of the underprivileged elements in South Asian society and used the post-modernist techniques of discourse analysis to unravel the autonomous consciousness of the dispossessed and the record of their resistance to exploitation and domination by the elite. This movement, too, has become an international enterprise with historians and social scientists from all parts of the anglophone world contributing to the *Subaltern Studies*.

Pakistani historians and their pre-independence predecessors who focused on the development of Muslim consciousness and aspirations in the sub-continent have been deeply influenced by the theory of two nations, the ideological basis of the demand for Pakistan. Their perception is in sharp contrast to the nationalist perception of co-existence and mutual accommodation between the major ethnic cultures of the region. The history of Sri Lanka, despite its many links with the civilization and society of the mainland, has been unjustifiably peripheral to the concerns of the historians of India. But there was a strong tradition of historiography in the region drawing, *inter alia*, on the Buddhist religious texts for the ancient period. Some of the products of this historiography are influenced by Marxist theories of history.

One marked feature of developments in the historiography of modern India is the diversification of its subject matter. History of art and its links with nationalist sentiment, women's studies, and ecological history are some of the areas explored in recent years. This has helped bring the subject within the sphere of contemporary intellectual interest and brings to an end its intellectual isolation.

Historiography and Historical Thought: Southeast Asia

Embracing the southeastern peninsula of Eurasia and the Indonesian and Philippine archipelagoes, Southeast Asia has recorded its history in a dozen written languages and countless oral traditions. Indic models of writing were influential in the millennium before 1200 CE, and Chinese and Islamic ones in the subsequent six centuries, while European enlightenment interpretations of history became increasingly dominant in the nineteenth and twentieth centuries. Diversity has always been a hallmark of this region. The Vietnamese emulated the Chinese literary tradition with their dynastic chronicles; cyclical Indic ideas had a longer career in the Theravada Buddhist societies of the mainland, while linear Muslim and Christian ideas became influential in the islands. Nevertheless, synchronicities are apparent in the developments within seemingly autonomous literary and historiographic traditions.

Oral poetry and traditions were important for most peoples, but particularly for those in the highlands and eastern islands (including the Philippines) which did not absorb Indic or Chinese literary forms. As late as the 1960s, at least one people in Roti (near Timor) retained oral historical narratives which accurately recorded the names of chiefs for three or four centuries. Most of the written chronicles which took shape in the sixteenth and seventeenth centuries incorporated older traditions with the repetitive features of oral narrative.

1. Chronicle Traditions

The dynastic chronicles of Vietnam were expressed in Chinese and followed the model of didactic Chinese chronicles heavily informed by the moral perspective of Tang and Sung Confucianism. Some such work survives from the fourteenth century, but the most important is the strictly Confucian chronicle composed by Ngo Si Lien in 1479. This in turn incorporates the *Dai Viet su ky* of Le Van Huu (1272), which included a historical justification for the independent imperial status of Dai Viet—then occupying little more than the Red River delta.

The remaining written traditions grew out of Indic models in Sanskrit and Pali, or in the Malay case from Islamic writing in Arabic and Persian. Sacred histories, in Mon (the then language of what is today southern Burma), Burmese, and Khmer, as well as in Pali, traced the establishment of Buddhist law and practice from the time of the Buddha to the founding of local temples in Southeast Asia. Among the earliest examples are the northern Thai *Mulasasana* (around 1420) and the Pali *Jinakalamalipakaranam* (1516), both written by monks in Chiang Mai.

Royal and dynastic chronicles are almost as old. The *Pararaton*, a unique chronicle in old Javanese of the Javanese kingdoms of Singosari and Majapahit down to 1481, was written after the fall of Majapahit to Muslim forces around 1527. The earliest extant *yazawin* (royal genealogy or chronicle) in Burmese was written by the monk Shin Thiawuntha in 1520. Dynastic chronicles (*phongsawadan*) were being compiled in Thai from at least the sixteenth century, although the Luang Prasoet text conventionally dated 1680 is the oldest of the extant versions which have come down to posterity. Written by an astrologer at the cosmopolitan court of King Narai (1657–1688), this chronicle marks a trend to more secular dynastic history well aware of Siam's position among its neighbors as well as European, Indian, and Chinese visitors.

The advent of Islam created more discontinuities in the south than Theravada Buddhism did in the north. As Southeast Asian Islam shifted from an Arabic to an indigenous idiom in the fifteenth and sixteenth centuries, the Malay language written in Arabic script

became its favored vehicle. Only in Java and South Sulawesi, and of course in non-Muslim Bali, did the older literary idiom and alphabet continue alongside the Arabic/Malay one. Probably the oldest extant Malay chronicle is that of the Kings of Pasai, in north Sumatra, the first substantial Islamic state in Southeast Asia, from the 1290s. This text, *Hikayat Raja-raja Pasai*, is known in only one copy, made in 1814 from an older version held in Demak, the fifteenth-century capital of Muslim Java. Since it ends with the story of the fourteenth-century conquest of Pasai by Hindu-Buddhist Majapahit (Java), and the bringing of many Pasai Muslims as captives to Java, its kernel may have originated with this group of Malay-speaking Muslim exiles. It represents a collection of semi-mythical stories about the Pasai kings, much more reflective of local oral traditions than of mainstream Islamic historiography.

Several Malay texts celebrating other royal lineages, first written down in the sixteenth or the early seventeenth century, take this story-telling mode to a high art form extremely illuminating for the historian, though usually devoid of chronology. The *Hikayat Banjar*, for example, tells the story of the establishment of the leading Islamic state in southern Borneo through a conservative ethic extolling the virtues of a Javanese cultural model. Much the best-known text of this genre is the 'Genealogy of (Melaka) Kings' (*Sulalat'us-Salatin*), a version of which Thomas Raffles printed and popularized in 1821 under the name 'The Malay Annals' (*Sejarah Melayu*), in a conscious attempt to provide a national history for Malays. It weaves through a host of lively anecdotes its political message that the great metropolis of Melaka fell to the Portuguese in 1511 because the fundamental contract between ruler and ruled was violated by the last Melaka ruler. Originating in some form a generation after this Malay disaster, the text appears to have been essentially created in the early seventeenth century by the Johor writer Tun Seri Lanang, though subsequently much modified. Not much later in time, but a great deal more Islamic in spirit, was the encyclopedic 'Garden of Kings' (*Bustan as-Salatin*), written by the Gujarat (India)-born theologian Nuruddin Ar-Raniri around 1640. Written in Malay at the behest of the Sultan of Aceh, in northern Sumatra, this includes a substantial chapter on the history of Aceh, and another on Melaka, and represents the most skilful use in Malay of Islamic traditions of historiography.

Java's conversion to Islam was a turbulent and drawn-out process centered in the fifteenth and sixteenth centuries. The syncretic Islamo-Javanese courts which emerged from it produced a chronicle tradition in Javanese verse known as *babad*, part mythical, part prophetic and instructional, and part genealogy. The central narratives designed to show the legitimacy of kings descending through the complex upheavals of the wars of Islamization are collectively known as the *Babad Tanah Jawi*. All modern historians, beginning

with Raffles, have drawn on this set of traditions, although the task of editing a canonical text has so far defeated modern scholarship. The most chronologically accurate of the early Javanese histories, the Kartasura verse chronicle *Babad Ing Sangkala*, was written in 1738 but thought to incorporate a particularly accurate text originally compiled before 1670.

A particularly interesting school of historical writing developed in South Sulawesi (Celebes) in the Makasar and Bugis languages. The written syllabary was only introduced (probably from southern Sumatra) in the fifteenth century, and appears to have been especially valued for the recording of aristocratic genealogies. Marriage alliances among the numerous Bugis and Makasar states required a careful chronicle of previous marriages and begettings going back to the supernatural origins of the leading families. From around 1600, genealogies were developed into state chronicles at Makasar, then a major maritime power much influenced by Islamic and European literary models. From the 1620s, this chronicle tradition could draw on court diaries, which recorded royal births, deaths, and marriages, as well as notable foreign visitors, wars, and innovations. Keenly aware of chronology, the state histories adopt a critical tone towards their sources, a distinctly linear notion of the progress of the kingdom through various innovations, and a desire to learn from failures as well as successes. The Goa (Makasar) chronicle began with an explanation of why it was important that future generations remember the past, 'to avoid the twin dangers, either of our thinking that we were all great kings, or of others alleging that we were worthless.'

2. An Autonomous Modernity?

While the seventeenth century witnessed remarkable new departures in historical writing, there was a further development in the late eighteenth century of more abundant historical writing in a self-conscious, secular, and historically careful pattern in several Southeast Asian traditions. While the better survival of manuscripts written after the wars of the eighteenth century may be one explanation, there also appears to have been a creative sense of crisis among Tai and Vietnamese writers in particular which gave rise to reflection on the past. An early sign of this trend was U Kala's *Great Chronicle of Kings* (*Mahazawingyi*), the first comprehensive and chronologically reliable Burmese chronicle, written in the 1720s. In the late eighteenth century this was incorporated into the first history which might be called national, the 'New Chronicle of Myanma' (*Myanma Yazawin*), also the first to use its sources in a critical sense.

Among Vietnamese, the new trend was embodied by the scholar-official Le Quy Don (around 1726–1784), who wrote a Le Dynasty history in biographical form,

often also referred to as a national history—*The Complete History of Dai Viet (Dai Viet Thong Su)*. His encyclopedic *Miscellaneous Records of Pacification in the Border Area (Phu Bien Tap Luc)* is a careful accumulation of primary sources relating to technological, economic, cultural, and political developments in the southern Vietnamese kingdom (known to foreigners as Cochinchina) which was a rival of his own. The Tai kingdoms endured a mauling from Burma in the late eighteenth century, and virtually all responded in the period 1790 to 1830 by carefully reconstructing their histories with a view to avoiding such disasters in the future. In Java for a similar reason there was a spate of chronicle-writing after a long period of warfare ended with the peace of Gianti in 1755.

3. European Influences

These elements of modernity all preceded any direct European influence on the writing of history. The nineteenth century, however, gave rise to numerous writers who were in contact with European scholar-officials with their own agendas for gathering histories of Southeast Asian societies. Among the earliest of these were writers in Malay who cooperated in the quest for manuscripts of English and Dutch officials. Munshi Abdullah bin Abdul-Kadir (1797–1854) was a Malay writer for Stamford Raffles, and used his understanding of British mores to launch a critique of the Malay society of the sultanates. In his vivid autobiographical works, *Hikayat Abdullah* (1849) and *Hikayat Pelayaran Abdullah* (Chronicle of Abdullah's Voyages), he introduced such concepts as progress, race, freedom and the rule of law into Malay historical writing. The Riau court writer Raja Ali Haji (around 1809–1870) was in regular contact with the Dutch Malay scholars of his day and learned something of their perspective on history. The spirit of his two outstanding histories, *Genealogy of Malay and Bugis Princes (Silsilah Melayu dan Bugis dan sekalian raja-raja-nya, 1865)* and *The Precious Gift (Tuhfat al-Nafis, around 1866)* is nevertheless heavily didactic in the best Islamic tradition.

European writer-officials brought to the study of Southeast Asia an approach often extremely skeptical of chronicles, and more concerned with the written records of European travelers and the epigraphic and archaeological evidence from the early states. Beginning with Stamford Raffles' *History of Java* (1817) there was a fascination with the ruins of vanished kingdoms, and a tendency to find their successors in a state of decline which could only be reversed by European rule. The Edinburgh-trained doctor John Crawfurd (1783–1868) deserves particular attention as an historian and encyclopedist of Southeast Asia as a whole. His *History of the Indian Archipelago* (3 Vols., 1820), followed by the *Descriptive Dictionary of the Indian*

Islands and Adjacent Countries (1856) covered almost the whole region, based on first-hand knowledge of Java and Singapore as an administrator, and the official missions he led to Burma, Siam, and Vietnam in the 1820s, each of which yielded published reports which began the rendering into English of the chronicle traditions of these countries.

The Philippines was the area best endowed with early European writings because of the prominence in the colonization of the islands of Spanish religious orders, each of which produced chronicles. Among the best of these, containing much material about the pre-Hispanic Philippines, were those of the Franciscan Marcelo de Ribadneyra (1601), the Jesuit Pedro Quirino (1604), and the Dominican Diego Aduarte (1640). An outstanding later example of the genre was the 14-volume chronicle of Spanish and missionary activity in the islands by the Recollect Juan de la Concepcion (1788–1792). As nineteenth-century Spanish accounts became ever more negative about the achievements of Filipinos, the first generation of nationalists turned for inspiration to the oldest of the Spanish secular writers, Antonio de Morga, whose *Sucesos de las Islas Filipinas* (1609) received its first modern edition in English in 1868. The intellectual pioneer of Philippine nationalism, Jose Rizal, published in Paris a new Spanish edition of the work in 1890, with the professed intention 'to awaken your [Filipino] consciousness of our past, already effaced from your memory, and to rectify what has been falsified and slandered.'

As Southeast Asia became partitioned among the colonial powers in the second half of the nineteenth century, the more talented colonial officials pioneered modern-style 'national' histories in English, French, and Dutch. These usually combined some of the chronicle record of ancient kingdoms, the interventions of foreigners, and the rise of colonial power within the borders later marked out by the colonial powers. Sir Arthur Phayre, an army officer who spent the years 1835 to 1867 in key posts in Burma, was the first of these with his *History of Burma* (1883), followed in 1926 by a book of the same name by G. E. Harvey. Adhémar Leclère wrote a *Histoire du Cambodge* in 1914, some time before the more demanding equivalent for Vietnam, *Histoire Moderne du Pays d'Annam (1592–1820)* (1920), by Charles Maybon. A history of Siam was first published in French on the basis of missionary accounts by Turpin in 1771, but the first of the modern European histories was that of the British Consul in Chiang Mai, W. A. R. Wood (1926), relying much on the chronicles.

Sir Richard Winstedt consciously shaped the Malay-language school syllabus with his revealingly-named *Tawarikh Melayu* ('Malay,' not 'Malayan' History, 1918), in collaboration with Daing Abdul Hamid. Winstedt's English-language *Malaya and its History* began its many editions in only 1948, long after the more blatantly imperial *British Malaya* of Sir

Frank Swettenham (1906). The best of the early Dutch writing on the archipelago was devoted to particular kingdoms and culture areas, particularly Java, though the encyclopedic *Oud en Nieuw Oost-Indien* (8 Vols., 1724–1726) of the protestant pastor Francois Valentijn ranged widely. Only with the need for text-books in Netherlands-Indian schools was there a coherent set of ‘national’ textbooks written, of which the most influential work was the Dutch-triumphalist *Geschiedenis van Nederlandsch Indie* (1930) of F. W. Stapel.

4. Nationalist History

All of Southeast Asia except Siam/Thailand was under Western colonial control from 1900 to 1941, and was ruled by the Japanese for nearly four turbulent years (1942–1945). The sudden Japanese surrender in August 1945 inaugurated a period of revolutionary struggles in the successor states, with relative peace imposed on Indonesia only around 1966, Vietnam after 1975, and Cambodia in the 1990s. The first half of the twentieth century was a period of extraordinary debate and rethinking of the meaning of history, as a Western-educated generation increasingly detached from cultural connections to the past developed new ways of using it for their modernizing purposes. First Social Darwinism and then Marxism were seized upon as means to explain what had to be done to save the nation from colonial humiliation. By the 1950s, a nationalist, anticolonial historiography was dominant everywhere except Malaya/Malaysia and Thailand, turning militant opponents of the colonial order into the most exemplary heroes. Marxist categories were selectively adopted, often to devalue the precolonial past as generically ‘feudal.’ Debates remained intense between communist, religious, and ethno-nationalist readings, and often between local and national perspectives.

In Indonesia, nationalist writers suddenly occupied center stage when the Japanese occupation removed all Dutch textbooks. Muhammad Yamin (1903–1962), a Sumatran convert to a Java-centric view of nationalist history, became the most influential writer and patron of a nationalist history which glorified Sriwijaya and Majapahit as precursors of modern Indonesia. His work on the fourteenth-century Javanese kingdom of Majapahit, *Gajah Mada* (1945) and *Tatanegara Majapahit* (3 Vols., 1962), has long-term significance.

In Thailand a similarly influential figure through the most nationalist phase was Wichit Wathakan (1898–1962), a commoner who became an immensely popular writer of historical novels and plays, as well as a 12-volume world history (1931). After the anti-monarchy revolution of 1932, he replaced Prince Damrong Rajanubhab (1862–1943) as the government’s arbiter of culture and history. Where Damrong had chron-

icled a Thai identity developed from the monarchy’s gradual adoption of liberal modern values, Wichit glorified the purity and heroism of the Thai race.

In Vietnam the debate between traditionalists, nationalists, and Marxists centered around the evaluation of the Nguyen dynasty which came to power with some French assistance in 1802, and of the Tay Son rebellion which preceded it in the late eighteenth century. Tran Trong Kim (1883–1945), author of the first modern Vietnamese history (1928, constantly reprinted until the 1960s) and briefly Prime Minister under the Japanese, broke with the dynastic chroniclers in accepting the Tay Son leader Quang Trung as a national hero. Nevertheless he accepted the first Nguyen emperor Gia Long, who defeated Quang Trung’s forces, as a dynastic founder and unifier. Dao Duy Anh’s *Short History of Vietnamese Culture* (1938) was the first and perhaps best of the Marxist-influenced studies which saw Vietnamese culture as constantly evolving through social forces. For later Marxists, the Tay Son were heroic peasant rebels, and the last dynasty a disaster which failed to adapt to historical conditions.

5. Historiography of Southeast Asia as a Whole

These nationalist preoccupations allowed little incentive for indigenous historians to enquire into larger Southeast Asian historical patterns except through the Marxist mold. One of the few exceptions is Nguyen Van Huyen (1908–1975), later Education Minister in the Hanoi government. As a student and Vietnamese teacher in Paris he discovered Dutch scholarship on Indonesia, and used it to good effect in his study of common patterns of housebuilding in the region—*Introduction à l’Etude de l’Habitation sur Pilotis dans l’Asie du Sud-est* (1934).

For the most part it was European scholars interested in the precolonial history of the region who found a broader regional perspective useful. German-speaking prehistorians like Heger and Heine-Geldern were the first to use the term in describing the presence of bronze-age Dongson drums throughout the region, or similarities in temple architecture. French scholarship of the 1920s and 1930s began to uncover the relations between the ancient kingdoms of Angkor, Champa, Pagan, and Java. George Coedès (1886–1969) first brought this material together in a path-breaking book he entitled *Histoire Ancienne des États Hindouisés d’Extrême-Orient* (Hanoi, 1944), though better known in its English translation (1968). Coedès broke with the ‘Greater India’ school which regarded the Southeast Asian kingdoms as Indian colonies, but continued to see Indian agency through visiting traders and scholars. Later historians such as Paul Mus, J. C. van Leur, Bernard Groslier, Ian Mabbett, Oliver

Wolters, and Claude Jacques, and still more the nationalists, were inclined to see Southeast Asians borrowing selectively and creatively what they found useful in Indian civilization, and even sharing in the creation of that civilization.

Histories of the whole region began to appear in English in the 1950s, the most influential being that of D. G. E. Hall (1955), who came to the first British chair of Southeast Asian History, that of the school of African and Oriental Studies (SOAS) in 1949, after an early career (1921–1934) at the University of Rangoon. The other colonial seedbed of historians of the region was the University of Malaya, opened in Singapore in 1949 and eventually spawning a range of institutions in independent Malaysia and Singapore. Such regional historians as Northcote Parkinson, C. D. Cowan, John Bastin, Wang Gungwu, Alistair Lamb, David Bassett, Jan Pluvier, Anthony Reid, Leonard Andaya, and Barbara Andaya learned their craft in these institutions.

The US borrowed from the British tradition initially, with first D. G. E. Hall and then Oliver Wolters pioneering the teaching of the subject at Cornell University. The first generation of American-trained historians, generally studying the dynamic of diverse nationalisms, were less inclined to perceive the region as a whole. The most important US history of the region to date, *In Search of Southeast Asia* (Sleinberg 1971), required the collaboration of six country specialists and is basically divided by country. In contrast, the *Cambridge History of Southeast Asia*, (Tarling 1992) took the heroic line that each chapter should be chronologically and thematically demarcated, but cover the whole region. This ambitious experiment was dominated by historians based in Australia, New Zealand, and Southeast Asia, reflecting a shift which had occurred in the previous two decades.

The approach of Fernand Braudel and the Annales School was brought to Southeast Asia in the 1980s in relation to the Early Modern, a period which had until then been largely abandoned to the 'European expansion' school. Denys Lombard (1936–1998), a colleague of Braudel and founder of the interdisciplinary journal *Archipel*, developed in *Le Carrefour Javanais: Essai d'Histoire Globale* (3 Vols., 1990) the kind of 'total history' pioneered by Braudel. Anthony Reid (b. 1939) found both the broad interdisciplinary and the ocean-centered focus of Braudel useful in giving coherence to his *Southeast Asia in the Age of Commerce, c.1450–1680* (2 Vols., 1988–1993).

In global terms, the practice of history in Southeast Asia since 1950 has been relatively weak in economic and institutional history, and has produced few outstanding biographies or intellectual histories in the strict sense. Its strengths have been its interdisciplinarity and its deep concern to explicate cultural diversity and autonomy. The two Southeast Asianists who have most influenced historians were trained in other disciplines. The cultural anthropologist Clifford

Geertz (b. 1926) defined his task as 'to uncover the conceptual structures that inform our subjects' acts,' and likened it to 'trying to read (in the sense of 'construct a reading of') a manuscript—foreign, faded, full of ellipses, incoherencies, suspicious emendations, and tendentious commentaries.' Though history is never absent from his numerous studies of Java and Bali, it is most salient in *Negara: The Theatre State in Nineteenth Century Bali* (1980), which influentially argued that elaborate royal rituals were the defining acts of Bali states, not simply their decoration or arcane cosmology.

Anglo-Irish Benedict Anderson (b. 1936) made his career at Cornell University, where his brand of culturally-informed political history had more influence on historians than on his own discipline of political science. His pathbreaking *Imagined Communities: Reflections on the Origins and Spread of Nationalism* (1983) was preceded by a series of more specific studies on Javanese and Indonesian political culture, and the influence of the Japanese occupation on them. In the 1980s, deeply alienated from Suharto's Indonesia, he produced revisionist essays which placed the histories of Thailand and the Philippines in a broader political economy perspective. Among the able historians trained at Cornell, Michigan and elsewhere were a number of Southeast Asians who had an impact in their own countries as well as internationally. Reynaldo Ileto (b. 1946) pioneered a new kind of history from below by beautifully demonstrating how popular Christianity provided the idiom of resistance in his *Pasyon and Revolution: Popular Movements in the Philippines* (1979). Nidhi Aevriongse wrote almost entirely in Thai after returning to teach in Chiang Mai, but his revisionism has shifted Thai historiography away from the agency of kings and Westerners to the social basis of cultural change.

Historiography and Historical Thought: Sub-Saharan Africa

The discovery of Africa as an object of scholarly research is part of a wider expansion of academic pursuit. It coincided with the emergence of women's studies. The focus of investigation shifted to the underdogs, including slaves, colonized nations, and other silent majorities of our day as well as the Middle Ages, in Africa, and elsewhere (Wachtel 1971, Clancy 1979, Ginzburg 1980, Feierman 1993).

This article concentrates on sub-Saharan Africa. It covers recent origins of written history, the 'discovery' and valuation of its oral traditions, the interaction of anthropology and history, the Anglo-American debate, and the role of the diaspora.

1. Origins of History

The first Sahel states emerged on the northern fringe of the savanna: Ghana (eighth to the eleventh century), Mali (thirteenth to fourteenth century), and Songhay (twelfth to sixteenth century).

Arab authors were the most knowledgeable on Africa's past. Those who made the largest contributions to reconstructing the history of Africa, and western and central Africa in particular, include al-Bakri (1029–1094), al-Idrisi (1154), al'Umari (1301–1349), and Hassan Ibn Mohammed al-Wuzza'n, known as Leo the African (1494–1552). Ibn Khaldun (1332–1406) is unquestionably the 'Father of History,' even though Ibn Battuta (1304–1369) remains the best thanks to his personal accounts and the detail in his descriptions (Levtzion and Hopkins 1981).

Written European sources followed, beginning in the fourteenth century. Their authors were Portuguese navigators. These documents preceded the substantial

addition made by codification or oral records in Arabic by Mahmoûd Kâti and Es-Sa'di, both Timbuktu scholars.

In the course of the nineteenth and twentieth centuries, accounts written by Africans in indigenous languages have abounded. A large share of these histories was in Kiswahili, Hausa, Fulfulde, Kanembu, Diula, and Malagasy.

The first professional historians, caught in the Hegelian trap, discounted the history of Africa (Neale 1986, Jewsiewicki and Mudimbe 1993, p. 1). However, the continent and its 'people with no history' were deemed worthy of a present. Ethnography was called upon (Jewsiewicki and Mudimbe 1993, p. 8) to justify the backwardness of the region. Underdeveloped Africa was expected to make do with a 'prehistory' (Moniot 1991, p. 197).

The International African Institute was established in London in 1928. The School of Oriental and African Studies began in 1948 to teach a new subject called history of Africa (Vansina 1992, p. 77). An overdue offspring of academic research was born. Curiously, African universities in French colonies, the local intelligentsia, and their backers in France did not see any need for the discipline (Vansina 1992, Moniot 1995, p. 647).

2. History and Anthropology

Almost eight years after publication of *African Historiographies* (Jewsiewicki and Newbury 1986), Jewsiewicki and Mudimbe published *History Making in Africa* (1993). The majority of the authors who contributed to the former work were historians. Anthropologists dominated the latter. This shift in the weight accorded to the two disciplines is a sign of the times. When focused on Africa, anthropology and history do not fit neatly into the university compartmentalization scheme. Rebellious grassroots reality has gradually overcome the rigidity that had governed the allocation of professorships.

As time passed most of the convenient cubbyholes have been banned to the realm of memory. It was once the fashion to contrast societies with no history, acephalous, precapitalist societies, with societies blessed with a state and a history culminating in capitalism. The first group was viewed as inherently handicapped by communalism, polytheism, oralism, and tribalism. The second group of nations was endowed with the virtues of individualism, monotheism, literacy, and polity, to name just a few. Criticism of the concepts of tribe and ethnicity took two different approaches, a French school and an Anglo-Saxon school (Coquerel 1983, Young 1986, Chrétien and Prunier 1989, Barber and Moraes Farias 1990, Coplan 1991, 1993, van Jaarsveld 1992, Harries 1993, Jenkins 1997).

The adoption of precolonial Africa as a concept for a catchall analysis of the continent marked a milestone. This approach created the illusion of a different, idealized world. Postcolonial Africa was viewed as the child of a past to which the umbilical cord had been severed. This is the country cherished by the nationalists during their struggle for independence and the image invoked by politicians. Cheikh Anta Diop was fond of climbing the continent's family tree back to its glorious Egyptian ancestors, while Joseph Ki-Zerbo (1972) and J. F. Ade Ajayi convey us to a not so distant past, labeled the precolonial era (Mudimbe and Jewsiewicki 1993, pp. 1–2). Historians responsible for this breakdown into periods have changed their minds and now support the anthropologists' view of the existence of a continuum between the colonial societies and their worthy successor, sovereign Africa (Bayart 1989, Paillet 1987).

The focus of historians on the past and the concentration of ethnologists on the present explain the farsightedness of the former and the shortsightedness of the latter. The outlook of these two isolated disciplines changes radically as soon as historians discover humanity as the center of their field of investigation and anthropologists take account of time, the framework for human behavior, and activity.

3. *The Silent Make Themselves Heard*

Africa is known for its chanted, sung, or simply recounted oral history. The *griots*, professional chroniclers of West Africa, the *biiru*, specialists in Rwandan royal ritual, ordinary storytellers in the cities and the country have provided a wealth of material to researchers accustomed to studying written material.

In 1962, Jan Vansina published his authoritative work, *De la tradition orale*. His name is invariably associated with the acceptance of oral accounts as a source of African history and with the elaboration of a rigorous scientific method. It took historians, or at least part of their fraternity, a long time to learn to appreciate the 'auriture' of oral genres (Coplan 1991, 1993, p. 8).

Zealous pursuit of sources engenders such excesses as equating the death of an old timer with the gutting of a library. This attitude refers us to a kind of precolonial library, to paraphrase Mudimbe. It is also called the memory of the griots and 'oral archives' (Bazin 1979, p. 450). Writing history Western style entails the fault of reducing documents recorded by interviewers to simple sources. This is denounced by Jewsiewicki (1986, p. 16) and Schoenbrun (1993, p. 55).

An increasing hue and cry (Farias 1992) has been raised in opposition to this tendency. The critics are anxious to upgrade the role of reputedly passive traditionists (Ba 1980). While David W. Cohen (1989,

p. 12) insists on the contrast between material provided by the Africanist community and that produced by Africans who collect data on a daily basis, Jan Vansina was an early advocate of another reading of these documents, as revealed in a text of Jewsiewicki (1979, p. 81).

As soon as we escape the pull of the two fetishes constituted by the roving reporter and the Western-style historiographer, we are attracted by other types of history, and vice versa. We can then pay heed to nonformalized oral texts, unofficial samples taken from lower rungs of the social ladder. Their particular form and their non-verbal character require another method of analysis, yielding a more fertile approach to Africanist research (Olivier de Sardan 1976, Diawara 1990, Barber 1991). The field is further enriched by the involvement of anthropologists who tap the upstream end of oral production and characterize its interface with society (*surface sociale*). Their tools bridge a major gap neglected by historical studies which concentrate entirely on the oral text and lose sight of the life, environment, and experiences of participants in society (Moniot 1986, p. 58).

The history of the continent has become a professional endeavor. It involves 'interrogating and revealing the historian's operation' (Moniot 1995, p. 647). From now on, the Africanists can forget the 'automatic legitimization of being specialists in a small exotic field' (Cooper 1995, p. 236).

4. *The Anglo-American Debate*

Vansina (1992, p. 91) takes advantage of the lessons of historiography consisting in recognizing the past in the present and vice versa, and aims his harshest criticism at the postmodern drift of David W. Cohen. The latter (1994, p. XV) stresses the fact that historical knowledge is not the monopoly of poetry or formalized narratives but that it is constantly being proclaimed and cited. Henige (1995, p. 314) vehemently attacks what he calls Cohen's 'predilection [...] for subordinating the substance of sources to their interpretation'.

5. *The Diaspora Includes Africa; in Fact, it Is Africa*

What position do African specialists take in this controversy, which almost boils down to an 'American-American' debate? Jewsiewicki (1986, p. 9) makes a statement that has lost none of its pertinence for historians and other Africanists. 'The Africanist historian and the African historian share neither the same responsibilities nor the same existential constraints' (cf. Vansina 1994, p. 221). This is certainly true, except that another schism has split the African scholars' camp, divided between a diaspora and a home com-

munity, and occasionally bridged by a coming and going between the two shores. Africans abroad still focus more on debates that are often kindled overseas, in America or Europe.

Nevertheless, practically everything written is in the language of academics, which is not the idiom of indigenous populations. A UNESCO policy to remedy this situation, adopted in the 1970s, remains a pious vow even though issues of *l'Histoire Générale de l'Afrique* have appeared in Kiswahili and Hausa. Anyway, who is able to read them? Where can you get a copy and what would it cost? Does the body of literature constitute history for the average person? The question posed by the *African Historiographies* subtitle, 'What history for which Africa?' is as relevant as ever. The role of Africans in this international forum appears to be rather marginal. The empire of Western historiography is bigger than ever (Vansina 1994, p. 220). The hopes raised by studies in the English-speaking world, which benefits from the North American alternative to the intellectual heirs of the British Empire and from a more substantial organization (Jewsiewicki 1986, p. 15), continue to fade. In the meantime, the New World option has become an attractive outlet for the brain drain from tropical dictatorships. Zaire has forfeited its chances to develop a school of thought liberated from the domination of Brussels. The ex-colonies reproduce the models elaborated in the former centers of colonial power (Chrétien 1997) despite the fact that English-speaking and French-speaking African authors have begun to read one another's works (Coquery-Vidrovitch 1997). Their marginality becomes even more pronounced as the tendency to consume (È Nzièm 1986, p. 25) concepts developed outside Africa grows. It makes little difference whether they are the products of non-Africans or of Africans of the diaspora, which never stops expanding (Jewsiewicki 1979, p. 81).

Intellectual dependence resembling the economic impasse of the continent is worsening. While additions to the circle of recognized Africanists are becoming rare, a heavy storm of productivity is brewing in Africa, as far as reading about and interpreting the past are concerned. Student theses, cassettes recorded by individuals in different villages, radio stations, and other relevant institutions are mushrooming. The harvest has never been so bountiful (Cohen 1994, p. XV, Diawara 1997).

This analysis is not intended to deny the essential, unanticipated impact of African studies on social sciences in general. The 'dissolution of world history' by the history of Africa is a reality (Feierman 1993). In evaluating African studies, one is inclined to dismiss the crucial role played by the diaspora, which actively propagates its share of the African experience (Macamo 1999). Expatriates are deprived of their birthright by attributing any success they achieve to their severance of ties to their dismal native lands in the tropics. Mudimbe and Appiah (1993, p. 113),

referring to the impact of African studies on American disciplines, cite the necessity 'to locate ourselves as much in the current history of those disciplines as in the current state of African Studies [...].'

In fact, a wider influence of African studies on intellectual life is detected—in Western Europe and elsewhere as well as in America (Feierman 1993, p. 200, note 13). The impact of Africanist historiography on that of France, the former métropole, is undeniable (Coquery-Vidrovitch and Jewsiewicki 1986, pp. 143–44).

A glimpse at what is on the horizon suggests the tide is turning, the groundswell stemming from the unprecedented creativity of local bards, both griots and other producers of historical material. This resurgence is amplified by a foreign legion, which gives a boost to those who have remained on their native soil. Hope is raised by the fact that disciplines applied to Africa are inevitably linked to academic trends in Europe and the US. No longer cramped by a narrow view of a particular field of study, Africanists have demonstrated the benefits of multidisciplinary collaboration. In addition, Africanists have been instrumental in fostering a dialog and creating an interface between traditional academic approaches in Anglo-Saxon and French-speaking countries.

M. Diawara

History and Literature

Literature and history have many things in common, and one of them is the aesthetic form of narration. The many contemporary experiments notwithstanding, modern historiography and the modern novel still share the common feature of narration. In narratology, some theoreticians have differentiated between the narrative modes in the two fields; others have shown how they conflate and that they can hardly be distinguished. This article wants to show what narration in literature and history has in common and in what respect the two modes differ from each other.

For Aristotle (see Chapter 9 of his *Poetics*) the matter of the division of labor between historiographer and poet was easily decided: the historiographer relates 'what has happened' and the poet 'what might happen'. In contrast to Plato's devastating criticism of literature, Aristotle considered poetry to be of high value. In his eyes, literature dealt with problems of a more general and thus more significant nature, while the historian had to report about specific, and thus, less important matters.

Until approximately 1750, historiography was considered a branch of literature. Since the eighteenth century (when Aristotle's distinctions were rediscovered), the differences between the two disciplines have been stressed, and it was only then that the term 'literature' became synonymous with 'poetry' and 'fiction.' Gottsched and Lessing still shared Aristotle's prejudice against history. For them the field of history was merely a quarry from which they mined some of the raw material they used to build their preconceived

literary plots. Of real importance to them was a moralistic story, and examples were taken from the repertoires in the areas of history, legend, and mythology. However, the late eighteenth century is an important turning point. As Koselleck has demonstrated, it is the time of the development of a genuinely new philosophical awareness about history (Koselleck 1976). The concept of a continuously progressing history as such replaces both the religious concept of a Christian teleology as well as the idea of history as a chaotic conglomerate of countless individual stories of an exemplary nature. Through this philosophical development, literature is seen as part of history, and thus it loses its Aristotelian superiority.

Today the relationship between fiction and historiography poses a number of hermeneutic questions, and there is no modern Aristotle who might offer a simple and acceptable solution fitting for our time. Narration can be viewed as one of the primary tools of knowledge, and it determines the structure and aesthetic form in the presentation of a real or a fictional event. Narration discloses the dimension of historical reality as well as the sphere of poetic fiction. The logic of narration provides access to the logic of historiography and fiction; it makes the structure of both historical consciousness and fantasy tangible. In every narrative, real or fictional events are supported by a structure through which happenings are accentuated, selected, or eliminated according to the law of relevance. Neither in historiographical nor in fictional narration are we dealing with a reproduction or duplication of events, but with a certain organization of actual or imaginary occurrences or experiences.

1. Narration in Historiography

Perhaps because it is so difficult to liberate it from its established forms, narration is constantly under attack. In the discussion of modern historiography from 1970–2000, it looked as if 'narration' would be replaced by 'description' and 'explanation.' 'Historiography,' Szondi argued, must 'divest itself increasingly of its narrative character'; narrative historiography must 'turn into description if a new concept of history is to do justice to our knowledge of history as an anonymous process, as a sequence of events and changing systems' (Szondi 1973). The arguments of the antinarrativists can be summarized in the following way: the narrative recording of events in historicism was based on the belief that history was made by individuals. However, this categorization did not adequately take into account the development of social processes. Processes and structures can only be described, not narrated. Thus the old '*histoire événementielle*' has to be replaced by the new '*histoire structurale*.' 'The nouvelle histoire' of French historians in particular, with their descriptions of structures

underlying long periods of time, and their quantifying methods, forced the old paradigm of writing history by narrating events into a defensive position (Furet 1982, LeGoff and Nora 1974).

However, according to some historiographers, history as a narration of events and history as a description of structures are not mutually exclusive. These historiographers concede that history as a narration of events is no longer the center of the historiographer's work and that it no longer provides the obvious support of historical writing. Nevertheless, they also concede that narration is allowed to stand as a possibility alongside the writing of history as a structural analysis of processes (Borst 1976). Other scholars will have nothing to do with a strict separation of the two methods and point out that narration and description are intertwined. The argument is that the fact that modern history is a series of processes, it can only be understood through the alternate explanation of events through structures and vice versa (Koselleck 1976 and Kocka 1984). Although the structures become more accessible through description and events through narration, nevertheless in practice it would be impossible to maintain a demarcation between the two methods. The complementary characters of description and narration are increasingly emphasized (Stone 1979).

The defenders of the descriptive method like to confront the narrators among the historiographers with their lack of theory. They assert that the historiographer must not only narrate but also explain, and that this is only possible by means of a theoretical concept of the realities, as it has long been practiced by social scientists. The proponents of the narrative method in writing history defend themselves vehemently against the charge of being anti-theoretical. From their initially defensive position, they have turned to attack. Danto has asserted that narration is vital for description and explanation; that the form of narration is at the same time a form of explanation. The narrative form always surpasses the given, and categorically uses all-encompassing concepts. Narrative structures influence our historical thinking in the same way theories do in the case of the sciences (Danto 1965). Ricoeur expresses the same idea in his phrase 'to tell a story means to explain it' (Ricoeur 1983). Rüsen agrees that narration is part of the logical structure of historiography and that consequently 'description and explanation have a function subordinate to the narrative scheme' (Baumgartner and Rüsen 1982).

2. Narration in Literature

In connection with Gottfried Benn's poetics, Grimm described a type of novel from which the narrator had disappeared. It was called 'the novel of the phenotype'

or 'the inward directed novel,' labels indicating a tendency toward lack of action and lack of characters (Grimm 1963). The world and its events are banned here. The reduction of the 'I,' the isolated subject, is significant for this novel: the 'I' speaks only of itself. Consequently, one reads in Rilke's *Aufzeichnungen des Malte Laurids Brigge* from 1910: 'It must have been before my time that stories were narrated, really narrated. I have never heard a person narrate a story.' Benjamin's discussion of the decline of storytelling in his essay *Der Erzähler* about the Russian writer Nikolai Lesskow echoes Rilke's statement (Benjamin 1972).

The aesthetic designation of the phenotype novel—exemplified in the novels of Virginia Woolf, Benn, and Rilke—is also appropriate for the writing of some contemporary authors; the authors of the French '*nouveau roman*' (like Alain Robbe-Grillet) as well as postmodern American writers (like William Gass) and contemporary German authors (like Peter Handke) come to mind. In the novel of the avant-garde (Joyce, Dos Passos, Gide, Döblin, Musil, Broch), narration was either complemented or largely replaced by montage techniques and cognitive means, by reflection or essayistic writing. Here it was not so much a matter of narration of events, action, and mimesis as one of the presentation of ideas and the provision of knowledge (Hinck 1995).

However, the best-known postwar novelists (like Garcia-Marquez, Vargas Llosa, Philip Roth, Bellow, or Grass) uphold traditional established narrative models. One can write purely narrative novels. However, nonnarrative epic fiction is nonexistent. Like historiography, the novel obviously cannot dispense entirely with narration, and thus it makes sense, now as ever, to adhere to the science of narrative technique (Lützel 1986). In the field of narrative technique, literary scholars are far ahead of the narratologists in the camp of the historiographers. Historians could learn from reader theories as developed by such literary theorists as Jonathan Culler ('the competent reader'), Umberto Eco ('the model reader'), Stanley Fish ('the informed reader'), Wolfgang Iser ('the implied reader'), Michel Riffaterre ('the superreader'), and Gerald Prince ('the narratee') (Culler 1975, Eco 1979, Fish 1970, Iser 1974, Riffaterre 1971, and Prince 1982).

3. The Conflation of Historiography and Fiction

In *Metahistory*, Hayden White draws interesting parallels between historiography and fiction. He strives for a poetics of historiography and attempts to describe the forms of historical presentation in order to compare them with literary forms (White 1973). White starts with the premise that no sequence of events—by itself—is a story; it is the task of the

historiographer to transfer the events, the facts, to the narrative framework of a story. The connections between happenings do not occur spontaneously; they are the result of the historiographer's reflection. In each historiographical text, White distinguishes between the 'what' (the narrated events) and the 'how' (the type of narration, the 'emplotment'). He was not the only scholar to see that historiographical and fictional narration are related, but he was the first to make a systematic attempt to study the structure of historical consciousness—to show the fictional elements and their formal manifestations in historiography.

The situation in nineteenth century historiography and philosophy of history serves as an example. White could have given his book the title *The Rhetoric of Historiography* as a parallel to Wayne C. Booth's 1961 study *The Rhetoric of Fiction*. In *Metahistory* he concludes that the writing of history has little to do with such qualities as true or false, correct or incorrect, and that ultimately historical writing cannot be distinguished from fiction. The historian's style, White argues, depends on the combination of the following elements: first, there are three different strategies; he calls them 'explanation by formal argument,' 'explanation by ideological implication,' and 'explanation by emplotment.' Specific modes of articulation correspond to each strategy. In this context we are only interested in the strategy of 'emplotment' (narration) with its four corresponding 'poetic' modes of 'romance,' 'comedy,' 'tragedy,' and 'satire.'

White's references to certain structural similarities between the unfolding of tragedies or comedies and that of historical representations are interesting, but these similarities should by no means be construed as an actual fictionalization of history. Demandt has shown how thought-structures were mirrored in the poetic metaphors used by historiographers, and how, in turn, the ideologies of the historiographers influenced their use of rhetorical figures (Demandt 1978). However, the use of metaphors does not signify a fictionalization of history. There exist basic narrative concepts that are equally valid for historical and for fictional narration. Without action, images, and metaphors, narration *per se* is unimaginable.

Returning to White's example of the different depictions and interpretations of the French Revolution, it is evident that this is not a case of fictionalization because the historical process is not depicted as an 'as if,' but as something that actually did occur. No one will deny that the depiction of history is a creative process. However, its qualitative difference from fictional narration remains, despite the use of literary interpretation patterns and flowery metaphors. While fiction has as its basis the so-called 'as-if' structure, and thus proves to be pretense, illusion, and unreality, historiography always relates to actual events. Hamburger clarified the difference through the example of a historical report about

Napoleon and a novel about the French emperor. The historiographer cannot see Napoleon 'in the subjectivity, the ego-originality of his inner thoughts, of his very "existence."' If he does so, however, we 'find ourselves in a novel about Napoleon, a piece of fiction' (Hamburger 1968).

The narrative techniques with which novelists depict the psyches of their characters have been analyzed by Dorrit Cohn. She differentiates between psycho-narration, quoted monologue, and narrated monologue (Cohn 1978). These are narrative techniques reserved for fictional narration, which cannot occur in historical writing. Just as the use of a literary (tragic or comic, for example) interpretive category cannot turn a historical narrative into a fictional one, a historical novel does not become a piece of historiography simply by including historical reality in the fictional field. Käte Hamburger validly defines the line between fiction and reality, 'where there is no crossing over from one category to the other,' when she discusses the different perceptions of mimesis in novel and historiography. According to her, there is a definite relationship between the narrating process and the narrated material in historiography, while characters created by novelists are simply narrated persons. In fiction, there is no relationship, only functional context, between the narrating process and the narrated material. In other words, the fictionalization of the persons described consists in the fact that the characters are not presented as objects but as subjects, as 'ego-origines' (Hamburger 1968).

This difference between historiography and fiction also becomes evident when we look at the results of more recent studies of the theory of functionality. Assmann has shown that scholars in the fields of analytic language philosophy and of pragmatic communication theory insist on this distinction (Assmann 1980). In the analytic philosophy of language the point is made that fiction has a very peculiar status as far as its logic of statements is concerned: the authors of fiction are not obliged to come up with any proof; their judgments are quasi, pseudo, or as-if statements. In communication theory, fictionality is studied with respect to its reception effects: it involves the elimination of the normal connection that exists between the participants of an act of communication. Dealing with fiction leads to a temporary liberation from thinking in terms of fixed institutions; it means the absence of social sanctions and a lack of verification.

4. The Concepts of Truth

Historia vero testis temporum, lux veritas, vita memoriae, magistra vitae, nuntia vetustatis: Cicero's classic definition of the function of historical writing is still valid today—with a few deviations and reservations. The modern formulations are somewhat less pre-

tentious, but given such terms as 'demand for truth,' 'imparting of meaning,' 'provision of identity,' and 'memory,' the function of historiography is not defined so differently from Cicero's wording. Only the postulate '*magistra vitae*' is viewed more skeptically. Authors of novels are equally concerned with the pursuit of truth, the imparting of meaning, the provision of identity, and memory. Friedrich Schlegel wrote in his introduction to the *Wissenschaft der europäischen Literatur*: 'As history aims at recognition and truth it approaches science, but as it is also representation (...) it is related to art.' Here the double-faced aspect of historiography has been precisely formulated.

No historiographer would be so arrogant as to assume that his or her report could encompass the whole truth of a historical event. Historiography can claim with justification that its statements are 'truthful' insofar as they have been gained 'scientifically,' that is in so far as they can be proven. And they can be proven because they can be proven wrong: the truth capacity of the narrative statements of historical writing is based on the fact that they can be falsified. In this respect, one can imagine no greater difference between historical writing and fiction.

Since the statements of a novel are fictional to begin with, they cannot be falsified. While writers of fiction may embellish an event from the past with fantasy, historiographers must check the sources, which dictate what they cannot say. The truth of a poetic statement is not achieved by fiction imitating the principles of historiography. The propensity for truth and truthfulness itself are presented differently in the two narrative modes. The intent to provide the truth does exist in both literature and historical writing, but it is aimed in different directions. Historiographers attempt to achieve the most exact comprehension and representation of actual historical events; novelists have no such ambition. On the contrary, their strength lies not in the realm of facts but in that of possibilities.

The aesthetics of the modern as well as of the postmodern novel are focused on the opening up of possibilities. Modernist literature aims to distance itself from the mimetic-realistic principle that dominated the novel of the second half of the nineteenth century. Musil, for example, in *Der Mann ohne Eigenschaften*, plays with several types of utopias and arrives at the category of 'possibility,' in opposition to confidence in the power of history. The same is true in the postmodern novels of Thomas Pynchon.

5. The Concept of Totality

In examining the truth postulate in literature and historiography, one must consider the premises on which historical and novelistic narration are based. In traditional narration the novelist, like the historiographer, is guided by ideas of totality as we know

them, on the one hand from the aesthetics of Hegel to Lukács, and on the other hand from Hegel's and Marx's substantialist philosophy of history. In both cases, the attempt is made to see events in such a way that they make sense within the context of a totality. Here the historical and artistic totalities are structurally identical. Danto has criticized as outdated the substantialist philosophy of history, with its concept of a teleological, continuous development. He states that this philosophy acts as if it knew of a 'divine plan' of history, as if one could determine past and present from the perspective of the future. Danto wants to replace the speculative and dogmatic substantialist philosophy of history with an analytical (descriptive and coordinating) theory of history. In this theory, the vantage point would not be from a postulated future goal back to the present and past, but rather from the past to the present, with no certainties about the future (Danto 1965). The ancient trust, reaffirmed by Nietzsche, in the continuity of history is questioned, as are the Christian and Marxist tenets of the eschatological or utopian direction of history.

Such beliefs once formed the foundation for the concept of continuity in history. Many contemporary historians shun these labels and are consequently faced with two choices: giving up the concept of continuity altogether, or adopting it from the tradition of historiography and perhaps developing it in their own fashion. Historians at present are more aware than ever of the heuristic character of the concept of continuity; they see it merely as a 'regulative idea' in historical narration (Rüsen 1982). Today the focus is more on discontinuity. In this respect the impact of Foucault as an outright anti-Hegelian thinker (especially with his 1969 study *L'archéologie du savoir*) is not to be underrated.

The dismissal of the concepts of continuity and totality has also had an impact on the writing of the novel. The idea of the 'self-contained' work of art that provides totality by way of typical characters is dead. Its place has been taken by the 'open' novel with its open-endedness, as first envisioned by the early German Romantics. In his *Theorie des Romans* (1916), Georg Lukács declared that the modern novelist could outdo the historiographer if, after the loss of totality of meaning and being, he or she would counter the partial insights into the course of history with concern for a new, homogeneous cosmology. In contrast, however, the modern novel plays an important role as an instrument of cognition because such concepts of systems are now distrusted. Not a new cosmology of being, but a view of the disparity of what is to be, of the diversity of possibilities, is what this medium can provide.

In twentieth-century philosophy, a similar discussion to the one between Plato and Aristotle about the truth-value of fiction took place. Adorno was convinced that, due to its autonomy, art 'as a creative, nonalienated work' was the last vestige of freedom.

According to him, art and literature alone can unveil what is hidden in reality and can destroy ideology and lies (Adorno 1970). What Adorno criticized as a web of ideological deceptions is close to what Roland Barthes calls the 'mythicizing' of everyday life. Like Adorno, Barthes affirms that poetic language maintains direct contact with reality and, unlike historiography, escapes mystification (Barthes 1957). In contrast to Adorno and Barthes, Eagleton and Jameson argue that the writing of literature is just another form of ideological production (Eagleton 1976). Jameson maintains the following position: 'Ideology is not something which informs or invests symbolic production; rather the aesthetic act is itself ideological, and the production of aesthetic or narrative form is to be seen as an ideological act in its own right' (Jameson 1981).

All four authors make extremely one-sided statements. The common ground of historiography and literature is narration. And when narration, through the eyes of Jameson, is seen as an ideological act per se, we cannot expect much truth in either historiography or fiction. But if, on the other hand, literature is able to destroy ideology and deception—to cite Adorno—this virtue should also be attributed to historiography. Narration can lead in both directions: it can help to approach truth, or it can produce ideological veils. Neither literature nor historiography is immune to the virus of error or the distortion of truth, but both are capable of making reality be seen more clearly.

6. Meaning, Memory, and Identity

Among the functions of historiography and the novel are, along with the search for truth, the imparting of meaning and the provision of identity. The imparting of meaning (*Sinnbildung*) is far from the creation of meaning (*Sinnstiftung*) (Rüsen 1982). Surely there were, and still are, historiographers and novelists who have declared themselves ideological creators of meaning, but neither modern novelists nor critical historiographers are interested in such ambitious goals. In historical narration, the imparting of meaning is achieved through memory alone. And although novelistic narration cannot be reduced to memory, it plays an important role here as well. This is especially evident when historians fail to bring to mind certain aspects of historical experience through memory; then it is often the novelist who must assume this task. The 1950s in West Germany provide a clear example of this phenomenon. With regard to the National Socialist past, repression rather than grief was prevalent. It was a novel that broke this taboo: *Die Blechtrommel*, by Günter Grass (1959). This literary breakthrough was followed by the works of the historiographers. George Steiner listed a number of examples of this function of the 'writer as remembrancer' (Steiner 1973). It is

particularly in cases of the conscious falsification of history by historians that the writer steps in.

Writers and historiographers can help define the identity of a generation, a nation, or a culture. Since the Enlightenment and secularization, historiography and fiction have been burdened increasingly with the function of providing an identity. By dealing with memories, the experiences of the present attain a coherent perspective that provides the reader with an orientation for the future. Repeatedly correlating experiences of the present with those of the past can bring about the dissolution of stagnant patterns of identity, with a critical view of ideological prejudices (Lützel 1998). The factual orientation of the historiographer as well as the novelist's interest in what is possible are part of the provision of identity. By means of memory, a potential of historical and literary meaning is activated that, along with the demonstration of actual limits and the allusion to yet untested possibilities, makes the provision of identity possible. Historical and literary consciousness is a complex construct in which memory is the prerequisite for interpretation and expectation. To structure an identity means, first, to identify with stories. During an identity crisis, society may show greater interest in historical remembering (as was the case in Europe in the nineteenth century), or demand a fictional provision of identity (as is presently the case in Latin America). The weaker the link with the historical past and the more suspect it appears, the stronger will be the desire for fictional patterns of identity.

History and Memory

1. The Alliance Between History and Memory

1.1 Remembered History

Before history is registered, chronicled, and interpreted by professional historians, it is witnessed and remembered by those that are contemporary to it. Such a memory of experienced history is necessarily

partial, biased, subjective, and, therefore, also highly variegated. While the present of experience is witnessed as a rather formless, dissonant, and even chaotic mass of perceptions, actions, and events, it assumes a much more unified shape and meaning when it is transformed into what is called the 'past.' To some extent, the multifarious, disrupted, and inchoate experiences of the former present are preserved in personal memories, if they manage to resist the tendency to adapt to the retrospective interpretation and normalization of the past. For many historians, there is very little overlapping between the present as experienced and witnessed and the past as reconstructed by historians (Koselleck 1997). While individual experience is particular, partial, and extremely limited in perspective, the reconstructed past provides a coherent and inclusive view of what was never in this way to be witnessed. In contrast to the past, the present does not produce a common reality that can be experienced by the witnesses in a similar way.

The plurality of lived experience and the unified reconstruction of history, however, are not fixed in a radical polarity. These poles are mediated in many ways, bringing the realms of present experience and retrospective history closer together. The personal experience of history is not only radically subjective, it is also shaped by the generalizing and collectivizing factors of social norms and cultural knowledge. Individual behavior and memory is not wholly erratic because it is stamped by generational patterns of experience, which means that it is already to some extent embedded in and framed by collective and cultural constructions of history.

It is true that personal memories of history differ as one individual life differs from another life. This, however, does not exclude certain similarities arising from biographical patterns. These life patterns with their respective perspectives, challenges, and responsibilities have their impact on the constitution of memories. The second world war, for instance, is remembered differently by the different nations as it is obviously remembered differently by the victims, the perpetrators, and the bystanders. But even among the Germans, it was remembered differently by different generations, by men and women, by those who remained in place and those who were forced to migrate from east to west. It is the task of the oral historian to acknowledge these individual and collectively typical memories as historical sources and to investigate history from below, collecting the various points of view of those who did not plan and control history but who were affected and afflicted by it.

There are other reasons why the singularity and interiority of memories should not be overestimated. Memories are generated in the individual very much like the linguistic capacity and in accord with it. They are elaborated and stabilized to the extent that they are transformed into narratives and exchanged in social

interaction. The memories of an individual are always supported and warranted by the memories of other individuals. Subjective memories are embedded in familial interaction and social communication. As individuals share the memories of their parents and grandparents, the range of remembered history is extended over three generations. Thus, an embodied and participatory historical memory of approximately a 100 years, is built up by oral transmission.

The three-generational oral memory is transient and perishes continually with every new cycle of oral memory that is built up. This continuous fading out of remembered history is a normal, natural, and necessary process of social forgetting which wipes the slate clean for following generations and their experiences. An exception to this rule occurs when the remembered history has an heroic or traumatic character. In cases of historical triumph or trauma, arts of memory are devised to stabilize the otherwise transient memory and anchor it in the consciousness of following generations (Giesen 2000). The survivors of the holocaust are bearers of such a memory which by a general cultural consensus is to be made permanent. The transformation of personal memories into cultural memory is achieved by media of memory such as writings, films, museums, monuments, and video testimonies.

In societies without writing, historical consciousness is divided into a recent and a distant past. The recent past is the three-generational oral memory which is transformed continually over time while the distant mythical past is a heroic memory which is preserved by epic poetry and other ritual and ceremonial arts of memory. This cultural heritage is re-enacted periodically and celebrated in public festivals by the community and carefully preserved and transmitted by bards and other memory specialists.

1.2 Commemorated History

Experiential subjective memory is embedded in collective memories of a widening scope: that of social interaction and that of cultural identity. The boundary lines between individual, collective, and cultural memory are not water-tight, but, as Ricoeur has put it: *'mémoire privée et publique se constituent simultanément selon le schéma d'une constitution mutuelle et croisée'* (Ricoeur 1998, p. 32). While private memory is informal and erratic, public memory shows a much higher degree of organization. It is mediated, ritualized, and based on social institutions. Other than remembering, the term 'commemorating' refers to an intentional, formalized, and collective action. Public memory is built on a collective will and communal actions. In the transition from private to public and cultural memory, the media play an important role. It is particularly writing that has revolutionized cultural memory. Following the anthropologist André Leroi-

Gourhan, Jacques Le Goff has described the history of cultural memory in five stages as the history of changing media from orality and writing to ever more mechanical technologies of storing information (Le Goff 1986). Not only did it vastly extend the range of remembered history, it also liberated the poets from their traditional office of 'remembrancers,' setting them free for other, more individual tasks. There are two kinds of media with which the historical memory of a group is stabilized and transformed into an extended and continuous past: material media and performative media. Among the material media are books, photographs, films, monuments, relics, and other material carriers of signs that retain traces of the past and can serve as documentary sources in the reconstruction of history. The performative media are symbolic forms of action, such as rites, festivals, and ceremonies linked to symbolic dates. Traditions and celebrations periodically renew and revitalize the memory of the past through acts of repetition and commemoration. While the material media store information for later use, they tend to generate specialized knowledge and to externalize the memory of a group. It is, therefore, the function of institutions of education and the performative media to check this tendency and to restore the mnemonic quality of historical knowledge, to bring it back to popular consciousness, and to reconnect it with the realm of lived experience. Usually, material as well as performative media are involved in acts of commemoration. Halfway in between material and performative media are the modern mass media such as newspapers, cinema, radio, and television, not to forget the large historical expositions that are becoming more and more important in shaping an image of the past and providing occasions that trigger collective memory through public debates.

In addition to their personal, local, and familial recollections, individuals also hold a share in that 'corporate memory' (Lewis 1975) which is constituted by public symbols and rites of commemoration. 'Commemorative ceremonies are distinguishable from all other rituals by the fact that they explicitly refer to prototypical persons and events, whether these are understood to have a historical or a mythological existence' (Connerton 1989, p. 61). The creation of a corporate memory was the aim of ancient societies and was revived by the modern nation-state and other politicized groups. A corporate memory is extremely limited in scope. Unlike books and libraries, it cannot contain many and diverse historical events, nor does it do justice to finer distinctions. It selects only very few items and reshapes these historical events for its purposes. The long chronicle of history has to be condensed into a few poignant moments that acquire a high symbolic value for the identity of a nation and state. Examples for history telescoped in national memory are the 4 July in the US or the 14 July in France. Such regularly recurring dates provide occa-

sions for speeches and celebrations which re-invigorate both the corporate memory and the collective identity. In Israel, the historical event of the fall of Massada became a national cult in the new state. For many centuries, Massada had been forgotten in the Jewish tradition and was restored by historical and archaeological scholarship only in the 1960s. For an historical event to become an item of public memory, the event has to be taken out of its context and to be transformed into a symbol. Among the first to emphasize this was the sociologist Maurice Halbwachs who wrote in his book on the social frames of remembering: 'In order for a person or historical event to enter social memory, it has to be transformed into an instruction, a concept, a symbol. It is invested with meaning, it becomes an element in the system of ideas of a society' (Halbwachs 1985a, pp. 389–390). In the case of Massada, the political message of the historical event was coined in a poem by a Palestinian Jew who in the 1920s had written the line: 'Massada shall not fall again.' The memory of Massada was restored from Hellenic sources that had not been part of the heritage of remembered Jewish tradition (Vidal-Naquet 1981). This memory was 40 years later corroborated by archaeological findings which in themselves, however, were rather scarce. Before these long forgotten external sources could become a cornerstone in the construction of a national myth, they had to be reanimated and kindled by the spark of historical imagination. The story of Massada became a central point of reference in Israeli corporate memory, because in the new state, a new future required a different past (Lewis 1975).

In antiquity, the commemoration of historical events took the form of religious feasts which were celebrated annually like the feast of Passover in which the Jews commemorated their liberation and exodus from Egypt. Such events were integrated into the religious calendar with the effect of turning history into myth. The English still celebrate annually the memory of the attempted catholic assault on their parliament of 1605, with the folkloristic rites of the Guy Fawkes-day starting as early as in 1606. Another way to commemorate historical events is to celebrate them according to the 'round' decimal dates of chronology. In contrast to annual feasts, these cyclical patterns seldom recur in a life-time and, therefore, lack the repetitive structure which is necessary for a continuous memory. This form of long term commemoration already goes back to antiquity. There is a stela of Ramses II commemorating the establishment of the cult of Seth in Avaris after 400 years. As a practice of communal commemoration, however, the decimal pattern was introduced only in the early modern era. One of the earliest examples is the commemoration of Luther's reformation in 1615, 100 years after Luther's actions of protest at the Augsburg Reichstag. This mode of recalling past events via anniversaries in the decimal system has become the

dominant mode of remembering history in the nineteenth and twentieth century. Examples are the 500th anniversary of the Turkish conquest of Constantinople which was celebrated in Turkey in 1953 or the 500th anniversary of Columbus' discovery of the new world celebrated in 1992. Such events do not recur within the lifetime of individuals. Therefore, it is rather a mode of spotlighting historical dates than a form of creating a continuous, communal memory.

1.3 Myth and History

Myth has been established by theoreticians of the nineteenth and twentieth centuries as the inveterate antagonist of history. Myth and history were considered as two incompatible modes of presenting the past, the one in a cyclical, the other in a linear time frame. In this polemical constellation, the term myth was also associated with fabrication and lie, while truth and objectivity were reserved for history as presented by critical historians. Beyond these well-known connotations of the cyclical and the untrustworthy, the term myth has in the meantime also acquired the connotation of 'meaningful history.' 'Myths create meaning through which the past is linked to the present in such a way that it can orient the future' (Münkler 1994, p. 21). This description is not far from Assmann's definition of myth as 'imagined and remembered history' (Assmann 1992, see also Kirsch 1998). Myths are conceived by him as a complex of icons, symbols, and narratives about the past that define the cultural identity of a community. Such a communally imagined and transmitted past provides for the group the basic values that it needs for an explanation of the present and an orientation for the future. It is exactly this symbolic use of the past for the construction of an identity that was suspended in the process of professional historical scholarship as developed in academic institutions in the nineteenth century. In this specific sense, the term 'myth' is used as an antonym to (modern) histor(iograph)y; while the former refers to the presence of the past, the latter insists on the pastness of the past, enforcing 'a liberation of the present from the past' (Arnaldi 1974). In the era of historiographic scholarship, however, remembered history is not the opposite of factual history, on which it has to rely as its basis and source of correction. If myth is defined as remembered history, it is severed from other connotations such as 'lie,' 'imposture,' or 'sacred history.' It refers to 'a foundational narrative with the aim to illuminate the present by an account of origins. It is through remembering that history turns into myth. This does not mean that it becomes unreal. On the contrary, it is by turning history into myth that history becomes reality and assumes the quality of a normative and formative power' (Assmann 1992, p. 52).

Myth in this new sense of remembered history stresses mnemonic qualities such as symbolic power, narrative form, iconic impact, and a highly focussed and sensual form of relevance. Invested with a memorable shape, symbolic meaning, and pragmatic relevance, myth provides qualities that professional history had explicitly discarded. With a developed sense of the shortcomings of both myth and history, they are no longer confronted as antagonistic and mutually exclusive but rather seen as complementary modes of referring to the past. The mnemonic and symbolic use of the past is no longer perceived as an abuse but as an important social function which cannot be provided by scholarly historiography.

2. Memory and Historiography

2.1 The Identity of Memory and History

The relation between historiography and memory has itself a history which has evolved over various stages. Before the foundations of critical historical scholarship were laid in the eighteenth and nineteenth centuries, history, memory, and myth were not yet clearly distinguished. On the contrary, it was considered the central function of the writing of history to preserve the memory of a dynasty, the church, or a state in order to legitimize such institutions and to ensure their continuity by providing for them an honorable past. In this first stage, historiography was the foundation of the community and the 'handmaid of authority' (Plumb 1969). The *res gestae* of heroes and kings were sung by bards and written down by chroniclers in order to rescue them from oblivion and to establish an honorable memory for the noble dead.

Although a consciousness of a specific function of historiography was established in the writings of Herodotus, he emphasized in the proemium to his work the traditional link between history and memory. While giving up a strictly ethnocentric stance, history, for him, is still 'an art of memory' where 'memory' is closely related to 'fame.' His project claims to ensure 'that the actions of people shall not fade with time' and that 'great and admirable monuments produced by both Greeks and barbarians shall not go unrenowned' (Herodotus 1992, pp. 3–4, see also Hutton 1993). His historiographical project is aimed at fixing the events of the past in the memory of those to come. For Herodotus, the function of historiography was already twofold: it was divided into a memorial function and a cognitive function ('to set forth the reasons why they, i.e., the Greeks and the barbarians, waged war on each other'). The memorial function of historiography was never given up throughout Greek and Roman antiquity. Cicero still defined historiography as a weapon against oblivion, a formula that became a topos and was elaborated in the Renaissance. Official historiography of the Tudor dynasty in sixteenth century

England still counters oblivion which is personified as 'the ancard enemy,' 'the suckyng serpent,' 'the deadly darte,' and 'the defacer' (Campbell 1964).

The intimate link between memory and history shaped the historiographic genres in a specific way. It narrowed the criteria for the selection of persons and events to be memorized; only those of highest rank were singled out for a continuation in memory and only those feats and achievements were selected that contributed to the honor and fame of those that were remembered. In addition to this, only such events were selected that supported the opinions and interests of the ruling class.

The non distinction between memory and history is not only a feature of early stages of civilization but also a characteristic of authoritarian and totalitarian rule. But, whereas in the early stages neither media nor institutions had been established to back up an authority-independent account of the past, in later stages censorship had the function to destroy the rivaling media and carriers of counter histories threatening the security of the uniform view and authoritarian voice of history.

2.2 The Polarization of Memory and History

2.2.1 *The discrediting of memory by historians.* The second stage is marked by a separation between memory and histor(iograph)y. This distinction was established when professional historiography arose as an independent and specialized institution. It was not before the nineteenth century that historiography turned into an autonomous discursive discipline which set up its own standards of truth and authority, developing specific rules of verification and inter-subjective argument. The development of modern historiography as a cognitive enterprise has its roots in classical antiquity and was revived in early modernity. Histor(iograph)y started from memory and it reached its new status in emancipation from memory. Before the rise of critical historiography, history had been adapted to the demands of the present; it served specific functions for the state or community such as justifying the present, controlling the future and legitimizing authority. A critique of memory, therefore, was also a critique of power and authority. Critical historians insist on their distance to the institutions of corporate memory. Lukian called them 'apolis,' thereby indicating that they are not committed to the norms and ideals of a particular community. In spite of their ideal of objectivity, of course, even professional historians are not completely free from loyalties and prejudices. But the professional historian differs from others in that 'he is aware of this fact, and instead of indulging his prejudices seeks to identify and correct them' (Lewis 1975, p. 52). The criticism of historical memory not

only aims at filling its gaps and correcting its errors but also to expose the intentional fallacies and forgeries of memory, the constructions that secure the establishment and maintenance of power. Critical historiography sharpened its tools in the period of Renaissance humanism in the struggles for power and truth, but it developed its ideal in disinterested objectivity only in the nineteenth century. It was in this period that the links between history and identity were severed and historical knowledge turned into a rapidly growing mass of abstract, disconnected, and disembodied information.

2.2.2 The rehabilitation of memory by philosophers and historians. It was Nietzsche who saw a connection between the massive production of abstract historical knowledge and a growing apathy of cultural memory, which led him to express an urging demand for new and invigorated identities (Nietzsche 1988). According to Nietzsche, the historical disciplines had become a dangerous burden for the wellbeing of society. Scholarship produced a pathological form of memory without the possibility of forgetting, an ever growing archive of irrelevant data. Every group and collective unit, however, was in need of a clear cut and limited knowledge of the past, i.e., of a usable past. Nietzsche diagnosed for his age a severe crisis and pathology of cultural memory which had lost its capacity of limitation. For him, the important function of memory was not the storing of knowledge but the limitation of knowledge, the creation of profile and relevance in an indifferent mass of information. Historical knowledge was no longer a tool for the creation of a meaningful life but an oppressive burden that crushed identity and extinguished the sparks of creative energy.

Nietzsche's polarization of history and memory became a topos among historians of the twentieth century. The specificity of histor(iography) was defined in contrast to the demands and mechanisms of memory. When Maurice Halbwachs defined the mechanisms of social memory in the 1920s, he introduced history as a negative foil for the process. Halbwachs investigated the function of shared memories for the cohesion of groups. He spoke of a collective memory and showed that the group was sustained and nurtured by common memories as these memories were in turn sustained by the group. This means that the stability of memories is linked to the stability of groups; when its members are disseminated, the memories are also dissolved. Erratic and dissonant memories had no place in Halbwachs's functionalist and constructivist theory of memory. Halbwachs compared historical discourse to an ocean which swallowed up all the partial narratives and memories (Halbwachs 1985b, pp. 72–3). For him, histor(iography) is the universal memory of humanity, while collective memories are embodied by specific groups and therefore always

partial and biased. In order to integrate these memories into the total view of history, they have to be severed from their carriers and their social milieus. With this transformation of memory into the abstract scheme of history goes the evaporation of live experience and meaning.

Sixty years after Halbwachs, the French historian Nora has revived the concept of collective memory and dispelled lingering critical doubts about its theoretical status. He has extended Halbwachs' notion of an oral memory shared by a social group to a cultural memory of symbols, values, rites, and local traditions that provide the cohesive cement of a society. These shared elements Nora called 'lieux de mémoire,' reinterpreting a term from the tradition of Roman mnemotechnics, the 'imagines' and 'loci' of the '*ars memorativa*.' Like Halbwachs, Nora stresses the nexus between memory and group identity, and like Halbwachs, he distinguished the symbols of collective memory from the scholarly discourse of historiography. For Nora as for Nietzsche, embodied collective memory is threatened to disappear under the burden of academic historiography. Nora defines memory and history as polar opposites. For him, the decisive distinction is that between a lived past which he calls memory and an abstract past which he calls history. Memory links the past to a group, it creates an emotional and symbolically charged bond between the past and a collective identity in the present, while history severs this bond; it is universal in character, therefore it belongs to everybody and nobody (Nora 1984/1992, pp. 23–43).

Whereas the pioneers of critical historiography discredited memory as a rival of history, theorists such as Nietzsche, Halbwachs, and Nora rehabilitated memory over against the ideal of objective and abstract histor(iography). They rediscovered the social functions of memory as an important and indispensable mode of assessing the past. In spite of their evaluations of memory and history, however, they share with the representatives of critical historiography the attitude of polarizing memory and history. In their different writings, this polarization takes the following form:

Memory

- is an embodied form of memory
- stresses differences and exists in the plural
- is linked to a carrier which may be an individual, a group or an institution
- bridges the past, present and future
- is highly selective, includes forgetting
- creates a profile of values supporting an identity and providing orientation for action.

History

- is a disembodied form of memory
- provides a universal frame and exists in the singular
- is disengaged from specific carriers

- separates the past from present and future
- develops an even and impartial attention
- is in search for truth, therefore values are suspended.

2.3 Mnemohistory—New Affinities Between Memory and History

The third stage in the relationship between memory and historiography is marked by a blurring of the distinction between history and memory. This, however, does not imply a simple return to the first stage. Despite postmodern qualms and revaluations, the self-imposed disciplinary regulations that were installed with the modern institutionalisation of critical historiography as a scholarly and intersubjective project may well be considered an irreversible evolutionary achievement. Historiography, writes Le Goff, 'must aim at objectivity and must be built on a belief in historical truth' (Le Goff 1986, foreword). If the third stage is not to be described in terms of a regression, it is perhaps more adequately described as a response to certain tendencies towards an extreme historical positivism inherent in the second stage. The professional historians as exclusive guardians of the past are challenged by those who invoke memory as alternative modes claiming an access to the past. The term 'history' is a collective singular; to this concept corresponded the idea of history as a universal memory of mankind. To say that history is universal memory may be another way of saying that it is indifferent to memory. The price that had to be paid for this generalized memory was a disregard of living and preserved memories.

The object of modern historiography was a past that was neatly separated from the present and the future. The historian Koselleck (1997) has coined the terms 'space of experience' (*Erfahrungsraum*) and 'horizon of expectation' (*Erwartungshorizont*) and stressed the point that in modernity, both dimensions have become radically separated. Along the same lines, history was defined by the philosopher Blumenberg as 'the separation of the space of experience from the horizon of expectation,' i.e., as a fundamental rupture between past and future (Blumenberg 1986, p. 61). From this point of view, memory was the other of history because collective memory tends to bridge past and future, creating a usable past for a changing present.

After the long period of polarizing history and memory, new affinities were discovered between both modes of rendering the past. They were due to a number of reasons: the discontents with positivist historiography and transcendental historiosophy, a reorientation in methodology, and the establishing of new themes for historical investigation. To begin with the discontents. In the 1980s and 1990s the universalist frame of academic historiography was severely shaken

when repressive and homogenizing ideologies such as communism and colonialism lost their power. Since then, many diverse memories of political groups have asserted their right. Historians were baffled by the enormous impact of these living memories that they had considered to be a negligible entity and which had reappeared with great aplomb at historical turning points. At such moments of sociopolitical reversal, social institutions as well as the cultural frame of perception and values changed. In the course of such changes, new memories emerged and old memories were seen in a different light. It is at such historical moments that the conflict between history and memory rises to consciousness and becomes a political issue. With the reconstruction of the political framework of society, there is a chance to narrate the past in a different way. Such a moment of retrospection is often a moment of revelation; then it suddenly becomes obvious that what had been presented and taken as objective history had only been a particular and biased form of memory. The experience of a fundamental change of values exposes the contingency of earlier accounts of the past. In such situations memory becomes self reflexive, developing a sense of its own constructedness.

Another way of approximating history and memory was to be observed in changes in the methodology of the discipline. The journal *History and Memory* which was founded in 1989 signals a shift in historical interest. Two years before that date, an important debate had taken place between the nestor of German *Zeitgeschichte*, Martin Broszat, and the Jewish Holocaust survivor and Holocaust scholar Saul Friedländer. The controversy which they discussed in their exchange of letters revolved around the key concepts of memory and history (Broszat and Friedländer 1988). Broszat argued for a form of presenting history that moves from the past into the present, thus adopting the perspective of the contemporary observers who experience it as an open process. Friedländer, on the other hand, argued for a presentation of history starting from its manifest results and moving backwards to the beginnings, thus adopting the perspective of the memory of the victims. For Dan Diner, Friedländer's co-editor in *History and Memory*, historiography is no longer an objective universalist discourse but one that is ethically committed to the participatory perspective of the victims. Thus, the two terms converge, history becoming a form of memory and vice versa. In his latest book on the persecution of the Jews in Nazi Germany, Friedländer develops a form of historiography that is not confined to the description of structures and processes but also seeks to give a voice to individual victims and agents thus translating the anonymous statistics of the holocaust back into the memories of those who participated in and suffered from history (Friedländer 1998). In books such as this one a new methodology of history is being developed that seeks

to enlarge the scope of historiography by integrating personal memories into historiography. Instead of being unified by the authorial voice of the interpreting historian, historiography thus becomes multivocal, mixing history with memories. In blending what is known with what is remembered, historical discourse is opened up to include contingencies and dissonances, forgoing coherence and closure in favor of marking what otherwise remains unrepresented and unrepresentable.

A third possibility of crossing memory and history lies in the discovery of new themes for historiography. Since the 1980s, historians have become more and more interested in modes of remembering as a form of social practice. What was known of the past in the past, which images of the past were constructed, which acts of commemoration were devised? In asking such questions, memory became itself the object of historiography. This form of historiography was favored by medievalists, who had already been used to investigating social forms of religious and secular memorialization (Oexle 1995). Such interests brought about a form of historical investigation which can be termed *mnemohistory*. *Mnemohistory* is what could also be called 'the reception history of history.' 'It concentrates exclusively on those aspects of significance and relevance which are the product of memory' (Assmann 1997, p. 9). To speak in this context of memory rather than of tradition is to acknowledge the constructive as well as the distorting power of memory. It takes into account the ambivalence of the past both as a conscious choice and as an unconscious burden, tracking the voluntary and involuntary paths of memory. 'The task of historical positivism consists in separating the historical from the mythical elements in memory and distinguishing the elements which retain the past from those which shape the present. In contrast, the task of *mnemohistory* consists in analyzing the mythical elements in tradition and discovering their hidden agenda' (Assmann 1997, p. 10).

An early and impressive project in *mnemohistory* was organized by the French historian Nora who published seven volumes on what he called the French 'lieux de mémoire' (Nora 1984/1992). Nora designed this historical enterprise which he carried out as team work with eminent historians in reaction to the publications of the *Annales* school of French historiography. In the scholarly works of this school, which had concentrated on structures, figures and processes in a *longue durée* perspective, history had more and more lost its meaning and memorability. The palpable dimension of history was restored by Nora who created an inventory of *mnemo-historical* items which included historical sites such as Vézelay, rites and songs of folklore, national symbols, commemoration dates and festivals, and more than 300 types of cheese. They are the 'lieux de mémoire' that, according to Nora, have constituted the French cultural memory and identity since 1789.

2.4 Memory as an Empirical Basis for Historiography

It is not easy to predict the next phase in the relationship between memory and history. It is possible that after their convergence, new efforts will be directed at their separation. There is also a new interest in memory from the point of view of a new kind of empiricism that is probing the criteria for historical truth. While one variation of *mnemohistory* tried to integrate personal memories into history and another sidelined factual history in order to focus on a remembered, reconstructed, or even repressed and forgotten past, there are some signs now of a new anthropological empiricism which turns away from memory as a social and cultural construct and concentrates on the neurological operations of remembering and forgetting. In an article with the title *The Veil of Memory*, the historian Johannes Fried noted 'a frightening backwardness among historians as far as questions of memory are concerned' (Fried 1997, p. 8). After the growing fascination and even obsession of historians with questions of memory since the 1980s, this statement can only make sense when it is applied to questions of memory from the point of view of the human brain and the neurosciences. He is interested not in cultural memory but 'the factuality of memory, its conditions and its effects on the historian's sources' because 'the neural connections or the mental processes determine what is preserved and remembered, and thus all knowledge and all history. The same applies to forgetting. The veil of memory, the river of oblivion is constantly in flow between the historian and its object' (Fried 1997, pp. 14, 16–17). This knowledge of the operations of memory also includes the mechanisms of distortion as explored in cultural studies and the neurosciences in the last ten years (Schacter 1999, Schudson 1992). For Fried, however, the crucial question for the historian to ask is no longer: how are texts connected? but: how does memory work? At this point, we return to the lived experience of individuals witnessing history as the starting point for historiography which was treated in the first paragraph of this article. Fried, however, no longer discusses memory in an existential or in a social but in a biological and anthropological perspective. He argues that everything that the historian deals with is primarily mediated by the human memory. Therefore, the historian must have recourse to anthropological empiricism in order to 'see through all this memory-activity' and probe the truthfulness of his one and only reliable source which is, after all, human experience.

History and the Social Sciences

History and the social sciences have developed and maintained complex relationships made up of commonalities and differences as well as divergences and convergences. In principle, both disciplinary areas are concerned with the scientific study of the human life-world and the whole range of human behavior, individual and collective, in time and space as well as in the past and the present. Both disciplinary areas originated with the rise of the modern world as a common enterprise to develop systematic, secular, and empirically validated knowledge about the historical-social reality. In this fundamental sense, history can be and should be seen as part of the social sciences or vice versa the social sciences as part of the historical sciences—both constituted by substantially interrelated modes of sociohistorical research (Gulbenkian Commission 1996, Hall 1999).

Despite their fundamental commonality, however, history and the social sciences have followed quite different and diverging epistemological and methodological tracks during their academic institutionalization in Western Europe and North America in the nineteenth and early twentieth centuries. On the one hand, the social sciences (economics, sociology, and political science as well as anthropology) came to be oriented towards the successful epistemological model of the natural sciences and defined themselves primarily as nomothetic and generalizing disciplines. On the other, history predominantly influenced by the humanities and critical against speculative social laws developed traits of an idiographic and particularistic discipline. Against these traditional disciplinary definitions, a converging interdisciplinary cooperation

between history and the social sciences has developed only in the second half of the twentieth century. The social-scientific orientation of history was programmatically formulated in approaches such as the 'new social history,' 'la nouvelle histoire,' 'Social Science History,' or 'Historische Sozialwissenschaft,' developing in leading journals such as *Annales Economies, Sociétés, Civilisations* (1946–), *Past and Present* (1952–), *Journal of Social History* (1967–), *Journal of Interdisciplinary History* (1970–), *Social Science History* (1976–), and *Geschichte und Gesellschaft* (1975–). In a parallel movement, the historical orientation of the social sciences crystallized in new areas like historical sociology, historical economics, historical political science, and historical anthropology. Sometimes even the epistemological identity of history and the social sciences has been stated in a fundamental sense.

More recently, however, this *rapprochement* between history and the social sciences was halted and partly reversed. Within the study and presentation of history a 'revival of the narrative,' a 'new cultural history,' and concepts of the 'historical cultural sciences' have emerged, emphasizing what distinguishes them from the social sciences proper. But it should be stressed that, in a parallel movement, the social sciences have been similarly challenged from within by alternative cultural, interpretative-hermeneutic, and deconstructive-postmodernist epistemologies. Often the so-called 'cultural turn' in history and the social sciences is seen as a replay of the traditional juxtaposition of idiographic and nomothetic positions and conservatively used to reconfirm the traditionally separate institutionalization of both disciplinary areas. But properly understood, this cultural turn can and should be rather viewed as a challenge to the still prevailing principled opposition of generalizing or particularizing disciplinary epistemologies and methodologies. The future task, then, would be to open the historical and social sciences towards a common and multivocal, intra- and interdisciplinary discourse of sociohistorical inquiry.

1. Disciplinary Divergence

In its originally institutionalized—but nowadays increasingly challenged—meaning, history is primarily concerned with the study, description, interpretation, and presentation of historical facts or relics from the past, focusing on: idiographic methods, the analysis of historical contexts and temporal change, and the conceptualization of historical phenomena as particular individualities, their inductive interpretation, and narrative presentation (Burke 1992, Zunz 1985). In the opposite—but also increasingly questioned—direction, the social sciences such as sociology, economics, political science, and anthropology have been traditionally understood as concerned with the study,

generation, and explanation of social facts in the present emphasizing nomothetic methods, systematic analysis, and theoretical explanation by reference to general laws or social regularities (Monkkonen 1994, Skocpol 1984).

This problematically polarizing division between history and the social sciences developed with the institutionalization of the university systems during the nineteenth century under the impact of the natural sciences. Science, since then, came to be equated primarily with the natural sciences and particularly with its conspicuous inorganic and organic branches of physics and biology. Taking the natural sciences as epistemological models, the social sciences emerged as an attempt to discover the general laws and evolutionary mechanisms of modern society (Lepénies 1988, Gulbenkian Commission 1996). Thus, political or classical economy as developed by Adam Smith or David Ricardo tried to find the general laws of modern capitalist market society or in a critical direction as formulated by Karl Marx to uncover the anatomy of emerging modern capitalism. In the same steps, the early founding fathers of sociology such as Claude-Henri Saint-Simon, Auguste Comte, or Herbert Spencer intended to find the structural and evolutionary laws of modern society. At the same time, with the advent of modern mass politics in the American and French revolutions, the emerging political science as in Alexis de Tocqueville or John Stuart Mill attempted to formulate the general features and bases of modern democratic politics. Finally, with the growing awareness of non-Western societies under the impact of European colonialism and imperialism, anthropology tried to analyze the archaic or 'primitive' societies as structural counterparts and evolutionary pre-stages of modern society.

By contrast, history in view of the contingent flow of historical events and human actions as well as the role of cultural and spiritual forces came to be skeptical of the search for quasi-natural laws of the historical-social world. Instead, history followed the humanities, art, and literature as culturally oriented disciplines that seemed to be closer to the spiritual, creative, and poetic aspects of historical development. Particularly under the impact of German 'historicism,' the epistemological and methodological principles of historical knowledge developed into a radical opposition to the positivist search for historical-social facts. The principle of Leopold von Ranke to narrate history 'wie sie eigentlich gewesen ist' formulated the conviction that the historical method has to grasp the historical reality in its manifold particularities. In epistemological terms as developed by Johann Gustav Droysen and Wilhelm Dilthey, history cannot be subsumed under deterministic-mechanistic laws, but has to be understood in its concrete, experience-near, and life-full quality. On this basis, not only were the historical subdisciplines such as political, legal, cultural, social, and economic history principally viewed as hermen-

eutic-interpretative disciplines, but also economics, sociology, and political science as promoted among others by Gustav Schmoller, Werner Sombart, or Max Weber were primarily conceptualized as cultural sciences rather than as social sciences in order to grasp the individual and collective meanings structuring socioeconomic and political actions and processes. These epistemological and methodological differences and divergences were characteristic for the relationships of history and the social sciences not only in Germany, but in all Western societies. However, through the particular influence of German 'historicism' refuting on ontological grounds the applicability of explanatory social-scientific methods to historical events and cultural individualities, these divergences often developed into a principled opposition (Iggers 1993, Lepenies 1988).

The interdisciplinary bridging of this epistemological, analytical, and methodological opposition only became possible with the increasingly historical orientation of the social sciences as well as the growing social-scientific and sociological orientation of history (Abrams 1982, Lipset and Hofstadter 1970, Skocpol 1984). In the first half of the twentieth century, this converging movement was seldom although of crucial significance in preparing the ground for the later developing convergences between the historical and social sciences. Of lasting influence was, first, Emile Durkheim and the continuation of his approach by Marcel Mauss and Henri Berr, attempting to combine the sociology of social change with anthropological comparisons and historical developments (Raphael 1994, Stoianovich 1976). Of fundamental importance was also, second, the German historical-comparative sociology, particularly in the hands of Max Weber, Otto Hintze, Werner Sombart, and in their continuity also of Norbert Elias, who tried to explain the specificities of the Western civilization, its unique economic, political, and cultural order by historical and universal comparisons (Lepenies 1988). Third, strongly influenced by European sociological traditions, modernization theory developed in the USA as a universal social-scientific approach closely connected with historical-comparative modernization research on the historical prerequisites and developments of modern societies on a world scale.

2. Interdisciplinary Convergence

Influenced by these precursors, the historical and social sciences combined programmatically, first in the Annales school (Raphael 1994, Stoianovich 1976) and then later in the American Social Science History approach (Tilly 1981), some proponents of English Marxist historiography (Kaye 1984) and in their emulation in the West German 'Historische Sozialwissenschaft' (Kocka 1977, Wehler 1980). This interdisciplinary convergence led to different forms of

'social-scientific history' or 'historical social science'—despite many national particularities. They materialized in the 1960s and 1970s in a parallel movement in the Western societies (Iggers 1993). In critical opposition to the received tradition of narrative and exclusively interpretive history, the major common methodological aims of social-scientific history or historical social science can be summarized in the following principles. First, social-scientific historical approaches should be oriented to a structural and processual perspective on the various (economic, sociopolitical, and cultural) dimensions of macro-historical change. Second, they should shift historical analysis from a 'top-down' elite perspective to a 'bottom-up' popular or people's history. Third, social-scientific historical approaches should give up the traditional emphasis on political and intellectual history and turn towards economic and social history. Fourth, they should make systematic use of the available social-scientific, theoretical, comparative, and quantitative methods in history and favor systematic explanation instead of hermeneutic interpretation. Finally, this movement to social-scientific history or historical social science was often motivated by a critique of traditional elitist-conservative historiography and a commitment to emancipatory, democratic, or enlightened values.

The common methodological aims of social-scientific history or historical social science, at the same time, were colored and refracted by the respective national intellectual and cultural environments. In France, the 'nouvelle histoire' promoted within the long established interdisciplinary tradition of the Annales school (Raphael 1984, Stoianovich 1976) was characterized by a rather balanced multilevel (*longue durée, conjonctures, événements*) and multidimensional (economy, social structure, and civilizational mentalities) mode of historical analysis. In England, a strong neo-Marxist influence shaped the rise of economic and social history with a particular emphasis on social inequality and class history (Kaye 1984). In the United States the interdisciplinary social science history was influenced by the development of historical-comparative multidimensional modernization research and the special attraction of econometric, statistical, and social research methods for the quantification of historical processes (Tilly 1981). In Germany, Marxian and Weberian traditions of scholarship combined with elements of Western modernization theories and led to 'Historische Sozialwissenschaft' and 'Gesellschaftsgeschichte,' in which the analysis of social inequality and political power with a particular emphasis on the German 'special path' were treated (Kocka 1977, Wehler 1980). At the same time, these national variations reflect not only differing intellectual and theoretical traditions, but also a different emphasis on the use of qualitative and quantitative methods in historical-social inquiry. This is also indicated by the paradigmatic oscillations between the concepts of

(a) historical social science, (b) structural history, and (c) social-scientific history.

'Historical social science' ('Historische Sozialwissenschaft') serves as a loosely defined summary category. Still, the historical-comparative analysis of large-scale and multidimensional processes of social change from traditional life-worlds to modern society has been at the center. In particular, the concepts of historical-comparative modernization research, historical sociology, societal history, and synthetic structural history, with different theoretical and methodological orientations, belong to this category. In the French *Annales* school in a mixture of Durkheimian and Marxian traditions, the comparative analysis of feudalism by Marc Bloch and the social history of capitalism by Fernand Braudel (to be followed by Immanuel Wallerstein's history of the modern world system) are important examples. Among English Marxist historians, the debate on the transition from feudalism to capitalism in a line from Maurice Dobb to Perry Anderson and the social history of modern classes, developed in different directions by Eric Hobsbawm and Edward Thompson, carried the field. In the United States, modernization research guided by a mixture of Max Weber's comparative sociology and Talcott Parsons' structural functionalist theory of social change was of major importance, resulting in path-breaking studies like Neil Smelser's analysis of social change in the English industrial revolution; Shmuel Eisenstadt's civilizational comparison of empires; Barrington Moore's historical explanation of the development of twentieth-century dictatorship and democracy; Tilly's edited volume on the formation of national states in Western Europe; and Reinhard Bendix's study on corresponding historical changes in the legitimacy of political domination (see as an overview Skocpol 1984). In Germany, the modernization paradigm in a mixture of Weber and Marx directed Ralf Dahrendorf's sociological analysis of Germany's troublesome process of democratization or Hans-Ulrich Wehler's (1987–95) and Jürgen Kocka's (1993) comparative social-historical investigations of the German 'special path' and the role of the social classes within it.

'Structural history,' again, has had different meanings with different outlooks. It materialized in innovative areas of a variety of 'new histories' along the lines between the main subsystems of modern society and the related social-scientific disciplines. In the 'New Economic History' of the 1960s, the application of economic concepts and theories has given rise to the history of economic growth, technology, capitalist markets, and institutions; here, David Landes' (1969) *Prometheus* or Sidney Pollard's (1981) *Peaceful Conquest* are examples of a qualitative type, whereas Gianni Tonioli's (1991) comparative history of European industrialization—debating Alexander Gerschenkron's theory of economic backwardness—represents a quantitative type of economic history. In

the 'New Social History' in the 1960s and 1970s, sociological concepts were used in the historical analysis of demographic development, social structure, and social mobility; social groups, occupational structures, and social classes; social institutions, associations, and interest groups; as well as social movements, social protest, and political mobilization (Kocka 1977). This was combined with the application of political-scientific approaches to the history of political modernization, state formation, nation building, the development of democratic regimes and party systems, as well as political power and contestation (Tilly 1984). Further, social-scientific approaches influenced by social anthropology have also been applied to cultural phenomena and developments such as family and socialization, religion and secularization, as well as value systems and mental structures (see different essays in Rürup 1977).

The concept of 'social-scientific history' has been used primarily for the application of rigorous quantitative research methods in structural or social history (Landes and Tilly 1970, Schröder 1994). Not always, but often it has been equated with historical social research or the systematic quantitative operationalization and measurement of historical-social variables. In addition, this often combined with a deductive application of theoretical models to historical data and their explanation through statistical-mathematical and increasingly computer-assisted methods. Also this type of social-scientific historical research followed, either in close cooperation or in separate organization, the main areas of the 'new histories.' Particularly, the 'New Economic History' has been suited to cliometric, statistical, and econometric research methods as for instance in Paul Bairoch's and Maurice Lévy-Leboyer's (1981) analysis of economic growth disparities since the industrial revolution. But also in the new social history, social-demographic family, mobility, and migration studies such as Richard Wall, Jean Robin, and Peter Laslett (1983) as well as time-series of social protest such as Charles Tilly, L. Tilly, and R. Tilly (1975) are prominent examples. In the new political history, the historical change of voting behavior, in particular, became an important field of historical social research (e.g., Best and Thome 1991). But also in the cultural history of mentalities as carried through particularly in the *Annales* tradition, the application of quantitative methods were fruitfully developed (e.g., Shapiro and Markoff 1998).

3. Interdisciplinary Challenges

Successful as these different new historical sub-disciplines in their qualitative and quantitative orientations have been, the guiding vision of social-scientific approaches to history has been the combination of the various structural histories in a unifying societal

history, 'histoire totale' or 'Gesellschaftsgeschichte' (Iggers 1993, Wehler 1980). This vision follows the epistemological ideal of merging the historical sciences and the social sciences in a common paradigm—as essentially expressed in the paradigmatic concepts of social science history, historical sociology, or 'historische Sozialwissenschaft' (Abrams 1982, Smith 1991, Wehler 1980). With this unifying vision, however, the disciplinary traditions and methodological differences between historicized conceptions of the social sciences and social-scientific approaches to history become easily blurred. On the one hand, historical approaches in the social sciences basically proceed within a generalizing frame of reference (Monkkonen 1994). For instance, historical economics follows the basic idea of uncovering time/space bound economic laws or regularities (Kindleberger 1990, Monkkonen 1994, Wallerstein 2000). Also historical sociology is primarily oriented to the general features of time/space bound social processes, patterns, and figurations (as exemplary studies see Eisenstadt 1996, Mann 1986/1993, Smelser 1992). In parallel, historical approaches in the political sciences concentrate on general features of political development (Monkkonen 1994). Also, historicized versions of anthropology are interested in the general evolutionary patterns of human behavior (Monkkonen 1994). On the other hand, social-scientific approaches to history as multidimensional structural or combined societal history usually remain in the confines of a narrative frame of reference—even when applying rigorously social-scientific theoretical concepts and research methods. Thus, in spite of all interdisciplinary convergence, there have been limits to a full merger between historically oriented social sciences and social science oriented history.

A second *problematique*, expressed in the oscillating meanings of historical social science, structural history, and social-scientific history, concerns the relationships between theory and method. Structural approaches to history often use social-scientific concepts in order to systematize, interpret, and explain long-term historical processes in one or another societal dimension. Social-scientific approaches to history are often oriented to theoretical models in order to explain deductively quantified historical-developmental data. Approaches in historical social science and related synthetic orientations to history often use multidimensional theories of social change in order to explain causal connections between the various societal dimensions. Many varieties of historical social science, structural history, and social-scientific history use theories and concepts, deductive and inductive modes of explanation or interpretation, as well as qualitative, quantitative, and comparative methods of analysis. In an effort to systematize these methodological strategies in historical-social inquiry, Theda Skocpol proposed to distinguish model-theoretical, causal-analytical, and interpretive modes of

explanation (Skocpol 1984, pp. 356–91). Charles Tilly, concentrating on the types of comparison and the number of cases and variables involved, differentiated between individualizing, generalizing, encompassing, and variation-finding forms of comparison (Tilly 1984, 84ff.). Charles Ragin (2000), attempting to bridge qualitative and quantitative modes of analysis, distinguished between case-analytical and variation-oriented methodological strategies. Fruitful as these methodological distinctions are, particularly the methodological relationships between explanatory and interpretive research strategies, the theoretical sources and analytical consequences of these methodological distinctions for sociohistorical inquiry still remain unexplored (Hall 1999, p. 173).

A third increasingly salient but divisive *problematique* concerns the role of culture in the differing modes of historical social science, structural history, and social-scientific history. Not only in practice, but also often programmatically, social-scientific approaches to sociohistorical inquiry tend to favor the analysis of the economic, social, and political dimensions and to limit the analysis of culture to value systems or cultural institutions. The contents and forms of culture in their constitutive or causal role in history are often neglected and the corresponding hermeneutic or deconstructive methods to interpret their meanings, symbols, values, and identities are often seen as secondary. Against these prevailing tendencies of social-scientific approaches to culture, there emerged an increasingly influential challenge by the 'new cultural history' or cultural-scientific versions of history (Hunt 1989, Dirks et al. 1994, Mergel and Welskopp 1996). This 'cultural turn' consists of different countercurrents against the social-scientific vision of a systematic, generalizing, and explanatory structural and societal history. First, the revival of the narrative insists on the interpretive, literary, and narrative tasks of history (Stone 1979). Second, the development of micro-history or 'Alltagsgeschichte' emphasizes the complexity of life-worlds as such or as microfoundations of historical macrostructures (Luedtke 1989). Third, the 'linguistic turn' presupposes the all-pervasiveness of language in the social world, thus stressing the analytical task of deconstructing discourses and decoding linguistic-symbolic structures (Hunt 1989). Fourth, the 'cultural turn' is consciously oriented to those social groups such as women, ethnic minorities, or the underclass, seen as neglected by the predominating social-scientific approaches to history (e.g., *History Workshop Journal* 1976— or *Radical History* 1975—). Finally, some authors are influenced by a postmodernist perspective emphasizing the fragmentation and decentering against the structuring and ordering of the social world (Iggers 1993). The result is not only the generation of a whole new set of historical sub-disciplines such as women's and gender history, ethnic and minority history, regional and local history as well

as the history of identities and memory, but also an influential shift from social-scientific history to cultural-scientific history (see however Bonnell and Hunt 1999).

In a sense, the 'cultural turn' signifies a revitalization of historicism and cultural-scientific approaches to history—re-emphasizing qualitative, interpretative, ethnographical, and hermeneutic methods against systematic-explanatory orientations and, with it, reversing the causal or structural determination of history from 'society' to 'culture.' At the same time, this theoretical and analytical movement reflects a parallel shift in the social sciences from social-structural to institutional and cultural paradigms (Skinner 1985, Matthes 1992, McDonald 1996). For instance, in economics and economic sociology the new institutionalism has gained wide recognition, but also cultural neo-Weberian approaches reappear (North 1981, Monkkonen 1994, Swedberg 1998). In various domains of sociology as well, the 'new institutionalism' and various forms of a 'new cultural sociology' become influential (Monkkonen 1994, Crane 1994). Further, in political science the traditional institutional approaches become challenged by cultural paradigms (Monkkonen 1994). All this is influenced by a crucial shift in anthropology from social and structural anthropology to various forms of interpretative, ethnographic, historical, and cultural anthropology (Monkkonen 1994). As a result, social-scientific history is not merely confronted with systematic, generalizing, and explanatory forms of the social sciences, but also with individualizing, interpretative, and reflexive varieties of the cultural sciences. In other words, new opportunities of interdisciplinary cooperation emerge.

4. Interdisciplinary Perspectives

The interdisciplinary cooperation and convergence of history and the social sciences have opened up novel and dynamical fields of sociohistorical research. At the same time, the *idées directrices* of that historical-social-scientific convergence have often privileged quasi-natural-scientific epistemologies and methodologies. As a consequence, generalizing modes of sociohistorical inquiry stand in tension with particularizing modes; structural and macro-analytical theories used in historical-social analysis conflict with action and micro-analytical theories; causal explanation is often limited to the application of theoretical models and causal-analytic methodologies in opposition to interpretation and hermeneutic strategies; and, accordingly, there are tensions between qualitative and quantitative methods, including generalizing and particularizing methods of comparison. These tensions are revealed, on the one hand, within the social-scientific convergence of history and the social sciences in the paradigmatic oscillations between the guiding concepts of historical social science, structural

history, and social-scientific history. These tensions develop, on the other hand, within the wider historical sciences, in the often polarized opposition to renewed historicist and culturalist, narrative and hermeneutic or deconstructivist modes of historical-social inquiry. At the same time, these theoretical and methodological oppositions and polarizations are not solely characteristic for the historical sciences. Parallel disciplinary developments can also be observed in the social sciences and the widespread and often sharp oppositions to cultural-scientific approaches in the various social-scientific disciplines.

These epistemological, theoretical, and methodological oppositions and conflicts have often led into a stalemate in both disciplinary areas of the historical and social sciences between renewed forms of narrative-interpretative and anthropological-cultural history in contradistinction to the nomothetic social sciences. However, these oppositions in the historical as well as the social sciences can and should be used to re-energize a wider intra- and interdisciplinary cooperation between the historical, social, and cultural sciences. These renewed cooperative efforts should concentrate on the crucial epistemological, theoretical, methodological, and analytical dimensions in socio-historical inquiry within and across the established academic disciplines: on the epistemological level, combining social-scientific and cultural-scientific as well as generalizing and particularizing modes of knowledge; on the theoretical level confronting systematically social-structural and cultural approaches to historical-social reality; on the analytical level, mediating between the social-structural, institutional and cultural dimensions as well as between the global, national, regional and local macro-/microdimensions in sociohistorical inquiry; and on the methodological level, clarifying the relationships between qualitative and quantitative as well as historical, social-scientific, and cultural-scientific comparative research strategies (Bourdieu 1995, Haupt and Kocka 1996, Spohn 1998). All these renewed epistemological, theoretical, methodological, and analytical efforts of an inter- and intradisciplinary cooperation should not be done in segmented isolation, but in a multidisciplinary and multivoiced context of practiced sociohistorical inquiry. Such an opening of the historical and social sciences, however, is not only a matter of an intellectual intra- and interdisciplinary cooperation, but also demands an institutional cross-cutting between and across the segmented academic disciplines of the historical and social sciences (Gulbenkian Commission 1996).

History: Forms of Presentation, Discourses, and Functions

History as an institutionalized, academic discipline is a continuation of extradisciplinary forms of dealing with the past and, therefore, has never enjoyed a monopoly on its representation. Narrative representations of origins—be it in the form of myths, legends, religions, or ideologies—are found in most cultures. These different forms of representing the past offer collectives an orientation in time: they give a meaning to the present by locating the present on a time axis between a future and a past.

Next to the variety of disciplinary forms of historical representation (Stern 1970, Kelley 1991, Lorenz 1997), these extradisciplinary representations of history still exist, often competing with others and disciplinary history. The problem of how to demarcate the extradisciplinary from the disciplinary ways of dealing with the past, has therefore haunted history as a discipline from its very beginning. Traditionally, the discipline's identity has been based on its truthclaim, its critical methods, and its archival foundation (see *History: Theories and Methods*). This article will only deal with the disciplinary representations of the past in the West. It will only take extradisciplinary representations into account in order to cast light on the origins and the official borderlines of the discipline (Fain 1970, McNeill 1986).

1. Historical Representation and its Function as a Historical Problem

Although the concept of representation has a clear-cut meaning in philosophy—that of an image, in which the structure of the represented phenomenon is maintained (Mormann 1997)—in history the term is usually used as an equivalent of concepts like image or construction. In titles like 'The representation of Hitler in the US press, 1933–1945' or 'The representation of the Black Woman in the literature of the Antebellum South,' historians emphasize the constructed and interpretative character of historical reconstructions: history cannot be directly presented, but is *represented* by the historian in language. This emphasis has roots in an awareness that historical representations are not mirror images of history itself. It is usually accompanied by an awareness of the fundamental plurality of historical reconstructions. At the same time it is sometimes accompanied by an awareness of the practical functions (or the politics) of representation.

For the consciousness of this 'representational' character of history, two developments were crucial. The first development was the perception of history as an object of knowledge, independent of its individual representations. According to Koselleck this development originated in Europe, in the mid-eighteenth century, when history as a process—*historia*—was first

distinguished from the traditional *historiae*, i.e., the stories told about the past. History could only be conceived of as an independent object of knowledge when it was no longer regarded as a binding tradition or as a practical craft belonging to literature or rhetoric, i.e., as the art of telling (his)stories in order to persuade a public, as had been the case in Europe from classical antiquity until mid-eighteenth century. History's functions only developed into a problem after the traditional idea, that past experiences were relevant for present purposes and histories could teach you by example what to do and what not to do (*historia magistra vitae*), began to lose its plausibility.

The second development, that promoted the awareness of the representational character of history, was the 'discovery' of its perspectival character during the Enlightenment. Although the possibility of multiple stories about the same events was known already—and a central concern of rhetorics—Enlightenment historians were the first to recognize explicitly that the historical representations necessarily vary with the perspectives of the historians and with the development of time. The Enlightenment also stimulated the tendency to identify cognitive, scholarly activity with empirical disciplines, which was a consequence of the competition of the *Geisteswissenschaften* with the modern natural sciences (Scholtz 1991, Momigliano 1990). Koselleck dates the fundamental change in the relationship between Europeans and their sense of the past halfway through the eighteenth century; according to Pocock these changes had already started in the seventeenth century (Koselleck 1979, Pocock 1961). The traditional idea of the continuity between the past, the present, and the future was gradually replaced by the experience of permanent change, so typical of modernity (Scholtz 1991, Hardtwig 1990). The past thus gradually turned into a 'foreign country' (Plumb 1973, Lowenthal 1985, Rüsen 1983–9).

Early nineteenth century, this experience of difference between the past and the present would lead to the association of history with the notions of non-recurrence and nongeneralizability, later expressed in the concepts of uniqueness and individuality (see *Historicism and History: Theories and Methods*). History thus came to be conceived of not just as change through time—which could be cyclical and thus repeatable—but as *change as a process of irreversible and nonrepeatable development*.

With the emergence of this specific new sense of the past, the stage was set for the development of history and the social sciences into separate disciplines. The object of history was increasingly identified with nonrecurring phenomena in the human past, while the social sciences were identified with recurrent phenomena in the human present. Because recurrence is a precondition for generalization and thus for (structural and processual) theories, history and theory gradually turned into opposites, excluding one another. Thus the idea was born that the forms of

representation in history differed fundamentally from those in the social sciences. While historical representation was usually characterized as time-oriented and narrative, social scientific representational forms were characterized as analytical and theoretical (see *History and the Social Sciences*, Meran 1985, Burke 1993, Lorenz 1997). The modern question of narrative in history was thus born in the eighteenth century as a concomitant of the rise of modernity.

2. The Classical Roots of the Modern Debate

2.1 The Aristotelian Heritage

Both the Enlightenment conception of history and its critique in Herder and in later, Romantic thinkers—the two conceptions of history that still define the terms of the modern debate—must be viewed in the context of Aristotelian philosophy, because the Aristotelian definitions and distinctions of disciplines were still very influential in the eighteenth century (Aristotle 1963). In Aristotle's (ca. 384–322 BC) philosophy, there is a basic distinction between empirical knowledge of singular facts and universal knowledge of general facts. Concrete, empirical knowledge just formulates the contingent and particular characteristics of its object, while theoretical knowledge formulates its necessary and universal characteristics. These latter characteristics are viewed as recurrent and unchanging and were therefore limited to the domain of nature. Theoretical knowledge was therefore limited to the domain of nature too. Theoretical knowledge, according to Aristotle, does not only inform us *what* reality looks like, but also *why* this is the case: theoretical knowledge is always explanatory knowledge, because it informs us about the causes of what happens. Therefore, explanations in science are causal explanations and are ideally based on theoretical knowledge. This idea would dominate later philosophy of science in the form of positivism from Auguste Comte to Carl Hempel (see *History: Theories and Methods*; Meran 1985).

Within Aristotelian philosophy the domain of human activity or culture (praxis) held a fundamental different status from nature, because contingency, particularity, and change characterize the first domain. This domain, therefore, was not open to theoretical knowledge and to scientific explanation in principle (*'de singularium non est scientiae,'* as Duns Scotus wrote in the thirteenth century). History, according to the Aristotelian system, belonging to the domain of culture, could never be regarded as a science and was located in the domain of practical knowledge, more akin to poetry (including literature).

Although both poets and historians dealt with the same phenomena, i.e. human actions and events (albeit respectively in verse and in prose), history only dealt with what was real and poetry with what was imagined.

The historian, according to Aristotle, 'describes what happened' while the poet 'describes what can happen' (Aristotle 1963). This distinction was later codified in the distinction between the *res factae* [Latin: *res* = affairs; *factae* = done] or 'things done,' which was the domain of history, and *res fictae* [Latin: *fictae* = imagined], which only concerned poets.

The duty of the historian to stick to the facts and to tell the truth, the whole truth and nothing but the truth, derived mainly from the model of Thucydides. It received its canonical formulations in Cicero (ca. 106–43 BC) and Lucian (ca. 125–200 AD), who also linked truth in history directly to impartiality by avoiding moral blame and envy (*sine ira et studio*). The German historian Leopold von Ranke (1795–1886) would only repeat these classical ideals in the nineteenth century, with great force and effect (Iggers 1997).

According to Aristotle, the poet enjoyed a 'constructive liberty' not shared by the historian. While the unit of the historian is defined by what had happened to specific subjects at a specific time at a specific place, the unit of the poet was not defined in such a way. In poetry actions and events are put together by a unit of meaning, that is by constructing a whole with a beginning, middle, and an end, held together by a plot. The parts of the poetic unit all fulfill a function in—i.e. derive their meaning from—this whole. Because of its constructive quality, Aristotle held that poetry was more philosophical than history. This characterization was also based on the idea that poetry—for instance, tragedy—was concerned with general problems—types—and not only with particulars, like history.

The Aristotelian definition of history would define the parameters of the debates on historical representation up to the present. The opposition of nature and culture and the identification of nature with necessity and repetition, and culture with contingency and change, has ever since defined the methodological battlefields in philosophy of history. This opposition linked nature to (universal) theory while excluding (particular) history from theory *a priori*. As influential has been the opposition of poetry and history and the identification of history with the domain of the factual in opposition to the domain of fictionality (see *History: Theories and Methods*). Last but not least the Aristotelian opposition of historical units and poetical units has put the relationship between chronological and narrative ordering of events on the agenda of philosophy of history, i.e. the relationship between chronology and narrative. This opposition raised the question what narrative explanations are and how they relate to causal explanations.

2.2 The Rhetorical Tradition

Another fundamental root of the modern debate on historical representation can be traced back to classical rhetoric (Koselleck et al. 1982). Accounts of the past

were dealt with by classical authors like Aristotle, Cicero, Lucianus and Quintilianus (ca. 35–96 AD) primarily in the context of rhetoric, especially forensic rhetoric, i.e., rhetoric used to persuade a judicial court. So, the problem how to compose and write an account of the past was primarily dealt with as a problem in a communicative context and not as a cognitive problem, as is the case since the nineteenth century. Therefore the question how to produce a convincing history loomed larger than how to write a truthful history—which in turn explains why rhetoric later acquired a doubtful reputation until it was officially expelled from the scholarly domain by Descartes only to return late twentieth century in the train of postempiricism and post-positivism (see *History: Theories and Methods* and McCloskey and Megill 1987). The origin in forensic rhetoric also explains why the domain of history was identified with the domain of human action.

Now to be convincing, according to rhetoric, truth may help, because Plato argued that true arguments are the most convincing. Quintilianus, however, later pointed out that truth as such was neither a necessary nor a sufficient condition for being convincing. Being convincing is directly related to being perceived as probable rather than as being factually true, because some truths are hard to believe. In order to be convincing, according to rhetoric, past action primarily must be explained in (motivational) terms understandable and plausible for the audience addressed. Therefore, the reconstruction of past actions was basically conceived of in the rhetorical tradition as an act of translation of factual information by a speaker, who has a specific aim and who addresses a specific audience.

The rhetorical emphasis on probability instead of on truth was a consequence of its focus on communication and the awareness that factual truth is not a communicative category. It did not imply any plea for blurring the distinction between facts and fiction in history, nor the idea that truth in history fulfilled no practical function. On the contrary, the truth of the past was sought after, because only true accounts of past actions were useful as *exempla* for later generations (Momigliano 1990, Hay 1977). History was thus usually regarded as inherently pragmatic for some 20 centuries until the presuppositions of this pragmatic conception lost their plausibility in the second half of the eighteenth century.

3. The Modern Debate on Historical Representation

3.1 The Problem of Narrative

Basically, the theories of historical representation developed since the eighteenth century can be classified on basis of their relationship with the Aristotelian and

the rhetorical characterizations of history. There is a genus of theories, that can be seen as a continuation of Aristotelian theory, and there is a genus of theories, that opposes Aristotelian theory. Both genus contain several species.

The first genus consists of theories that have transformed the Aristotelian analysis of poetical or literary narrative into theories of historical narrative. According to these theories, historical narratives are structured by plots (P. Ricoeur, P. Veyne, H. White, D. Carr), colligatory concepts (W. Walsh), configurational ideas (J.-G. Droysen, L. Mink), or metaphors (F. R. Ankersmit). This view implies that historical narratives are not structured by a chronological order; instead they are structured by linguistic instruments, which synthesize chronologically disparate elements into a synchronic unity (as, e.g., is done by concepts like 'The Enlightenment,' 'feudalism,' or 'imperialism'). Narratives, thus, are fundamentally different from chronologically ordered historical representations, such as chronicles and annals. The fundamental difference between literary and historical narrative, according to most of these narrative theories, is the difference between fiction and fact: while the construction of literary narratives is only restricted by what is plausible, historical narratives are restricted by what is factually true. Therefore, history could and did claim a scholarly status in being empirical or a *Wissenschaft*.

This position was first developed by the Historical School from Niebuhr and Ranke onwards and is philosophically legitimized by historicism that posits a fundamental connection between the narrative form of representation and the notions of time and of individuality. The basic idea is that narrative is the linguistic medium, which shows how a phenomenon (a person, nation, idea, etc.) develops its defining characteristics—its identity or individuality—in time, just as a biography shows how an individual has developed its identity in time (Lübbe 1977, Veyne 1978, Ankersmit 1994). Although most narratives appear to follow the natural flow of time, it is, in fact, the other way around: the central idea of a narrative (e.g., the Enlightenment, the Age of Revolutions, etc.) determines which temporal units and orders (periodization, etc.) are the relevant ones for the narrative in case. Narrative time is thus always constructed time. Droysen formulated this insight in 1857 (Droysen 1977).

Within this first genus of narrative theories, there are several species which show important differences. The first species, exemplified by Louis Mink, Herman Lübbe, and Frank Ankersmit, has developed the argument that explanation by narrative is *sui generis* and is logically independent of causal explanation. All advocates of this species hold that the narrative mode of representation is explanatory in itself.

The second species, exemplified by Arthur Danto and Jörn Rüsen, holds that explanation by narrative,

although different from lawlike explanation, is based on causal explanation nevertheless. The narrative mode of representation is analyzed here as a set of causal chains. A third species of narrative theories, exemplified by Paul Ricoeur, David Carr, and Paul Veyne, has developed the argument that historical explanation has a narrative form and a plot structure. Ricoeur and Carr, moreover, argue that human experience itself is narratively structured and that there is an *a priori* fit between human experience and narrative explanation. Both individuals and communities can be said to have the same narrative form of self-constitution, because their identities can only be represented in the form of narratives.

Whatever their differences, all of these three species of narrative theories regard narratives primarily as explanatory schemes. All three try to answer the Aristotelian question how narratives explain, if not straightforward causally.

A fourth species of narrative theories is not primarily focused on issues of explanatory logic, but on the rhetorical problem why narratives are regarded as plausible and convincing. Ann Rigney and Hayden White in his *Metahistory* exemplify this type of narrative theory. First, White argues that all historical narratives fulfill an ideological function, aimed at specific audiences. Second, he argues that historical narratives contain one of four literary plot structures: comedy, tragedy, satire, or romance. Third, he argues that all history can be emplotted freely in these four manners. Narratives are accepted by an audience as probable and as plausible, according to White, when the narrative plot structure and its ideological implication are recognized and accepted as such.

The acceptability of historical narratives, so White, is thus relative to audiences and relative to ideological aims and not only dependent on the truth of the factual statements in the narrative. In this respect, White's theory has a rhetorical ring, although his fixation on plot structures is at the same time Aristotelian. However, on the issue of narrative truth, White deviates fundamentally from both Aristotelian and rhetorical presuppositions. Contrary to Aristotle, he blurs the borderline between fact and fiction in history by stating that historical narratives are 'fictions of factual representation.' Consequently, according to White, there are no epistemological grounds for preferring one historical representation over another, only political and aesthetic ones. So, along with rhetoric, he holds that plausibility bears no necessary relation to truth. However, contrary to both Aristotelian and rhetorical theory, White severs the crucial link between research and composition of historical narrative: the composition of narratives is not treated as following from—and restricted by—research, but as a fully independent process (Lorenz 1998).

The second genus of theories of historical representation somehow opposes Aristotelian theory. Historically this genus derives from eighteenth century

Enlightenment conceptions of history. Contrary to Aristotle, Enlightenment historians like Voltaire, Condorcet and Chladenius held that history could be both theoretical—in the sense of containing knowledge of a general character—and scientific—in the sense of being empirical. 'Theoretical' or 'hypothetical' history was thus claimed as a legitimate 'scientific' project, in which 'theory' and empirical knowledge could be integrated. Theoretical knowledge was no longer exclusively identified with the domain of nature and no longer exclusively interpreted as knowledge of what is necessary and universal. All knowledge of a general character was regarded as theoretical, including empirical generalizations and theories of the middle range. In the twentieth century this type of position has been defended by the proponents of the conception of history as a social science, who conceived of history as a mix of particular and general characteristics. As the general characteristics could be theorized, they emphasize the importance of theories and models in historical reconstructions (Wehler 1973, Kocka 1977, Tilly 1981, Burke 1993, Iggers 1997). This type of representation, being explicit about the concepts and arguments used, is often called analysis instead of narrative, emphasizing its affinity to the social sciences. This happened especially when 'traditional' history and its function were seriously questioned between 1960 and 1980.

4. *The Nineteenth-century Origins of the Modern Debate on the Functions of History*

From classical antiquity until the eighteenth century the pragmatic presupposition that past experience was meaningful for present purposes was not questioned seriously, nor that the (empirical) truth coincides with the (ethical) good. From the end of the eighteenth century onwards, however, historians and philosophers began to doubt the salutary nature of history seriously and therefore the function of history: when history is no longer experienced as a meaningful and salutary process, what good is the study of history then? Nietzsche's all too nasty question in *The Use and Disadvantage of History for Life* (1874), whether the study of history had any use at all, was the logical endpoint of this vanishing faith in history. European historians basically countered these doubts by two strategies of demarcation. First, by attempts to enhance the scholarly status and 'objective' credentials of history by increasingly expulsing the rhetorical and artistic dimensions from its disciplinary domain. An increasing tendency to conceive of history as a *Wissenschaft*, opposed to *Kunst* or art, by identifying the discipline with its empirical research methods (*Forschung*) at the cost of the literary and artistic methods of its presentation (*Darstellung*) was the result (see Hardtwig 1990, Scholtz 1991 and *History: Theories and Methods*).

Second, these doubts were countered by demarcating disciplinary history sharp from any substantial philosophy of history, especially from its Enlightenment and Hegelian variants (including Marxism), and from any practical function. In the famous words of Ranke historians were not to pass any judgement on the meaning of the past—as the Enlightenment had done—but only ‘to show what actually had happened.’ By this demarcation strategy the reflection on the practical functions of history was excluded from the disciplinary discourse and was expelled to philosophy of history.

This epistemological demarcation had become possible while history was professionalizing and attaching itself to the national states both institutionally and financially. Because both the state elite’s and the majority of the professional historians presupposed that education in (national) history was essential for ‘nation building,’ the practical functions of history stopped being a problem. The practical function of history was now conceived of as indirect—through individual and collective identity formation alias *Bildung*—rather than as direct through *exempla*. This view was also held by proponents of a ‘contemplative’ function of history, like Ranke.

The ideal of objectivity was silently identified in historical discourse by promoting the practical cause of the nation state. This identification was not seen as a problem, because in the dominant conceptions of history the historical process itself was identified with the genesis of nations and states. It would take two world wars before this identification turned into a serious problem due to an increasing lack of plausibility. Nietzsche’s nasty question, until then comfortably put aside by many professional historians as ‘philosophical,’ had to be faced at last: what good is the study of history anyway?

Nietzsche’s analysis and classification of the functions of history in *The Uses and Abuses of History* although framed as a critique of nineteenth century discipline of history in Germany, has proved to be very fruitful up to the present day (Rüsen 1983–89; Kocka 1989, Hardtwig 1990, Tollebeek 1990). Basically, Nietzsche distinguishes three ways to deal with the past and three types of history that correspond with three different attitudes and basic needs of human beings. Therefore, history has three basic functions, which cannot be reduced to each other and which serve as mutual correctives.

The first way to deal with the past is pragmatic, as an active *acting* being. Actors may address the past in search of examples, which, according to Nietzsche, deserve imitation. The past addressed in this way is treated as ‘a collection of monuments.’ That’s why Nietzsche calls this pragmatic type of history *monumentalistic history*.

The second way to deal with the past is full of piety, as a *contemplative* being, when one is looking for one’s roots in the past in search of one’s identity. The past

addressed in this way is treated as ‘a collection of antiquities’ or as ‘a museum’; therefore, this ‘pious’ type of history, i.e., history just for the sake of the past, is labeled *antiquarian history* by Nietzsche. Because man is not only directed towards the past, but also towards the future, it is impossible always to treat the past as a ‘museum.’ In order to create something new it is necessary to break with the past to some extent and to replace it. Therefore, it is also necessary to address the past in a critical way, as something to be criticized as fit for replacement. This type of handling the past, which Nietzsche compares to ‘cutting one’s roots loose with a knife,’ is called *critical history*.

All three types of history have their own type of dangers and deficiencies, which can only be remedied by history of the other types. Monumental history, for instance, tends to equalize the past and the present and to be very selective, obliterating differences and huge parts of the past, unfit for the monumental function. This tendency can only be counteracted by the antiquarian impulse, which in turn suffers from ‘historical myopia’ and from a ‘blind drive to collect.’ This tendency, in turn, can only be counteracted by the critical impulse, which in turn must be held in check by the other two in order to prevent critical history from degenerating into a war against one’s past.

Historiography can be seen as the combined product of these three impulses, in varying mixes. Disciplinary history since the nineteenth century, however, has usually—although not exclusively—embraced the antiquarian self-image and legitimization, because the recognition of both the monumentalistic and the critical approaches to the past would raise the problem of its practical functions and its objectivity. In accordance with this contemplative self-image of most historians, the antiquarian presentation of identity—i.e., the narrative reconstruction of the genesis of individuality in time—is usually presented as the discipline’s only practical function. As in Nietzsche’s time, the monumental and the critical functions of history are usually not discussed within the disciplinary boundaries (Angehrn 1985). At times, however, as in the 1970s, the situation has been different, because of an influential number of ‘critical’ historians in the profession (Kocka 1989).

Symptomatically for this state of affairs is that recently the monumental function of history has been delegated to a separate domain, i.e., the domain of collective memory and of *lieux de mémoire* (see *History and Memory*). The same holds for the critical function of history, which is central to projects like gender history, postcolonial studies, and Foucault’s critical history (which replaces the Enlightenment self-image of the West by an image of a disciplined ‘carceral society’). These forms of critical history were often not regarded as belonging to the domain of history proper or are at best tolerated in its margins (Foucault 1980, Scott 1988). Mainly in one historiographical domain—that of the Holocaust—reflection on the functions of

history has included both its critical and monumental functions, because the very possibility of the anti-quarian approach is fundamentally questioned here. Historical representation as such has turned into a problem, because it is doubted whether the normal categories and procedures of historical representation in order to 'objectify' the past can function in this 'unspeakable' domain. Some hold that psychoanalytic categories like trauma, repression, transfer, splitting off, and working through are more apt to characterize the relationship between the historical representations and represented historical reality. Others have suggested that the 'unspeakable' and 'overwhelming' dimensions of the Holocaust can be better characterized through the notion of the sublime, suggesting a deep analogy between the confrontation with the Holocaust and the confrontation with an earthquake or an avalanche (see *Holocaust, The*, Friedländer 1992, LaCapra 1994).

Mainly in this historiographical domain, the discussion about the functions of history is directly connected to the discussion on representation and its limits. Whether this more inclusive type of debate will alter the dominant discourse on history remains as yet to be seen.

History of Science

The history of science studies the emergence and development of systematic knowledge. Just what kind of knowledge that is—whether it is defined by subject matter, reliability of results, contradistinction to technical know-how, cumulative progress, disciplinary consensus, and/or method of inquiry, demonstration, or explanation—is a point of persistent debate and reflection within the history of science and its cognate fields in philosophy, sociology, and anthropology. Linguistic and historiographic traditions diverge sharply on this point. Whereas Francophone and Anglophone scholars have since the mid-nineteenth century largely reserved the honorific ‘science’ for the natural sciences and mathematics (influenced by Auguste Comte’s hierarchy of sciences in his *Cours de philosophie positive* 1830–42, in which only some had reached the stage of ‘positive’ knowledge), the German *Wissenschaft* still refers to the range of fields covered by the Latin *scientia*, from physics to philology. Moreover, recent explorations of experiment and other practices have blurred the venerable boundary between *ars* and *scientia*, technique and systematic knowledge (whether understood narrowly as ‘science’ or broadly as *Wissenschaft*); close investigation of the sciences even in the restrictive English and French usage has furthermore revealed considerable variety among methods and explanations in, for example, biology and physics. Finally, studies of pre-seventeenth-century and non-Western intellectual traditions have made the creation of categories like ‘science,’ as well as the classifications of knowledge that order such categories, themselves objects (rather

than presuppositions) of historical research. Hence this article will not attempt to delineate sharply the boundaries of ‘science,’ but rather briefly survey the (a) emergence and status of the history of science as a recognized field of inquiry; (b) principal divisions of the field and disciplinary affinities; (c) periodizations and narratives that have shaped those divisions; and (d) major historiographical developments since about 1970 (for an earlier survey see Kuhn [1968] 1972).

1. Emergence and Divisions of the Discipline

The history of science is an ancient pursuit, but a relatively young discipline. From Aristotle through the early nineteenth century, practitioners of one or another branch of knowledge have variously used the history of their field to argue for its dignity and importance, introduce it to beginners, situate it within a broader cultural milieu, summarize the literature to date, position themselves in relationship to that literature, praise and blame predecessors, give evidence of progress, extrapolate a program for future research, and draw lessons concerning the nature of knowledge and the conditions for its flourishing. In works like Joseph Priestley’s *The History and Present State of Electricity* (1767) or Georges Cuvier’s *Rapport historique sur les progrès des sciences naturelles depuis 1789* (1808), the history was inseparable from the science. Particularly in fields dominated by empirical research, the judicious sifting and ordering of past results was a precondition for coherence and a means for achieving consensus on what was reliably known and where the major challenges for future research lay. These functions are preserved today in the scientific review article and the posing of key ‘problems’ (e.g., the celebrated Hilbert problems), and practicing scientists occasionally still appeal to the past history of their field for present guidance, especially in times of crisis (Graham et al. 1983). By the mid-nineteenth century, however, histories of science had become distinct from scientific publications, although they were still written primarily by scientists, including prominent figures such as William Whewell, Marcellin Berthelot, Ernst Mach, and Pierre Duhem. Their histories often criticized the current state of science by establishing the genealogy of a controversial hypothesis (e.g., atomism), analyzing the origins of a suspect concept (e.g., absolute space) for hidden flaws, or pleading the superiority of one approach to science over another (e.g., Kantian ideas over Comtean facts). By 1900, histories of science had become a genre distinct from science, but they were still motivated by, and deeply engaged with, contemporary scientific developments (Laudan 1993).

History of science coalesced only gradually as a recognizable discipline in the twentieth century, with its own distinctive program of training, institutions (journals, professional societies, university positions), and scholarly standards. Spurred by the organiza-

tional efforts of such scholars as Paul Tannery in France and Karl Sudhoff in Germany, there was a spurt of professionalizing activity around 1900, when the first international congress on the subject was held in Paris. The German Gesellschaft für Geschichte der Medizin und der Naturwissenschaften was established in 1901; the first chairs in the history of science also appeared at European universities around this time (Kragh 1987). The Belgian historian George Sarton, who emigrated to the USA after World War I, brought with him the journal *Isis* (est. 1912), which became the official organ of the American History of Science Society after its establishment in 1924.

Although Sarton's Comtean view of the history of science as a saga of intellectual and moral progress that should evaluate the past in light of present scientific understanding (Sarton [1927] 1948) has left little trace in current historiography, his tireless attempts to institutionalize and organize the discipline in the form of university departments, specialized journals, and research tools like the *Isis Current* (earlier *Critical Bibliography*) (History of Science Society 1967) and *Dictionary of Scientific Biography* (Gillispie 1981) had a lasting impact on the field (Thackray and Merton 1972). During the 1950s graduate programs dedicated to the history of science (sometimes in conjunction with the philosophy of science) multiplied; the 1992 *Guide to the History of Science* lists 188 programs in 25 countries, led by the USA with 72 institutions granting doctorates in the subject.

By no means all history of science is done under the auspices of university departments or published in journals expressly devoted to the subject. The disciplinary affinities of the history of science are many and mutable, with distinctive national differences. Until the 1970s the primary connection, both in Europe and North America, was probably with the sciences themselves. This connection was rooted deep in the origins of the field and sustained by the continuing importance of some form of the history of science in the intellectual and social initiation of young scientists, as well as by the recruitment of historians of science from the ranks of those with scientific training. In the UK and North America, history largely replaced philosophy during the 1980s and 1990s as the discipline to which historians of science felt most akin, although interactions with sociology and, more recently, anthropology have also exerted a powerful influence. In France, Germany, and Italy, philosophy has remained a significant framework for the history of science, in diverse forms ranging from neo-Kantianism to logical empiricism. In addition to its disciplinary polyvalence with respect to choice of problems and methods, the history of science is closely linked by its subject matter to the histories of medicine and technology, albeit to differing degrees depending on the historical period in question. The phrase 'science and technology studies' bears witness to these criss-crossing ties to other

disciplines, serving as an abbreviation for the conglomerate 'history, philosophy, sociology, and anthropology of science, medicine, and technology'—which, however cumbersome, accurately reflects the ecumenical perspective of many historians of science.

2. Narratives and Periodization

Because of its links to philosophy, sociology, and anthropology, as well as to the natural sciences and mathematics, the history of science has been highly theorized for centuries. Theories about what scientific knowledge is, how it develops over time, where and when it expands and contracts, and in which ways it interacts with extrascientific contexts have profoundly shaped the way in which the history of science has been periodized and narrated. The more recent developments (since about 1970) in the historiography of science are incomprehensible without some background concerning the dominant theoretical schemes that had molded the field previously.

All history is inevitably written to some extent from the standpoint of the present, but present science—its orthodoxies and heresies, its controversies and critics—has exerted a mighty influence on the history of science since the Enlightenment. The great bulk of the history of science has been written explicitly or implicitly to illuminate, justify, or criticize the current state of science. In the Enlightenment histories, e.g., Jean-Étienne Montucla's *Histoire des mathématiques* (1758) or Jean-Baptiste Delambre's *Rapport historique sur les progrès des sciences mathématiques depuis 1789* (1810), the aim was to demonstrate that at least some of the sciences had shown steady and irreversible progress, especially since the Renaissance, and that the history of science was therefore a more edifying genre than the chronicles of human folly recounted by political and military history. The notion of progress was originally applied to art (by Giorgio Vasari in 1550) and to technology (by Francis Bacon in 1620), not to science. Once this interpretation of scientific change took hold in the eighteenth century, however, science became the premier example of progressive advance and scientific progress; a criterion by which to judge the comparative worth of civilizations. Whatever may have been the cultural achievements of the Latin Middle Ages or the Chinese empire, the stagnation of the sciences in these milieux, so ran the argument of the Enlightenment historians, revealed fundamental intellectual and social limitations—limitations that in the nineteenth and twentieth centuries came to be described as characteristic of 'traditional' or 'premodern' societies. Hence narratives of scientific progress eventually became part and parcel of larger narratives about modernization and European superiority.

Although the assumptions underlying the Enlightenment vision of scientific progress are seldom invoked

explicitly by contemporary historians of science, the reigning periodization of the field and the definition of specialties as central or peripheral still bears the traces of the traditional/modern division. Despite their glaring differences in many substantive aspects, the study of science in antiquity, the Arabic and Latin Middle Ages, and in non-Western civilizations such as China and India has often been amalgamated into a shared problematic: to what extent did the knowledge of these highly disparate cultures anticipate/approximate the science of post-Renaissance Europe? And to the extent that it did not, what were the intellectual and social obstacles that blocked the way (e.g., Huff 1993)? Hence the pioneering works in these areas (e.g., Duhem 1908, Maier 1949–58, Clagett 1959, Needham et al. 1954) foregrounded possible forgotten contributions to, and missing preconditions for, the Scientific Revolution.

Knowledge traditions that did not lead to modern science, understood to commence in early modern (a term as saturated with hindsight as ‘the Middle Ages’) Europe, were generally relegated to the periphery of the discipline, whatever their intrinsic interest and however excellent the scholarship devoted to them. Conversely, the Scientific Revolution has remained oddly central to the historiography of science: oddly, because recent scholarship on the sixteenth and seventeenth centuries has emphasized the heterogeneity and regional variations in the developments in anatomy, astronomy, natural history, mechanics, chemistry, mathematics, and physics once summarily lumped together as ‘the Scientific Revolution’ (Lindberg and Westman 1990, Porter and Teich 1992, Shapin 1996, Osler 2000), and because the steep increase of studies of nineteenth- and twentieth-century science since about 1980 has highlighted the novelty and significance of post-1800 developments, as the steady increase in the number of entries under these rubrics in the *Isis Current Bibliography* bears witness.

Yet the Scientific Revolution retains much of the original status first granted to it by the Enlightenment historians as the mold in which modernity was cast, one of the few points upon which both the apostles of progress and the critics of modernity agree. This periodization has left traces in the division of sub-specialties within the history of science, which tend to be chronological or geographic (‘ancient,’ ‘Southeast Asian’) for knowledge traditions prior to, or uninfluenced by, the Scientific Revolution, but disciplinary (‘physical sciences,’ ‘biomedical sciences’) for those following that original event—even for disciplines (e.g., astronomy) with histories that long antedate the sixteenth century and with geographical distribution well beyond Europe.

The progress of the sciences (especially mathematics and the exact sciences) set forth by the Enlightenment historians was cumulative but not revolutionary. In their accounts, knowledge steadily expanded around a

stable core of permanent truths, which may have taken millennia to discover, but which were thereafter firmly established beyond challenge. The language of ‘revolutions’ declined among early nineteenth-century scientists, perhaps in order to distance the permanent improvements of natural knowledge from the brusque reversals of politics; instead, the language of ‘law’ (e.g., Comte’s ‘Law of Three Stages’) was applied to the historical development of science (Cohen 1985). In the middle decades of the nineteenth century, however, this view of durable, inexorable scientific progress gave way to one of the rapid succession of scientific theories, even in areas (e.g., optics) long believed to rest upon unshakable foundations. Scientific progress had become vertiginous and open-ended; today’s truth might be discredited as tomorrow’s error. Under these conditions, it became increasingly difficult for historians of science to portray the steady growth of knowledge as culminating in present triumphs, since the endpoint was constantly changing. Instead, the history of science turned critical and conceptual: in the hands of Mach, Ostwald, and other scientist-historians, history of science revealed the past roots of present incoherences and taught the mutability of scientific theories. Within the revised interpretation of scientific progress, the purpose of the history of science was to use past science to change, not confirm, present science. Despite the dramatic shift in the narrative of scientific progress and in the goals of the history of science, its presentist orientation remained unchanged.

Almost all the strands of early twentieth-century historiography of science can be seen as attempts to come to grips with the peculiar character of scientific knowledge, which seemed to be simultaneously mutable and cumulative, driven by an internal dynamic and yet sensitive to ambient social conditions. These attempts often tugged in opposite directions. For example, the logical positivist program that stamped the history and philosophy of science in the middle decades of the twentieth century, especially in the modified form imported from the Vienna Circle to the UK and the USA, fixed upon the empirical findings of science as its enduring core in the Heraclitean flux of hypotheses and theories. These ‘protocol statements’ (Carnap 1928) were likened to simple observations, bringing science into the neighborhood of common sense. In contrast, the French historian and philosopher Gaston Bachelard, drawing upon the insights of psychoanalysis, insisted upon the necessity of overcoming everyday experience and intuitions in the formulation of successful scientific concepts (Bachelard 1938).

A many-cornered debate was ignited by the attempts of Marxist historians to relate the rise of modern science to specific socioeconomic conditions (Hessen 1931, Bernal 1939), out of which emerged the opposition of ‘internal’ to ‘external’ approaches to the history of science (Kuhn [1968] 1972, Shapin 1992). External approaches found a non-Marxist model in

Robert K. Merton's influential study of how science came to be valued in seventeenth-century England (Merton 1938, Shapin 1988). Informed by German and French neo-Kantian traditions in the history of philosophy, Alexandre Koyré's studies of the development of science in the broader intellectual context of early modern Europe stamped the work of historians of science, especially in France and the USA, trained in the 1950s and 1960s (Koyré 1939–40, 1961, Jorland 1981).

Common to all of these otherwise highly diverse perspectives on the history of science was an engagement with contemporary science and its lineage. Whether positivist or psychoanalytic, externalist or internalist, the history of science took the form of a genealogy leading to ideas and discoveries canonized by contemporary science. However much they may have disagreed on historical methods and forms of explanation, the combatants agreed on what and who in the history of science was worthy of explanation, namely that which had turned out to be pregnant with the future. In these histories a potent telos was at work, making present science appear to be not only the actual but also the inevitable outcome of past developments.

3. *Developments Since 1970*

Thomas S. Kuhn's *The Structure of Scientific Revolutions* (Kuhn [1962] 1970) broke decisively with this historiography, and stimulated new trends (not all to Kuhn's liking) in the history, sociology, and philosophy of science that have transformed the understanding of science and its growth in these fields since 1970. Kuhn argued for a plurality of scientific revolutions, in addition to the Scientific Revolution, which alternate with periods of 'normal science' framed by a 'paradigm' that models what can count as an acceptable problem, method, and solution in a given science in a specified period. It was less, however, Kuhn's 'structures' or patterns of long-term scientific development that exercised a deep and enduring influence on the history of science (although this feature of the book dominated its reception in other disciplines, particularly the social sciences) than his frontal attack on progressive narratives, his sketchy but evocative notion of 'paradigm' that embraced practices as well as theories, and the thoroughgoing historicism of many of his examples. All of these lines of thought were further cultivated in the history, philosophy, and sociology of science (the three disciplines were drawn into intensive interaction in part through their differentiated reception of Kuhn's book) during the subsequent three decades, often with consequences that led in directions diverging markedly from those plotted in *The Structure of Scientific Revolutions*.

Kuhn's rejection of progressive narratives in the history of science derived from his view that successive paradigms established and later overthrown by scientific revolutions were, first, internally coherent, and second, in a strong sense incommensurable with one another. This implied that science could not be cumulative in any progressive sense, one paradigm extending and building upon its predecessors. Kuhn's claim that conflicts between rival paradigms were not necessarily resolved by paradigm-independent criteria (e.g., predictive accuracy of explanatory unity) unsettled the inevitability of scientific development still further. Sociologists of science Barry Barnes and David Bloor took these claims as the basis of an approach called 'constructivism' (Golinski 1998), in which the development of scientific knowledge was to be explained without appeal to its truth or falsehood, on the grounds that the truth of a proposition is neither a necessary nor sufficient condition for its acceptance (Bloor [1976] 1991).

For historians of science, this program proved stimulating in at least three respects. First, in conjunction with Kuhn's focus on periods of conflict between rival paradigms, it prompted detailed studies of how scientific controversies were in fact resolved. Second, it enlarged the definition of what could count as 'science' for the purposes of historical investigation by ruling out hindsight judgments about what was and was not legitimate by present standards (to the benefit of specialties such as the history of premodern science and of the human sciences). Third, it encouraged a broader exploration of the grounds for scientific conviction by enforcing a 'symmetric' treatment of reasons for embracing false as well as true beliefs. This deliberate refusal to adopt the perspective of present science in the investigation of past knowledge went under the name of 'anti-Whiggery' among historians of science (in allusion to Herbert Butterfield's critique of 'Whig' political history). Among sociologists of science, the symmetry principle led to an increasingly distanced approach even to present science, to the point of adopting the ethnographer's estranged perspective (Latour and Woolgar [1979] 1986). The overall impact of the constructivists in both sociology and history of science was to highlight the contingency of the development of scientific knowledge, in stark contrast to earlier narratives of inexorable progress (Pestre 1995, Rheinberger 1997).

Kuhnian paradigms drew upon the philosophical reflections of Ludwig Wittgenstein (Wittgenstein 1953) and Michael Polanyi (Polanyi 1958) to stress the importance of knowledge that could not be reduced to rules or algorithms or even to words in a normal scientific tradition. In the history, sociology, and philosophy of science a rich literature on 'scientific practices' has taken the inadequacy of the formal aspects of theory to explain the distinctive aspects of scientific knowing as its departure point. Although scientific practices may embrace everything from a

knack for integrating equations to the deft adjustment of finicky instruments, studies of experiment have taken on an exemplary character in this branch of the field. Interactions among historians (e.g., Shapin and Schaffer 1985, Galison 1987, Gooding et al. 1993), philosophers (e.g., Cartwright 1983, Hacking 1983), and sociologists (e.g., Collins 1985) created a discussion that blended epistemological, historical, and social analyses.

Experiment and scientific practices more generally have emerged as autonomous forms of knowledge, no longer subsidiary to and in lockstep with theory, that depend crucially on local factors (including skill, material culture, values) that travel only with difficulty. This emphasis upon the locality of scientific knowledge has spawned a new set of problems: How is local science made global? In the earlier historiography, science had been assumed to be universal because nature was so. For historians of scientific practice, in contrast, further explanation is required to show the ways in which localized achievements can be made at least partially communicable among practitioners divided by geography, history, or culture (Schaffer 1992, Galison 1999). Sociologists of science have attacked this problem from the standpoint of 'actor-networks' (Latour 1987).

Both the rejection of presentist perspectives and the close study of scientific practices have pushed historians of science toward a more thoroughly historicist approach. Whereas their predecessors practiced anachronism openly and with conviction, on the view that past science must be understood by the lights of present science, most historians of science now writing insist upon some attempt to reconstruct the conceptual and cultural categories of historical actors. This historicism has expressed itself in two important movements in recent historiography of science: the aim to understand 'science in context,' and attempts to write histories of entities previously assumed to be transhistorical.

'Science in context' (which lent its name to a journal) thickens the connections of science with its historical place and time, as well as blurring the boundaries between factors previously regarded as either internal or external to a discipline. Indeed, one of the consequences of the studies of science in context has been to make the emergence, persistence, and occasional disappearance of such boundaries, topics of historical investigation in their own right. One of the most important of the new strands of contextual history of science, because of its potentially wide application, has been the investigation of how ideas and practices of gender have shaped the modern sciences (e.g., Haraway 1989, Jordanova 1989, Schiebinger 1993).

Although some critics of this embedded view have feared that context impugns scientific autonomy and therefore validity, many recent studies have depicted the social, technological, and economic milieu of science as resources for scientific creativity, not merely

as ideological contaminants (e.g., Wise 1989–90). Histories of supposedly transhistorical entities such as experience (Dear 1995), truth (Shapin 1994), and objectivity (Daston and Galison 1992, Porter 1995) make use of the tools of science in context to anchor these Kantian abstractions in specific historical circumstances; they are also at least indirectly indebted to the remarkable studies of Georges Canguilhem (Canguilhem [1943] 1966) and, especially, Michel Foucault (Foucault 1969) that challenged the universality and permanence of fundamental modern categories like normalcy and sexuality.

The most recent developments in the history of science might be briefly described as materialized and embodied. The material culture of science, ranging from the architecture of the spaces in which science is done (Rheinberger et al. 1996, Galison and Thompson 1999) to the machines that do the science, have shifted from the periphery to the center of historical attention. Hands-on experience with objects is no longer understood as a means to a greater end, but as a force that shapes the culture and penetrates into the metaphysics of science (Galison 1997). Embodiment has entered the history of science through several doors: the study of the interaction of experiment and craft traditions (Sibum 1995), the investigation of the scientific persona in historical context (Lawrence and Shapin 1998, Shortland and Yeo 1996), and the making visible of the role of women in science (Rossiter 1982, Rossiter 1995). All of these explorations of embodiment challenge the Cartesian image of the disembodied knower, as well as the hagiography of great individuals; they aim at the reconstruction of collective identities of scientists, as well as their consequences for who was allowed to do what kind of science.

Given the profusion of topics and approaches in the history of science, it is understandable that one historian might wonder 'whether the history of science is a coherent discipline or just a collection of scholars aggregated by the accidents of history and the accretion of a common historiography' (Rosenberg 1988, p. 570). This is a doubt that in large part revolves around the difficulty of defining the *sine qua non* of scientific knowledge, if it has one. Yet in this still somewhat undisciplined discipline, the reward of permeable boundaries has been a rare dialogue, ongoing and sometimes heated, among the natural sciences, social sciences, and humanities.

History of Science: Constructivist Perspectives

The last quarter of the twentieth century saw the emergence of an important and challenging new perspective on the sciences and their history. Drawing largely on developments in the social studies of science, but also on new trends in labor and social history, historians began to look at science as local practice, rather than as an abstract, disembodied, and universal set of ideas. Rather than seeing science as somehow outside culture, historians started looking at science as part of culture, locally constituted in particular material,

social, and even political practices. Constructivist historians are interested in the detailed processes of scientific knowledge production, dissemination, and reception. They differ from more traditional social historians of science in their insistence that the content as well as the context of science is a proper focus of cultural historical analysis. Crucially, constructivist historians see science as being a species of skilled practice and therefore inquire into the cultural origins of those skills, the means through which they are produced, validated and disseminated, and the ways in which particular forms of inquiry—and particular kinds of knowledge—have historically been characterized as scientific.

1. Local Cultures

In their exemplary study of the early modern culture of experiment, Shapin and Schaffer lay out some of the central concerns of the constructivist history of science (Shapin and Schaffer 1985). Focusing on the dispute between Robert Boyle and Thomas Hobbes concerning the validity of Boyle's famous air-pump experiments, they use Hobbes's critique of Boyle's experiments to lay bare the interests underlying them and the strategies that Boyle and his allies adopted to convince others of the experiments' reliability. They demonstrate how even such an apparently universal cornerstone of the scientific method as experiment has its origins in particular local and contingent circumstances. Making science local and examining the interests that underlie the articulation and resolution of scientific debates have been preoccupations of constructivist history. Other pioneering studies include accounts of the ways that disillusionment with rational philosophy and mechanistic notions of causality in postwar Weimar Germany informed interpretations of quantum theory (Forman 1971), and of the role social interests played in debates concerning the anatomical structure of the brain in early nineteenth-century Edinburgh (Shapin 1979). Such studies emphasize the way in which such interests are constitutive rather than contingent features of even the most apparently abstract and technical forms of knowledge.

One important outcome of constructivist history is the recognition that even the issue of what kind of activity might count as science is often the product of locally articulated debates and controversies. Not only did Boyle and Hobbes disagree as to what might reliably be inferred from the outcome of air-pump experiments, but they also disagreed as to whether or not doing such experiments should be counted as a reliable way of generating scientific knowledge at all. Similarly, the scientific and the medical establishment who opposed the introduction of continental ideas concerning evolution and transmutation into early

Victorian England did so both because they did not recognize the practices or the practitioners involved as being properly scientific and because they disagreed with the theories themselves (Desmond 1989). As the labels 'science' and 'scientific' gained in cultural value, so too did different groups of knowledge producers disagree more vociferously as to what kinds of people and what kinds of activity should be accorded those labels (Gieryn 1999). Constructivist historians have identified the business of policing the constantly changing boundaries of science as a crucial part of science's history. Through institutions, regimes of training, control of resources, and access to networks of patronage, natural philosophers and scientists have struggled to circumscribe and discipline their own and others' knowledge producing activities.

This localist historical perspective leads to recognition of the extent to which the production and validation of scientific knowledge are contingent upon more or less informal networks of trust. In order for particular groups or individuals to be considered reliable spokespersons for nature, they have to be trustworthy. They have to be the kinds of people who can be relied upon to tell the truth. This opens up the possibility of producing a cultural history of truth and objectivity. The marks of being trustworthy vary according to time and place. In early modern England for example, trustworthiness was considered the hallmark of the gentleman (Shapin 1994). As a result, many of the informal (and more formal) rules of early modern gentlemanly behavior became enshrined as codes of conduct for the nascent scientific community as well. Some historians have argued that the increased scientific reliance on precision measurement and self-registering instrumentation since the beginning of the nineteenth century may be regarded as efforts to circumvent the need for trusting individuals with knowledge production (Schaffer 1988). Others have pinpointed the increasing quantification of science as a means of overcoming the problem of trust in the production and particularly in the transfer of knowledge (Porter 1995).

2. The Material Culture of Experiment

The constructivist history of science pays attention not only to experiment as a form of inquiry, but also to the process of experiment. Experimentation is taken to be a matter of human agents actively engaged in constructing the natural world around them (Gooding et al. 1989). From this perspective, the material culture of experiment becomes a crucial focus of attention. Historians have worked to recover the kinds of material resources required for successful experimentation. They have traced the emergence of the laboratory as a specialized space within which experiments take place. They have emphasized the ways in which successful manipulation of nature requires the

experimenter to manipulate material and social resources successfully as well (Latour 1988). Michael Faraday's discovery of electromagnetic induction, for example, involved as much his marshalling of the Royal Institution's considerable resources as it was the outcome of his artful manipulations in the laboratory (Morris 1998). Constructivist historians have identified as well the important ways in which individual scientific reputations hinge upon recognition of the property relationship between experiment and experimenter. Priority disputes in science are frequent and virulent precisely because of the ways in which experiments embody the skills and reputations of their makers (Iliffe 1992).

Seeing experiment as a skilled activity, constructivist historians have focused much attention on understanding the historical origins of the kinds of skills required in order to carry out experiments. They have investigated how particular skills have been transferred into the laboratory from other settings, such as workshops or factories. Historical experiments have been replicated in an effort to better understand the tacit, unarticulated skills required for their successful performance. Such studies have shown how iconic experiments such as James Prescott Joule's famous paddle-wheel experiments establishing the mechanical equivalent of heat during the 1840s, were contingent upon the technical know-how that Joule and his workers derived from their experiences in the family brewery (Sibum 1995). Increasingly also, historians have looked at the politics of skill in the laboratory and elsewhere, investigating the division and distribution of hierarchies of skilled activity within science at different times and places. Much attention has been devoted to the historical transmission of material resources and skilled personnel that accompanies the standardization of experimental practices. Work in this vein has shown how experiments move from being instances of highly skilled, difficult to replicate, and delicate procedures performed in highly circumscribed settings to being robust, standardized, and readily reproducible embodiments of group knowledge (Galison 1987).

Apparently self-evident features of experimentation, such as precision measurement, are similarly shown by constructivist historians to have a history. Far from being a routine and unproblematic aspect of scientific activity, measurement can be taken to be an expression of particular cultural values (Wise 1995). The rise of metrology, for example, was an expression of science's increasing embeddedness in and contribution to a rapidly bureaucratizing and industrializing Western culture. Measurement could be regarded not only as a means of disciplining nature, rendering it more amenable to standardized routines of inquiry, but also as a means of disciplining the scientific workforce. Nineteenth-century scientific managers such as George Biddell Airy, the English Astronomer Royal, regarded their laboratories and observatories as

industrial workplaces and used regimes of routinized measurement and calculation to impose an industrial discipline on their workforces (Smith 1991). In late nineteenth century laboratories at Cambridge or Glasgow, natural philosophers such as James Clerk Maxwell or Lord Kelvin saw the imposition of regimes of precision measurement in teaching and research as an expression of their affinity with industrializing society (Schaffer 1992). Increasingly, constructivist historians have investigated how adherence to cultural values like precision came to be taken as a hallmark of what it meant to be properly scientific. More recently, some historians have returned to matters of theory, using the analytical tools developed to understand experiment to look at theory as a form of cultural practice as well. From this perspective, processes of theory construction and dissemination are seen in terms of the pedagogical training and practical skills required to participate in highly specialized theoretical cultures (Galison and Warwick 1998).

3. Science as Performance

One notable outcome of constructivist historical work has been to make the identity of the scientific practitioner itself problematic. Being a scientist is not a self-evident activity: the word itself is of comparatively recent, early nineteenth century origin. Scientific practitioners in the past occupied a number of different cultural niches. Crucially, constructivist historians have shown how natural philosophers at different times and places have been engaged actively in carving out social spaces for themselves and their work. Galileo's position at the Medici court in Renaissance Florence, for example, was not ready made. Galileo had to work hard to promote the idea of a philosopher or mathematician courtier that he could then fulfill (Biagioli 1993). He had to fashion himself into the kind of person who could easily inhabit that cultural niche and then to orient his work so that it would fit into the milieu of Italian Renaissance court life. The same could be said of Humphry Davy and his efforts to forge a place for the fashionable natural philosopher in Georgian London (Golinski 1992). Constructivist approaches share with the 'new history' an emphasis on the important role of individual agents' artful engagement in constructing both themselves and their worlds.

Recent constructivist work has paid particular attention to the body of the scientific practitioner (Lawrence and Shapin 1998). This is an outgrowth of the constructivist insistence on viewing scientific practices and the knowledge they produce as being in crucial ways embodied. Scientific practitioners at different times and places have needed to be particular kinds of human beings with specific bodily attributes. The ways in which those attributes were held to be best produced—whether by birth, self-discipline, or

rigorous training—have been a focus of increasing historical attention. Historians have examined, for example, the emergence of particular regimes of mental training in Victorian Cambridge and the ways in which candidates for mathematical honors were encouraged to train their bodies into being fit receptacles for their minds (Warwick, in Lawrence and Shapin 1998). The bodily interaction of practitioners with their experimental apparatus and the spatial organization of their laboratories have come to be recognized as playing an important role in the production of knowledge. The organization of such spaces and the kinds of material interactions between practitioners, and between them and their instruments, that have been taken to produce reliable knowledge are now seen as contingent and open to historical investigation.

Not only the identity and activities of the practitioner producing knowledge, but also the role of the audience for such productions are now recognized as constitutive. Audiences for scientific knowledge do not simply act as passive receivers of settled and unproblematic matters of fact. They have an important and active role to play in the articulation and resolution of controversies. During the early modern period and well into the nineteenth century, experiments were often performed before an audience. This was not simply a matter of demonstration. Members of the audience—prestigious and often named individually—played an important role in validating the knowledge produced. Their reputations could be used to underwrite the matters of fact they had witnessed. Audiences have participated in and responded to the processes of knowledge production through a variety of media, from direct witnessing to the virtual witnessing of reading a scientific paper at first hand, to the reception of second or third-hand reports in museums, newspapers, reviews, or popular handbooks. In the hands of states, public instrumental uses of science and technology have become devices for legitimating political power (Ezrahi 1990). Public scientific performances are an important part therefore of the dynamic process of knowledge-production and validation.

4. Science at Work

Constructivist historical analysis looks as well at the many ways in which nature has been used historically as a model for social organization. The constitution of the natural economy has frequently been used as a powerful argument in favor of particular ways of ordering society. Natural theology in the late eighteenth and early nineteenth centuries, for example, was widely used as an argument in favor of existing social hierarchies. Evolutionary theories were similarly cited to support new, meritocratic visions of society. The proper social economy was often held to mirror the natural order. Constructivist historians have shown

how models of nature and society in the past were frequently mutually sustaining. They were produced together. Discussions in mid-nineteenth century thermodynamics surrounding issues of work and waste in natural economies were coextensive with arguments concerning the proper organization of work and the minimization of waste in political economy (Smith and Wise 1989). Proponents of new forms of industrial organization, for example, looked to nature for their models. At the same time, scientists looked to factory organization as a model for the best means of ordering the search for truth.

In turn, different models for the organization of scientific work often expressed different understandings not only of how nature was ordered but also of the proper politics of knowledge production. Nineteenth-century scientific gentlemen, for example, regarded scientific work as a highly disciplined, hierarchical, and increasingly specialized activity. In principle, it was open to all. In practice, however, it could only be conducted properly either by, or under the supervision of, properly trained and vocationally committed 'gentlemen of science' (Rudwick 1985). Other social groups had different notions of the politics of knowledge. The gentlemen's vision excluded women and artisans, for example, from anything other than a supportive role in making knowledge. Working-class men, on the other hand, could construct their own very different accounts of how knowledge making ought to be organized (Secord 1994).

Through constructivist historical analysis, many of the traditional analytical categories employed by historians and sociologists of science have become recognized as being themselves in need of careful historical contextualization. Pronouncements by historical actors concerning matters such as the scientific method, experimentation, objectivity, or even more novel analytical categories such as skill, are not to be taken at face value. Such pronouncements usually carry considerable weight. The issue of what kind of activity might properly be considered as carrying out an experiment, for example, is not straightforward. At different times, experimentation has been regarded as both a public and a private process. It has been characterized as both a fundamentally communal and an essentially individual activity. What it means to be a skilled worker, again, has changed a great deal since the early modern period. Skill, like method, or even science itself, is a historical construction. By looking at science as a pre-eminently cultural activity, constructivist histories of science have made it possible to raise a whole host of new questions concerning the ways in which human beings, in the past, have tried to make sense of the world around them. Rather than seeing science as a static, monolithic edifice, constructivist history recognizes it as a constantly changing process of production, reproduction, and consumption, its boundaries continually shifting and its meaning always open to renegotiation.

History of Technology

Historians interested in technology have written articles and books about the subject for at least since 1900. Only since World War II, however, has the subject taken on some of the attributes of a discipline through the establishment of graduate programs and a scholarly journal of international reputation. History of technology includes the history of invention, the history of engineering, and social history of technology. Scholars with varied backgrounds, some formally trained in the history of technology, contribute to the field.

1. Defining the History of Technology

Because technology defies simple definition, its history as a field of study is not easily defined. Editors of the five-volume *History of Technology* (1954–1958, Oxford University Press, London) broadly define ‘technology’ as ‘how things are commonly done or made ... [and] what things are done and made.’ Finding this definition too diffuse, the editors of the two-volume *Technology in Western Civilization* (1967, Oxford University Press, New York,) reject, as well, the oft-encountered definitions of technology as applied science or as a rational attempt to control nature. They associate technology with human work, ‘with man’s attempts to satisfy his wants by human action on physical objects.’

Technology and its history are as difficult to define as history of politics or history of economics which experienced scholars refuse to define except by countless examples.

It is also hard to characterize a historian of technology. Unlike general historians, who usually

have graduate training in history departments, historians interested in technology enter upon the study of its history from a variety of backgrounds, besides graduate study in the history of technology. Persons trained, for example, in engineering, history of science, economic history, general history, and sociology, do outstanding works in the field. Professional writers also contribute works addressed to a general public including essays that appear in widely circulated journals such as the *American Heritage of Invention and Technology*.

2. Handbooks and Histories of Invention and Engineering

During the nineteenth and early twentieth centuries, scholars, especially German, nurtured the history of technology by publishing information-rich encyclopedias and handbooks. Franz Marie Feldhaus’s *Die Technik der Vorzeit, der Geschichtlichen Zeit und der Naturvölker* (1914, Engelman, Leipzig) and Ludwig Darmstaedter’s *Handbuch zur Geschichte der Naturwissenschaften und der Technik* (1908 Springer, Berlin) continue to be useful sources for the history of invention and discovery.

In the early years, biographies of engineers and histories of engineering appeared alongside histories of invention. Samuel Smiles, a railroad manager and medical doctor, in his influential *Lives of the Engineers* (1861–2, Murray, London,) cast problem-solving, project-managing engineers of the British Industrial Revolution in a heroic mold. They surmounted technical, political, economic, and organizational hurdles to transform undeveloped land into industrial regions by means of canals, roads, and improved harbors. In the twentieth century engineers have played a more enigmatic role than did Smiles’s heroes. Karl-Heinz Ludwig in *Technik und Ingenieure in Dritten Reich* (1979, Princeton University Press, Kronigstein), Kendall Bailes in *Technology and Society under Lenin and Stalin* (1978, Harvard University Press, Princeton, NJ), and Loren Graham in *The Ghost of the Executed Engineer: Technology and the Fall of the Soviet Union* (1993, Harvard University Press, Cambridge, MA) follow the tragic path of engineers under totalitarian regimes.

3. Early Monographs

Lewis Mumford, a public intellectual and professional writer, remains a seminal contributor to the field. Painting with broad-brush strokes on a canvas of western history, his approach is imaginatively interdisciplinary as he draws upon secondary works in western history, sociology, and anthropology. Prolific, he appealed to an interested, educated public, and

simultaneously influenced the scholarly world with his insightful concepts. *Technics and Civilization* (1934, Harcourt Brace, New York), his most enduring history of technology, surveys the development of technology from pre-historic to modern times. He acknowledges the deterministic role technology often plays in history, but he also stresses that values shape technology. His later works, including *The Myth of the Machine: The Pentagon of Power* (1970, Harcourt Brace Jovanovich, New York, NY), lament the rise of megamachines, or large bureaucratic, military, technological systems that deny individual's freedom and sweep them towards catastrophic wars.

Swiss architect and historian Siegfried Giedion's *Mechanization Takes Command* (1948, Oxford University Press, New York) ranges from medieval to modern times. A highly original study, it seeks to explain the mechanization of dwellings, food, furniture, and other aspects of everyday life. Anticipating the attitude of post-World War II historians of technology, he laments in particular the way in which mechanization has displaced organic processes and substituted abstract reason for feeling.

Louis C. Hunter's *Steamboats on the Western Rivers, an Economic and Technological History* (1949, Harvard University Press, Cambridge, MA), and Lynn White Jr.'s *Medieval Technology and Social Change* (1962, Clarendon Press, New York) also anticipate the contextual and social history approaches of a later generation of historians of technology. Hunter shows how the natural environment of the Mississippi River shaped the design of nineteenth century steamboats. On the other hand, White believed technology brought manorialism and feudalism (see *Technological Determinism*).

4. General Histories of Technology

The publication of the information-rich *A History of Technology* (1954–8, Oxford University Press, London) edited by Charles Singer, E. J. Holmyard, A. R. Hall, and Trevor Williams gave the field substantial scholarly credentials. Museum curators, engineers, and natural scientists figure prominently among the authors of the more than 100 chapters that tell of the development of technology from its beginnings to 1900. The authors do not integrate political, social, and economic history into their deterministic account of a nature-mastering, society-shaping, western technology that, they believe, had become science-based by 1900.

Published about a decade later, *Technology in Western Civilization* (1967, Oxford University Press, New York), another collective work, differs notably in approach from *A History of Technology*. Trained in general history before turning to history of technology, editors Melvin Kranzberg and Carroll Pursell, Jr., in

contrast to the editors of *A History of Technology*, urged their 34 authors to integrate history of technology with social, economic, and political history. The majority are historians of science, historians of technology, and economic historians, and they tend to take a contextual approach and to focus upon the British and American industrial revolutions. By stressing the interplay of technological and social factors, Kranzberg and Pursell move away from technological determinism encountered in *A History of Technology*.

Kranzberg and Pursell anticipate the recent trend among historians of technology to emphasize the interaction of technology and the natural environment by including three chapters on land use and resources. In a concluding chapter about the challenge of technology for the future, they also take a more critical view of the interaction of technology and culture than did the editors of *A History of Technology*.

Other broad ranging histories of technology have emerged from several national sources. Under the general editorship of Maurice Daumas, *Histoire Générale des Techniques* appeared between 1962 and 1979 (Paris). *Propyläen Technikgeschichte* (Berlin 1990–1992), a German collective survey under the general editorship of Professor Wolfgang König, also moves from ancient times into the twentieth century. A. A. Sworykin, N. I. Osmova, W. I. Tschernyschew, and J. W. Schuchardin published a Soviet version of the general history of technology translated into German as *Geschichte der Technik* (Leipzig 1964).

Recognized as a major scholarly achievement, Joseph Needham's multivolume *Science and Civilization in China* (Cambridge, UK, 1954) integrates from a Marxist perspective the history of medicine, technology, and science in a non-Western civilization. Among national histories of technology is *Geschiedenis van de Techniek in Nederland: de Wording van een moderne Samenleving, 1800–1890* (Zutphen 1992–1993) under the general editorship of Harry W. Lintsen.

5. Society for the History of Technology

The year of 1958 brought a turning point in the development of the history of technology with the establishment of the Society for the History of Technology (SHOT) and its journal *Technology and Culture* (*T&C*). Earlier, in 1920, the British Newcomen Society for the Study of the History of Engineering and Technology began publishing *The Transactions* which attracted, in particular, engineers interested in the history of their profession. The influential French journal, *Les Annales*, occasionally carried articles about the history of technology, and in 1935 published a special issue on the subject with a wide-ranging article on the history of water mills by its distinguished editor Marc Bloch.

Originally edited by Kranzberg and subsequently by Robert Post and John Staudenmaier, *Technology and Culture* attracts essays and readers from history of science, technology, and economics. The annual bibliography of the history of technology prepared initially by Eugene Ferguson proved especially valuable for researchers in the field. Within a few years, SHOT and *Technology and Culture* became the primary organizational framework for historians of technology in the USA and Western Europe. With several thousand individual members, SHOT includes non-US members on its governing committees and regularly has annual meetings in Western Europe. The International Committee for the History of Technology (ICOHTEC) provides through its colloquia and publications, a forum not only for US and Western European historians of technology, but also those from Eastern Europe, Russia, and elsewhere.

6. Graduate Programs in the History of Technology

Not only did SHOT and *Technology and Culture* provide an institutional framework for the history of technology, but the establishment of several graduate programs did as well. In 1954 the Eleutherian Mills-Hagley Foundation of Wilmington, Delaware with its archives, library, and museum, concentrating on history of technology and business organized, in conjunction with the University of Delaware, a graduate program for historians of technology. In 1973 the University of Pennsylvania initiated a doctoral program for the history of technology within its History and Sociology of Science Department. Other US universities followed suit, including the Massachusetts Institute of Technology. In Europe, Svante Lindqvist founded a history of technology and science program at the Royal Institute of Technology in Stockholm which has become a model for other institutions of higher learning in Western Europe. The research centers at Munich's Deutsches Museum and London's Imperial College also cultivate graduate training in the field.

7. Emerging Themes

7.1 Technology–Science Relationship

Since its founding, the pages of *Technology and Culture* express thematic concerns of scholars publishing and teaching in the field. In the 1960s, they often explored the relationship between technology and science. Motivation for this interest came in part from their wish to establish an identity for their subject other than as the history of applied science, a linear model

often adopted by historians of science and science policy makers. Historians of technology point out how often scientific theory rationalizes earlier technological practice.

Historian of technology Edwin Layton argued cogently in the 1970s that engineers develop their own applicable theoretical structures from practical experience and experimentation. Recently Walter Vincenti, eminent aeronautical engineer and historian of technology, has expounded this position persuasively in *What Engineers Know and How They Know It* (1990, Johns Hopkins University Press, Baltimore, MD).

Besides writing biographies of Thomas Edison and other independent inventors who experimented beyond scientific frontiers, historians of technology and science publish works about industrial research. John Beer provided a model for such studies with his essay on [German] 'Coal Tar Dye Manufacture and the Origins of the Modern Industrial Research Laboratory,' *ISIS* 49, (1958). Histories of the General Electric, Bell, and other major industrial laboratories followed. In these, fundamental research, in contrast with pure research, brings improvements in existing technology such as the three-element vacuum tube and incandescent lamp filaments.

7.2 Invention, Development, and Innovation

Technological change and creativity, a perennially intriguing human activity, became another early thematic concentration of historians of technology, especially those interested in economic and business history who see innovation as a source of economic development. After World War II, *The Sources of Invention* (Jeukes et al., 1969, W.W. Norton, London), which includes more than 50 case histories, stimulated a shared discourse about invention, as did historian Abbott Payson Usher's *A History of Mechanical Invention* (Cambridge, MA, 1954) and sociologist S. Colum Gilfillan's *Supplement to the Sociology of Invention* (San Francisco, 1971). Sociologist of science Robert K. Merton's seminal study, *Science, Technology & Society in Seventeenth Century England* (New York, 1970), broadens the discourse by demonstrating that attitudes and values stimulate technological innovation which in turn stimulates the search for underlying scientific knowledge.

The shared discourse usually defined technological creativity as consisting of three phases: invention, development, and innovation. Professional inventors and researchers in industrial laboratories were seen as presiding over the process of invention from a concept to a physical model. Development, a collective venture, moved the simple model through testing stages until a full-scale version could be tested. Innovation brought the device, process, or system into use. *Technology and Culture* authors usually situated the

three-phase process in an economic, political, and social context. The ongoing publication of the extensive Thomas Edison papers, along with Paul Israel's *Edison, a Life* (2000, New York) based on these, provides historians with an unprecedented rich source of information on a master of invention, development and innovation.

7.3 Industrial Revolutions, Systems, and Management

Industrialization also stimulated research and teaching among historians of technology. The rise of the USA to a position of preeminence among industrial nations raised questions about the nature of the industrialization process, especially as embodied in putative industrial revolutions in the UK and the USA.

Influential scholars exploring the process tend to see it as systematic. In *Das Kapital* (1867), Karl Marx portrays a factory as a system of textile machines driven by a single steam engine. Widening his perspective, he insightfully understands that textile factories interact with transportation, energy, and other systems to produce an industrial revolution, one scholars now label the 'British Industrial Revolution.'

David Landes an American economic historian, in *The Unbound Prometheus* (1972, Cambridge University Press, Cambridge, UK), writes of an interrelated succession of technological changes culminating after 1750 in the British Industrial Revolution and its spread throughout Western Europe. He shows how the coming of the steam engine, for example, depended upon developments in coal mining, iron manufacture, and railroad transportation. Ken Alder discusses the systematic interaction of military culture, industrialization, and politics in *Engineering the Revolution: Arms and the Enlightenment in France, 1763–1815* (1997, Princeton University Press, Princeton, NJ). *Histoire des Techniques* (Paris, 1978), edited and mostly written by Bertrand Gille, presents a history of successive technological systems and industrial revolutions from the earliest times into the twentieth century.

Historians customarily deal with the industrialization of the USA in the early nineteenth century as the spreading of the British Industrial Revolution by technology transfer and adaptation. David Hounshell in *From the American System to Mass Production, 1800–1932* (1984, Johns Hopkins University Press, Baltimore) challenges this interpretation by stressing the originality of the American system of production that developed in the nineteenth century and reached its apogee in the Ford system of mass production. Historian of technology Merritt Roe Smith in *Harpers Ferry Armory and the New Technology* (1977, Ithaca, NJ) sees the early nineteenth century American system as both a technical and managerial enterprise, and

places it within a shaping community, or social, context.

Only a relatively few historians explore a second Industrial Revolution in the USA and Germany after 1870 with its technical core of electrical and internal combustion technology.

Hugh G. J. Aitken surveys the spread of radio in *The Continuous Wave: Technology and American Radio, 1900–1932* (1985, Princeton University Press, Princeton, NJ) and Susan Douglas amplifies the story in *Susan Douglas, Inventing American Broadcasting, 1899–1922* (1987, Johns Hopkins University Press, Baltimore, MD). Within the frame of a Second Industrial Revolution, Leslie Hannah gives the history of electrical supply in the UK in *Electricity before Nationalisation* (1973, Johns Hopkins University Press, Baltimore, MD). *Networks of Power: Electrification in Western Society, 1880–1930* (1983, Johns Hopkins University Press, Baltimore, MD) by Thomas P. Hughes gives a history of electric power systems since 1880 in major urban centers in the USA, the UK and Germany. He defines systems as embodying in a seamless web a multitude of technical and organizational components and follows their development through stages characterized respectively and successively by the problem solving of inventive, managerial, and financial/political system builders. Hughes's methodology has spread among historians and sociologists who characterize it as a pragmatic, systems approach.

US historian of management Alfred D. Chandler in his seminal work *The Visible Hand: The Managerial Revolution in American Business* (1977, Cambridge, MA) stimulated a number of historians of technology interested in a Second Industrial Revolution to consider his proposition that innovative management since the late nineteenth century has done more to increase productivity than technical advances. Jurgen Kocka describes in a broad context large-scale, enterprise management at the Siemens company during German industrialization in *Unternehmensverwaltung und Angestelltenschaft am Beispiel Siemens, 1847–1914* (1969, Stuttgart), James R. Beniger in *The Control Revolution: Technological and Economic Origins of the Information Society* (1986, Harvard University Press, Cambridge, MA) moves from a second to an information revolution.

David Noble in *America by Design: Science, Technology, and the Rise of Corporate Capitalism* (1977, Alfred A. Knopf, New York) takes a strikingly different approach from Chandler on the rise of modern management. Reasoning from a Marxist perspective, Noble contends that US corporate culture represented by engineers and industrial scientists co-opted invention, research, and technical education in the interest of capitalism. Philip Scranton, a historian of technology and labor, offers in *Endless Novelty: Specialty Production and American Industrialization, 1865–1925* (1997, Princeton University Press, Prince-

ton, NJ) a correction to both Chandler and Noble by pointing out that small-scale, proprietary management and batch production continued to flourish in the era usually associated with large-scale mass production.

Military technology has been a constituent factor of modern history, especially during and since the Second Industrial Revolution. William H. McNeill in *The Pursuit of Power: Technology, Armed Force, and Society Since A.D. 1000* (1982, University of Chicago Press, Chicago) integrates military technology into general history. Technological developments during World War II and after, are described in Edward W. Constant's *The Origins of the Turbojet Revolution* (1980, Johns Hopkins University Press, Baltimore, MD). Richard G. Hewlett and Oscar E. Anderson, Jr. provide a detailed account of wartime atomic energy in *A History of the United States Atomic Energy Commission: The New World, 1939/1946* (1962, Pennsylvania State University Press, University Park, PA) and Richard Rhodes dramatizes the story effectively in *The Making of the Atom Bomb* (1986, Simon and Schuster, New York). Walter A. McDougall *The Heavens and the Earth* (1985, Basic Books, New York) places space technology in a political context.

Donald MacKenzie in *Inventing Accuracy: A Historical Sociology of Nuclear Missile Guidance* (1991, MIT Press, Cambridge, MA) and Gabrielle Hecht in *The Radiance of France: Nuclear Power and National Identity after World War II* (1998, MIT Press, Cambridge, MA) place political decision-making in the shaping context of evolving nuclear technology. A number of historians are exploring the recent history of the computer and biotechnology, but the definitive history has not yet appeared. Paul Edwards *The Closed World: Computers and the Politics of Discourse in Cold War America* (1996, MIT Press, Cambridge, MA) goes beyond narrative history to suggest that information systems are increasingly the shaping context within which military and political decisions are made.

7.4 Environment: Natural and Built

During the 1990s, the history of technology and environmental history intersected in the works of a number of historians. Earlier Leo Marx in *The Machine in the Garden: Technology and the Pastoral Ideal in America* (1964, Oxford University Press, New York) discussed the ideas of early American visionaries, such as Ralph Waldo Emerson who envisioned the harmonization of nature and technology in a pastoral landscape. In *Nature's Metropolis* (1991, W.W. Norton, New York). William Cronon describes the way in which Chicago's transportation and manufacturing technologies interacted seamlessly with the exploitation of the hinterland's natural resources to produce enormous quantities of marketable goods and nurture the enormous growth of Chicago.

Richard White, a social and environmental historian, further explores the seamless web theme in an imaginatively titled book *The Organic Machine* (1995, Hill and Wang, New York). It tells of the transformation of the Columbia River Basin in the states of Oregon and Washington into an artifact blending the natural and human built. White believes that the history of technology and the history of the environment can no more be told separately than the story of a marriage.

7.5 Gender, Race, and Technology

In the 1990s historians also began to explore assiduously the mutual shaping of gender and technology. 'Gender Analysis and the History of Technology,' a bibliographic essay in a special issue of *Technology and Culture* 38 (1997) documents the extensive literature emerging in the field. Ruth Schwartz Cowan in *More Work for Mother: the Ironies of Household Technology from the Open Hearth to the Microwave* (1983, Basic Books, New York) demonstrates that the household is a context within which factory-produced goods and consumption interact. Other historians further develop the consumption junction theme by showing that consumers, male and female, are not simply passive users of technology, but shape artifacts through their consumption preferences.

Judith McGaw opens another area of gender studies in *Most Wonderful Machine: Mechanization and Social Change in Berkshire Paper Making 1801-1885* (1987, Princeton University Press, Princeton, NJ) in which she demonstrates that women have gendered niches in the workplace which often perpetuate inequalities. Other historians argue similarly that some technological developments are shaped by ideas about racial differences and conversely that technology often defines racial roles, especially in colonial and developing areas. Michael Adas in *Machines as the Measure of Man: Science, Technology, and Ideologies of Western Dominance* (1989, Cornell University Press, Ithaca) demonstrates that nineteenth century colonial ideology associated technological progress, or the lack of it, with racial characteristics.

8. Methodology: Social Construction and Actor Networks

Until the 1980s histories of technology were generally written as narratives with little formal analysis. Then, European sociologists and anthropologists began shaping the field through the introduction of social construction and actor network methodologies. (See *Technology, Social Construction of; Actor Network Theory*.) French sociologist Michel Callon in several

influential articles including 'The State and Technical Innovation: A Case Study of the Electrical Vehicle in France,' *Research Policy*, 9 (1980) presents an actor-network model. It draws upon, but differs from, the Hughes systems approach previously described.

Callon uses an abstract concept 'actor' to signify—without distinguishing between—animate and inanimate components in a network. An actor-network creates and sustains a complex technological artifact such as an electric automobile. French professor of sociology Bruno Latour in *Aramis, ou l'Amour des Techniques* (1993, Paris) utilizes actor-network theory to present the history of a failed effort to introduce a radically new subway system in Paris. Deploying relativist sociology, Latour lets the actors, animate and inanimate, speak for themselves and offer conflicting, but equally valid, accounts of the evolution of a fluid project characterized by conflicting visions and policies.

Together with the systems and actor-network, the social construction approach of Trevor Pinch and Wiebe Bijker became a widely adopted methodology among historians and sociologists of technology in Europe and the USA. Influenced by the sociology of scientific knowledge cultivated at the University of Edinburgh, Pinch and Bijker offer a seminal example of social construction in an essay entitled 'The Social Construction of Facts and Artifacts,' *Social Studies of Science*, 14 (1984). They demonstrate that social environments shape the technical characteristics of an artifact, in this case the late nineteenth century bicycle. Social groups of varying class and different gender pursuing their interests and values define and determine the solution of bicycle-development problems thus embodying meaning in bicycle design.

Essays by Pinch and Bijker, Hughes, Callon, John Law ('Technology and Heterogeneous Engineering: the Case of Portuguese Expansion'), Donald MacKenzie ('Missile Accuracy: A Case Study in the Social Processes of Technological Change'), and by others are collected in *The Social Construction of Technological Systems; New Directions in the Sociology and History of Technology* (1989, MIT Press, Cambridge, MA). From this volume a language of analysis has spread, a language which includes 'seamless web,' 'systems,' 'actors,' 'network,' 'closure,' 'stabilization,' 'conservative and radical innovation,' 'technological momentum,' 'system builder,' 'heterogeneous engineer,' 'reverse salients,' 'interpretive flexibility,' 'translation,' and 'black box.' *The Social Shaping of Technology* (1998, Milton Keynes), edited by Donald MacKenzie and Judy Wajeman, also explores methodological and social construction themes. These concepts and the new approaches to the history of technology did much to discredit technological determinism so widely accepted among the laity, so persuasively argued by Karl Marx, and so eloquently enunciated by White in *Medieval Technology and Social Change*.

T. P. Hughes

History: Overview

1. Anthropological Universals

Human beings must interpret their world, themselves, and their coevals in order to live. Human activities, sufferings, and desires are formed by definitions of meaning and of purpose, which incorporate such

interpretations. An important area for such interpretation is the experience of time, and here memory plays a central role. The interpretations of the present that disclose it to us as a world, and allow us to act in this world, always refer to the past; the past is differentiated from the present and is thus related to it in that the future can be shaped as a perspective on action.

On this general anthropological level, history is the totality of the cultural practices through which human beings interpret their past in order to understand the present and anticipate the future. In other words: history is the generation of sense out of the experience of time.

But not every interpretation of time is historical. What determines the historical quality of an interpretation is the fact that time confronts human beings in two ways: as *real change within the world*, in which contingent events occur and are experienced, and as an *interior, temporal extension of consciousness* (and of the unconscious). Here, intentions and objectives, guided by the elemental mental forces of fear, anxiety, desire, hope, and longing, play a central role. We interpret the 'objective' time of real change (the present) through the recollection of another time (the past); thus the 'subjective' time into which we project a future is bound to our approach to past experiences. This is human culture's specifically historical procedure for experience and interpretation. What defines the historical interpretation of time is its implicitly meaningful and thus orientative conception of the course of time. The latter comprises the past, the present, and the future, and at the same time articulates experiences and intentions; it is thus empirical and normative at the same time. The philosophy of history explicates this conception of the course of time as a particular mental structure. Even without philosophical reflection or justification, such a conception of the course of time organizes historical thought, and shapes its content. History interprets the contingent events of the past and defines their significance for the present. It organizes historical narrative as a particular kind of explanation (Danto 1965). It is this 'explanation through narration' that defines the logic of historical thought in its academic form as well.

2. Conceptions of Time

The different conceptions of the course of time important for historical interpretation employ various temporal categories in various constellations (e.g., cyclical time, linear time, the concept of the *kairos*), each encouraging particular expectations: decline, progress, permanence, recurrence, revolution, destruction, and so on. They relate real temporal processes to the active intentions and self-conceptions of the subjects that make use of them. In other words, history mediates the subjectivity of acting and suffering

human beings with the objectivity of the temporal process of their world. In early societies, this was accomplished by an appeal to divine forces, which impel the transformation of the world and the human spirit at the same time; in other societies these divine forces are replaced by humankind as a spiritual and moral being, its ability to create symbolic worlds or to plan the conquest of the natural and social world through knowledge. Finally, nature, too, can be invoked as a sort of metaphysical instance for the continuity between the two temporal dimensions of human historicity. Nature can thus be understood as that which compels the human race, by means of social antagonisms, to create culture (as in Kant, for example), or as struggle of the races in Social Darwinist terms. Psychoanalysis, on the other hand, posits an interior, psychological nature, in order to explain the historical movement of the human world by means of the dynamics of the unconscious.

The idea of a 'history' comprising all temporal change within the human world is of modern origin (Koselleck 1985). However, it has a premodern equivalent in older cosmogonies, theogonies, and anthropogonies, as well as in the concept of redemptive history.

3. History as Event and Narration

In every culture and epoch, 'history' has a double meaning. On the one hand, it designates temporally organized events in the past. At the same time, and inseparably from the first meaning, 'history' also means the account of these events that articulates their significance for our understanding of ourselves and of our world. The first meaning has to do with temporal succession and the second with its narrative representation.

Not everything that has happened can be called history, but rather only that which is somehow meaningful in the present; for example, the foundation of a city or a kingdom is significant to its inhabitants, a person's birthday is significant to him or her, and so on. Usually, this event is described as a sequence of occurrences. These may often be the actions of human beings, heroes, or divine beings, as in myth or epic; however, they may also involve more complicated phenomena, such as the development of a manufacturing process, the evolution in the meaning of a concept, the epochal transformation of a mentality, an 'axial time,' and so on.

In its second meaning, history is the representation of the past in the culture of the present. Here, 'history' is the product of historical consciousness: through memory, the past has become present and meaningful in narrative form. In this way, the past 'in itself,' that is, everything that has happened, and persists only in the form of trace, relic, memorial, tradition, ethic, and so

on, becomes history 'for us.' The basic mental procedures involved can be organized somewhat artificially into four:

(a) the *perception* of 'another' time as different: the fascination of the archaic, the obsolete, the mysterious trace, the insistent memorial, and so on;

(b) the *interpretation* of this time as temporal movement in the human world, according to some comprehensible aspect (e.g., as evidence of the permanence of certain values, as examples of a general rule, as progress, etc.);

(c) the *orientation* of human practice through interpretation—both 'outwardly,' as a perspective on action (e.g., as the increase of political legitimacy through political participation, as the restitution of the world before its destruction, as the institution of 'true' conditions against the decline of morals) and 'inwardly,' as identity conceptions (e.g., 'we are the children of the sun,' or 'we as a nation stand for the universality and fulfillment of human rights,' or 'we belong to the communion of saints,' or 'we represent true spirituality as against others' materialism');

(d) and finally, the *motivation* for action that an orientation provides (e.g., a willingness to sacrifice, even die, for the sake of historical ideas of national greatness, the missionary spirit, etc.).

4. Memory, History, and Metanarratives

The relationship between memory and historical consciousness continues to be debated. Memory in the everyday sense is directed toward the experiences of individuals in their own lives, whereas historical consciousness primarily thematizes a past that exceeds an individual life span. Both, however—the individual memory on which individuality and social affiliation are built as well as the expansion of 'history' beyond the limits of a single lifespan back into the past—are as inseparable as two sides of a coin: human beings tend to transform their own identity into temporally more inclusive structures, such as the communion of saints, the nation, the people, the culture, and so on. The basis of individual subjects' self-esteem and of their practical temporal orientation tends to exceed their lifespan or to outlive them. It therefore usually extends far back into the past.

'History' generally performs its orientative function through a 'master narrative' or 'metanarrative.' This describes the conception and evolution of the addressee's world in order to legitimate its normative framework. At the same time it provides an experiential inventory, which is available whenever problems of orientation require consensus. It legitimates not only systems of politics, economics, and the environment, but also the collective and individual subjectivity and identity of the people. Metanarratives represent social affiliation and differentiation internally and externally.

Metanarratives generally organize social inclusion and exclusion *ethnocentrically*, assigning one group a positive normative weight, and other different groups a negative weight. One's own life world appears as culture or civilization, other worlds are looked upon as savagery and barbarism. This difference can be articulated in different ways: as an opposition, as deviation from a norm, as atavism on a progressive scale, etc. Just as history presents past experiences as a 'mirror' in which the present perceives itself, the image of others in the same historical mirror has a contrastive function: it defines a self-image. Under the special conditions of an orientation crisis, the 'other' can assume admirable features, as in the image of the 'noble savage.'

5. Historical Culture

The interpretive work of historical consciousness and its product called 'history' is concretely manifested in a society's historical culture. Historical culture is multidimensional, like every other culture. It has religious, moral, pedagogical, political, and rhetorical expressions; its cognitive substance is always the knowledge of '*wie es eigentlich gewesen*,' how it really was. We can distinguish three basic dimensions of historical cultures as an ideal type, each different in its logic and thus accountable to different criteria of meaning.

(a) The *political* dimension is concerned with the legitimation of a certain political order, primarily relations of power. Historical consciousness inscribes these, so to speak, into the identity concepts of political subjects, into the very construction and conception of the I and the We, by means of metanarratives that answer the question of identity. There is no political order that does not require historical legitimation. The classical example, applicable to every culture and every epoch, is genealogy. Even the pure rule of law that appeals only to the applicability of formal decision procedures must be historically based if these procedural rules are to be plausible to the participants. Charismatic leadership also cannot do without historical elements. Generally, the vehicle of political charisma will refer to the spiritual or natural forces that, within his culture, guarantee the world's temporal coherence.

(b) The *esthetic* dimension is concerned with the psychological effectiveness of historical interpretations, or that part of its content that affects the human senses. A strong historical orientation must always engage the senses. Masquerades, dances, and music can all have historical content. Many older metanarratives are composed in poetic form and are celebrated ritually. A formal defect can destroy the effect of such a presentation, and even endanger the world's continued coherence. Historical knowledge must employ literary models to become discursive. In

many cultures, historical narrative occupies a secure place in the literary canon as a genre of its own. In modern societies, memorials, museums, and exhibitions are among the familiar repertoire of historical representation. In older kinds of social systems, objects such as relics, tombs, temples, and churches obligate the present to the legacy of the past, indeed make the present, in its relationship to the future, responsible for the vitality of historical memory.

(c) The *cognitive* dimension is concerned with the knowledge of past events significant for the present and its future. Without the element of knowledge, the recollection of the past cannot effectively be introduced into discourses concerned with the interpretation of current temporal experience. Mythical metanarratives, too, have a cognitive status, although science would eventually deprive them of it. They lose their orientative power when confronted with a science of the past that possesses a more elaborated relation to experience. Metanarratives then become prosaic, as they already did in antiquity, with Herodotus and others. In modern societies, the cognitive dimension of history has become an academic discipline.

6. Typologies of the Historical

Synchronic and diachronic typologies of the historical can be generated out of the particulars of historical thought, and inquire into its carriers, functions, class and gender specificity, and other factors within the social context's framework of determinations (Rüsen 1996). They become historically specific, however, only when they differentiate the specific interpretative work of historical consciousness and of its product—'history' as the cultural orientation system of temporal consciousness—according to the different possibilities of historical meaning construction. Such differentiation from a metacultural perspective has been little attempted. Previous efforts have usually focused on functional and formal aspects, and have thematized less the total domain of human temporal interpretation than simply the domain of historical writing, and if at all they only inspected the Western tradition. Nonetheless, such typologies can also be used as analytical tools for research in the wide areas of historical culture and for intercultural comparisons.

Nietzsche (1985), for example, differentiated the monumental, the antiquarian, and the critical uses of history in terms of their advantages and disadvantages for life:

(a) the *monumental* approach inspires action by recalling the creative deeds and great moments by which the world was actively transformed, and emphasizes the greatness of man as the agent of historical change;

(b) the *antiquarian* approach serves the preservation of tradition and the affirmation of existing conditions by its reverence for and transfiguration of their origins;

(c) the *critical* approach, finally, defeats the power of memory, breaks the control of tradition, and liberates life for new orientations.

Hayden White (1973) presented a very influential model for the analysis of historical writing, and applied it to the nineteenth century's most significant historians and philosophers of history. It consists of a complex system of emplotment, formal argument, ideological implication, and tropes of historical discourse.

(a) The narrative forms that connect a sequence of historical events can follow the patterns of romance, tragedy, comedy, or satire.

(b) Formal argument no longer concerns so much the narrative combination of events into a story or narrative, but rather the explicit explanations within these narratives. They can be formalist, emphasizing the uniqueness of an event; they can be organicist, integrating isolated phenomena into larger totalities for explanatory purposes; they can argue mechanistically, in terms of causal regularities; and they can operate contextualistically, in terms of functional relationships between events.

(c) Ideological implications relate to the standpoint within the present from which a history develops its perspective on time. Such a perspective (White is most concerned with the nineteenth century) can be anarchistic, conservative, radical, or liberal.

(d) What is decisive for the extensive and foundational meaning of a narrative is the verbal factor that brings the different elements of historical narrative into a coherent whole. White identifies and explains this factor in terms of rhetorical figures or tropes that underpin the four possibilities for historical meaning: the latter is generated out of metaphorical, metonymic, synecdochic, or ironic uses of language.

White developed this typology for the analysis of historiographical texts; nevertheless, it can be applied to other manifestations of history, such as historical museums (Bann 1984).

Rüsen (1993) also developed a universally applicable typology of historical sense generation according to its most basic principles: its particular referents, its conception of temporal movement, its communicative form, and its identity concept. All these factors are communicated through and constituted by the principle of historical sense.

(a) The *traditional type* recalls the origins grounding present relations. Traditional history represents the course of events in terms of the persistence of these origins and their normative power, and represents identity by affirming prior interpretive models of human subjectivity (e.g., social roles). Past and present fuse into the permanence of currently effective social relations that are conveyed by time yet are above transience. Traditional narratives eternalize time as meaning. This type predominates in mythical thought.

(b) The *exemplary type* recalls past facts that concretize the rules of current conditions. Exemplary

history represents a course of events in terms of the transtemporal applicability of these rules, and constructs identity by generalizing various temporal experience into rules for action (e.g., as rule-based competence). This narrative type is represented in Europe by the classical motto *historia vitae magistra*, and in China by the metaphor of the mirror. This type predominates in the historical thought of great civilizations up to the modern period.

(c) The *critical type* recalls past circumstances in order to interrogate present conditions. Critical history represents a course of events as the transformation of prior and, in the orientative framework of life praxis, effective interpretive models (i.e., as rupture or as alternation). It constructs identity by negating pregiven identity-forming interpretive models; in other words as the power to say 'no.'

(d) The *genetic type* recalls qualitative changes in the past by which other, strange conditions become present familiar ones. The genetic construction of meaning presents a course of events as evolution, in which conditions change in order to become dynamically permanent. It constructs identity as the synthesis of permanence and change; in other words as a dynamic process. This type predominates in modern societies.

7. Media

The diverse manifestation of history, in its dual significance as fact and as interpretation, depends crucially on the medium through which temporal experience and interpretation are communicated. Language is always predominant, although there are other creative areas of historical perception and representation, such as the visual and musical arts, architecture, and dance. The modes by which language orders human communication are decisive for the expression of historical consciousness.

(a) History was originally communicated orally, as it is even now—at least in the private sphere. In preliterate cultures, history becomes oral history or oral tradition (Vansina 1985). Such a history is usually politically conservative: the traditional world order becomes obligatory; new experiences have to be integrated into it so as to confirm the collective's basic norms and identity. Such representations are sensually immediate and concrete; they are communicated face to face and correspondingly have immediate effects. Cognitively, they contain the cumulative experience of many generations; experientially, they reach into a mythical time that genealogically connects the present to the all-determinative origin of the world and include the more recent generations' memory which contain real events. Its criteria of significance are of a mythical nature; in other words, topical and in the narrow sense 'historical' events are not the vehicles of orientative normativity. Its validity claims are raised and made

plausible through ritual and repetition. In modern historical research, oral history is the method for gaining historical knowledge from the recollections of acting and witnessing people. It provides an important source for research into the mechanisms of biographical memory as an element of historical culture in the intersection of the public sphere and individual biography. The memories of witnesses to historically significant events, communicated orally, acquire an important role in public historical culture—especially the testimony of survivors of great catastrophes such as the Holocaust (Langer 1991).

(b) The medium of *writing* has dominated for millennia and continues to dominate hegemonic historical culture (in which, of course, oral elements continue to be important and effective, even constitutive—at least in education). Written history frees participants from the immediacy of the communicative situation and creates a distance between history as content and history as a form of communication (Ong 1982). This distance increases considerably the experiential horizon of historical consciousness, and facilitates new methods for accumulating and managing experience. Literacy liberates memory, fixes facts, creates new communicative forms, disconnects the cosmos of temporal meaning from immediate practical relationships, and allows it to become a phenomenon *sui generis*. Along with new opportunities for objectivation in the approach to historical experience, it also discloses new opportunities for subjectivation through historical interpretation: the narrator can become an author, and readers can obtain expanded scope for critical readings. Validity claims either are raised through canonization, or become an opportunity for discursive justification. In either case, interpretation becomes a discrete practice of historical meaning construction, with its corresponding specializations and the attendant problems of mediation and popularization. The original relationship between poetry and truth dissolves; mythology is now subject to a fundamental critique. Explicit conceptualization becomes an essential cognitive element in historical interpretation, so that history can, at least in the long term, be an object of study and of theory.

Entirely new media have transformed the historical mode of thought. We cannot yet discern distinct lines of development and stable structures, but we can certainly indicate new developments from which we might expect transformations of the most basic kind.

In the historical culture of the public sphere, collective memory is being overpowered by the torrent of historical images. The forms of consciousness created by literacy—and above all the distancing effect of rationality—may quickly decrease in significance, and especially in political efficacy. The grammar of history is becoming an imagology of presentations in which every era is contemporaneous, and the fundamental idea of a single linear movement of time is

disappearing. The constitutive difference of temporality can be suspended into a universal contemporaneity that can no longer be narratively put in order. Whether there can then be a specific 'historical order' within the orientative temporal continuity between past, present, and future has at least become a problem. The very term *post-histoire*, and the related discussion of a mode of life without genuinely historical interpretation (Niethammer 1992), suggest that these questions are now open. At the same time, there has been an immense increase in access to data. New storage media allow new modes of historical experience, and radically call into question previous criteria of significance. At the same time, new media of communication such as the Internet permit no single, politically sanctioned decision. The abundance of possibilities and the diversity of new voices require new strategies, new forms, and new contents of historically grounded participation and exclusion. In each case, fixed ideas of the permanence and substance of individual and collective identity are being outstripped by the diversity of global communication, in favor of more dynamic and more open differentiations. This process then provokes reactions, often expressed through these new media, that stubbornly insist on ethnocentric distinctions.

8. Developments

The transformation in the media of historical thought sketched above suggests a transcultural, macro-historical transformation, that will ultimately leave no culture unaffected. This provides us with a support for a diachronic classification for historiographical variety. Such a classification could be organized in terms of epochal distinctions, yet still have a typological quality. For example, White's or Rüsen's typologies could both be used to characterize historical processes. White's sequence of tropes can be understood as cyclical, and Rüsen's distinction between traditional, exemplary, and genetic historical thought can describe the great transcultural epochs where the critical type of historical thought mediates the transition between the other types.

One of the most important distinctions concerns the relationship between myth and 'history,' where the latter is understood as mundane occurrence. Myth relates to a divine prehistory as the source of meaning (Eliade 1991). In contrast, 'historical thought' in the stricter sense discerns the meaning of history in the immanent dimension of a chain of events (*res gestae*). The Judeo-Christian sacred history mediates between these two modes of thought, and allows events in the world to appear as the manifestation of God's power and God's will. In other cultures, the divine and the mundane are mediated differently: mundane but somehow significant events have to be integrated into a comprehensive cosmic order. History becomes mean-

ingful through nature, which is conceived as divinely ordered. With increasing complexity in human praxis, more and more mundane incidents are integrated into this order until it is finally 'historicized' and 'denaturalized.' Yet this process is often opposed by attempts to renaturalize it as biological racism.

Comprehensive large-scale developments of historical thought have often been conceptualized as leading to the current status of historical studies. That is often criticized as too one-sided and the diversity of new media and the different dimensions of the historical culture are emphasized instead; nevertheless plausible accounts of a developmental process can be articulated (in the form of typological hypotheses). These accounts can be used to discern and analyze transformations of historical thought in the diversity of different cultures.

Max Weber's conception of a universal process of rationalization and disenchantment seems as relevant as ever (Weber 1988). The classical philosophy of history of Voltaire, Kant, and Hegel had presented these criteria in the form of the actual course of events. To the extent that historical studies acquired increased competence in investigating and representing real events in the past, the question of meaning was investigated within the framework of a logic of historical thought (Dilthey, Max Weber, Rickert). This question is now perceived primarily as the concern of the central verbal procedure of historical thought, as historical narrative (Danto 1965). Issues of scholarly standards and truth claims (Appleby et al. 1994; Evans 1999) can be obscured by only focusing on the rhetorical and poetic strategies of historical writing (Rigney 1990).

Despite this formalization of historical understanding, the structures of real historical processes remain important points of reference. Here, the global and often conflictual transformations brought about by modern industrial societies are in the foreground. Their developmental dynamics can be understood only by a concept of time in which the horizon of experience and expectation structurally diverge, and can only be reconnected by a fundamental temporalization of the human world (Koselleck 1985).

Narratives of progressive rationalization and disenchantment must, of course, be complemented by an account of a critical and transcendent re-enchantment resistant to rationality, such as the endlessly renewed rationality of sense (value rationality); it refuses to dissolve in methodical rationality of the control of experience. Historical studies, the development of which in Europe from the eighteenth century has been the most effective factor in the modernization of historical culture, must employ sense criteria that methodical rationality alone cannot generate.

The rationalization of modern historical culture is constituted by a universalization of the norms and values that make the past significant for the present.

The ethnocentric logic of identity formation always has a universalizing tendency, insofar as it describes its own world as both unique and normatively obligatory. 'Humanity' is a common frame of reference for historical identity. In the focus of historical experience, humanity is extended to the limits of the known world. This creates a fundamental, structural conflict of cultures in historical thought, which has repeatedly led to violence, to the legitimation of domination, and even to genocide.

This leads us to a fundamental problem in contemporary historical thought. It is shaped by the rationalism that culminates in historical scholarship and related human sciences (Bentley 1997). This rationalization of history as scholarship corresponds to the modern rationalization of all knowledge, without which the organization of modern societies would be inconceivable. Is historical thought inseparable from the value system of Western culture in its current form along with this methodological rationality? If so, how can it conceive of history in such a way as to account for the diversity in different cultures' articulations of 'history' as the orientative framework of human praxis? Does this diversity, once it has been researched and analyzed by scholarship, not always appear in the light of a particular interpretation—namely the interpretation to which methodological reason essentially belongs?

Current tendencies in historical thought (post-modernism, postcoloniality, the 'cultural turn') are determined to overcome modernity in this sense. They want to create a pluralism of 'histories' that can break the spell of uniformizing rationality and generalizing normativity. They thereby destroy the orientative power of modern historical thought with its notion of a unified direction of development, or 'progress.' At the same time they problematize the claims of the scholarship that describes the laws of such development along with the desire for mastering them, e.g., in Marxism.

In the age of globalization, in spite of the critique of the claim for hegemony inherent in Western historical thought, we cannot do without either methodological rationality or the universal regulative of communication. We need this regulative to understand the present by the interpretation of the past to define inclusion and exclusion, and to act in anticipation of the future. Yet, if the ethnocentric logic of such a universalization is to be broken or overcome, the truly universal regulative of historical thought and of the historical culture can only be a mutual and thereby universal recognition of difference and particularity. This idea is and will remain counterfactual, even utopian; nevertheless, it could disclose new dimensions of historical experience and lead to new and politically significant orientations.

Certainly the terrors and catastrophes of the twentieth century, such as the Holocaust, provide a new challenge to historical thought. Only with difficulty

can they be integrated into older conceptions of historical meaning. They require new strategies of interpretation and representation. The question of human 'nature' must be radically reconsidered, and senselessness itself should be taken as a constituent of a meaningful conception of history (Friedländer 1998).

History, Professionalization of

It is evident that the term professional in this connection has two different meanings, which are related to each other but are not equivalent. The first (a) is professional in the sense of being able to live by the trade (in the meaning of occupation, such as the French word 'profession'). The second (b) is professional as a qualified person who is recognized by society (not least by his or her fellows in academia) as competent to practice the trade with a closure directed against nonprofessionals, i.e., amateurs and those writing on history without being 'real' researchers.

1. The Historian's Profession as Bread-winning

In the first sense of professionalism (see *Professionalization/Professions in History*), there have been professional historians for a long time but there is no distinct collective process of professionalization. The writing of history is age-old. Some famous history writers were active in the European antiquity, and especially Herodotus and Thucydides of Greece have won lasting fame. These and other early European historians were not writing history for their living. In China from at least the second century BC, and later in Korea and Japan, historians were engaged to describe the history of their country under a dynasty. This usage involved a real employment in China and it even entailed a personal responsibility of the historian for what he wrote. Sima Qian (born 145 or 135 BC), known as the Grand Historian, was employed to make justice to the Han dynasty but he also maintained a theoretical discourse on history (Wang 1995). He and other Chinese dynastic historians were obviously fully occupied and cannot even normally have worked alone but must have had a small office with clerks at their disposal. The Chinese professionalism among its historians had no known counterparts. In Korea the first well-known historians (eighth century AD) were politicians who wrote on their own behalf. In India there were no real historians until the thirteenth century because of the dominant cyclical time perception in the Hindu culture. The late Roman and medieval European historiographers had little profit from their writing and could not live from it. 'A book belonged to its author for as long as it stayed in his

hands. After that it was free as air' (Smalley 1974). Some late medieval chroniclers in Europe however managed to live by their work as historians. Such chroniclers were employed by princes or cities in order to relate the important events that took place within the principality or city.

In Europe, the chroniclers employed by princes and cities (those active in monasteries were not employed for the purpose and formally not living by their historical writings) were followed later by official historiographers hired by kings and states for the 'proper' recording of the wars where their masters were engaged. Titles like Historiographer of the Realm (in variations all over Europe) make clear the official mission of the historian. The French *Historiographe du Roi*, was a title used from 1554 to 1824, and 104 persons bore the title. It was not so much a function as a title with a reward, and the historiographers were not highly regarded at court (Boer 1985). For most such official historiographers, the revenue from the title was only a side income and not enough to live on. Quite another type of professional historians in this sense arose with the great wars in Europe in the seventeenth century: those who lived from their reports from the war scenes. They established a form of market situation for themselves, and especially those behind the *Theatrum Europaeum* were successful in their branch, a sort of intermediary between history and journalism.

Already from the late eighteenth century another type of professional historians, in sense (a) of the word, appeared in Europe: the literary men writing history and more or less living by their literary accomplishments. Men like Voltaire, Gibbon, Robertson, and, to an extent, Schöler and Herder made themselves known as historians (though primarily as learned and literary men) and their works were sold in editions of considerable numbers. Their ambition was to a large extent to give to the reader an impression of historical personalities and their struggle with moral problems, a sort of applied political science or applied moral philosophy. These historians did not strive for new factual knowledge at first hand but rather a better insight into the moral problems of politics pursued by states and kings. Such literary professionals who worked with historical subjects were more successful than the contemporary professors of the universities of Europe, who also earned their living from history and who were mostly not well known.

Still in the (a) sense of the word professional the authors of the 'broad' literature on history which grew up from the early nineteenth century should be mentioned. Many narrators of history wanted to give to their countrymen a better understanding of the past of their nation. Publishing narratives on national history for the broad layers of the population sometimes also gave a living to the authors already in the first half of the nineteenth century. It is easy to see the continuation of such popular narrative into the twentieth century. The number of persons who have had

the possibility to earn their living by telling history in different media and not only in printed books has increased enormously. The demand for history as entertainment, originating in the eighteenth century among the upper classes, has grown and spread in society. In the twentieth century, publishers have been interested in different types of books, such as specialized historical works, textbooks for schools and universities, historical journals, historical fiction and pure historical entertainment. Adaptations of history in various forms for radio and television have also gradually increased their share in the total turnout, and art film has been used for telling stories with a historical setting. The comprehensive number of persons who make their living from these forms of writing and processing history has never been calculated.

In the twentieth century, though starting earlier, there has also been a great growth of the number of professional historians in sense (a) of the word, who have been employed in teaching. Here must be included all teachers specializing in history, both in secondary schools and at the university level. Historians working in archives and museums also belong to this category. With the great expansion of secondary and tertiary education, the sector has been steadily growing in the twentieth century, especially after World War II. For France in 1910, Boer has estimated the number of historians in these categories to 1045 (Boer 1985). On the eve of the 1950s the number of professional historians in France has been approximated as less than 3,000 but then this number does not include archivists and historians employed in museums. In 1967, the number of the same limited category of professional historians had grown to close to 8,000 (Charle 1995). German and Australian calculations go in the same direction. (Raphael 2000, Macintyre 2000).

2. Establishing Professionalism Among Historians as a System of Norms

The second sense in which the term professional is used, 'professional as a qualified person who is recognized by society (not least by his/her fellows in academia) as competent to practice the trade,' has a more complicated historical reference. Historians who were recognized as competent historians by their contemporaries have existed for long. But in regard to the recognition by fellow historians, especially those with university posts, this is something much newer. If recognition is taken to mean an inclusion into a network, group or a formal association, only the history of the period from 1750 provided any means for the realization of such professionalism. If, further, a sort of common program of the network or group is required, the field is narrowed even more.

From the middle of the eighteenth century we can discern the beginnings of a formation of schools

among academics in general and also among historians in Europe. It is difficult to say if anything comparable has been at hand in other parts of the world earlier. This was the period when German universities were flourishing and universities in other parts of Europe and its colonies were not. Because of the low level of state power in Germany not only free authors could express their views but also civil servants, such as professors. This made German universities, especially those in Halle and Göttingen, serve as a nursery for new notions in the humanities. Linguistics and history prospered. In the nineteenth century, 130 Protestant historians (plus an unknown number of Catholics) became full professors of history at German universities and for most of them this chair meant a culmination of their academic career. For the first time an occupational group of historians developed. Their competence for the professorship was mostly carefully examined and a discourse on history emerged (Blanke 1991). Mostly, however, these were individual accomplishments and the level of coordination between the learned men was low. No common rules for historical works were acknowledged, though an effort to write a manual of historiography was made by G.A. Will. Many other historians, e.g., Johann Martin Chladenius and Johann Christoph Gatterer, lectured on rules and wrote on the theory of history (Reill 1975). The process of standardization of methodological rules was, however, regarded with skepticism by some of the most important historians, such as August Ludwig Schlözer, who talked about imprisonment in scholarly rules, as Blanke has noted (Blanke 1991). In the early years of the nineteenth century at least four introductions to historical studies were published. As to rules for the critical use of sources and general methodological emphasis the introductory book by Friedrich Rühs from 1811 is noteworthy.

There were hardly any 'schools' of historians before well into the nineteenth century. Academic teaching of history and research in history were well established in many countries in the eighteenth century, though without a canon of methodology or a professed normative system, which applied to history as a discipline. History was rather regarded as a part of a wider discipline of morality, the French *sciences morales et politiques*. Past events could be used to show the consequences of different types of conduct and new enlightenment notions made it possible to analyze historical processes without referring to God or providence (Heilbron 1990). For centuries history had been used for this purpose, but the morality concerned changed its content and its stability in the eighteenth century. The new directions were not diffused to students in standard formulations or transformed into methods and manuals. The cohesion among enlightenment historians was low and this continued to be the case up to around 1830.

The change brought about primarily by Leopold von Ranke was to create the conditions for a network

of historians under the guidance of the master. He had meetings with his disciples, later known as his seminar, where problems of history were discussed. Ranke himself was a spokesman for three main principles of historical interpretation: the state as a central entity, the state system as the polity of international relations, and the necessity for the historian to evaluate each single entity for its role in history and not from its relation to contemporary politics. The first of these principles was a common ground for many thinkers of the period, but combined with the other two it formed a specific analytic system. The third principle has been partly traced back to forerunners in the eighteenth century (Meinecke 1936, Blanke 1991, Blanke and Rüsen 1984) and it created the basis of the thought system, which became known as *Historismus*.

In the German academic community of historians the combination of *Historismus* and teaching through seminars became an instrument for the professionalization of historians. A common evaluative system was created in the latter half of the nineteenth century. A methodological part was often combined with individualization of persons and collective entities of the past, especially among the historians of the Middle Ages who were concerned with the editing of the *Monumenta Germaniae historica*. This work elaborated further methodological principles for editing which had been developed in France by Jean Mabillon and others from the seventeenth century and onwards, and which gave rise to the *École des Chartes* at Paris. Methodology became important and the principles for the evaluation of sources became more and more systematized. A methodological direction of historians within the *Historismus* has therefore been discerned, with a philosophical direction as its counterpart. The former was characterized by its devotion to empirical studies with a sincere application of methodological principles in order to obtain objective knowledge, while the philosophical direction generally rejected the possibility of reaching any form of certainty and proclaimed relativity of knowledge. In fact it will seem that the differences within *Historismus* were great. On the one hand were those who saw historical relativism as fundamental and regarded history primarily as a means of orientation in the present. On the other hand were those who wanted to overcome as much as possible the constraints of the sources for understanding the past, though still with a considerable relativism in regard to values (Oexle 1996, Scholtz 1997).

In several respects a new turn of historical professionalism grew out of the empirical *Historismus*. It was important that new methodological manuals were published and widely accepted in the European community of historians. J. G. Droysen had published his *Grundriss der Historik* (1868), but its emphasis was rather on the principles of *Historismus* than on the strictly methodological side. Ernst Bernheim's *Lehrbuch der Historischen Methode* (1889) and

Charles-Victor Langlois' and Charles Seignobos' *Introduction des Études Historiques* (1898) were in this regard epoch-making. These books were in the first hand methodological (from the 1903 edition Bernheim added a section on philosophy of history), and they received a very wide circulation. They taught how to find secure knowledge in history. The authors sought somewhat different philosophical bases for their standpoints but the authors of both books turned their back to the relativism of knowledge. Their differences mattered less than their methodological aims, which found appeal among historians.

The first decades of the twentieth century witnessed a change in the general approach to historical professionalism. The emphasis had been on the theory of the state or the theory of state systems or the theory of the (individual) nation. Now the methodological element became central. Without the proper knowledge of how to evaluate sources a historian was not accepted as a professional. Several factors helped to make methodology a central element in the professionalism of historians. One was the rise of national historical associations. This was a process that took place all over Europe (and also beyond Europe in some countries) in the latter half of the nineteenth century. Philosophical and political issues divided all such associations and, thus, only methodology was really a common basis. This was even more the case with the international organization of historians, later known as the *Comité International des Sciences Historiques*, which can be traced back to 1898. In the early programs of its international congresses from 1900 and 1903 methodology played an important role and the object of the discussion was rather which were the conclusions for the philosophical foundations that must be drawn from the established methods than the other way round. After the congress of 1908, the French historian Simiand complained in a review article that methods had not been sufficiently emphasized in the congress contributions (Erdmann 1987).

In the last decades of the nineteenth century and the early part of the twentieth century the historical associations of the European countries also in most cases started journals (Stieg 1986). The influential German *Historische Zeitschrift* was, however, founded in 1859 as a private initiative by Heinrich von Sybel. The earliest still existing seems to be the Danish from 1838. During the twentieth century the creation of journals of history has become usual in all parts of the world, and some of these are much more than national journals but quite general (such as the *American Historical Review*, founded in 1895) or thematic for studies of the history a major part of the world (such as the *Journal of Asian Studies*, founded in 1957). Other journals and reviews with a thematic or rather broad methodological focus, such as the *Revue de Synthèse Historique* (1900–31); the *Annales d'Histoire Économique et Sociale* (founded in 1929, from 1946 called *Annales: Économies, Sociétés, Civilisa-*

tions); the *Past and Present* (founded in 1952); the *Journal of Contemporary History* (founded in 1966); the *Journal of Modern History* (founded in 1929), etc., were mostly later creations. In most of the journals, articles on themes of history were combined with critical reviews of books. An important element in such reviews was to examine the methods used and the shortcomings of authors in respect to methodological rules. Thus, in the form of critical reviews of the works on history, the methodological norms were spread. These norms were also commonly accepted. In the case that a historian wanted to contradict criticism he or she had to show that the principles had been observed rather than that these principles were not valid. This is something that characterizes methodology but is not valid for the kind of substantive norms that formed the major part of *Historismus*.

For the formation of the profession of historians, the debates on the application of historical methods were very important. A series of such debates took place in different countries in the first decades of the twentieth century. There was a big debate in Germany, called the *Methodenstreit*, on the correct use of methods in regard to any scientific activity. Generalization and interpretation were advanced as alternatives. Karl Lamprecht, with his concept of social and cultural history, was rather lonely in Germany and is often regarded as defeated. In fact, part of the issue was the theories of *Historismus* and the alternative professed by Lamprecht. Another part dealt with methods and their application in the strict sense, where individualization (W. Windelband, H. Rickert, M. Weber, F. Meinecke, and others) was opposed to views based on structures and collectivities (W. Sombart, H. Pirenne, F. Simiand and others) (Iggers 1984). The struggle was reflected in other countries such as Finland. In other countries, e.g., Sweden, Norway, and China, there were other straightforward struggles about the use of methodological principles and the consequences for national history. The historians who advanced new and radical consequences of methodologies, which were already well known, had a program. They wanted to establish firm knowledge in history, a knowledge that was contrasted to guesses and conjectures, not to historical relativism. In the USA, the focus of the debate was the possibility of establishing objectivity (Novick 1988).

Historical professionalism also increased through the ongoing specialization of all historical fields. In the beginning of the twentieth century, it was no longer the normal thing for a historian to take as the theme of an investigation the history of a country during a certain period. This had been quite usual in the middle of the nineteenth century, but in the first decades of the twentieth century this had changed. History had begun its separation into specific subfields, and economic, social and cultural history were regarded as major such parts. Specialized research institutes came into existence and specialized journals were published: the

Economic History Review from 1927, the *Vierteljahrschrift für Sozial- und Wirtschaftsgeschichte* from 1903, the *Journal of Contemporary History* from 1966, and the *Vierteljahrshefte für Zeitgeschichte* from 1953. Similar journals were published in many countries with specific reference to the speciality in the national context. Specialization went further, chronologically and thematically. Investigations became very specialized in regard to field and object of study, and period of investigation. There was a dramatic change in the themes regarded fit for doctoral dissertations from the middle of the nineteenth century to 1920. Dissertations then were also outcomes of extensive archival research where the author could and should show his or her (some women were achieving the doctoral degree at the time) acquaintance with sources and with the appropriate methods. Academic professionalism aiming at firm knowledge had found its way of expressing itself in such specialized studies.

At the same time as the second phase of historical professionalism in the sense of recognition among equals was triumphing in the interwar years, a distrust in the validity of its central notion, the idea of secure knowledge, was winning ground among historians. The philosophical direction of the *Historismus* had long since brought about doubts as to the possibility of reaching to security in historical research. Its proponents had allied to the old tradition of hermeneutics, grown out from Bible studies, for acquiring a system of understanding. It contained two main requirements: pre-knowledge as the conceptual apparatus and direction of interest; and empathy as the means of acquiring an understanding of human thoughts and actions. Hermeneutics was regarded as a means to acquire more or less probable statements on the past and the most general formulations included an ambition to maximize the probability through research. Collingwood (1946) worked in this direction, and after World War II, Hans-Georg Gadamer brought out his influential interpretation of hermeneutics, *Truth and Method* (1960), which was later overshadowed in some circles by Paul Ricoeur's *Time and Narrative* (1983–85).

Common to these works was that many historians accepted them as important foundations for the work of the historian. This meant that a new professional identity arose among some historians, conflicting with the earlier established group identity based on firm knowledge. As long as a basic norm in the hermeneutical camp was to increase probability of historical statements through empirical research, the conflict could be kept within close bounds. After the 1980s, this was no longer possible. Various theoretical directions have taken the relativistic claim further. The debate in the 1980s and 1990s has gone out from Hayden White and his rhetorical analysis of historiography (White 1973, 1978). The analyses of his standpoint have been numerous, above all in the USA, and have led to a variety of relativistic positions as regards the theory of

history based on the assumption that history is basically a rhetorical and aesthetic discipline. At the same time, in Europe, postmodernism has influenced other philosophers of history. A far-going relativism in different forms thus has more or less superseded the earlier basis of professional identity among historians.

Social theories in the broad sense of theories of the social sciences have since long occasionally been used by historians. More regularly has this been the case from the 1960s and onwards. In economic history it was already earlier the rule to rely on and use theories of economics, but theories of management and organizations and sociological theories have been used to a large extent by historians in historical studies only in the 1970s and 1980s. The professionalism of economic historians has come to rely on the ability to apply such theoretical instruments as well as specific economic (statistical) methodology. The analysis of social structures and social dynamics has also developed through the use of social theory. This approach had one of its origins in the *Annales* circle, then most often directed towards demography and geography and their social consequences. More explicitly, social science theory in general, including sociological and organizational theory, was proposed as the proper instrument for historical research by the so-called Bielefeld school, consisting of a group of historians who had some relation to the university of Bielefeld in the 1970s.

What they proposed was in line with what had been done by several American historians earlier, such as Merle Curti and Stephan Thernstrom, but their efforts had not been coordinated into a program. The Bielefeld historians advanced the concept of a 'historical social science' (Kocka 1977, Wehler 1980). This type of history found much appeal in the 1970s and 1980s. Although parts of this enthusiasm for social sciences were criticized later, it is rather the theories used than the close link to social science (including social anthropology, which found growing appeal among historians) that have met opposition. The use of social science theories has thus been one source of professional identity among historians in the recent decades.

The conflict between ideals inspired by traditional approaches, relativism and social science has not been resolved. In fact historians have no longer (if they ever had) one source of professional identity. This is not only a consequence of the fights between different convictions within the academic community. All through the twentieth century historical professionalism has also been challenged from political quarters. Autocratic regimes all over the world have tried to make historians into docile instruments for the propaganda of the ruling ideology. Many have suffered for their professional ideals, others have accepted the norms of the state instead of the norms of the profession.

By the end of the twentieth century, when historians tried to base their professionalism on interpretative

theories, methodological rules and social science theories, all without general acceptance, the history of historiography seems to have met a new interest. Different standpoints to historical knowledge may unite in the interest in investigating the history of historiography, and it is equally important for all different standpoints. The role of this disciplinary self-understanding for a renewal of professionalization should not be overrated, however. The history of the discipline cannot meet the requirement of providing the norms through which a closure can be upheld against nonprofessionals and, as regards norms there is no unanimity. In many countries it seems that the professional closure has become softened in recent decades and no sharp line is often drawn between historians and persons of literature. If history is at a point of crisis as a discipline, as is frequently said, it might be a consequence of two facts. No single normative theory is prevailing and the profession seems to rely on the quasi-theoretical field of its own history to reproduce a common professional identity.

History: Theories and Methods

Since history turned into an academic discipline in the nineteenth century and professional historians claimed a privileged epistemological status for their approach vis-à-vis non-professional approaches to history, debates about the role of methods and theories in history have been characterized by a certain conjuncture. In periods of relative uncertainty and crisis about the status of history as a distinctive, academic discipline—such as the periods between 1880 and 1920 and 1965 to 1985 in the West—a substantial body of historians

participated in these debates. In those periods, *Methodenstreit* is more or less intense and visible, while in periods of relative certainty and academic recognition, this type of debate usually recedes into the background. So, seen from a historical point of view, reflection on the role of methods and theories in history is in a sense a symptom of crisis; at least outside the small group of historians and philosophers who permanently reflect on history in their capacity as philosophers of history. This direct connection between a 'reflective mood' among professional historians and their sense of professional uncertainty makes sense because, as will be elucidated below, method and/or theory have usually been presented as the discipline's cognitive foundations, especially its claim to produce 'objective' knowledge of the past. Therefore, doubts and debates about method and theory in history are always doubts and debates about the discipline's cognitive status, its academic credentials, and its claim to objectivity.

Seen from the point of view of the sociology of science, debates about the role of methods and theories in history have usually been directly linked to battles waged by the proponents of different conceptions of history for academic legitimacy and supremacy, that is, for academic recognition and reputation. In periods of serious competition for 'intellectual capital' (Bourdieu) between several competing groups, operating within the same 'academic field,' debates about methods and theories in history have been intense. This not only holds true for history, but also for other social sciences such as sociology, economics, psychology, etc., and, therefore, are a characteristic of pluralistic or poly-paradigmatic disciplines.

Characteristic for the periods of increased interest in theory and method is also an increased interest in the history of the discipline in case from both an intellectual and from an institutional angle. This interest in disciplinary history is usually motivated by a desire to locate the origins of the preferred conception of historical theory and method in the discipline and to generate academic credentials by locating prestigious founding fathers or precursors of the preferred conception in the discipline's pedigree. Therefore, in history, an increased interest in the history of history writing alias historiography can usually be observed alongside an increased interest in theory and method: theoretical and methodical reflections usually are accompanied by reflections on the origins, nature, and variety of historiography.

Seen from a philosophical point of view, debates about the role of theories and methods in history often have a blurred character due to the vague philosophical status of the central concepts of theory and method. Therefore, some elementary conceptual clarifications are called for in order to answer the question why theory and method in history have turned into a heavily contested area at times since history turned into an academic discipline.

1. Theory and Method in History: Some Preliminary Distinctions

In discussing the role of theory and method in history, it is necessary to introduce some basic distinctions. Due to the double meaning of history as *res gestae* and as *historia res gestae* (see *History: Overview*), theory in history can refer both to history as a process and to the knowledge of that process. Therefore, the first basic distinction to make is the distinction between:

(a) theories, which deal with characteristics of history as a process (such as, for instance, Marx's theory of history as class struggle); and

(b) theories, which deal with the characteristics of knowledge of history (such as, for instance, that scientific knowledge of history has the form of law-like knowledge or the form of concrete particulars).

Theories of type (a) can be called substantial or material theories of history, while theories of type (b) can be called cognitive theories of history, i.e., theories of historical knowledge.

Cognitive theories of history can further be subdivided into:

(a) epistemological theories and

(b) methodological theories, while substantial theories of history can also be subdivided in finer subsets (see *History: Forms of Presentation, Discourses, and Functions*).

Substantial and cognitive theories usually have been interrelated, because presuppositions about what can be known about the past are linked to presuppositions of how the past can be known. Substantial theories, for instance, which hold that the historical process is characterized by underlying mechanisms and regularities, analogous to theories of classical mechanics, have been interrelated with cognitive theories that posit that real knowledge of history implies knowledge of general laws (see *Positivism, History of*). And the substantial theory that the historical process is characterized by a fundamental chaos or contingency and not by hidden regularities alias a 'motor,' has been interrelated with cognitive theories which posit that real knowledge of history is knowledge of particular facts instead of general laws (see *Historicism*).

Substantial theories, in this way, not only have consequences for methodological positions, but also for epistemological positions. Substantial theories, which posit some kind of affinity or even identity of the knowing subject and the object of history in contrast with nature (as was the case with Hegelian idealism and its offshoots in historicism, such as Droysen and Dilthey's versions of historicism), have usually been interrelated with methodological theories. These posit a distinct kind of method for the human sciences—such as understanding, or *Verstehen*, or interpreting—in contrast with the methods of the natural sciences (usually defined as some form of causal or law-like explanation). And these distinct methodological theories have, in their turn, usually been inter-

related with distinct epistemological theories, linking methods of understanding to hermeneutic or phenomenological theories of knowledge and methods of explanation to empirical theories of knowledge. Before taking a better look at this terrain, however, it is first necessary to clarify the central concepts of method and theory as well as their interrelationships in history. When analyzed more closely, both method and theory in history appear to have a broad variety of meanings.

2. Historical Method(s): Concept and History

Analyzing the meaning of 'method' in history, it is useful to start with a clarification of the term 'method' in other disciplines first (Meran 1985). In the mathematical sciences it is common to refer to axiomatic-deductive, to infinitesimal, and to inductive methods, meaning a set of formal, technical procedures in order to solve problems within a specified range. Outside the mathematical sciences, the meaning of method is usually far less defined. In philosophy, for instance, there is a long tradition referring to methods of all sorts, ranging from Descartes' discourse on method to Kant's transcendental method, from Marx's dialectical method to Husserl's phenomenological method, and to De Saussure's structuralist method, to name just a handful. These 'methods' in philosophy, however, do not constitute defined formal rules for specified ranges of problem solving, but constitute complex sets of ideas, concepts, and rules of thumb on how to analyze specified domains, such as:

- (a) scientific knowledge;
- (b) the human consciousness;
- (c) the history of mankind;
- (d) the meaning of concepts;
- (e) the meaning of language in use; or
- (f) language as a system of signs.

'Method' in philosophy, thus, is definitely not identical with a set of formal techniques, but a loosely circumscribed research program. This diffuse and nonformal meaning of method is also characteristic of the human sciences.

In history, the term historical method was first introduced in a systematic way in the sixteenth century by Jean Bodin in his treatise of source criticism, *Methodus ad facilem historiarum cognitionem* (1566). Characteristically, Bodin's treatise intended to establish the ways by which reliable knowledge of the past could be established by checking sources against one another and by so assessing the reliability of the information conveyed by them, relating them to the interests involved. Historical method was thus at the same time intended to defeat the skeptical doubts with regard to the possibility of reliable knowledge of the past. Skepticism (alias historical Phyrhronism) had been fed by a large quantity of scriptural forgeries parading as original historical documents, primarily produced by competing churches and nobles to back

up their claims to rights and property. Therefore, the traditional claims to impartiality, truth, and trustworthiness of historians, dating back to classical Antiquity, were no longer believed, and were now replaced by a claim to impersonal and intersubjective method.

This direct relationship between history's claim to truth and method would characterize all later treatises on historical method, although what was meant by method did change over time. In the eighteenth century, historians of the Enlightenment, such as Schlözer, included not only the source critical techniques as the historical method (*Forschung*), but also the way the results of historical research were synthesized into a textual whole (*Darstellung*) and presented to an audience. This broader conception of method had its roots in the classical rhetorical tradition and would only recently be rediscovered in historical theory, that is from the 1970s onwards. The German historian and historical theorist Johann-Gustav Droysen (Droysen 1977) has become one of the pivotal historians behind this 'rediscovery' of the textual and rhetorical dimensions of history, because his treatment of historical method in the earlier and the later versions of his *Historik* embodies the transition from the broader to the narrower conception of historical method (Meier and Rüsen 1988).

The larger part of the nineteenth and twentieth centuries would be dominated by the research-oriented conception of historical method of the so-called Historical School in Germany, led by historians as Leopold Ranke and Berthold Niebuhr. Their conception of history, long been regarded as the beginning of modern, 'scientific' history, harked back to the 'narrow' conception of historical method, limiting the methodical character of history to source criticism. The historical composition and presentation—the *Darstellung*—was no longer regarded as methodical and was now seen as the literary, artistic, or aesthetic component of history. Therefore, the question of whether history belongs to the arts or to the sciences could and did arise from the nineteenth century onwards, a question that became part of the continuing *Methodenstreit* (Stern 1970, Fay et al. 1998).

In the nineteenth century, during the process of rapidly increasing disciplinary differentiation and academic institutionalization, it became customary in the human sciences to identify disciplines with one specific method, which was presented as the guarantee of its 'truth' and 'objectivity.' In this process, sociology was identified with the sociological method and history with the historical method. Canonical formulations of this conception of historical method can be found in E. Bernheim's *Lehrbuch der historischen Methode* (1889) or in Ch. Langlois and Ch. Seignobos' *Introduction aux études historiques* (1897).

Historical method in the nineteenth century usually referred to the techniques on how to conduct historical research of written materials, the so-called sources.

These techniques were traditionally subdivided in three parts, corresponding to three subsequent steps in research:

(a) heuristics, that is the techniques how to locate the relevant sources;

(b) source criticism, the techniques by which the temporal and spatial origins of the sources are established as well as their authenticity; and

(c) interpretation, by which the 'cleansed' information derived from the sources is put together by means of interpretation in order to infer 'what really happened.'

Usually a distinction was made between primary and secondary sources. Primary sources consist of the written material produced more or less contemporaneously with the object of research, ideally recorded by eyewitnesses (model: the official records of parliamentary debates). The time span between primary sources and what they represent is thus as small as possible, because distance in time is regarded as a major source of unreliability of the information conveyed. Secondary sources consist of records written a considerable time after the fact and not by eyewitnesses (model: 'hearsay'). As the information in secondary sources is based on other sources, it is, at best, 'second hand'; therefore, it is regarded as less reliable than primary source information. According to the dominant, Western conception of history since the nineteenth century, serious academic history can only be based on primary sources, because those are the only reliable source of information on the past. Therefore, the archives (see *Archives and Historical Databases*) were usually considered the workshop of the professional historian. According to the same nineteenth century Western conception, non-scriptural or 'low' cultures were primitive by definition and simply had no history comparable with 'high cultures.' In this way the scriptural, source based conception of historical method defined, and limited, the object of academic history to the history of 'high cultures,' especially the history of the West. It would last until the second half of the twentieth century before these Western biases in the very conception of historical method would be seriously criticized, especially by postcolonial theory (see *Subaltern History*).

Another traditional distinction was that between internal and external source criticism. Internal source criticism is actually textual criticism, i.e., the hermeneutic procedures by which a text is reconstructed (if it is passed down in an incomplete form or in several variants) as a whole and the textual procedures by which authorship and textual authenticity are checked and its meaning established. External source criticism consists of those procedures by which a source is checked by information derived from other sources, written and material. The so-called auxiliary sciences, such as paleography, chronology, sillography, toponymy, numismatics, and diplomatics, usually play an important role in this phase when historians are

dealing with older periods. And when modern historians are dealing with nonscriptural, oral cultures or with cultures that left few or no scriptural traces, archeology and anthropology often function as auxiliary science. Reference to multiple methods within one discipline became the rule only in the course of the twentieth century, thereby reopening the problem of truth and objectivity and paving the way for a new wave of skepticism. For if the method can no longer be regarded as the procedural guarantee for the truth and objectivity of the discipline, what could, so an influential argument ran (Bernstein 1983, Megill 1994)? Recognition of plural methods within one discipline, therefore, has often been regarded as a threat of the disciplines academic credentials.

From the late 1960s onwards, the process of methodological differentiation within all of the human sciences took an unprecedented pace, leading to a temporary fragmentation of most disciplinary fields and a questioning of most traditional disciplinary boundaries and self definitions. Significantly, the new, 'poly-paradigmatic' self-image was at the same time regarded by many as a crisis of their discipline. This also held for history, in 1960s and 1970s regarded by many as one of the social sciences (Novick 1988, Appleby et al. 1994, Iggers 1997 see *History and the Social Sciences*).

Historians identified the quantitative method (see *Quantification in History*), the biographical method (see *Biography: Historical*), the comparative method (see *Comparative History*), the ideal typical method, understanding as a method (*Verstehen*), the causal method (*Erklärung*), discourse analysis as a method (see *Linguistic Turn and Discourse Analysis in History*), the micro-historical method and a psychoanalytical method in history (see *Psychohistory*). Other historians claimed that the concept of method had become severely overstretched, holding that most advertised methods in fact were theories about historical knowledge, which could only be checked by the historical method of source criticism. Therefore, a closer look at the relationship between historical method and theories is necessary.

3. Theories of Historical Knowledge

3.1 Empiricism and Anti-empiricism

The connections between historical method and historical theory can be located both on the level of epistemology and on the level of methodology. As epistemology is the theory of knowledge, historical epistemology deals with the theory of historical knowledge, i.e., the conditions of its possibility, range, sources, and foundations. Two epistemological positions have been defended in relation to historical knowledge from the nineteenth century onwards, empiricism and anti-empiricist idealism.

The problem of whether and how it is possible to acquire knowledge of other minds, i.e., the mental states of others, such as thoughts and intentions, separated from the knowing subject in both time and space—the typical problem of the historian—has been a fundamental one since mid-nineteenth century. According to empiricism, mental states could only be known as far as they correlated with empirically observable epiphenomena. The empirical dispositions or expressions of other minds are seen as the only access to other minds (Hempel 1966).

The proponents of phenomenological and hermeneutic views (hermeneutics is the theory of interpretation, originally of text interpretation), to the contrary, have always affirmed this possibility of a non-empirical access to mental phenomena. Phenomenology claimed introspective methods as the access to the mental universe; hermeneutics, far more influential in theory of history than phenomenology, claimed that 'reading' other minds could be conceived of as analogous to reading texts.

The fundamental cognitive activity in all hermeneutic theories is the interpretation of meaningful symbols and symbolically structured phenomena (like actions and cultural objects), whereas all empiricist theories regard the observation of objects as the fundamental cognitive activity. Just as it is possible to know the ideas expressed in a text by reading and interpreting, it is possible to know the ideas expressed in actions and in all human made objects by inferring the unobservable ideas from their observable expressions through re-enactment and interpretation by the historian (Droysen 1977, Dilthey 1981, Collingwood 1993). This possibility was guaranteed, according to the hermeneutic views, by the basic unity of humanity, implying the basic unity of subject and object of knowledge in the human sciences. Therefore, each alter was an alter ego, accessible through a process of intuitive identification and transfer in thought or in idea (therefore: idealism). So in historical epistemology, just as in the other human sciences, the basic divide between 1850 and 1970 has been the one between empiricist and anti-empiricist, idealist positions. It would last until the 1980s, with the rise of postmodernism and its offshoots in the discipline of history, before the unitary presuppositions of hermeneutic theories would be seriously criticized and questioned. Western (white) male was no longer accepted by all as the model of all humankind. This has led to a renewed emphasis on the basic diversity of knowing subjects and their epistemological and methodological relevance for disciplines like history (Scott 1991) (see *Gender History; Subaltern History and Linguistic Turn and Discourse Analysis in History*).

3.2 Unity vs. Duality of Method

Between 1850 and 1970, this basic divide in the domain of epistemology roughly corresponded with the basic

divide in the domain of historical methodology, i.e., the divide between the proponents of the theory of the unity of scientific method and the proponents of the theory of a fundamental methodological dualism of the human and of the natural sciences.

Methodology as such aims at the rational reconstruction of the normative rules, which are constitutive for a specific discipline and its development. Rational reconstruction, in contrast with historical reconstruction, presupposes that disciplinary practices and their development can be reconstructed in terms of logical and empirical arguments; this presupposition is, of course, an idealization of the rationality of real disciplinary practice, because apart from rationality, power and privilege also play their role in reality. Methodology abstracts from those non-rational factors in disciplinary life and aims to reconstruct the cognitive criteria and ideals, by which the practitioners of a discipline judge one another's products and evaluate their relative quality. Methodology, therefore, presupposes the existence of a basic cognitive consensus and rationality among the practitioners of a discipline. This presupposition, of course, has been criticized both for the natural as for the human sciences (Goodman 1978, Rorty 1986, Novick 1988).

Next to the basic ideal of truth, other cognitive ideals of a discipline are reconstructed by its methodology, such as the explanatory ideals of the discipline and its criteria of progress. At this level the basic methodological divide between the proponents of the unity of scientific method and the proponents of the dualism of scientific methods must be located, because the divide revolves around the question whether there is one explanatory ideal for all disciplines or not. This issue has dominated the methodological debates for more than a century since 1850 and is known under the labels of the explanation vs. understanding controversy (Gardiner 1959, Hausmann 1991). According to the unity of science view, also often labeled as positivism, there was just one model or logic of explanation and development for all empirical disciplines. Classical mechanics in the nineteenth century was usually considered the paradigm for all other disciplines, including human sciences like history. The only difference between the various disciplines was their phase of development. Underdeveloped disciplines (like history) showed little similarity to Newtonian mechanics while developed ones did. Immature disciplines only produced 'explanation sketches' (Hempel 1966), which had to be developed into real explanations. The only difference between disciplines was thus a matter of scientific maturity and not a matter of explanatory logic.

Real scientific explanation boiled down to subsuming an event to be explained under a general law. Therefore, the event to be explained can be logically deduced from the general law in combination with the given circumstances (the so-called initial conditions) and is at the same time, given the law and the initial

conditions, predictable. According to this view on the logic of scientific explanation, that is also known under the headings of the subsumption model, the deductive nomological model, or the covering law model of explanation, explanation and prediction in science are basically the same; explanation is really prediction in the past alias retrodiction. Scientific explanation, in this view, is showing why what happened, was—given the known laws and circumstances—expected to happen because it was bound to happen: explanation boiled down to show what happened was logically necessary. Given the fact that the general laws were usually (though not exclusively) interpreted as causal laws, formulating universal and invariant connections between causes and effects, scientific explanation was usually seen as causal explanation and explanatory necessity also as causal necessity: scientific explanation specifies the causes of what happened by formulating its causal determinations.

Now although this unitary theory of scientific explanation was amended and modified in time, in order to account for statistical and probabilistic forms of explanation in the natural sciences, its status was based on the assumption that 'positivist' theory at least provided an adequate reconstruction of natural science and its development from the seventeenth century onwards. This assumption has been increasingly undermined by postempiricist and postpositivist philosophies of science roughly since the 1960s and 1970s. Both the empiricist underpinnings of the covering law model and its logical claims were undermined by historical examples, arguing that the supposedly paradigmatic cases in the history of science did not fit the basic logical models of philosophy of science. Therefore, this 'turn' in the philosophy of science is often called the historical turn, because history was mobilized against explanatory logic (Lakatos and Musgrave 1970). However, before examining the implications of postempiricism and postpositivism in the philosophy of science for the opposition between classical unitary and dualistic methodological theories, an overview of the dualistic positions and arguments is called for.

3.3 *The Autonomy of History*

The philosophical defense of the autonomy of historical explanation vis-à-vis the explanatory models of natural science usually has started off with a critique of the unitary claim. From Droysen and Dilthey, through Windelband, Rickert, Weber, Collingwood, and Gadamer, to White and Ricoeur, the argument has been developed that historical explanation is not only empirically different, but logically different from the covering law model. This claim of autonomy has

traditionally been defended in three variants: an ontological version, an epistemological version, and a methodological version.

The ontological argument for methodological dualism was first systematically developed by Droysen and later by Collingwood and his school. It usually harks back to Vico and Hegel, because it is based on an idea of a subject-object identity in history: in history, humankind confronts themselves, and history, therefore, is the autobiography of humanity. History is fundamentally the process in which humankind expresses and develops themselves in the form of diverse cultures; and because humankind has made history, they are capable of knowing history in a direct way, according to this argument, just as the writer of an autobiography knows the history in case in a direct way. Historians try to reconstruct cultures and the particular ideas expressed in its cultural practices (such as religions and rituals) and its material artifacts (such as its temples and sacred objects). When historians offer explanations for the past, they construct intelligible and plausible connections between the culture and the ideas expressed in it on basis of their research of the sources in case. When they succeed in this task, they offer an understanding of the phenomena in case (*Verstehen*). Understanding history is conceived of as similar to understanding a text; the major difference is that the texts of history have more or less disappeared and therefore must be reconstructed first based on their traces by research. This type of intelligibility is possible, because in history, human beings confront themselves and therefore intuitive understanding is possible in contrast to the situation in the sciences of nature, where the knowing subject confronts an external object.

The intelligibility sought for by historians—historical understanding—is thus centered on connecting ideas to their expressions in particular spatio-temporal contexts, and proceeds by going back and forth between parts and whole in the so-called hermeneutic circle or spiral. Historical understanding is therefore logically different from scientific explanation: the type of connections, which historians present, is not causally determined and cannot be deduced from general laws. Historical connections are not necessary but contingent connections, which always could have been different from their actual form.

Neither are they based on empirical observation, but on plausible inferences, based on critical research of the sources and on analogical reasoning. Historical understanding at best produces plausible and probable knowledge and never certain or founded knowledge, as scientific explanation, based on sensory experience and logic presumably does. And being dependent on intellectual, interpretative activities by the historian, which can be trained but not formalized, historical understanding, thus, remains 'subjective,' i.e., embedded in the culture, time, and place of the historian. Based on this argument, Gadamer in his

Truth and Method (1972) would radically historicize the idea of historical understanding.

The second type of argument in defense of methodological dualism is not ontological, but epistemological. It was first systematically developed by Wilhelm Dilthey and bears a resemblance to Droysen's argument, because it also harks back to Hegel's idea of a subject-object identity in history with its implied 'history as the autobiography of mankind model.' However, Dilthey does not ground historical method directly in the subject-object structure of the historical process itself, but in the 'inner experience' (*innere Erfahrung*) of historical facts as 'mental facts' (*geistige Fakten*). The 'mental facts' of history and of other *Geisteswissenschaften* consist of feelings, thoughts, and strivings of human beings living in the past, which are only accessible through the mind and the inner experience of the historian. Like Droysen, Dilthey posits that the historian makes the mental facts of the past intelligible as expressions of ideas, by putting them in a particular spatio-temporal context alias in a *Lebenszusammenhang*. And, like Droysen, he contrasts historical understanding with scientific explanation by rejecting causal, law like reasoning for history. But unlike Droysen, Dilthey emphasizes the contrast of the 'inner experience' of the historian with the 'outer experience' of the scientist as the foundation of methodological dualism.

The third type of argument in defense of methodological dualism is of a methodological character. It is not based on an ontological claim that history deals with an object fundamentally different from nature, and neither is it based on an epistemological claim that the historical facts are different from natural facts, being accessible to an 'inner' way of knowing. According to the methodological argument, as developed by Windelband, Rickert, and Weber, two fundamental ways of knowing or methodological approaches can be distinguished, which are connected by two fundamentally different aims or knowledge interests. The first way to approach an object is a generalizing method; in this case, one abstracts from the particularity of the objects of knowledge and tries to detect and explain its general characteristics. According to Windelband, this generalizing method was specific for the nomothetic sciences (Greek: *nomos* = law, *tithemi* = to posit), such as the natural sciences.

The second fundamental approach to an object is the particularizing method; in this case one abstracts from the general characteristics of an object of knowledge and tries to describe its specific characteristics. According to Windelband this particularizing method was specific for the ideographic sciences (Greek: *ideos* = particular, *graphein* = to describe), such as history. However, both the generalizing and the particularizing methods are independent of the nature of their objects of knowledge; nature can be studied in an ideographic way (for instance, in geology) and history can be studied in a nomothetic way

(for instance, in developmental psychology). It all depends on one's methodological interest in case.

Rickert and Weber would develop Windelband's basic ideas by introducing the dichotomy between sciences of nature (*Naturwissenschaften*) and sciences of culture (*Kulturwissenschaften*). Rickert introduced the idea that knowledge interests behind disciplines were guided by values (*Wertbezogenheit*); Weber pointed out that values usually change through time. According to him, the change of the guiding values behind the sciences of culture could explain why those disciplines did not accumulate knowledge in the systematic form like the natural sciences, and why they seemed to enjoy an 'eternal youth' (Weber 1973). At best, the sciences of culture could accumulate knowledge at the intermediate level between individualizing descriptions and universal explanations in the form of ideal types, according to Weber. He suggested comparison as the method at this intermediate level. Lübke, Veyne, and Mink would develop the Weberian methodological position later, identifying history with the particularizing methodological interest (Lübke 1977, Veyne 1978, Mink 1987).

All in all, different conceptions of historical method are connected to different theories of historical knowledge. Since the characteristics of historical knowledge are usually defined in contrast with scientific knowledge as the major 'contrast class,' theories of natural science are also presupposed in theories of historical knowledge. Fundamental changes in theories of natural science, therefore, affect theories of historical knowledge by detour. The rise of postempiricism, postpositivism, and of the historical turn in the philosophy of natural science, thus have undermined most traditional, classical defenses of methodological dualism in an indirect way by undermining the classical unitary model of science. A few remarks must suffice.

Postempiricism has effectively undermined the presupposition that scientific knowledge can ever be grounded on certain foundations in sensory experience. The opposition between grounded and certain knowledge at the one side—traditionally attributed to the natural sciences—and inferential and probable knowledge at the other—traditionally attributed to the human sciences—has thus vanished. This opposition has been replaced by the insight that all sensory experience is guided and framed by concepts and theories. All empirical knowledge, therefore, is based on interpretative activities of the knowing subject because it is 'theory-laden.' Therefore, all knowledge is fallible and open to later reinterpretations. Postempiricism, thus, has dissolved the presupposed absolute contrast between a 'subjective' kind of knowledge, based on interpretation—characteristically for the *Geisteswissenschaften*, the *Kulturwissenschaften*, or the historical sciences—and an 'objective' kind of knowledge, based on empirical observation and experiment, not in need of interpretation. Postempiri-

cism has thus relativized both the distinction between theoretical knowledge and empirical knowledge, at the one side, and the distinction between interpretative knowledge and empirical knowledge, at the other. Thus, it has brought conceptualization and interpretation to the center of the stage in all disciplines. In doing so, postempiricism has undermined traditional underpinnings of the idea of fundamentally distinct scientific and humanistic methods and the idea of a fundamental contrast between the 'objectivity' of science and the 'subjectivity' of the humanities. Both scientific domains aim at empirical argument and inter-subjectivity (Megill 1994, Oexle 1998).

Postpositivism, based on postempiricism, in turn, has effectively undermined the presupposition that all scientific explanations can be reduced to one basic model, i.e., the subsumption model of explanation. By discrediting this presupposition for natural science, (Salmon 1990), postpositivism *a fortiori* has discredited the subsumption model for the humanities. Moreover, the fact that the explanation of mental states by nonmental states has not succeeded up to the present has also discredited unitary views. (Bohman 1991).

In the theory of history, postempiricism and postpositivism have led to a renewed reflection on the nature of historical knowledge in postmodernism and in a renewed interest in approaches inspired by literary theory (see *History and Literature*). Now the classical science model was discredited, the roots of history in rhetoric and literature were rediscovered, leading to a renewed interest in the linguistic forms in which history is represented, i.e., in theories of historical representation. The postmodern vanguard, oft identified with the linguistic turn (see *Linguistic Turn and Discourse Analysis in History*), pushed both theory and method in history into the background, locating historical representation beyond epistemology and methodology, on the terrain of aesthetics, rhetoric, and politics (White 1973, Ankersmit and Kellner 1995, Fay et al. 1998).

This move, in fact, harks back to the premethodical and predisciplinary roots of history, cutting history loose from its claim to constitute a truth-seeking discipline and to produce 'objective' knowledge (Rüsen 1983–89, Lorenz 1997). The history of theory and methods in history, thus, has come full circle at the turn of the twentieth century. Nevertheless, the pendulum is already swinging back, leading to broader approaches of history, which keep up the cognitive claims of the discipline based on both research (*Forschung*) and composition (*Darstellung*), while integrating the literary and the practical dimensions of history (see *History: Forms of Presentation, Discourses, and Functions*).

C. Lorenz

HIV and Fertility

It is widely recognized that HIV had a catastrophic impact on mortality from the early 1990s in much of sub-Saharan Africa, and significant impacts in a few high prevalence countries of South East Asia. The interactions between HIV and fertility are not so well known, but they deserve the special attention of epidemiologists, demographers, and behavioral scientists since they influence our understanding of the epidemic trends and the sexual behavior which underlies this. Limited evidence of the impact of HIV on fertility is available from developed nations with low-level epidemics concentrated in high risk groups such as intravenous drug users, recipients of blood transfusions, and men who have sex with men, but this review concentrates on the situation in African countries with generalized, heterosexually transmitted epidemics. The fertility effects in these populations are much more clear cut, both because the high numbers involved make it relatively easy to collect representative data, and because historically low rates of contraceptive use make it feasible to distinguish between involuntary, biological effects and behavioral responses to the epidemic.

1. The Nature of HIV and Fertility Interactions

Early speculation on the likely effects of the HIV epidemic on fertility tended to concentrate on change in intentional behavior, and predicted resulting fertility increases. Some authors believed that increases in child mortality might fuel increases in childbearing activity, as parents would want to have many children to ensure that at least a few survived (Caldwell et al. 1992). Others feared that in their quest for safe, uninfected partners, men would seek partnerships with progressively younger girls, thereby lowering the starting age for childbearing. Later writing (e.g., Gregson 1994) has given much more weight to biomedical factors and to unintended consequences of changing behavior.

1.1 Biomedical Factors

HIV lowers fertility directly in several ways, not all of them yet fully understood. Most importantly, it causes

spontaneous abortions and stillbirths (Brocklehurst and French 1998), and in the later stages of the disease women may suffer from amenorrhea (Widy-Wirsky et al. 1988). In men, it may reduce spermatogenesis (sperm production) (Krieger 1991), and lower coital frequencies have been reported by couples in which the male partner has begun to suffer from opportunistic infections.

Fertility impairments are also caused by other sexually transmitted diseases (STDs), such as syphilis, chlamydia and gonorrhea. HIV is much more prevalent among those who have other STDs, partly because of common behavioral risk factors, partly because HIV-positive individuals are more vulnerable to these infections, but most importantly because the presence of ulcerative STD infections increases the likelihood of HIV transmission (Fleming and Wasserheit 1999). These direct biological factors affect only a minority of couples in the population, namely those in which one or the other partner is already infected with the HIV virus. Therefore they may not have a large impact on fertility at the population level, but they are important determinants of fertility differentials between HIV-positive and HIV-negative women.

1.2 *Biosocial Responses to the Epidemic*

A range of behavioral responses to the epidemic may alter fertility in the whole population, even though they affect HIV-positive women more than the HIV-negative. Studies in Zimbabwe have indicated higher rates of widowhood, higher divorce rates as a result of knowledge or suspicion of HIV infection in either partner, and lower remarriage rates (Gregson et al. 1997). Increased condom use was reported in Uganda, especially in casual relationships, and there was a decrease in extramarital sexual activity (Kilian et al. 1999) and a postponement of entry into sexual unions by adolescents. These factors would tend to decrease nonmarital fertility. Other behavioral changes in response to the epidemic may tend to cause increases in fertility—for example, in Zimbabwe, some women have chosen to curtail breastfeeding, since it is becoming more widely known that the virus may be transmitted to infants through breastmilk (Gregson et al. 1997). Traditional periods of postpartum abstinence may be shortened to curb the tendency for men to indulge in extramarital affairs—Cleland et al. (1998) showed that in Benin this was more likely to happen when the period of abstinence was lengthy.

1.3 *Behavioral Change Consciously Intended to Affect Fertility*

There is little evidence that insurance or replacement effects motivate fertility increases: on the contrary,

opinion surveys in Tanzania, Rwanda, and Zimbabwe show that the majority believe HIV-infected women should refrain from childbearing in order to limit vertical transmission of the virus and to avoid leaving behind large numbers of orphaned children (Setel 1995, Keogh et al. 1994, Gregson et al. 1997). Followup studies of women in Zaire who were aware of their HIV status have indicated more contraceptive use by the HIV-positive (Ryder et al. 1991), and higher rates of induced abortion have been reported in some developed countries (Thackway et al. 1997).

1.4 *Changes in Population Structure*

Changes in the birth rate can come about not only because of changes in age-specific fertility rates but also because of structural changes in the population. Gregson et al. (1999) showed that HIV-related mortality will tend to make the population structure younger, and with proportionately more women in the peak childbearing ages of 20–29 this would tend to push up the crude birth rate. Similarly, over time, the excess mortality suffered by HIV-positive women with primary or secondary sterility due to coinfection with other STDs would tend to raise the proportion of fecund women in the population and thereby raise the overall birth rate, even if the fertility rates of HIV-positive and HIV-negative women did not change. Fecundity could also rise if interventions to treat classical STDs were successful.

2. *The Scale of the Effect of HIV on Fertility*

Empirical evidence for fertility differentials between HIV-positive and HIV-negative women has accumulated from various longitudinal studies. It is summarized below. It is rather more difficult to find unambiguous direct evidence for population level effects, though approximate effects can be estimated by assuming that in the absence of HIV infection all women would experience the fertility patterns currently experienced by the HIV-negative. However, this does not allow for the fact that HIV-positive women may be selected for high levels of other STDs and recent involvement in sexual activity.

2.1 *Differences in Fertility Between HIV-positive and HIV-negative Women*

Figure 1 is based on data from the longest running observational study of HIV in a developing country setting, in the Masaka district of Southern Uganda (Carpenter et al. 1997). It shows the typical relationship between fertility in HIV-infected and uninfected women. At ages under 20, HIV-infected women have higher fertility than the uninfected, but at age 20 and

Figure 1

Age specific fertility by HIV status, Masaka, Uganda, 1989–1996

over HIV-positive women have significantly lower fertility than the HIV-negative. This is because in the youngest age group those women who have borne children are selected for an early start to sexual activity—virgins are not at risk of childbearing nor are they exposed to the risk of sexually transmitted HIV infection. At later ages, when almost all women are—or have been—sexually active, these selection effects are not so important, and the fertility-reducing effects of HIV, described above, clearly predominate.

2.2 Population Level Effects

Table 1 (adapted from Zaba and Gregson 1998) indicates the proportionate reduction in fertility attributable to HIV in a number of severely affected populations in Eastern Africa. HIV prevalence in these populations ranges from 8 percent to 30 percent, and fertility in the population as a whole is 4 percent to 12 percent lower than the fertility of HIV-negative women. This represents an average reduction of around 0.4 percent in total fertility for every percentage point increase in HIV prevalence. These observations are all based on studies in populations with low acceptance of family planning—the populations in Table 1 all have contraceptive prevalence rates of less than 15 percent.

Table 1

Population level effects of fertility reduction associated with HIV

	Mwanza, Tanzania 1992–1994	Kisesa, Tanzania 1994–1997	Masaka, Uganda 1989–1996	Rakai, Uganda 1994–96	Ft Portal, Uganda 1994–1995	Lusaka, Zambia 1995–1996	Mposhi, Zambia 1995–1996
HIV prevalence (%)	15.6	8.4	11.8	21.2	26.0	29.9	17.4

HIV-women	4.29	6.41	6.80	4.75	7.95	5.69	7.40
all women	4.09	5.89	6.54	4.34	6.97	5.09	6.86
% attributable change	–4.7	–8.1	–3.8	–8.7	–12.3	–10.6	–7.3

There is some indication (Zaba et al. 2000) that fertility differentials between HIV-positive and HIV-negative women are not as pronounced in African countries with higher rates of contraceptive use, such as Kenya and Zimbabwe, where over 30 percent of women use modern contraception. However, in these populations fertility had already begun to fall before the HIV epidemic took hold, and it would appear highly likely that the impetus towards lower fertility in both HIV-positive and HIV-negative women would be reinforced by the behavioral changes described above. It would be difficult to ascertain whether fertility would have fallen more slowly in the absence of the epidemic. The ‘attributable change’ statistic is an indicator of the overall effect of differential fertility. It does not take account of the common secular trends for infected and uninfected women.

3. Consequences of HIV and Fertility Interactions

As a result of the overall fertility reduction in populations severely affected by the HIV epidemic, population growth rates will be even lower than would be expected on the basis of the dramatic increases in mortality. A fall of 10 percent in total fertility would cause a reduction of the order of half a percentage point in the growth rate, making it more likely that some of the worst affected countries could experience periods of negative growth. Since falling fertility causes population aging, this will counter the tendency of HIV-related mortality to make the age structure of these populations even younger.

4. Measurement of HIV Prevalence in Sentinel Surveillance Populations

One of the more problematic effects of the relationship between HIV and fertility is on the measurement of HIV prevalence. The most widely used source of prevalence data—indeed the source on which all national-level estimates of HIV prevalence are based (US Bureau of the Census 2000)—is sentinel surveillance in antenatal clinics. Since HIV positive women have lower fertility, they will be underrepre-

sented in antenatal clinics, so that the resulting estimates of HIV prevalence underestimate the true extent of infection among women of childbearing age. Where community-based data are available it has been noted that HIV prevalence among adult males is generally lower than that in the female population (UNAIDS 2000), but conventionally the estimates based on surveillance of pregnant women continue to be used to represent prevalence for adults of both sexes. To obtain reliable estimates of HIV prevalence levels in women of childbearing age, one needs to adjust prevalence data collected in antenatal clinics (Zaba et al. 2000), particularly if one seeks to derive estimates of HIV incidence from trends in prevalence in young women. Prevalence estimates for young women may also be affected by changes in the age of sexual debut.

4.1 Trends in Orphanhood and Child Mortality

Reduced fertility in HIV-positive women implies lower effects of HIV on child mortality than were originally anticipated, and fewer orphans will be left behind at the death of an HIV-positive mother than for one who is HIV-negative. At the individual level, many of the fertility reducing factors (such as HIV-associated illnesses or the likelihood of divorce and widowhood) strengthen with duration of infection. As a result, the downward pressure on fertility, and the associated secondary effects on orphanhood and child mortality, will change with the duration of the epidemic, as the balance between women who have been recently infected and those who have been infected for longer periods shifts in favour of the latter. Gregson et al. (1999) have modeled the effect that such trends will have on the number and age distribution of orphans and child deaths.

4.2 Family Planning in the Era of AIDS

Family planning programmes in sub-Saharan Africa have traditionally promoted hormonal contraception, namely oral contraceptive pills, injectibles, and implants. Barrier methods are regarded with suspicion, as they are considered to be less reliable than hormonal methods and because of their association with commercial and illicit sex. However, effective and systematic use of condoms for disease prevention would also make them highly effective contraceptives. Conversely, an acceptance of condoms for family planning purposes in stable marital unions would destigmatize them and make them more acceptable in other circumstances also. The AIDS pandemic will require a major shift in the contraceptive mix offered by family planning programs and a new willingness to discuss STD prevention in the context of family planning services.

HIV Risk Interventions

Human Immunodeficiency Virus (HIV) infection, the cause of Acquired Immune Deficiency Syndrome (AIDS) has become a significant threat to global public health faster than any previous epidemic (Mann and Tarantola 1996). The genetic nature of HIV evades the development of a preventive vaccine and a cure for HIV infection remains a distant hope. HIV is transmitted through direct contact with HIV infected blood, semen, and vaginal secretions. Although HIV is transmitted during birth from mother-to-infant and through contaminated blood products the majority of AIDS cases in the world have resulted from HIV transmission between adults engaged in high-risk practices. Behavioral interventions therefore remain the most realistic means for curtailing the spread of HIV infection. Effective HIV risk reduction interventions target two principle behaviors: (a) sharing HIV contaminated drug injection equipment and (b) decreasing exposure to HIV infected semen, vaginal secretions, and sexually derived blood. Interventions to change injection equipment sharing and high-risk sexual practices can, therefore, dramatically effect the spread of HIV. In this article, factors associated with HIV transmission risks and interventions directed at reducing risks associated with injection drug use and sexual relations are examined.

1. Factors Associated with HIV Transmission Risks

Effective HIV risk reduction interventions are tailored to the immunological, epidemiological, cultural, and social correlates of HIV transmission risk behaviors. HIV transmission risk is affected by both biological and sociocultural co-factors.

1.1 Biological Co-factors

A variety of genetic subtypes of HIV exist, with each having its own unique features relevant to trans-

mission susceptibility. Genetic subtypes of HIV also differ in their geographic distribution. Therefore, genetic subtypes of HIV that are most efficiently transmitted during vaginal intercourse are more prevalent in some regions of the world than others and partially account for the regional differences in epidemic patterning (Mann and Tarantola 1996). Sexually transmitted infections, particularly syphilis, chancroid disease, and gonorrhea, cause ulcers and degradation of mucous membranes increasing both HIV transmission and susceptibility. Another biological factor associated with HIV transmission risk is the infectious state of infected persons. Individuals with lower blood concentrations of HIV, or viral load, may be at lower transmission risk than persons with greater concentrations. Therefore, the availability and use of HIV suppressing medications may influence the transmission of HIV. These biological influences on HIV transmission risks will likely interact with specific prevention strategies targeted by given risk reduction interventions.

1.2 Sociocultural Co-factors

Culture and social structures create a context for HIV transmission risk. Gender biases, power in sexual relationships, social norms supportive of risk and protective behaviors, poverty, drug addiction, and homophobia are known factors that influence HIV subepidemics (Kalichman 1998). HIV transmission occurs in personal relationships. Therefore, the social connections between persons, or social networks, play a critical role in both risk producing and risk reducing behaviors (Friedman et al. 1999). Social environments necessitate tailoring behavioral interventions to sub-population characteristics. Also, behavioral interventions must adapt over time to the ever-changing social context of HIV-AIDS.

2. Interventions for Injection Drug Use Risks

HIV and other diseases are spread through sharing contaminated needles and syringes for injecting drugs. Tainted injection equipment, therefore, not the drugs themselves transmit HIV. The use of sterile needles and syringes assures prevention against HIV and other diseases. Syringe access and exchange programs have demonstrated substantial reductions in new HIV infections among drug injectors (NIH Panel 1997). Another effective means of preventing HIV transmission via injection drug use is availability of drug treatment on demand. Obviously, when one stops injecting drugs the risks for injection-related HIV also ceases. Yet despite the known public health value of providing access to syringes and to drug treatment, political forces and limited economic resources have

prohibited policies for wide-scale implementation of these intervention strategies (National Academy of Sciences 1995). Cleaning injection equipment is considered a reasonable alternative when sterile syringes are unavailable. Behavioral interventions have shown success in training injection drug users in proper needle and syringe hygiene skills.

HIV risk reduction for injection drug users, therefore, occurs along a spectrum of health objectives. Drug treatment is the ideal intervention because it addresses the risks posed by drug addiction as well as HIV infection. Persons who do not receive drug treatment, however, can reduce the harm of drugs by using sterile injection equipment. When sterile equipment is unavailable, persons are advised to practice needle and syringe cleaning. The philosophy of accepting incremental steps to reduce risks when risks cannot be eliminated is called harm reduction and has been highly effective in framing the expected results of HIV risk reduction strategies.

3. Interventions for Sexual Relationship Risks

The vast majority of AIDS cases in the world have resulted from exposure to HIV in sexual relationships. Interventions designed to reduce sexual risk practices that permit HIV transmission—vaginal, anal, and oral intercourse without condoms or other barriers—have occurred at three primary levels: individual risk reduction counseling, small group workshops, and community mobilization campaigns. In each case, effective interventions that reduce high-risk behavior almost universally include three primary elements: educational information about HIV and how it is transmitted and prevented; motivation to induce individuals to make behavioral changes; and interactive exercises to improve risk reduction behavioral skills, such as sexual assertiveness skills and condom use skills (Fisher and Fisher 1992).

3.1 Components of Sexual Risk Reduction Interventions

Skills enhancement interventions consist of education, sensitization, and instruction in specific behavioral skills to reduce risk for HIV infection. Educational exercises and activities designed to help individuals take steps toward risk reduction are tailored to reflect the context, values, customs, and language of targeted populations. Therefore, similar intervention content is used for men and women of various backgrounds, but the contextual issues and examples vary accordingly.

3.1.1 HIV risk information and motivation enhancement. HIV prevention interventions provide basic in-

formation related to HIV transmission, illness, and prevention. Risk education can include facts about viral transmission, local prevalence of HIV and AIDS, clarification of misconceptions, dispelling AIDS myths, and description of HIV antibody testing. Discussions often couch information in personal life situations, relationships, risk behaviors, and increased motivations to reduce risk. Education also encourages individuals to assess their own behavioral risk histories and initiate discussions of individual life-situations that have placed them at risk. Theoretically, increased understanding of risk and personalization of vulnerability to contracting HIV are believed to increase one's readiness to change and enact behaviors to reduce risks.

3.1.2 Behavioral self-management skills. Behavioral self-management skills related to HIV risk reduction are acts that individuals can perform to reduce their risks for HIV infection with minimal involvement of their sexual partners. Individuals are instructed in techniques for examining their risk and cues that precede sexual risky situations. For example, persons are instructed in ways to identify environmental and cognitive-affective cues that serve as 'triggers' for high-risk situations, including mood states, substance use, settings, and sexual partner characteristics. Strategies for avoiding or managing high-risk triggers and situations are discussed with individuals generating their own risk avoidance behaviors. Coping strategies for high-risk situations may include performing safer sex acts, redirecting sexual activities toward safer sex alternatives, carrying condoms, and avoiding sex after substance use. Identification of barriers to risk reduction, such as substance use and access to condoms are placed in the context of problem solving.

A key to behavioral self-management skills is condom use during sexual intercourse. Interventions educate individuals about the efficacy and proper use of condoms, but the skills training component goes beyond education by including safer sex exercises. Instruction, modeling, practice, and guided feedback desensitizes individuals to condoms, capitalizes on changing negative attitudes toward condoms. Increased experience with condoms has been shown to decrease rates of condom failure, a potential benefit of condom skills training. It should be noted, however, that condom use is a behavioral skill that includes interaction with one's partner, and in the case of women in heterosexual relationships as well as men who are the receptive partner during anal intercourse, use of male condoms can require techniques for putting condoms on partners as well as discussing and persuading partners to use condoms.

3.1.3 Sexual communication skills. Sexual negotiation, sexual assertiveness, refusal of high-risk sex,

and nonverbal communication are the most common types of communication skills included in HIV risk reduction interventions. Increasing skills for resisting partner coercion to engage in sexual intercourse without condoms, and increasing comfort discussing safer sex with partners in advance of sexual activity occur through instruction, modeling, and practice in communicating sexual decisions and discussing individual limits on behavior. Role playing situations allows for experience in what it may be like to talk with partners about risk and risk reduction. Modeling effective responses, practice, and guided feedback again form the core for the skills training model. Individuals learn techniques to communicate feelings and sexual behavior limits through practice sessions conducted to increase proficiency in communication skills and comfort in discussing sexual alternatives with partners.

4. Levels of Sexual Risk Reduction Interventions

HIV risk reduction intervention elements that include risk education, risk sensitization, and behavioral and communication skills building are found in all effective HIV risk reduction interventions delivered to individuals, groups, and communities. The most common HIV prevention activities occur in face-to-face counseling sessions, usually in conjunction with HIV antibody testing. Risk reduction counseling can be effective when it includes information, motivation, and skills building components, even when delivered in as short a time as 20 minutes (Kamb et al. 1998). However, there is now compelling evidence that HIV testing delivered with information-based counseling that does not include behavioral skills building components is ineffective at reducing HIV risks (Weinhardt et al. 1999).

Workshops delivered to small groups of individuals, typically 6 to 12 persons, that include information, motivation, and skills building activities have been shown effective in rigorously controlled studies with men who have sex with men, heterosexual men, women, and adolescents (Kalichman 1998). Finally, HIV prevention efforts delivered at the community level have also been shown effective when they include information, motivation, and behavioral skills. For example, peers and natural opinion leaders trained in skills for disseminating information and motivational messages can successfully change patterns of risk behaviors for entire populations (Kelly et al. 1997). Thus, sexual risks for HIV infection can be effectively reduced when they provide information, risk sensitization, and behavioral skills building opportunities in highly interactive formats.

S. C. Kalichman

Hobbes, Thomas (1588–1679)

Thomas Hobbes was born on Good Friday, April 5, 1588, in Malmesbury in Wiltshire, UK. It was not until some months later that the Spanish Armada appeared in the Channel, but the threat that it would do so was widely known and there was widespread apprehension. Hobbes was fond of referring to this conjunction of his birth with the Armada:

For Fame had rumour'd, that a Fleet at Sea,
Wou'd cause our Nations Catastrophe;
And hereupon it was my Mother Dear
Did bring forth Twins at once, both Me, and Fear.
(*The Life of Mr. Thomas Hobbes of Malmesbury, written by himself.*)

This statement of Hobbes' is often referred to because of the role that fear played in his account of human nature and the genesis of political order.

Hobbes was born of a poor family, but obscure birth was no bar to the career of a clever young man at that time. His education made him a fluent linguist and translator, and though he wrote a considerable amount in Latin, which was still the common language of the learned, he became the first philosopher to write his most significant works in English. After study at Magdalen Hall in Oxford, he was recommended by the Principal of his hall to take the role of tutor and secretary in the household of William Lord Cavendish, who ten years later became, Earl of Devonshire. Hobbes spent almost all of the rest of his life in the employment of the Earls of Devonshire or their close relatives the Earls of Newcastle.

As a member of such households, Hobbes several times took sons of his employers on tours of Europe, which gave him a probably unparalleled chance to meet intellectuals: he met Galileo, whose work greatly influenced him as a response to the widely accepted scepticism of the time, Gassendi, Mersenne, and later Descartes, amongst others. These acquaintanceships continued through correspondence and when he fled to France in 1640 in reasonable fear that his political writings might result in threats to his life or liberty. In England, too, he met important people and intellectual leaders; Aubrey records that at one time he acted as secretary to Francis Bacon and also helped to translate some of Bacon's essays into Latin, with Bacon commenting that he liked Hobbes best of all those who had taken dictation from him because Hobbes understood what it was that he was writing.

Modern science was in a formative stage at that time, with no generally accepted scientific method. As an intellectually lively man, Hobbes in middle life became caught up in the arguments about this set of problems about the investigative methods appropriate to science, and Aubrey records him as saying that it was first reading Euclid, whom he took to produce definitive proofs, which made him alive to the problem and possibility of establishing a scientific method. He was also quite explicitly influenced by Galileo's *Dialogue Concerning the Two Chief Systems of the World*, published in 1632. Part of his concern with method came out in his dispute with Boyle (an account of which is given in Shapin and Schaffer 1985) about the significance of experiment, which Hobbes downplayed. Hobbes distinguished quite sharply between knowledge and opinion, knowledge requiring the sort of certainty he found in geometry. He held to the view that people were not capable of genuine knowledge of the external world or its characteristics, but that we can know, with the certainty required for knowledge, the contents of our minds. Genuine knowledge will therefore be of ideas and the relations between them. Observation can give us opinion, but cannot provide genuine knowledge. Nevertheless, Aubrey says, 'He

was wont to say that he had rather have the advice, or take Physique from an experienced old Woman, that had been at many sick people's Bed-sides, then from the learnedst but inexperienced Physitian,' so he did not ignore the importance of experience. His interest in optics and ballistics, which developed his interest in mathematics, arose from the Newcastle family's interest in the production of an effective telescope for military purposes, and he generally took science to be important because of its practical consequences.

This practical approach probably explains at least part of the dispute about the historians' Hobbes and the philosophers' Hobbes. During the 1960s and 1970s, Quentin Skinner produced a set of articles (1964, 1965, 1966, 1972) about the interpretation of Hobbes's writings on politics, the writings for which Hobbes is still remembered. Skinner's thesis was that more detailed consideration needed to be given to Hobbes's relationship to other writers of his time and the responses that he and they showed to the political events they lived through. Philosophers, it was implied, had taken Hobbes ahistorically and hence misinterpreted him. The most detailed reply (Warender 1979) does not deny that Hobbes was concerned to contribute to practical political debate of his time, but does deny that the differences between philosophers in their interpretations of Hobbes simply reflect a failure to put Hobbes in his historical context: they are, rather, differences about the account to be given of the philosophical backing for Hobbes's position. Skinner is clearly right in his understanding of why Hobbes took up the issues he took up, why he thought that certain problems needed to be dealt with, what allusions he might be making, and what he was trying to contribute to the current political debate, etc., that require the historical context. However, it is also true that Hobbes was not simply contributing to the practical debate but thought that he had a special contribution to make because he was producing a science of politics, the science involving timeless truths. He thought that his views were just as relevant to French disturbances of the time as to those in the UK. There is philosophers' Hobbes to study, and omission of the philosophical aspect of his work leads to misinterpretation.

The events at issue in the dispute he saw himself as entering, though Hobbes did not see himself as only, or always as primarily, concerned with politics, were political events. Hobbes was born in the reign of Elizabeth I and died on December 3, 1679, in the reign of Charles II, during which time he had been a tutor in mathematics to the Prince of Wales (accepting the position in 1646), had been awarded a pension by Charles II, was probably invited to stand as a candidate for the Short Parliament, and had lived through the English civil wars of the 1640s and the Commonwealth. He had had his books burnt in the University of Oxford and had been forbidden to publish his ideas in England, had (with some reason),

felt threatened with accusations of heresy, and had seen much turmoil in Europe. The issues that concerned him in politics were basically issues of stability. He was concerned with what was required for a state to remain stable and peaceful so that people could live their lives with the security they needed in order to be able to pursue their projects.

Hobbes's initial intellectual interests were in such fields as optics, ballistics, and mathematics, especially geometry. He is remembered by many for his attempts to square the circle, and he took part in vituperative disputes with the Savilian Professors of Mathematics at Oxford and especially with Wallis. His enduring contribution to our intellectual heritage, though, is in the fields of morality and politics, which he tried to establish in a scientific manner. His main publications in these fields were *The Elements of Law; De Cive* (originally in Latin, but there soon appeared an English translation about which there is some disagreement concerning the extent to which Hobbes approved of it); *Leviathan* (originally in English but translated with changes into Latin so that it could be read elsewhere); and *De Homine* (which still lacks a complete English translation, though there is a partial translation in Gert 1972). The translations show Hobbes's keenness to make his ideas available as a contribution to the current political debates in a number of countries, and this is also reflected in the changes in his styles of presenting his ideas (see, for example, Johnston 1986). His *Behemoth*, an account of the causes of the English civil wars of the 1640s, also reflects his ideas on politics. He discusses methods of proof and the nature of science and true knowledge frequently, the most extended discussion being in *De Corpore*, an English translation of which appears in volume 1 of the Molesworth edition of *Hobbes: English Works*.

Hobbes's best-known work is *Leviathan*, the last of his English writings directly on the science of politics. It appeared in 1651, at the time of Hobbes's return to England. There are two different stories about how it fits into the historical context and what it was intended to achieve. The Royalist Earl of Clarendon (in *A Survey of Mr Hobbes his Leviathan*) reports Hobbes as saying

... that he knew when I read his Book I would not like it, and thereupon mentioned some of his Conclusions; upon which I asked him, why he would publish such doctrine: to which, after a discourse between jest and earnest upon the Subject, he said *The truth is, I have a mind to go home.*

Many Royalists did take the book that way, as a defence of Cromwell and his Commonwealth. Aubrey, on the other hand, says

He wrote and published the *Leviathan* far from the intention either of disadvantage to his Majestie, or to flatter Oliver (who was not made Protector till three or four yeares after) on purpose to facilitate his returne; for there is scarce a page in it that he does not upbraid him

and goes on to suggest that the purpose was to provide justification for those who had fought on the Royalist side until all was lost and now faced the prospect of losing all their property if they did not recognise Cromwell's authority. The most that can be done to sort out this disagreement is to see what the arguments of *Leviathan* will support.

Hobbes's moral and political theory is presented as an account of how and why people emerge from their natural condition and live together in civil society. This involves giving an account of human nature, of the natural condition of mankind, and of the laws of nature that make the transition possible. There is still argument about just what Hobbes's position is on each of these matters. It is clear that Hobbes takes the natural condition of mankind (he rarely uses the expression 'state of nature') to be a state of insecurity and constant fear. Though not always a condition of actual fighting, it is a condition in which people will take an aggressive stance towards each other and in which nobody can be trusted and fighting is always likely to break out. The reasons for this are to do with human nature, and the solution is the making of a contract to establish a sovereign.

Hobbes has more to say about the actual origins of states in *A Dialogue Between a Philosopher and a Student of the Common Laws of England*, but what he is intending to do with his story of the contract is to set up a model for the establishment of a state. This, on his account, is what is involved in explaining something or giving its causes. Establishing the cause of something, on Hobbes's account, is not the searching after particular matters of fact in the situation that we might go into in investigating a traffic accident. He gives an example to explain his method in chapter 1 of *De Corpore*. A figure placed before us might look like a circle, but mere observation cannot assure us that it is one. Knowledge of its cause assures us of that.

For let it be known that the figure was made by the circumduction of a body whereof one end remained unmoved, and we may reason thus; a body carried about, retaining always the same length, applies itself first to one *radius*, then to another, to a third, a fourth, and successively to all; and, therefore, the same length, from the same point, toucheth the circumference in every part thereof, which is as much as to say, as all the *radii* are equal. We know, therefore, that from such generation proceeds a figure, from whose one middle point all the extreme points are reached unto by equal *radii*. And in like manner, by knowing first what figure is set before us, we may come by ratiocination to some generation of the same, *though not perhaps that by which it was made, yet that by which it might have been made*; [italics added] for he that knows that a circle has the property above declared, will easily know whether a body carried about, as is said, will generate a circle or no. (Hobbes 1839, Vol. 1, p. 6)

The last sentence here makes clear that Hobbes does not seek causes as we usually do at the beginning of the twenty-first century, but seeks a model that will explain

what it is to be a circle, or a civil society. He is not committed to the idea that states actually do begin from contract, and he certainly recognizes that many begin with, or are expanded by, conquest. A civil society, then, will be something that has the features of an institution established by contract. It will involve obligations on people, and those obligations will depend on reciprocity. One of the distinguishing features of Hobbes's account is that the reciprocity would not primarily be between sovereign and citizen, but between citizens (as it is in such present-day theories as Rawls 1972); the sovereign, importantly, is outside the contract. Were he not outside it, then somebody else would have to hold the authority to determine whether the sovereign was behaving properly, and that person would then have the ultimate authority and be the actual sovereign. This is the absolutism of the Hobbesian sovereign to which so many have objected. Hobbes, both in not depending on an actual contract and in making the mutual obligations between citizens rather than between citizen and sovereign, was moving beyond the other contract theorists of his time.

Why would the natural condition, in which people have no common sovereign, be the unpleasant state that Hobbes describes? He gives several significantly different examples in discussing the natural condition, American Indians and the relationships between sovereign states amongst them, which can be confusing. The core of the notion is that people are in their natural condition if they have no common sovereign, so that somebody might be in his natural condition with respect to one person but not with another. It is not that the whole world must be in either the natural condition or civil society or that an individual person must be either in the natural condition or not. Within a family we might not be in our natural condition with respect to each other, but each of us might be in the natural condition with respect to people outside our own family.

Why should people who lack a common sovereign be unpleasant to each other? One thesis is that it is because they are self-interested and will therefore naturally clash in the absence of a coercive power to prevent them. This is the interpretation that has led to games theorists taking up Hobbes (e.g., Gauthier 1969, Hampton 1986, Kavka 1986) and to his being taken as providing a 'realist' model for international relations (e.g., Bull 1980) with reasons of state and pursuit of national self-interest at the center of concern, that is, of international politics as power politics. This is, perhaps, a plausible picture of international politics. Along with this idea goes the interpretation of the laws of nature as policies to be followed out of self-interest, fitting with Hobbes's description of them as rules of prudence.

Bernard Gert (1972) argues strongly against the claim that Hobbes is a psychological egoist who believes that people always seek their own narrow

interest. Certainly it seems clear that Hobbes did not believe that people could do no other than try to preserve themselves when their lives were threatened: not only did he comment on those who give their lives too cheaply in duels because of a confused notion of honor, but he admired some of those who gave their lives in defence of the Royalist cause in the civil wars and made laudatory remarks about one of them in dedicating *Leviathan* to his brother. This position, then, requires a different account of the laws of nature.

Hobbes was clear that the laws of nature are effective only in conditions of reciprocity and preferably conditions in which there is a sovereign to guarantee reciprocity. This at least looks as though it supports the idea that the only reason for obeying them is self-interest and particularly fear of the sovereign, but drawing that conclusion means ignoring the fact that Hobbes treats prior performance by one party to a contract as making an obligation effective on the other party just as much as does having a sovereign who will force one to comply. The laws of nature, he says, obligate *in foro interno*, in conscience, in the natural condition, that is, they bind in the intention, but they bind *in foro externo*, in the act, only in civil society. Virtues are more complex than they are sometimes treated as being: Hobbes's point is that benevolence, for example, is a good thing because of the role it actually plays in civil society. Handing a knife to somebody who wants to kill me is not benevolent; it is simply stupid. Handing over money to a grocer who refuses to provide me with the goods I want is not required by justice. The virtues actually require a setting of relatively peaceful and secure life if they are to be possible to exercise, and Hobbes's stronger thesis that they can be exercised only by people who are subject to a common sovereign obviously bodes ill for a morality of international relations and explains why Hobbes has been taken up by some proponents of world government. (On this interpretation of Hobbes, see, for example, Bull 1980 and Ewin 1991.) On this account, the story Hobbes tells of people agreeing on principles of peace is a model of the sort he describes in the account of the circle, and the model is for virtues. Certainly, for all his objections to Aristotle, his objections to what Aristotle said about virtues is that he identified them as means, and not in terms of their being, as Hobbes put it, 'not properly Lawes, but qualities that dispose men to peace, and to obedience' (Chap. 26 of *Leviathan*). That is, he suggests agreement with Aristotle's general position about morality, but disagrees with the principles by which virtues are to be identified. And this fits, not with games theory, but with the accounts of ethics that now seem to be emerging from evolutionary theory about the characteristics that make our social species capable of surviving (see, e.g., Alexander 1987).

If people have these virtues as part of human nature, even if they do not have them perfectly, why would the

natural condition of mankind be as horrible as Hobbes suggests? Because, in the absence of a sovereign, the virtues cannot be operable; the laws of nature will not bind *in foro externo*, that is, to any overt action. We are all equal in the natural condition not only in that we are all vulnerable to sudden death, but in that there is no particular reason why any of us should subject his or her reason to that of another. If we differ and neither of us can persuade the other, then there is no reason why either should submit. And in this world we do differ: we see the world in different ways from different backgrounds, are struck by different features of the situation, and we calculate differently. We have differences about the nature of justice, and we differ about who did what to whom. When we differ about something like justice, there is no reason why one should submit to the view of another and do what he simply regards as unjust. It is differences of judgment, rather than clashing interests, that the sovereign must deal with, providing an artificial reason to replace the right reason that fails to do the job. Those who insist on right reason in a dispute, Hobbes says, are simply insisting on being judges in their own case, for each man takes for right reason what is his own.

His first argument for the sovereign in *Leviathan* appears early in Chap. 5 in the discussion of disagreement and the need to establish an arbitrator or judge to determine disputes (though the arbitrator or judge might be a meeting of the populace voting on the matter or any number of other things, and is best thought of as a procedure rather than as a person), an arbitrator whose judgment we agree to accept before we know what it is, thus establishing rights. Without those rights the virtues will not be operable, and without the virtues, at least to a degree, the rights could not be established. The recognition of authority, on Hobbes's account, is something without which humanity could not survive. Our moral views have the status of private views in which we can clash, but people have a capacity for politics that makes it possible for them to establish a public morality (or law) of rights that determines the sphere within which each person's private judgment can operate.

This shows some of Hobbes's relationship to modern liberalism. And because people do have failings, and because we need security even though we know that there are dangerous people whom we could not recognize at first sight, the sovereign must have coercive powers including the powers to tax people to cover the costs of his activities; there will be clashes of interest as well as clashes of judgment. The sovereign must be absolute in that his function is to resolve disputes, and he cannot do that if his authority depends on his agreeing with both parties. But that, Hobbes suggests, is a logical truth about any system of government and is compatible with our choosing government even by a meeting of all the citizens; it does not require subjection to the arbitrary will of one person, but does require subjection to the decisions of

the community however they are determined. This brings out some of Hobbes's relationship to modern democratic theory. The sovereign makes it possible to resolve disputes peacefully and be sure that the resolution will be enforced, so he makes it possible for us to act as one; he determines for us the will of the community, and thus makes us one person. This Hobbesian idea of sovereignty as ultimate and absolute remains influential.

Holocaust, The

'The Holocaust' is the term most widely used in reference to the systematic extermination of the Jews of Europe by the Nazis during World War II. Usually, the term also alludes to the historical background of the extermination and to related contemporary circumstances. The first section of this entry will deal with some aspects of the historical background, the second will briefly present the immediate context of the 'Final Solution to the Jewish Question,' while the third and central part will address the extermination *per se* and the reactions to it. This chronological presentation does not imply an unavoidable passage from one phase to the next. However, while the link between the evolution of German history during the first two decades of the twentieth century and the onset of the Nazi regime was in no way evident, the causal relation between the anti-Jewish policies of the early war period and the extermination was much closer.

1. The Background

The historical origins of the Holocaust remain an object of ongoing debate. Whereas some scholars consider the extermination of the Jews as the consequence of a specific evolution of German history, at least from the end of the nineteenth century onwards, others interpret the Holocaust as an outgrowth of modernity, the implementation of a pitiless instrumental rationality at the service of a totalitarian racial utopia. Both approaches are not incompatible.

The rise of racial anti-Semitism, the spreading of social Darwinism, and the publication of the first theories of racial anthropology and eugenics turned the late nineteenth century into a breeding ground of ideological trends that were to become central tenets of the Nazi worldview. And, although political anti-Semitism declined in the Wilhelminian Reich at the beginning of the 1900s, an increasingly vocal anti-Jewish hostility spread throughout wide sectors of German society. In this evolution, the outbreak of World War I became a major turning point.

After a brief period of national unity, the unforeseen prolongation of the conflict and the growing political polarization which it induced triggered a radicalization of anti-Jewish attitudes, mainly in the nationalist-conservative camp. The defeat of Germany, the revolutionary upheavals that followed, and the birth of a republic hated and rejected by an important sector of the population, as well as the vast majority of the traditional elites, fanned the already virulent anti-Semitism even further. The Jews were accused of bearing the responsibility for the national humiliation (the 'stab in the back' myth), of controlling the new

republic, of instigating bolshevism and, above all, of conspiring to dominate the world, as described in the most widely read anti-Semitic forgery of the century, *The Protocols of the Elders of Zion* (1919).

It was in this postwar atmosphere that Adolf Hitler began his political career by joining the tiny German Workers' Party (DAP) in Munich, in late 1919. In 1920, the DAP became the National Socialist German Workers' Party (NSDAP) with anti-Semitism figuring prominently in its twenty-five point program. Notwithstanding the failed putsch of 1923 and Hitler's brief incarceration, the resumption of his political agitation in 1925 along with systematic organization, unrelenting propaganda, and, more than anything else, the impact of the Great Depression, propelled the party into prominence on the national scene.

Anti-Semitism lay at the center of Hitler's worldview from the outset of his political career and remained so after his accession to power on January 30, 1933. Reduced to its core, this anti-Semitism viewed historical evolution as determined by a merciless racial struggle dominated by the confrontation between Aryan and Jew. The outcome of this struggle was to decide the fate of mankind and particularly of the Aryan race. Hitler's faith had an apocalyptic dimension, presented in terms of 'scientific' theories. But how far this worldview concretely led to the systematic planning of the anti-Semitic policies of the regime, or, obversely, to what extent these measures were the result of uncoordinated initiatives stemming from a growing radicalization of the party and its agencies, remains an open question. One could argue that the ideological guidelines indicated a general framework for action, but that the 'twisted road' followed by the implementation of the anti-Jewish policies was dictated by changing circumstances. In any case, during the 1930s, no plan for a physical extermination of the Jews existed; the ever-more extreme anti-Jewish policies of the prewar years had two successive and identifiable aims: the exclusion of the Jews from the national racial community (the *Volksgemeinschaft*) and, thereafter, their expulsion from the Reich.

From the outset of the new regime the Jews were dismissed from the civil service, from a growing number of professions, and from all major fields of German cultural life. Moreover, all that belonged to or had been influenced by the 'Jewish spirit' had to be cleansed from the German cultural sphere: Freud's or Einstein's theories, Heine's poetry, Mendelssohn's music, books, works of art, memorial plaques, films, libretti—anything. A stream of anti-Jewish incitement was daily spewed out by all the propaganda channels of party and state, under the guidance of Propaganda Minister Joseph Goebbels and chief party ideologist, Alfred Rosenberg; it found its most rabid expression in *Der Stürmer*, the 'specialized' anti-Jewish organ of the Gauleiter of Franconia, Julius Streicher. The entire education system soon absorbed the anti-Semitic

message, as did the Hitler Youth (HJ) and the League of German Girls (BdM). The indoctrinated youngsters of the 1930s were to become the soldiers of the 1940s.

In September 1935, the Nuremberg Laws added strict biological separation to social and cultural segregation by forbidding marriage and sexual relations between Jews and Germans (the Law for the Protection of German Blood and Honor). The Reich Citizenship Law reduced the Jews to second-class citizens. Finally, the first 'Supplementary Decree' to the Reich Citizenship Law defined who was a Jew or, alternatively, a 'mixed breed' of the first or second degree (November 1935). Any transgression of the 'Blood Law' was considered as 'race defilement' (*Rassenschande*), and the offenders (usually the Jewish male offenders) were sent to jail or a concentration camp.

In 1936, the *Reichsführer SS*, Heinrich Himmler, was put in command of all German police forces. This reorganization of the control and terror apparatus led to the appointment of SS General Reinhard Heydrich, previously chief of the security service of the SS (*Sicherheitsdienst* or SD) to the command of both the SD and the newly established Security Police (*Sicherheitspolizei*), which included the Gestapo and the Criminal Police. After the outbreak of the war, these agencies were further centralized within the Reich Security Main Office (*Reichssicherheitshauptamt* or RSHA). While the planning of direct anti-Jewish terror was mainly Himmler's and Heydrich's preserve, the plundering of Jewish assets and enterprises was orchestrated by Hermann Goering's Four Year Plan Administration, and, after the dismissal of the conservative minister of the economy, Hjalmar Schacht (who had managed to protect some measure of Jewish economic life), by his Nazi successor, Walther Funk.

After the annexation of Austria, in March 1938, the drive to compel the Jews to leave the 'Greater German Reich' ('Old Reich' and Austria) became overwhelming. During that year, 'compulsory Aryanization' and, ultimately, the prohibition of any Jewish economic activity destroyed the material basis of Jewish existence in Germany. Notwithstanding the widespread reticence of most countries to take in Jewish refugees (easily identifiable since, at the demand of the Swiss government, their passports were marked with a 'J'), forced emigration and even expulsion over the borders became standard Nazi practice. Finally, on November 9 and 10, following the killing of a German diplomat by a Jewish youth in Paris, a nationwide eruption of state-organized violence, the so-called 'Night of the Broken Glass,' destroyed the remnants of Jewish life in Germany. The Jews of the Reich now desperately attempted to flee. The panic soon extended to the Jews of the 'Protectorate of Bohemia and Moravia,' after the German occupation of Prague in March 1939. Yet, it was the German attack on Poland, on September 1, 1939 and the outbreak of World War II that entirely changed the fate of European Jewry.

2. *The Immediate Context of the 'Final Solution' (1939–41)*

During the first two years of the war, the goal of Nazi anti-Jewish policies still appeared uncertain. Jewish emigration from the Reich and occupied Europe remained a possibility, although wartime conditions soon reduced it to a trickle. The goal frequently alluded to was a territorial concentration of Europe's Jews, first in the easternmost part of Poland, in the Lublin area of the newly established 'General Government' (the name used for the nonannexed area of Poland which was put under the authority of the Nazi 'Governor General,' Hans Frank), then, after the victory over France, in the French island colony of Madagascar, and, finally, after the attack on the USSR, in Arctic Russia or Siberia. None of these plans ever materialized, except for some short-lived attempts to deport Jews from Vienna and the Protectorate to the Lublin area, in the fall of 1939 and in early 1941.

A few months after the occupation of Poland, the Nazis started to deport hundreds of thousands of Jews and Poles from territories annexed to the Reich, such as the Warthegau (a part of western Poland), into the General Government; they drove the Jews into ghettos in larger towns and even dumped Jews from the Reich into Vichy France, in the fall of 1940. The deportations within ex-Poland may have been linked in part to the regime's policy of ingathering ethnic Germans from the Baltic countries, the Russian occupied territory of Poland, and the Balkans in the 'Great Germanic Reich.' Thus, the deportations of Jews and of Poles from the Warthegau were meant to make space for the incoming *Volksdeutsche*. The policy was pursued under the orders of Himmler, as newly appointed 'Reich Commissar for the Strengthening of Germanism' (RKF). It was meant to be the first stage of what became known as 'General Plan East' (*General Plan Ost*), aimed at establishing German domination in the East for centuries to come. The enslavement of entire nations and the death of tens of millions of local inhabitants was taken into account. This policy was probably not directly linked to the genesis of the 'Final Solution' since it cannot explain the deportations from the west (to be described later on).

Simultaneously, from October 1939, an entirely separate but not unrelated operation had started in the Reich: the systematic mass murder of the mentally ill, the so-called euthanasia or 'Aktion T-4': personnel were trained and killing methods were developed that were to be used for the mass extermination of Jews after the scaling down of T-4, in the summer of 1941, to a less visible 'euthanasia' operation (Aktion 14f13).

In Western Europe, the much smaller Jewish populations were not secluded (except for the establishment of a semi-ghetto in Amsterdam) or as brutally treated as the Jews of Poland. But their exclusion from public service and the liberal professions, growing curtailment of their economic acti-

vity, the registration of persons and property, limitations on travel, and police surveillance, turned them into pariahs. Their persecutors were not only the Germans, but also satellite regimes such as Vichy France.

After the German occupation of Yugoslavia and Greece in April 1941, Serbia remained under direct military control and Croatia became a satellite; in both countries, harsh anti-Jewish measures were introduced. Slovakia's anti-Jewish policy followed strict German orders. Romania implemented fierce anti-Semitic measures of its own, and only Hungary and Bulgaria maintained semi-independent policies in this domain.

In order to facilitate their control over the Jews—beyond territorial concentration—as well as to degrade them, the Nazis compelled all those over the age of six to display a 'Jewish star' on their clothing, first in Poland, then, from September 1941 on, in the Reich and the Protectorate, and, in the spring of 1942, in all countries of occupied Western Europe. But the principal instrument of Nazi domination was the 'Jewish Councils.' These councils, composed of representatives of the Jewish communities, received German orders, conveyed them to the Jewish populations, and were responsible, upon pain of death, for their implementation. Moreover, in Eastern Europe the Jewish Councils became agencies of a Jewish self-administration of sorts, struggling against impossible odds; justly or unjustly, they often became targets of sarcasm, resentment, and even hatred in their own communities. Some historians have adopted a highly critical stance toward the councils, considering them as instruments in the hands of the Nazis for the destruction of their own people. Others have questioned this overall characterization as the differences in the behavior of the councils were considerable. All in all, the councils' members were ordinary people confronted with entirely unprecedented circumstances: their own reasoning was incompatible with the murderous strategy of the Nazis.

3. *The Extermination*

Systematic mass extermination of Jewish populations began with the German attack on the USSR, on June 22, 1941. Whereas in most newly occupied Soviet territory mainly Jewish men were executed until August 1941, in the Baltic countries and in Transnistria (where the Romanian army was the principal ally of Germany), entire Jewish communities were butchered from the outset. The killing of Jews in party or state positions had been ordered by Heydrich on the eve of the campaign; the perpetration of pogroms by local inhabitants was also explicitly fostered by the Germans. Whether the killing that engulfed the entire

Jewish population from August 1941 onwards was independent of any instrumental goals, or whether, as with the starving to death of two million Russian POWs before the spring of 1942 (around 3.3 million died before the end of the war), it derived from difficulties experienced by the Wehrmacht in securing sufficient food supplies for the army is not clear. In any case, the mass murder of Jews on Soviet territory (around 500,000 victims by the end of 1941) was not perpetrated solely by the 'intervention units' of the Security Police and the SD (*Einsatzgruppen*), by local auxiliaries, and by the Romanian army in the south, but also by tens of Reserve Police Battalions and regular Wehrmacht units. In other words, not only the 'troops of the ideological war' (the SS) but ordinary men, possibly ten of thousands of them, were involved, often willingly so, in the mass murder of the Jews.

Few historians would now argue that the decision to exterminate all the Jews of Europe predated the attack on the USSR. Some contend that this decision was taken by Hitler soon after the German onslaught, during the period of 'euphoria,' due to the apparent success of the invasion, and that it found its expression in Goering's letter to Heydrich of July 31, 1941, ordering him 'to take all necessary measures to prepare the Final Solution of the Jewish Question in Europe.' Others argue that such an order was issued in the early fall, when doubts may have risen in Hitler's mind about the prospects of a quick victory in the East. Others still link the order to the USA's entry into the war, in other words to the transformation of the European war into the 'world war,' which, as Hitler had 'prophesied' in his Reichstag speech of January 30, 1939, would see 'the extermination of the Jewish race in Europe.' This last interpretation seems bolstered by documentary evidence. On December 18, according to Himmler's appointments diary, the SS chief met with Hitler and wrote down: 'Jewish question/eradicate as partisans.' The reference to 'partisans' is clearly a way of describing an enemy lurking behind the lines, an internal foe, who, just as in 1917/18, would stab Germany in the back if given the chance. Finally, some historians doubt the existence of any clear order given at the highest level and consider total extermination as resulting from the cumulative effects of local initiatives.

By October 1941, the killings had extended to Jews from the Greater Reich and the Protectorate who were deported mainly to Lodz, Riga, Kovno, and Minsk. In Riga and Kovno, thousands were shot on arrival. The others were exterminated later with the inhabitants of their ghettos. They had also spread to Serbia, where the Wehrmacht executed some 6,000 Jews in reprisal for partisan attacks. During the same month, Jews were forbidden to leave the continent, 'in view of the coming final solution of the Jewish Question' and the construction of the Belzec extermination camp (possibly that of Sobibor too) began in the General Government.

In early December, the first extermination site became operational at Chelmno, near Lodz, principally for the murder of Jews from the Warthegau. On January 20, 1942, in a meeting in Berlin (*am Grossen Wannsee*), Heydrich informed an array of state secretaries, senior SS officers and other selected officials of the general extermination program that, according to his computations, was to apply to 11 million European Jews. From then on total extermination became a problem of logistics and of some measure of haggling between the Germans and various governments or local authorities about handing over their Jews. In almost all cases, foreign Jews were arrested and delivered first, local Jews followed (as will be indicated further on, in some rare cases Jews were not handed over at all).

The arrests of Jews, mainly in Western Europe, and the logistics of the deportations were coordinated between the Higher SS and Police Leaders (HSSPF), Himmler's delegates to each occupied country or major area, local authorities and police forces, and the Jewish Affairs section at the RSHA (IVB4) under Adolf Eichmann. Furthermore, the deportations demanded joint planning with the Reich Railways Authority (*Reichsbahn*) and its territorial subdivisions (*Ostbahn*, etc.). Once the Jews reached the camps, they passed under the command of the SS Economic and Administrative Main Office (*SS Wirtschafts- und Verwaltungshauptamt*) under SS General Oswald Pohl (except for the *Aktion Reinhard* camps). In the camps, the Jews were destined for extermination; however, mainly in Auschwitz, selections separated the healthiest and the strongest from the mass of the inmates, submitting them to slave labor before sending them to their death.

The first stage of the extermination chiefly included the Jews of the Warthegau and of the General Government who, through 1942, were killed in the *Aktion Reinhard* camps (Belzec, Sobibor, Treblinka, and Majdanek), as well as in Chelmno. The deportation of the Jews of Warsaw to Treblinka began in July 1942. Simultaneously, deportations from Western Europe (France, Belgium, and Holland) started. By then, the principal Auschwitz extermination camp (Auschwitz II or Birkenau) had become fully operational. The killing method shifted increasingly from the use of carbon monoxide gas to that of Zyklon B, a powerful pesticide utilized in the fumigation of army barracks and ships' holds. Before they were killed, the victims' valuables and clothes were taken away and their hair was shorn; after the gasings, gold teeth, and artificial limbs were removed from the corpses. The German economy recycled the 'booty': gold was smelted and delivered to the *Reichsbank*; hair was used for mattresses, slippers, etc.; clothes were distributed by the *Winterhilfe* (the German winter-relief organization). Homes, furniture, and other belongings left behind by the deportees, were distributed to deserving *Volksgeossen* or acquired, usually at dirt-cheap

prices. This allocation of spoils spread to occupied countries in the West. Particularly valuable objects, mainly art, looted all over Europe by the *Einsatzstab Reichsleiter Rosenberg* or ERR, were offered to Nazi leaders (Hitler and Goering headed the list), to German museums, and various other German institutions.

In 1943, the last batch of German Jews was deported to the extermination camps; the deportations from Western Europe continued, and, simultaneously, the Jews of the Balkans and, by the end of the year, of Italy (following the German occupation of the greater part of the peninsula) were included in the killing process. From March 1944 onward, after the occupation of Hungary by German troops, this country's Jews became the last large national group of victims (over 400,000) to be sent to Auschwitz-Birkenau. On November 2, 1944, Himmler ordered the cessation of the mass exterminations; his order was frequently disregarded, even after the liberation of a growing number of camps by the Allies. 'Death marches,' organized by camp commanders or SS personnel, went on throughout the winter of 1944-5 and practically until the German surrender in May 1945. By the time the war in Europe drew to a close, approximately 5.5 million Jews had been exterminated.

The exterminations on Soviet territory had become widely known by the fall of 1941. Information about the mass killing of European Jewry beyond the Soviet border spread throughout the continent, and in Allied and neutral countries from the second half of 1942 onward, although the technical details of the 'Final Solution' may not have been widely known until 1944. The overall reaction was one of indifference and inaction, sometimes of outright collaboration. While Vichy authorities and police collaborated with the Germans in the arrests and deportations, Switzerland hermetically closed its borders to the Jews who attempted to flee. In general terms, the Christian churches intervened feebly, mainly on behalf of converted Jews. Thousands of Jewish children were hidden in Christian institutions; in most cases, their lot was conversion. The silence of Pope Pius XII, notwithstanding some help from the Vatican in hiding Jews in the fall of 1943, has, to this day, remained a matter of heated debate.

In some cases, the reactions were different. Spain and Portugal allowed the transit of Jews through their territory. Sweden attempted to take in the Jews of Norway when the deportations started and it took in almost all the Jews of Denmark (most of whom were transported to safety by the Danes themselves). Protests against the anti-Jewish measures were staged in Holland, in early 1941; the Italians tried to protect the Jews in their own country as well as those under their control. Bulgaria refused to deliver its own Jewish citizens, although it did deliver the foreign Jews. Finland rejected all German demands regarding its small Jewish population.

'The abandonment of the Jews' by the Western Allies is largely undisputed nowadays. Rejected or fatally delayed rescue plans involved transfers of ransom money to the Germans or their allies, or the bombing, in 1944, of the Auschwitz gas chambers and of the railway line connecting the camp with Hungary. Such refusal to help, whether known or merely sensed, could but contribute to the feeling of total isolation of the Jews of Europe in the face of the German extermination process.

The concrete possibilities of Jewish resistance were almost nil. Moreover, by the time most European resistance movements became active, the bulk of European Jewry had been exterminated. Hence Jewish armed revolt in the ghettos (the best-known instance being the Warsaw ghetto revolt of April 1943) or even in the camps, although hopeless, carried the utmost symbolic significance. As for the immense majority of European Jews, they had practically no options even when impending murder was obvious: flight and hiding were limited options; despair and numbness, overwhelming.

Home in Anthropology

1. Definition and Meaning of 'Home'

The term 'home,' being of Anglo-Saxon and Germanic origins, often carries rational and irrational connotations at the same time: house, landscape, habitat vs. place of belonging, object of nostalgia, place of origin. The German equivalents, *Heim* and *Heimat*, originally meant 'house' and 'owned land,' but later on denoted ideal and material spaces offering homeliness or German *Gemütlichkeit*. Not coincidentally, the term *Heimat* was re-introduced into the German written language through the reception of British gothic ideas and romanticism. Moreover, *Heimat* was adapted by many other languages as a lean word signifying a mixture of connotations all tending towards an emotionalized interpretation of the place a person feels adapted to: 'my home is my castle.' While loaded with emotional charge, the term 'home' usually also carries allusions to very profane and unromantic connotations, such as in the euphemistic names given to institutions catering for the poor, old, and disabled, or in the meanings expressed by the untranslatable German term *unheimlich* (the 'uncanny' of Freudian philosophy).

Anthropologically relevant references to 'home' initially appeared during the nineteenth century in Anglo-Saxon and German romantic and gothic styles of writing in which it denoted *Ur-Heimaten* or certain groups of humankind, such as the 'Aryan' origins in Asia or people's origins in other 'cradles' (Kuper 1988). Later on the term 'home' acquired a more specific political meaning as in the case of the 'homelands' assigned by the South African apartheid regime to ethnicized groups of 'black' citizens, which had the purpose of containing them in reservations or similar constructions of 'home rule.' More recently, the term has gained some significance again in anthropological studies of migrant, diaspora, and fugitive populations (Malkki 1995, Vertovec and Cohen 1999).

The related discussions move between two poles, one pole being represented by the 'invention of

tradition' approach (Hobsbawm and Ranger 1982), and the other pole tending towards sociobiological and ethological claims about the existence of a human instinct which orientates us towards distinct 'environs' or natural habitats (Wilson 1975). From an anthropological perspective, the often rather unreflected and untheorized use of the term 'home' in scientific texts offers a good opportunity for checking the process of translation between European and non-European cultures. For the discussion of universalistic assumptions about a human drive for being 'at home' involves very heterogeneous forms of belonging, alienation, or indifference towards a 'home.' Often the 'drive' to be at home seems quite easily contented with illusions of a spiritual home; yet in some cases historical processes lead to violent conflicts about presumed 'home countries' between certain groups.

Mary Douglas (1966) introduced anthropologists to a world of symbolic attributions, in which the body can signify everything, and everything can mean the body. The same applies to homes, when looked at as a rational construction of territorial belonging on the one hand, and as an image of embeddedness in a particular social and geographical landscape, or nostalgia about such a situation, on the other.

2. Ways of Being 'At Home'

Obviously, the portable shelter constructed by a group of Kung hunters and gatherers is not the same as the proverbial British or German 'castle.' Anthropologists observed, however, that so-called bush people in Africa, traditional Australian aborigines, as well as groups inhabiting the rainforests of South Asia and South America, have developed elaborate systems of navigation in their regions, based for example on landmarks or tactile qualities of the ground (Widlok 1997). In the nineteenth century, Australian aborigines imagined their ancestors to wander around and with their actions invent the current topographical shape of their habitat. In so doing they related to the 'ground' in a way not at all alien to European conceptions of identity defined by geographical, social, genealogical, and individual physical characteristics of a given group in a given area (Spencer and Gillen 1938). Attracted by some of the benefits of provincial town life or driven away by colonial powers from their places, their twentieth-century descendants may insist on returning to their promised lands, if their means of living allow such a step (Berndt 1977). Welfare programs can thus paradoxically lead to a partial return to traditional ways of living and especially of nurturing their ancestors' grounds. However, often we are no longer able to discern whether indigenous nationalists adhere to old projections of a social and spiritual life onto certain 'hunting grounds' and places of survival through gathering activities, or whether this just

follows Western concepts of belonging, grounded and capitalizing on geographical features of a given area.

There is varied ethnographic and mythological evidence of responses to loss of old nurturing grounds, including the wish to re-enchant the relationship between humans, heaven, and nature, although so far there is not enough comparative research available on the symbolism of land and house. Yet there is some evidence that human groups that succeed in storing greater amounts of food develop more closely-knit local mythologies bound up with the topography of landmarks, human dwellings, places for growing and harvesting food, as well as holy places. Horticulturists and cattle-breeding populations living in segmentary societies or low-grade forms of centralization tend to organize the household, the surrounding area, and far-away places that are of interest to the group by socially constructing ancestors and territorial spirits or divinities (Lienhardt 1961, Lévi-Strauss 1955). The 'juridic domain' (Fortes 1969) concerning the simple facts of life—dwelling together, dividing up food, working a territory, keeping a herd, and maintaining property rights—is thus organized by an explicit ideology of belonging, descent, holy grounds, and the profane (Kramer and Kramer-Marx 1993). A supernatural interpretation of shrines and natural features, even of artificially organized biotopes, can be the territorial expression of a temporal cult of vegetation which unites social groups in a harmonious view of the ego, the household, the family, and other related persons with its ground, including all the plants and animals living or to be raised therein (Turner 1969).

A 'system of total exchange' (Mauss 1960), of generalized reciprocity, seems to pervade and bind human groups and their natural surroundings together. Paradoxically, this can privilege those groups which have reasons to claim to have been the first humans in a particular region and can give them a superior status, heavily defended in conflict, or lost and exchanged with the status of a pariah. The conflict between Hutu and Tutsi in Central Africa has had such a component (Maquet 1961). In a time of international arms traffic, and armed interventions into local cultures, tensions of this kind can lead to severe cases of mass violence.

There is a definite difference between such closely knit groups or networks of groups and the nation states of world society, insofar as the 'total social fact' (Mauss 1960) of traditional societies is organized into a tight overlapping of the domains of landscape, social structure, cosmology, etc. (Fortes 1969). The father or uncle can be the earthmaster, celebrating a holy shrine, and the next moment he can be the leader of a group of young warriors. This does not mean, though, that the social reality of these groups is more homogeneous than ours. Whilst subscribing, like their fellows, to a certain degree to the governing harmonious ideology of space, time, and home, some outsiders, skeptics,

and dissidents always disagree and hold rational or disenchanted views of their group's attempts to maintain a homeland (Radin 1957).

By exchanging 'stigma' for 'charisma,' such outsiders can strongly affect or change their society. Thus, the classical 'big men' of New Guinea who constructed the 'pig festival' through the vegetational and reproductive cycles draw on a whole system of credits and cliental relations countering the heroic culture of the 'great men' who search for the spiritual gratification of the warrior (Godelier 1982). Early imperialist states seem to have been based on a similar mixture of exploiting nature, fellow, and other groups, on the one hand, and heroic fantasies about extending a holy landscape to other regions, on the other (Wolf 1999).

The study of nomadism might be particularly instructive with respect to human ideas about finding or having a home (Mauss 1960). For the layperson, nomads just seem to wander around without clearly relating to certain features of the landscapes. The experience of wandering and fugitive groups in Europe, such as the Sinti, Roma, and many others, may support this conception of a 'wandering' part of humanity that does not feel bound to certain cycles of exchange. Wanderers are always suspect to sedentary populations, and this resentment can remain through long periods of sedentarization, if it is supported by political powers. One of the starting points of German anthropology in the nineteenth century was a series of heated discussions about whether or not Jews felt any obligation of fairness and civil behavior towards non-Hebrew populations (Gilman 1990).

In the anthropological data, nomadic constructions of a unified horizon of landscapes abound, as does information on nomads treating their tents, carriages, or cars as 'mobile homes' (Rao 1987). Motifs in Oriental carpets, manufactured by nomads, often appear to carry the signum of descent and territorial rights as well as some kind of report of the group's history and historical claims for grounds and herds (Schuster and Carpenter 1996).

Not only nomadic populations but many other groups convey an ideal of homogeneity, tradition, and *mise en scène* of an environment of 'being at home' through their material culture, such as dress and costumes. This continues right up to European medieval, Ottoman, and today's international regulations of clothing and corporeal signs. Also the often painfully achieved imprints on the skins of members of more marginal populations seem to have the same rational and spiritual aim of demonstrating a form of belonging together (Clastres 1973). It is the invention of an 'environment,' in the sense that this term is used in modern art. Human environmental creativity ascribes to a certain space the property of being a home. These autopoietic processes of representing and creating an order of time, space, and body are perhaps most obvious in rural societies with their regional and

class-bound costumes, their festivals, shrines, and clear-cut regional politics of power.

But even in the case of feudal societies, which often enough did not allow their underclass members to leave their 'homes'—even in this continuum of slavery on the one hand and enthusiasm for one's own 'ground' on the other—we can find distinct groups who, through historical experience or the subtleties of property rights, seem to have acquired a very distanced attitude towards their houses, fields, and cattle (Lopreato 1967). In times of famine or collective violence, these groups were probably among the first to leave their grounds and wander to the cities or the promised lands, over the mountains and across seas, as soon as the opportunity was offered by the modernization of the world economy into the global capitalistic project.

3. Modern and Postmodern Homes

In cities and other modernized landscapes, anthropologists have observed distinct techniques deployed in designing the 'home' of migrated groups or former peasant inhabitants of the area (Hannerz 1980). Conscious city design, the building of ghettos for reasons of controlling the 'bio-power,' and the process of identity formation in subgroups of a given population all go hand in hand here. Homeland associations as well as informal networks amongst industrial workers and employees ascribe to their private and sometimes also their professional life characteristics of tribal life. The elite of industrialized areas tend to form closely-knit networks, sometimes secret, sometimes formally recognizable, which transform their actors into something reminiscent of the earthmasters and segmentary war chiefs as encountered in traditional societies.

In the third millennium, two-thirds of the world population are expected to live such a metropolitan way of life, and from what we know about the older metropolitan areas in the world, we can deduce that the postmodern metropolis will be partly made by neighborhoods defining and defending themselves like traditional 'villages in the city,' like those in Naples, Cairo, Rio de Janeiro, or New York. These 'lieux' and 'milieux' of trust and similarity will be defined by criteria of class and taste as well as ethnicity and religious confession. Homelessness will abound as well as those of the better off desperate to (re)create a home as an anchor to a very mobile style of life (Dehavenon 1999). The inhabitants of big cities try to overcome the anomic atmosphere of 'non-lieux' by staging and topographically creating city life through festivals and customs, charity and sport events, as well as a home life through decoration, invitations of friends, meals, and so on (Augé 1992, Cieraad 1999).

In addition to the withdrawals and the small refuges of identity, however, an extension of the word 'home' has become important. With the advent of the nation states, millions and even billions of humans can unite in very large conglomerations of landscapes, and by means of national symbolism they try to find not only a common political but also symbolic denominator. An organicist idea of the state—'a sound family makes a sound state' (Norman 1991)—may help to transfer feelings which were originally connected with house, family, regional polity, and local religion to the higher spheres of a fatherland united in the sign of a mother language, a home country (Gellner 1998).

This is where ethnicizing or nationalizing politics have often overlapped with anthropological science, a science often intended historically as a kind of school for learning how to invent nations. Not only under Hitler and Stalin did the 'nations of anthropology' (Borneman 1995) stand in close conjunction with their host nations, so did American cultural anthropology and other well-respected disciplines.

Today's 'United Nations' comprise groups that are divided by very different models of inventing traditions as well as interior constructions. Some of them are founded on the basis of the one and only territory alone, others claim that a common language, cultural heritage, race, or historical traumatization provide the fundament of their existence. However, the whole system of nations nowadays demands that no single person, house, or territory can be without a host nation. This is supported by older ethnographic constructions, which always attributed a group of people to a certain territory. Today, such origins of ethnic topographies frequently turn into a topography of terror, while at the same time international movements of refugees and migration make such attributions obsolete. Another form of homebuilding, however, will apparently continue to exist even in the most technologically advanced systems on Earth. Against all the prognostics of the social sciences, the 'home' seems to survive even its most important carrier, the family. Statistical evidence indicates that single households abound in all metropolitan areas of the world, yet this 'yuppie' culture maintains that people ought to belong to some house, some household (often lovingly decorated and furnished), a certain area, a group of friends and colleagues. Big festivals like Christmas—which is, indeed, the only feast of a truly international character celebrated today, not only in the West but in most parts of the world including China and Africa—provide this 'home' with an anchor in time and space. Groups of families and friends reunite during these days to have traditional forms of communality, exchange, and mythopoesis about a bearded old man leaving his occult home in the last area on the world that still proves unreachable for globalization, the polar circle, carrying with him gifts and goods that will help to make people feel more at home (Miller 1993).

4. Final Thoughts

In the era of 'moving targets' (Marcus 1999), anthropological fieldwork has partly lost its central referent: the small group inhabiting a restricted area since immemorial times—the field. However, it seems that humans all over the world are struggling to recreate homes under the circumstances created by today's form of globalization. The anthropological 'field' therefore re-emerges over and over again, sometimes 'under fire' (Nordstrom 1995) and sometimes in a peaceful dialogue with the anthropologist, that 'professional stranger' who leaves his home to study others' homes.

T. Hauschild

Homelessness: United States

Homelessness has now been a fixture on the political scene in the United States and other countries for two decades. Yet the scope of the problem and the appropriate remedies for it still prompt fierce debates. This article examines the difficulties of defining homelessness and establishing useful estimates of population size and dynamics. It then provides basic descriptive information about homelessness in the United States and looks at its patterns and antecedents. The article ends by describing the growth of homeless-specific service programs and considering the probable future directions for homeless research and policy. Information about homeless populations and services for the United States is based on data

collected in October and November of 1996 by the National Survey of Homeless Assistance Providers and Clients (NSHAPC). NSHAPC provides the most comprehensive overview available for the country as a whole (Burt et al. 1999).

1. Defining Homelessness

Homelessness did not exist as a public policy issue from the end of the Great Depression until the early 1980s. Certainly there were people without homes, or with very inadequate or dangerous homes. In some poor areas of many cities known as 'skid rows,' shelters, or 'missions' run by religious groups offered a bed and sometimes a meal in exchange for the chance to save a soul. These skid row areas also contained hotels where one could rent a small room, with perhaps a hotplate and a small sink, for a day, a week, or a month depending on how much money one had. In addition, rooming or boarding houses offered inexpensive accommodations.

Before 1980, the US Census classified people as 'homeless' if they lived by themselves and not with family members. Thus, all of the single people living alone in skid row areas (and elsewhere) might have been called homeless—a definition quite different from the one in use today, when very large numbers of the general population live alone by choice. Because of definitional problems and the absence of a concept close to what today would be called homelessness, there are no good estimates of the size of the literally homeless population for the 1960s and 1970s. The best guess is that in the late 1970s formal shelters (i.e., missions) for the homeless might have been able to accommodate about 50,000 people at any one time in the entire country, and that the number of literally homeless people probably was no more than 100,000 and could have been considerably less.

Since 1987, official US policy defines people as literally homeless if they sleep in a shelter for homeless people or in places not meant for human habitation such as vehicles, abandoned building, outdoor locations, or transportation facilities or stations. However, the people included in any actual study of the homeless, and therefore the descriptions of homeless populations and estimates of their size, will vary greatly depending on study methods (Taeuber 1991). If studies go only to shelters they will miss all homeless people who do not stay in them. Even studies that include searches of nonshelter locations have a very hard time finding most unsheltered homeless people. The best methods developed to date use services such as soup kitchens and outreach programs to find the nonsheltered homeless, and succeed better than street searches. In some European countries with a right to housing, homelessness is sometimes defined quite differently, as people who come to a housing authority needing housing (which they usually receive). Ob-

viously both definitions of homelessness and methods used to find homeless people will affect estimates of population size, while public policies will affect the types of remedy available and the probable length of homeless careers.

2. Homeless Numbers and Rates

The best point prevalence estimate of the size of the homeless population in the US before the early 1980s was 100,000 or fewer. By 1984 the estimate was up to 250,000 to 300,000, and by 1987 to 500,000 to 600,000. Estimates for 1996 of homeless people *using homeless assistance programs* (not all homeless people) range from 444,000 for October to 842,000 for February (Burt et al. 2001). All of these rates include any children accompanying a homeless adult, but not runaway and homeless youth.

The best way to compare estimates over time and place is to convert them to rates, which for homeless estimates is usually a rate per 10,000 population. Homelessness rates based on the 1987 estimate of 500,000 to 600,000 homeless people were 19.4/10,000 to 24.3/10,000. Projecting the February 1996 estimate of homeless service users to the whole homeless population assuming that service users during this winter season were 80 percent of the population produces an estimated rate of 38.0/10,000. This significant increase in the estimated rate of homelessness at any given time owes a good deal to the more than 200 percent expansion of homeless shelter capacity between 1987 and 1996 (see below), all of whose residents are classified as homeless.

Annual prevalence rates are a far better vehicle that point prevalence rates for understanding the proportion of a population affected by homelessness over time, because they account for the very large number of homeless spells lasting less than one year. Estimates for New York and Philadelphia indicate that 1 percent (100/10,000) of the entire population of those cities used a homeless shelter during a year's period (Culhane and Hornburg 1997, pp. 101–34). The same level of homelessness was estimated for the entire US for 1996 by Burt et al. (2001). When considered as a proportion of the *poor* population, the rate is close to 10 percent experiencing homelessness in a year's time.

3. Major Characteristics of Homeless People in the United States

3.1 Demographic Characteristics

In 1996, information from NSHAPC indicated that about one-third of homeless services users were mem-

bers of homeless families; 23 percent were the children in these families, and 11 percent were their parents. These families comprised 15 percent of all homeless *households*; 86 percent of which were headed by women. Among family households, 38 percent were white non-Hispanic, 43 percent were black non-Hispanic, 15 percent were Hispanic, and the remainder were from other races/ethnicities. Forty-one percent had never married, and only 23 percent were currently married. Educational attainment was very low, with 53 percent having less than a high school education. These families had a mean monthly income of \$475, or less than half of the US federal poverty level for a family of three (Burt et al. 1999).

Nonfamily homeless households were 61 percent men by themselves, 15 percent women by themselves, and 10 percent men or women with at least one other adult (Burt et al. 2001). Among nonfamily homeless service users, 41 percent were white non-Hispanic, 40 percent were black non-Hispanic, 10 percent were Hispanic, and 9 percent were from other races/ethnicities. Half of these homeless adults had never married, and only 7 percent were currently married. Equal proportions (36–37 percent) had completed high school and had less than a high school education. Mean monthly income was \$348 or 51 percent of the federal poverty level for a single person (Burt et al. 1999).

3.2 Other Characteristics

In 1996, less than 10 percent of homeless adults worked in a regular job while homeless. However, 44 percent did some paid work for a month. Homeless adults were almost disconnected from the financial support of family and friends, with only 21 percent receiving money from these sources in an average month. Homeless families were somewhat better connected to public benefits, with 52 percent receiving the primary public welfare benefit of Aid to Families with Dependent Children and associated food and healthcare benefits. About 1 in 10 homeless adults received Supplemental Security Income, a program for people with serious long-term disabilities preventing them from working. Many studies find high levels of alcohol, drug, and mental health problems among homeless populations; the NSHAPC included. During the year before the study, 46, 38, and 45 percent of homeless adults reported alcohol, drug, and mental health problems, respectively. Only one in four did not report any of these problems. Homeless women were more likely to report mental health problems without either alcohol or drug problems, while homeless men were most likely to report having problems only with alcohol and not with drugs or mental health issues.

3.3 Patterns of Homelessness

Peoples' experiences of homelessness vary considerably. Many researchers have differentiated three patterns of homelessness—first-time/crisis/transitional, episodic, and chronic—although the exact classification criteria vary across studies. The first group includes individuals or families who are homeless only once or twice and usually for a relatively short period of time (e.g., less than 3, 6, or 12 months). Often they have been precariously housed and find themselves homeless after an unexpected crisis such as unemployment, divorce/separation, or eviction. They usually secure some type of housing relatively quickly and often do not become homeless again. Episodically homeless people are defined by their pattern of cycling in and out of homelessness over significant periods of time. Many spend time in various institutions such as inpatient treatment centers, detoxification programs, and jail. Chronically homeless people have relied on shelters or lived on the streets for many months or years, and usually have multiple barriers to securing stable employment and housing. They may have only a few distinct spells of homelessness, but each one lasts for a very long time.

Point-in-time studies, which overestimate the proportion of homeless people with long spells, usually find that about one-quarter of homeless adults are in the first group, and that half or more have extensive histories of either episodic or continuous homelessness. Studies that are able to observe flows into and out of the homeless condition over time give a different picture, showing only 10 to 20 percent with long-term homelessness and up to half with quite short-term or crisis patterns (Culhane and Hornburg 1997, pp. 101–34).

4. Antecedents of or Factors Associated with Homelessness

Both societal and personal factors affect homelessness. The societal factors predict *when* and *where* homeless populations will increase or decrease; the personal factors help to predict *who* will be vulnerable to these societal pressures. The two sides of the equation determining the ability to afford housing are household income and housing costs. In the US, housing costs for the lowest-cost units has increased significantly in the past 2 decades. Also, homelessness most recently became a public issue in the early 1980s, during a time of record-high unemployment (the recession of 1981–1982) that reduced household income among both low-wage workers and workers in manufacturing, many of whom lost their jobs. The record prosperity of the US during most of the 1990s has been accompanied by the development of a two-tiered labor market that has relegated many people without a college or technical education to low-paying service jobs. At the

same time, wealthier households have pushed housing costs to record-high levels. The differential between earning power and housing costs sets the societal stage for homelessness. A public safety net of housing and other programs could assure that households do not founder under such circumstances. Some European countries have such a safety net, but the US does not. Some level of homelessness is the result.

That being said, certain people are more likely than others to become homeless. Poverty is the *sine qua non* of homelessness. The explanatory value of demographic characteristics such as race/ethnicity diminish or disappear in many analyses that simultaneously include income variables plus characteristics such as physical health, childhood experiences, and variables relating to alcohol and drug use and mental health problems. Regression results from an increasing number of studies on both families and singles confirm that sexual or physical abuse by a household member, foster care, or other out-of-home placement in childhood differentiate both homeless families and homeless singles from their housed counterparts. Physical and mental health conditions in adulthood, and early and current alcohol or drug use are also usually found to increase the probability that a person will experience homelessness when other things are held constant.

5. Growth in Services and Evidence of Effectiveness

5.1 Shelter/Housing Capacity

NSHAPC offers the first opportunity in many years to update knowledge about homeless assistance programs from the national perspective. Estimates based on NSHAPC data indicate that the nation's shelter/housing capacity within the homeless assistance system grew by 220 percent between 1988 and 1996, from the 275,000 beds estimated by the US Department of Housing and Urban Development (HUD) for 1988 to more than 600,000 beds in 1996. This growth came on top of the 275 percent increase in shelter capacity between 1984 and 1988 from 100,000 to 275,000 beds. One of the most striking things about the growth of shelter/housing capacity is the extent to which the system has gone beyond emergency shelter to include large numbers of transitional housing units, and permanent housing units for disabled people who were once homeless. In fact, relatively little growth occurred in emergency shelter programs, or beds specifically, between 1988 and 1996. HUD estimated 5,400 shelter programs in 1988, with a capacity of 275,000 beds. Virtually all of these programs and their beds supplied emergency accommodation, either through emergency shelters or through voucher arrangements with hotels and motels. In 1996, NSHAPC data indicate that the number of beds available through more than

8,800 emergency shelter plus voucher distribution programs had grown to only 333,500, or a mere 21 percent over the level in 1988.

In contrast, transitional and permanent housing units exploded, going from basically none in 1988 to about 275,000 in 6,300 programs by 1996. Thus, this entirely new capacity to help people with housing needs beyond emergency shelter was essentially equal, in 1996, to the entire homeless assistance system in 1988. This growth coincided with the initial availability and eventual expansion of federal funding for new types of shelter/housing stimulated by homeless legislation.

5.2 Soup Kitchen/M Meal Capacity

No national data exist to describe soup kitchen and other prepared meal distribution programs for 1987 that are equivalent to HUD's 1988 survey of shelter capacity. However, a 1987 Urban Institute study (Burt and Cohen 1989) did provide a roughly equivalent look at soup kitchen and mobile food program capacity in cities over 100,000, which can be contrasted to NSHAPC's estimates for central cities in 1996. Big-city prepared meal capacity increased almost four-fold between 1987 and 1996, from 97,000 up to 382,100 meals a day. Nationally, NSHAPC estimates are that soup kitchens and mobile food programs expected to serve almost 570,000 meals a day in February 1996, of which one-third were served in suburban/urban fringe areas or rural areas outside of central cities.

Unlike most shelter/housing programs, users of which are presumed to be literally homeless, soup kitchens and mobile food programs commonly serve many nonhomeless people (although some may have had earlier episodes of homelessness). In addition, people may eat more than one meal a day at these programs. For both these reasons, the estimate of meal service levels in 1996 cannot be interpreted as a level of homelessness. However, it certainly can be interpreted as a level of need. Also, soup kitchen/prepared meal programs have not had even one-tenth of the federal financial incentive to increase their service level that has been available to open or expand shelter programs over the past decade. This makes the service growth in the emergency food arena between 1987 and 1996 even more remarkable than the growth of the shelter/housing segment of homeless assistance. It attests to the responsiveness of many communities' emergency capacity, as well as to the ongoing problem of hunger even in a decade when most Americans enjoyed remarkable prosperity.

5.3 Evidence of Effectiveness

Effectiveness should only be assessed against expectations that are realistic to the programs and

services examined. If the goal is to supply shelter and food, then shelters and soup kitchens are effective in meeting that goal. If the goal is to end, or prevent, homelessness, then the growth in shelter capacity in the US has probably had the opposite effect. This perverse result arises from the definition of homelessness, which includes residence in a homeless shelter. It is unclear whether the underlying level of need—the pool of people desperate enough to seek shelter from the homeless service system—grew in the 1990s. But the expanded shelter capacity gave such people a place to go that did not exist in the 1980s, and they have used it.

In 1999, a federally sponsored symposium featured papers summarizing ten years of research on the effectiveness of services for homeless people (Fosburg and Dennis 1999). Most of the findings revealed that intermediate program goals were being achieved. For instance, outreach programs were able to engage homeless people with serious disabilities, and eventually connect them to services. Case management programs were also able to connect homeless people to services. Psychiatric services were able to help mentally ill homeless people with their mental health problems. However, on average, none of these programs were able to end homelessness for their participants unless they supplied housing (Shinn and Baumohl 1999). If they supplied housing, especially with supportive services as required, programs could help even the most disabled homeless people leave the streets and maintain themselves in stable residential situations.

6. Future Directions for Policy and Research

In the US the argument has come full circle after almost 2 decades. The notion that homelessness was a problem of 'housing, housing, and housing' was made forcefully in the early 1980s, and has now proved to be quite accurate. Service programs have helped many homeless people in many ways. But to help people leave homelessness for good, or to divert people from entering into homelessness, the resources required are housing resources. These include help with landlords, back rent, evictions, and move-in expenses as diversion outlays, and actual housing as a means to end homelessness. A big question exists as to the value of supportive services to accompany the housing, once the housing itself is supplied. Research on this issue is summarized by Shinn and Baumohl (1999). Some research, mostly on homeless families, suggests that housing is the key and that services add little or nothing. Other research, more focused on chronically homeless people with significant alcohol, drug, and/or mental health problems, indicates an important role for supportive or supervisory services to accompany housing.

Future research could profitably take two directions. The first direction would focus on what supports

or services made available *just before* a homeless episode or at the moment of its precipitating event could avert the transition to literal homelessness by stabilizing the situation or simply redefining the issue. For instance, some community support services for persons with chronic mental illness offer 'respite' facilities where a person can stay for several days during a crisis in their illness. Respite stays avert complete dissolution of the person's life in the community, including loss of housing. It would be important to learn how these types of interventions can work best, for whom, and when. The second direction for research would focus on what services *in addition to housing* would make the most difference for people who are already homeless. Some communities in the US have already shifted resources from emergency shelter to affordable and supported housing, actually reducing the need for emergency shelter beds. More attention needs to be focused on developing a range of such approaches, because it should be clear that continuing to increase the capacity of the homeless service network will only serve to bring more and more people into the category of homeless.

Homosexuality and Psychiatry

Psychiatry has served both to reflect and to help define Western societal attitudes toward homosexuality for much of the past two centuries. Perspectives on homosexuality—concerning its origins, its social and personal meanings, its diagnostic implications, and its clinical relevance—persistently represented one of the most contentious issues within American psychiatry during the latter part of the twentieth century. With a primary emphasis on the American experience, this article presents current definitions related to homosexuality and sexual orientation and examines the history of psychiatric theories and findings about homosexuality. The relationship between homosexuality and psychiatry in other countries and cultures has often paralleled what took place in the US but also reflects the diverse attitudes and policies regarding both sexuality and mental illness throughout the world. An example of such diversity is the recent legislation of gay and lesbian relationships by some European countries in contrast to the continued opposition to such acceptance in the United States.

1. Definitions

Increased understanding of sexuality in general has led to greater specificity in the use of terms related to sex, gender, sexuality, and sexual orientation. Terms such as gender identity and gender or sex role tended to be confused with sexual orientation in early writing about homosexuality; however, it is now recognized that these are related but discrete characteristics that may interact with but are not synonymous with homosexuality.

Sexual orientation refers to a person's erotic response tendency, homosexual, bisexual, or heterosexual, toward persons of the same or other sex as reflected in such indicators as the proportion of dreams and fantasies directed to one or the other sex, the sex of one's sexual partners, and the extent of physiological response to erotic stimuli associated with one or both sexes. Sexual orientation consists of three components, desire, behavior, and identity, which may or may not be congruent in an individual. The Kinsey scale—a 7-point continuous scale, with 0

representing exclusive heterosexuality, 6 representing exclusive homosexuality, and 3 representing equal amounts of both, or bisexuality—is the most widely used scale for describing sexual orientation. The terms homosexuality, heterosexuality, and bisexuality have not been applied consistently in theoretical, research, or popular discourse; they have been used to refer to a wide range of constructs, including categories of sexual desire, gender role attributes, forms of sexual behavior, personal and social identities, types of personalities and persons, degrees of normality and abnormality, and the presence or absence of mental illness.

The presence of erotic desire for someone of the same or other biological sex does not imply the concurrent existence of any other characteristics in that individual. Thus, for example, a woman may engage in homosexual behavior, demonstrate typical feminine gender role characteristics, be married to a man, and experience a heterosexual identity; or a man may have homosexual desire, have sex only with women, and show gender role nonconformity.

The terms gay, gay man, lesbian, and bisexual are used to refer to men or women who have developed a sexual orientation identity that is homosexual or bisexual. While gay sometimes is used as an inclusive term to refer to both men and women, reference to two distinct groups, gay men and lesbians, is more appropriate because of the significant differences between these groups in their development and experiences.

Homosexual, or lesbian and gay, and bisexual identities are the subjective experiences of being homosexual or bisexual—being significantly or exclusively attracted to someone of the same sex—with the identities being both self- and other-ascribed. Models of lesbian, gay, and bisexual identity development usually portray a series of linear progressive stages involving tasks such as coming out (the process of recognizing one's homosexual or bisexual attraction and acknowledging it to oneself and to others), involvement in lesbian, gay, and bisexual communities, establishing same-sex relationships, and integration of one's sexual identity into other aspects of the self. Not all persons who experience homoerotic desire or participate in homosexual behavior also develop a lesbian, gay, or bisexual identity.

In contrast to sexual orientation, gender identity generally is understood to refer to a persistent sense of oneself as being male, female, or ambivalent and is contrasted with sex, which refers to the biological attributes of being male or female. While gender identity describes an inner experience of being male or female, gender role and social-sex role are defined as the degree to which an individual's outer behavior or appearance can be described as masculine, feminine, or androgynous. The large majority of persons, regardless of their sexual orientation, have a gender identity and gender role consistent with their bio-

logical sex, though sometimes gay and lesbian persons may demonstrate a greater range of gender role attributes.

2. Historical Conceptualizations of Homosexuality within Psychiatry

Prior to the time homosexuality was first studied as a psychiatric condition in the second half of the nineteenth century, the meaning of homosexual behavior was very different than it is today in Western culture. Homosexual behaviors take place in all societies and homosexual acts have been both ritualized and prohibited in various cultures. However, the contemporary idea of identifying a type of person based on regular participation in homosexual behavior and on development of an identity associated with this behavior is generally believed to be a product of the medicalization of homosexuality during the nineteenth century.

2.1 Medicalization of Homosexuality

During the second half of the nineteenth century a number of individuals in Europe began to study homosexuality scientifically. The term homosexual was first coined by the Hungarian physician Kertbeny in 1869. The conceptual basis for homosexuality arose from the earlier ideological construction of two genders, male and female, with dichotomous characteristics, and the attempt to find explanations for homosexuality derivative from these male and female categories. Thus, the homosexual was conceived of as a person of one biological sex with the sexual longing of the other sex, as portrayed, for example, in the German jurist and homosexual rights advocate Karl Heinrich Ulrich's description of the male homosexual as a female soul in a male body.

Subsequently, the German psychiatrists Carl Westphal and Richard von Krafft-Ebing adopted many of Ulrich's ideas, but they considered the traits he described to be unnatural. The German physician and sexual emancipator Magnus Hirschfeld also believed that there was a genetic basis for homosexuality. While he understood homosexuality to be a malformation in development and ascribed to a number of different biological etiologies, he also asserted that it was natural. Similarly, the English sex reformer Havelock Ellis based his efforts to alter attitudes about homosexuality on the belief that homosexuality was an inborn trait. Specific biological theories about the origins of homosexuality began to be examined during this period, including a variety of constitutional factors, such as different anatomical structures in the brains and in nerves in the rectums of homosexual men, and endocrinological determinants, including atrophied and abnormal testicles in homosexual men.

These early biological theories about the origin of homosexuality, with their emphasis on heredity, endocrinological influences, and anatomical or structural differences between homosexual and heterosexual persons, presage many current efforts to find a biological basis for homosexuality. Their almost exclusive emphasis on the study of homosexuality in men also parallels later twentieth-century biological research, which largely has ignored homosexuality in women. Further, the biological arguments helped to create the notion of a homosexual person by emphasizing the existence of fundamental constitutional differences between those who are attracted to persons of the same sex and those who are attracted to persons of the other sex.

2.2 Psychoanalytic Approaches

During the latter part of the nineteenth and the first half of the twentieth century, psychoanalysis, with its emphasis on intrapsychic and interpersonal development, represented an alternative approach to the biological sciences for studying and understanding homosexuality. Freud believed that heterosexuality was the natural outcome of normal development and that homosexuality represented an arrest in development from an instinctual bisexuality to a mature heterosexuality that arises as the result of a variety of factors. However, he did not view homosexuality as a sign of degeneracy and even asserted that homosexuality could occur in persons who had no other signs of deviation and no impairment in their functioning. Later psychoanalytic theorists, including Sandor Rado, who refuted Freud's model of innate bisexuality and developed his own theory of homosexuality as a type of phobia, emphasized far more heavily the beliefs that homosexuality is the result of problems in psychosexual development and that its occurrence is a sign of severe psychopathology.

The outcomes of the growth of interest in studying homosexuality within the biological and psychoanalytic fields during this period were similar: to establish a focus of interest about homosexuality outside of the realms of morality and religion within science and medicine; to reify a category of person, the homosexual, associated with homosexual behavior; and to confirm the abnormality and the pathology inherent in homosexuality.

2.3 Normalization of Homosexuality

The publication of the two volumes on male and female sexuality by Kinsey et al. (1948, 1953) marked the beginning of the move away from the view of homosexuality as pathology and toward an understanding of homosexuality as a normal variant of

sexual desire and behavior. Kinsey's studies demonstrated the widespread presence of homosexual feelings and behavior among samples of several thousand American men and women thereby suggesting that homosexuality was not an isolated and aberrant phenomenon. Kinsey's conceptualization of sexual orientation as a continuum also introduced the idea that homosexuality and heterosexuality were not dichotomous categories, but rather occurred in varying degrees in individuals.

Ford and Beach (1951) demonstrated that homosexuality was common across cultures and occurred in almost all nonhuman primate species. The psychologist Hooker's (1957) publication of the results of her ground-breaking study comparing the projective test results from 30 homosexual men and 30 heterosexual men showed that experienced judges could not distinguish between the two groups based on their test results, a finding which established for the first time that homosexuality in men was not associated with mental illness. The effect of this significant finding was to require that future views of homosexuality as an illness could only be based on an *a priori* assumption that homosexuality itself was pathological. By the 1970s, influential psychiatrists like Judd Marmor, a psychoanalyst and president of the APA, began to publish works that moved the psychiatric profession further away from the perspective of homosexuality as a type of mental illness and toward a consideration of the perspectives offered in the newer research findings.

During this period of transition and in spite of the availability of contradictory findings from empirical studies, some psychologists, particularly behaviorists who attempted to extinguish homosexual expression through aversive techniques, and psychiatrists, primarily psychoanalysts such as Irving Bieber and Charles Socarides, persisted in publishing works that presented homosexuality as the outcome of developmental disturbance and as a sign of severe psychopathology. Bieber's work (Bieber et al. 1962), which has been criticized extensively for its methodology, was particularly influential in its portrayal of a pathogenic family type, consisting of a detached and rejecting father and a close-binding and domineering mother, that led to homosexuality in adult men.

3. Classification of Homosexuality by the American Psychiatric Association

Homosexuality was classified as a type of mental disorder in the first *Diagnostic and Statistical Manual of Mental Disorders (DSM-I)* (1952). It was designated, along with the other conditions labeled as sexual deviations, as a type of sociopathic personality disturbance, defined by the existence of certain behaviors and not by the presence of distress or dysfunction. This classification of homosexuality as a

form of mental illness was not controversial at the time *DSM-I* was published, reflecting as it did the negative societal attitudes about homosexuality and the prevailing medical views of homosexuality. In *DSM-II* (1968), homosexuality continued to be listed as a type of sexual deviation.

Beginning in 1968, gay activists began to confront the APA about its classification of homosexuality as a type of mental disorder. Following a series of dramatic encounters between gay rights advocates and psychiatrists at several annual meetings of the APA, the organization began officially to re-evaluate its position. Following further political protest and significant scientific study of the issue, a proposal from the Nomenclature Committee of the APA to eliminate homosexuality from the *DSM* was approved by the APA's Council on Research and Development, Reference Committee, and Assembly of District Branches before being accepted by the APA's Board of Trustees in December 1973. As a result, for the first time in modern history homosexuality *per se*, was not classified as a type of illness. This action had enormous social significance in shifting the predominant and official view of homosexuality from one of sickness to one of acceptable behavior. The decision to declassify homosexuality was accompanied by passage of a position statement by the APA that supported the protection of the civil rights of homosexual persons:

Whereas homosexuality in and of itself implies no impairment in judgment, stability, reliability, or vocational capabilities, therefore, be it resolved that the American Psychiatric Association deplores all public and private discrimination against homosexuals in such areas as employment, housing, public accommodations, and licensing, and declares that no burden of proof of such judgment, capacity, or reliability shall be placed on homosexuals greater than that imposed on any other persons. Further, the APA supports and urges the enactment of civil rights legislation at local, state, and federal levels that would insure homosexual citizens the same protections now guaranteed to others. Further, the APA supports and urges the repeal of all legislation making criminal offenses of sexual acts performed by consenting adults in private.

The rationale for removing homosexuality from the *DSM* was based, in part, on the clarification of the definition of a mental disorder as meeting the criteria of either experience of subjective distress or of generalized impairment in social effectiveness or functioning as a result of the condition. Neither of these criteria applied to homosexual persons who were satisfied with their sexual orientation and who did not demonstrate impaired functioning. In what appeared to be a compromise between opposing views, a new diagnostic category, 'sexual orientation disturbance,' was introduced to apply to those homosexual persons who 'are either disturbed by, in conflict with, or wish to change their sexual orientation.' When the *DSM-III* (1980) was published, sexual orientation disturbance

was replaced with a new diagnostic category, 'ego-dystonic homosexuality,' a type of general psychosexual disorder that labeled homosexuality as a mental disorder only when it was accompanied by persistent distress. Finally, after further review of the appropriateness and utility of this diagnosis, all reference to homosexuality was removed from *DSM-III-R* (1986), representing the final acknowledgment by the American psychiatric profession that homosexuality is not a type of mental illness. This change in the official view of homosexuality signified a dramatic conceptual shift in the cultural meaning and significance of homosexual behavior within American society.

4. *Effects of Declassification*

The decision to remove homosexuality from the *DSM* led to widespread effects within psychiatry. At the organizational level, groups of lesbian, gay, and bisexual psychiatrists formed and many issues relevant to the mental health of lesbian, gay, and bisexual persons could now be considered. At a clinical level, while controversy has persisted among psychiatrists about how to conceptualize homosexuality, new understandings and techniques for evaluation and treatment based on gay and lesbian affirmative approaches were developed.

These changes were accompanied and shaped by larger contextual shifts that occurred as a result of removing homosexuality from the realm of pathology. Thus, for example, once homosexuality was no longer viewed as a disease, it became a topic that could more legitimately be studied within a variety of fields outside of psychiatry and medicine with their emphasis on pathology, such as the law, the social sciences, and the humanities. The expansion of gay and lesbian identities, communities, and culture in the years since the APA's action produced a plethora of new issues that interacted with and influenced mental health, such as coming out, relationship concerns, childbearing and raising, family interactions, and spirituality. Finally, new health concerns, particularly AIDS, substance abuse, and reproductive issues, have created a whole set of additional mental health issues relevant to lesbian, gay, and bisexual persons.

Following the APA's action to depathologize homosexuality, the formerly secretive 'GayPA,' consisting of an informal group of closeted homosexual psychiatrists, began to evolve into a more open and extensive social and political network of gay and lesbian psychiatrists. At the 1978 annual meeting, a formal structure was adopted for the Gay, Lesbian, and Bisexual Caucus of the American Psychiatric Association, which was subsequently re-named the Association of Gay and Lesbian Psychiatrists (AGLP). Consisting of several hundred members, the AGLP is an affiliated group of the APA and is one of

the largest organizations of gay and lesbian physicians in the world. Many of its members served as founding members of other gay and lesbian medical groups, and it has continued to provide support to members and to raise political and clinical issues relevant to gay, lesbian, and bisexual mental health within the psychiatric profession. In addition, a Committee on Gay, Lesbian, and Bisexual Issues was established within the structure of the APA to study and make recommendations regarding mental health concerns. As a designated minority and underrepresented group within the APA, members of the Caucus of Lesbian, Gay, and Bisexual Psychiatrists elect representatives to the Assembly of District Branches, and openly lesbian and gay psychiatrists have been appointed and elected to many leadership positions within the APA.

The substantive issues discussed within the APA relevant to gay, lesbian, and bisexual concerns have involved a variety of topics, such as parenting and custody, education, reparative therapy, and AIDS. This activism and openness could not have occurred without the radical paradigm shift that took place when homosexuality was no longer considered a disease. The reconstruction of homosexuality as a normal variation of sexual desire, behavior, and identity allowed its introduction as a legitimate topic for discussion within the field of psychiatry.

Within the 1980s and 1990s psychiatrists in academic settings have been acknowledged and promoted for their work on gay and lesbian topics. Openly gay and lesbian researchers and clinicians have helped to establish a whole new field of gay and lesbian mental health. Publication of a section on homosexuality in the *Review of Psychiatry* (Oldham et al. 1993), a comprehensive *Textbook of Homosexuality and Mental Health* (Cabaj and Stein 1996), a curriculum for learning about gay, lesbian, and bisexual issues in psychiatry training programs (Stein 1994), a *Journal of Gay and Lesbian Psychotherapy*, and numerous scholarly articles and volumes on affirmative approaches to working with gay, lesbian, and bisexual patients has provided a breadth of valuable resources for helping gay men and lesbians within mental health settings. As a result of this material, many mental health facilities and practitioners are increasingly sensitive to gay and lesbian needs and informed about gay and lesbian concerns.

Problems have remained even after the revolution in perceptions of homosexuality precipitated by the diagnostic change made by the APA in 1973. Some psychiatrists and other mental health professionals continue to view homosexuality and gay, lesbian, and bisexual persons in negative ways and to perpetrate harmful practices, such as involuntary hospitalization of gay, lesbian, and bisexual youth because of their sexual orientation and presentation of unsubstantiated claims for 'curing' homosexuality. Groups within the APA concerned with gay, lesbian, and bisexual mental health concerns have worked to enact

new policies that will eradicate the vestiges of heterosexism and antisexuality. In December 1998 they were successful in having the APA approve a Position Statement on Psychiatric Treatment and Sexual Orientation which states that:

... the American Psychiatric Association opposes any psychiatric treatment, such as 'reparative' or 'conversion' therapy which is based on the assumption that homosexuality *per se* is a mental disorder or based on the *a priori* assumption that the patient should change his/her homosexual orientation.

5. Future of Homosexuality and Psychiatry

While the discourse within psychiatry regarding homosexuality has been expressed primarily in the form of scientific arguments about developmental and therapeutic conceptualizations related to sexual orientation, these arguments reflect the larger social debate within the US about attitudes and policy toward homosexuality. The psychiatric profession specified a clear governing principle—that homosexuality is not a type of mental illness—in its 1973 decision to de-pathologize homosexuality, but struggled for the next 25 years to articulate a consistent strategy for dealing with the implications of this decision. Perhaps official psychiatric policy was ahead of the larger society in its unequivocal rejection of a view of homosexuality as a type of disease. Like American society in general, however, psychiatry continued to maneuver to accommodate two totally conflicting viewpoints about sexuality, morality, and social values that were condensed in attitudes toward homosexuality. It remains to be seen if the definitive opposition to reparative therapy approaches to homosexuality expressed in the 1998 position statement represents final closure within psychiatry on this enduring debate.

The impact of diagnostic and treatment changes in relation to homosexuality within psychiatry during the past three decades has extended far beyond the mental health field. First, in 1973, by removing homosexuality itself from the medical spheres of etiology and pathology, the psychiatric profession yielded dominion over sexual orientation to those who dealt with normal variations of behavior, such as psychology, sociology, and other biological and behavioral sciences. The freeing of homosexuality from its century-long ownership by psychiatry can be seen as a major impetus to the expansion and deepening of understanding about the topic within many fields and to the burgeoning growth and expression of gay and lesbian identities and communities. Once the gate to the prison of pathology had been unlocked, those who had previously been incarcerated because of their sexual identities lost no time in claiming their newly found freedom and, at the beginning of the twenty-first century, are demanding assertively equal access to fundamental social institutions and rights such as

marriage, parenting, and legal protection based on an assumption of their normality.

Honor and Shame

Anthropologists conducting research into Mediterranean societies first developed the notions of honor and shame to describe the particular complex of values they found there. Honor comprised both an individual's sense of self-worth and this person's reputation in the surrounding community. Shame, by contrast, arose from the failure to act according to social values and it entailed public disgrace. This article traces the development of these concepts within anthropology and considers their current applicability.

1. Honor in Anthropology

By the middle of the twentieth century the word 'honor' was well on its way to obsolescence in ordinary English language usage. The practice of dueling to redress injuries to one's honor had ended and consequently honor had ceased to be a topic of public concern. The term was mainly frozen into stock expressions such as 'word of honor' or fixed in the aspic of formalized conventions such as the Queen's Honours List, or the school honor roll. Honor was still a familiar word, yet people were not absolutely certain what it meant; it was rich in connotations, but poor in denotation.

The Oxford-trained anthropologist Julian Pitt-Rivers, scion of a venerable English family whose forebears may well have participated in the culture of honor dueling in the last century, capitalized on the evocativeness of 'honor.' He reintroduced the word in a wide-ranging essay that drew principally on data from early modern European history. In this historical period honor drifted away from its medieval sense of a monarch's gift of fiefs in return for (military) services. In the seventeenth century it came to mean a general social reputation and then in the early nineteenth century it took on a more interiorized sense of integrity or moral dignity. If publicly insulted—called a liar or cuckolded, for example—a man was within his rights to demand the satisfaction of a duel to restore his honor.

Pitt-Rivers used a polysemous amalgamation of the historical senses of honor to interrogate his own contemporary ethnographic data from a Spanish village. His essay appeared alongside studies of other Mediterranean societies in a book entitled *Honour and Shame: The Values of Mediterranean Society* (Peri-

stian 1965) that launched honor and shame in anthropology. The premise of the volume was that '[M]editerranean peoples ... are constantly called upon to use the concepts of honor and shame in order to assess their own conduct and that of their fellows' (Peristiany 1965, p. 10).

For the most part honor and shame were conceived to be opposites and furthermore to orient different gender-linked ideals. Men were most likely to claim honor aggressively through acts of violence or cunning that earned them a fearsome reputation. This reputation was maintained by an ongoing performance of swagger and gruffness that staked out an inviolable space around a man's property, livestock, and women. As Peristiany noted (1965, p. 9), if provoked, 'a Greek Cypriot, a Bedouin and a Berber may answer "I also have a moustache"'.

For their part, women protected this honor by comporting themselves with the modesty born of a sense of shame. Among the Sarakatsani shepherds of northern Greece described by Campbell (1964, p. 287), women do not run for fear that they might fall over backwards and expose their underwear, thereby shaming themselves irretrievably. Ideally a young woman should stay at home working on her dowry, well away from the public gaze so that her name will not be on people's lips.

2. Comparative Considerations

The Mediterranean focus of the *Honour and Shame* volume spurred further ethnographic research within this 'culture area' and also attempts to theorize why such a similar set of values had been arrived at in this region. Virtually all anthropologists assumed that honor and shame were relatively consistent in form throughout the Mediterranean until Michael Herzfeld (1980) pointed out, on the basis of research in two very different Greek communities, that honor amounted to 'socially appropriate behavior.' In a quiet, law-abiding village, macho swagger and aggressivity do not form the basis of honor.

The appreciation of the relativity of honor forced specialists into a theoretical stock taking (Gilmore 1987). Two definable tendencies emerged: (a) honor and shame vary in form in different communities, and indeed may be found in completely non-Mediterranean societies such as Japan where there is a great emphasis on shame; (b) although not exclusive to the Mediterranean, Mediterranean societies do, nonetheless, seem to converge on some strikingly similar cultural expressions of honor and shame. The gestural sign of the billy goat's horns made with extended index and baby finger, for example, signifies that a man has been cuckolded in a number of Mediterranean societies. The northern European resort to the image of the cuckoo bird to represent marital betrayal

indicates the imagery of a different cultural area. In Mediterranean societies goats furnish the relevant vocabulary. A man who has been betrayed by his wife wears horns in Greek (*keratás*) and in Italian (*cornuto*) while in Spain he is just a big goat (*cabrón*). Unlike rams, billy goats allow their females to be mounted by other males without protest.

3. Performance: Class and Gender

In early modern Europe honor was mainly an affair of the aristocracy; slights from social inferiors could be ignored without consequences. The majority of early Mediterraneanists worked in small rural communities where everyone was putatively a social equal. All men began with an equal portion of honor that they could increase or lose. A single system of honor and shame thus permeated the whole community but in larger, stratified towns or cities there could be several parallel systems of honor by class. Honor itself was not economically determined, but the circles within which it was contested, and the modes of contestation, were.

There can be few societies lacking altogether in notions of precedence and social failure. The particular expressive performance of prestige in Mediterranean societies was surely what attracted the attention of anthropologists. These performances might involve elaborate verbal displays such as the spontaneous exchange of insulting rhyming couplets, or the skilled telling of tales of sexual prowess or daring animal theft. The anthropologists recording these stories usually came from the middle classes of northern European or North American societies. Their fascination with difference precluded the recognition of their own participation in systems of honor (Pina-Cabral 1989, p. 402). If transgressed a middle class person might conceivably report the incident to the police and perhaps bring charges. If defamed in public, this person might well register an accusation of libel and fight the case through the legal system rather than by direct, violent retribution. This configuration is no less a system of honor and shame, but it is not *the* system of honor and shame that Mediterraneanists had in mind.

Mediterranean honor assumed its particular form as a mode of direct action in the absence of moderating state institutions. The place to find similar configurations of honor and shame in many Western societies is often among the working classes or in criminal subcultures. American inner-city gangs have developed an honor culture that is perhaps even more 'Mediterranean' than that of Mediterranean societies as can be seen in the following statement by a Los Angeles Chicano gang member:

Honor is important to me and every homey [gang member] because if you ain't got honor, you got nothing, man. I mean,

no amount of money can buy you honor, so you do everything you can to protect it. I mean, without honor, nobody will respect you, not your friends or your family (Jankowski 1991, p. 143).

That middle class anthropologists were apparently oblivious to these alternative systems of honor in their own societies exemplifies the earlier contention that parallel, discrete codes for honorable comportment may operate in stratified societies.

Feminist studies of honor and shame have rejected the idea that honor is exclusive to men, and contended that women are not to be construed primarily as the passive defenders of male honor. Although their silence has been taken as a sign of submissiveness it might actually be a form of subversive irony through which women mock the supposed gender hierarchy. Furthermore, women's performances of suffering (their own pain, or on behalf of family members) can be understood as claims to respect in the community of fellow women sufferers. Dubisch (1995) has observed that Greek women engage in competitive suffering as a means of gaining prestige in the community. A gender studies model, then, where performances and social constructions of masculinity and femininity are treated independently, is increasingly replacing the honor and shame model which linked them together in a version of normal patriarchy.

4. The Migration of Honor

Just as the initial optimism in the revelatory power of honor and shame began to wear out in anthropology, scholars in other fields discovered the formulation and adopted it with excitement. Where only a few books about honor and dueling in European history had been written before 1970, by the 1990s many titles had been published analyzing these themes in several European countries. In his *Southern Honor* (1982), Wyatt-Brown acknowledged the influence of Pitt-Rivers and speculated that the similarities between the American South and the Mediterranean arose because 'primitive conditions of life often produce elemental social values sometimes roughly parallel from one society to another.'

Like *mana* (to which Pitt-Rivers compared it), taboo, or shaman, honor belongs to middle-range anthropological theory—terms discovered ethnographically in one region and then applied to guide investigation in other societies. The Azande distinction between witchcraft (innate) and sorcery (learned), for example, has been used in the identification of witchcraft in numerous other societies. Honor and shame appear to have been discovered in Mediterranean anthropology and to have traveled out to other societies and other disciplines. Yet if we look more closely honor and shame had already traveled from

early modern European history into Mediterranean anthropology via Pitt-Rivers' essay. That these concepts now seem more attractive to Europeanist historians than they do to Mediterraneanist anthropologists may well be because they actually arise directly from these historical societies. Honor and shame were indigenous concepts in early modern European society.

The future of honor and shame in Mediterranean studies is murky precisely because they do not emerge from, or perfectly correspond to, local vocabularies. It is striking how few Mediterranean societies actually have words for 'honor' in the sense advanced by Pitt-Rivers and how infrequently equivalent terms are employed in daily life. In Greece the words *timi* 'honor' and *philótimo* 'sense of honor' are rarely heard while in Italy the operative concept is neither shame nor honor, even though the latter would seem to be readily accessible in the Italian word *onore*. Instead, exemplary moral fiber is displayed by following 'the code of silence' (*omertà*) and not disclosing details of criminal or other in-group activities to inquisitive authorities. In his early monograph describing an Andalusian village, Pitt-Rivers (1954) focused attention on 'shame' (*vergüenza*) and made no mention of 'honor.'

The conception of honor brought into anthropology by Pitt-Rivers was always slightly vague and polysemous and this was its theoretical attraction. Honor could involve criminal aggression or Christian virtue, its forms extended into gender relations and equally into the politics and economics of patronage and mafia protection. Anthropologists now find that the vagueness of honor and shame and their mismatch with comparable local concepts blunt their usefulness for ethnographic research and for comparison. Perhaps the most important legacy of the honor and shame formulation may prove to be in the area of the anthropology of self and emotion.

Hope and Hopelessness

According to mythology, only hope remained in Pandora's jar after envy, spite, and revenge had been unleashed. But, how are we to interpret this ending? Was hope to be the antidote for these evils, or a counterproductive force? Although Judeo-Christian writers espoused the virtues of hope, Plato, Sophocles, Nietzsche, and others have criticized it for prolonging suffering. Even more problematic, however, are the prevalent historical views of hope and hopelessness as being vague and useless concepts. Contrary to these traditional perspectives, however, hope and hopelessness have emerged in recent decades as having clearly articulated definitions, reliable and valid instruments for their measurement, and relationships with crucial life outcomes.

1. Definitions and Measures of Hope

In the 1950s and 1960s, psychologists (e.g., Stotland 1969) and psychiatrists (e.g., Menninger 1959) described hope in terms of positive expectations for goal attainment. In the 1970s and 1980s, researchers used experiential, spiritual, cognitive, and interpersonal frameworks for their positive expectancy hope models (Farran et al. 1995).

Three approaches to hope have received the most attention. First, Stotland (1969) hypothesized that hope reflected a greater than zero expectation of attaining important goals, and that it helps in understanding how antecedent events lead to subsequent outcomes. To measure hope, people are queried about their goal attainment expectations, or observed by raters. Although Stotland allowed for the possibility of trait propensities, he focused upon hope in particular situations.

Second, Averill et al. (1990) used a semistructured questionnaire approach, and found that people view hope as being appropriate when it is: (a) a short-term response to specific environmental conditions, and (b)

tapping important, societally endorsed goals with 50 percent attainment probabilities.

Third, Snyder (2000) and colleagues, in what is called 'hope theory,' have posited that goal-directed expectancies involve two separable cognitive components—agency, or the person's perceived capability to initiate and sustain movement toward a goal, and pathways, or the perceived capability to produce effective routes to goals. Using this model, trait and state measures of hope in children and adults have been developed and validated (e.g., the 12-item dispositional Hope Scale for adults, Snyder et al. 1991).

2. Similarities and Differences of Hope Relative to Other Constructs

Because of its increasing scholarly attention since the early 1990s, hope theory will be used in order to explore the similarities and differences of hope to other theories. Viewing hope as agentic and pathways, goal-directed thinking provides an overlap with the Scheier and Carver (1985) generalized positive outcome expectancies model of optimism (indeed, this latter model is similar to the definitions of hope in the 1950s through 1980s); however, the pathways component of hope theory adds an explicit recognition of mental 'routing' capabilities in goal-directed thought.

In contrast to the Seligman (1991) model, in which learned optimism is viewed as an attributional process for distancing oneself from undesired outcomes, hope theory emphasizes a person's self-referential thoughts about reaching desired goals.

What about hope and self-esteem? It is posited (and supported in research) that perceptions of successful goal-directed activities (i.e., hope) drive a person's self-esteem. Thus, hope is a causal determinant of self-esteem.

Hope also resembles the self-efficacy model, with the pathways component being similar to what Bandura (1997) has called outcome expectancies, and agency being similar to his efficacy expectancies. A fundamental difference in the two models, however, is that the self-efficacy thoughts are given the pivotal driving role in Bandura's theory, whereas the agency and pathways goal-directed thoughts of hope theory are given equal weight as they iterate throughout the thinking process toward the attainment of goals.

3. Definitions and Measures of Hopelessness

Beck et al. (1974) defined hopelessness as a lack of enthusiasm, a motivational tendency to give up, and a dearth of positive expectancies. Using this definition, they developed the Beck Hopelessness Scale. Patterned theoretically after the Beck Hopelessness Scale, Kazdin et al. (1983) developed and validated the Hopelessness Scale for Children (ages seven and older).

Reasoning that elderly persons often perceive pessimism and futility about their futures, Fry (1984) conceptualized this perspective as hopelessness; moreover, he developed the Geriatric Hopelessness Scale to measure diminished abilities, lost interpersonal worth, and difficulty in recovering spiritual faith.

4. Hope and Hopelessness as Related to Other Variables

Dispositionally high-hope, as compared to low-hope, persons appraise their goals more in terms of successes than failures, they have higher perceived probabilities of attaining goals, and are more likely to experience positive emotions. Also, the positive appraisals of high-hope relative to low-hope people become especially advantageous when coping with stressors. Likewise, higher hope correlates positively with subsequent successful academic outcomes throughout the range of grades (elementary school through college), and better athletic performances (Snyder 2000).

Turning to the antithesis of hope, elevated hopelessness has correlated significantly with higher depression, as well as to more suicidal intentions and suicide completions in adults (Beck et al. 1990); moreover, greater hopelessness in children has related to more depression and suicidal ideation (Asarnow and Guthrie 1989).

5. Developmental Processes

5.1 Building Hope in Children

Newborns supplant raw sensations with perceptual representations. This learning of 'What's out there' leads to the selection of important objects (e.g., mother's face), thereby reflecting the emergence of desired goals. Infants also learn to recognize co-occurrence in events, and babies can anticipate events and act with intention (Schulman 1991). Also, babies learn 'what goes with what' survival skills by attending to those persons and things that fulfill their needs. Additionally, by age three, children can articulate their expectations about desired outcomes.

From ages three to six, hopeful thinking is enhanced as the child's vocabulary grows from approximately 50 to 10,000 words. By providing the means for describing goals and communicating with others, words and language help to frame hopeful thinking.

Through their reading or physical exploration, 7 to 12-year-old children expand their knowledge for use in goal pursuits; moreover, they increase their memory storehouses. These children also realize that their hopeful thoughts must be negotiated in the contexts of other persons (Flapan 1968).

Spanning the years 13 to 18, adolescents test their hopeful thoughts by gaining more understanding and experiences with interpersonal relationships.

5.2 Undermining Hope in Children

The events that diminish hope typically are more damaging when encountered earlier in the child's life, or when they continue for longer periods of time over childhood. Neglectful caregiving interferes with hopeful thinking because children in such circumstances do not have anyone educating them about goal-directed thinking. Likewise, abuse is particularly damaging because children fear the very caregivers who are supposed to instruct them in hopeful thinking. Also, parental loss by divorce or death can diminish hopeful thinking because children come to doubt the stability of relationships, as well as the fact that one can meet goals in the contexts of such relationships. Lastly, caregiving in which children's efforts are not supported lessens hope (Dweck 1999).

6. Increasing Hope

6.1 Children

In regard to goals, babies are aided by caregivers in identifying, naming, and using specific words for desired objects. The caregiver's interest and conversations about the child's goals are productive, as are reinforcements of goal-making.

To increase agentic thinking, children profit by being reminded that they are responsible for making things happen. Praise when children show determination to reach their goals solidifies their subsequent agentic thoughts. Similarly, helping children to practice positive self-referential talk (e.g., 'I can do this') enhances agency (Kanfer et al. 1975).

Pathways thinking can be promoted by showing babies how causality works (e.g., using drums). Songs, stories, and rhymes illustrate how words are sequenced, and how one thing leads to another. Teaching mental scripts about what children are to do in given situations is helpful, as are instructions about how to break routes into smaller, more easily attained steps.

For all of the aforementioned hope lessons, it should be emphasized that close attachments with caregivers are essential for fostering children's hopes.

6.2 Adults

It is important in producing hope that adults set goals based on their desires rather than what other people want for them. Additional helpful strategies include producing an array of goals, setting goals that stretch one's talents, and clearly articulating and setting concrete goal markers so as to facilitate the noticing of progress (Nezu and D'Zurilla 1981).

To enhance agentic thinking, particularly during difficult times, positive self-talk is useful. By learning to anticipate blockages, and to think of these impediments as challenges, people can enhance their determination (especially for when they encounter prob-

lems). People also gain mental lifts by remembering previously successful experiences. Furthermore, switching from truly blocked goals to more reachable ones increases agency.

To enhance one's pathways thinking, breaking a long-range goal into smaller subgoals is helpful. Other productive strategies include developing mental maps to goals, planning alternative routes, and rehearsing mentally. Friendships also provide powerful guidance for pathways-related thinking.

7. Future Directions

Research is needed into parental and school environments that are maximally conducive to hope, as well as the environments that must be avoided so as to lessen hopelessness. Also, additional hope and hopelessness research is warranted in regard to health, psychotherapy, interpersonal relationships, worker satisfaction and performance, stress and coping, and aging.

Horticultural Societies

A horticultural society is one in which people's livelihoods depend on the cultivation of small plots, commonly called gardens. These frequently support a wide range of crops and meet staple subsistence needs. The proportion of produce sold on the market varies, to finance the purchase of commodities manufactured elsewhere (e.g., clothing, processed food, hardware, etc.). The scale of society and its organization may vary widely too, from small tribal groups to large peasant populations.

1. The Term 'Horticulture'

Horticulture is distinguished from agriculture by scale of production, specialization, and commercialization. Agriculture features in industrialized societies supplying food to large urban populations. It is, in some regards, the reverse of horticulture. It involves the farming of large fields, usually under a monocrop (all wheat, potatoes, beans, etc.), whereas the gardens of horticulturists usually feature intercropping, the mixing up of several different crops, as opposed to their segregation in separate rows or plots, for which there are sound ecological reasons (e.g., pest and disease control, maximizing nutrient and water availability, increasing photosynthetic efficiency, exploiting micro-environmental variations to best effect, and so on). Agriculture features highly mechanized production techniques, whereas horticultural societies rely more on human labor and animal drought power. Farmers in agricultural systems meet few of their own subsistence requirements, specializing in the large-scale production of a few foodstuffs for sale on the market. They engage in agribusiness, intensive production making wide use of inputs to boost yields, frequently

obtained from off-farm and industrially manufactured (inorganic fertilizers, biocides, etc.). The term horticulture has a quite different meaning in urban-industrial societies, which can confuse the unwary. It refers to the intensive production, often under artificial glasshouse conditions, of high-value crops, such as early vegetables, salads, and flowers by commercial growers.

Other food production regimes from which horticultural societies are distinguished include gatherer-hunters and pastoralists, which support lower population densities (Forde 1934), industrialized urban ones having higher densities. These categories were bequeathed to us by Victorian scholars who thought of them comprising an evolutionary hierarchy, putting horticultural societies somewhere in the middle of the range between the gatherer-hunter and industrial poles. This scheme continues to inform thinking to the current day (as evidenced by entries in this encyclopedia), and underpins notions of development conceived as facilitating the passage of communities to the urban-industrial pole. Anthropologists continue to use it, although unhappy with the continued evolutionary implications, arguing that we should not judge urban-industrial life, notably liberal market democracy, as the superior socioeconomic order to which all human beings should aspire. It is an approximate classification scheme. At some ill-defined point, populations are thought to manage their natural resources sufficiently closely to move beyond gatherer-hunting to farming, this is accompanied by a more sedentary lifestyle. They qualify as horticultural societies when they emphasize crop cultivation over animal herding, although mixed arable and livestock farming is common. The label horticultural society covers a wide range of different subsistence regimes and socio-cultural orders. The term is more commonly used in North America than Europe, where instead of lumping these societies together, it is more usual to distinguish the different agronomic regimes that comprise horticultural orders.

2. Agronomic Regimes

We find varying degrees of sedentariness among people who depend largely on cultivation to supply them with their food. The variation informs a preliminary distinction between different horticultural strategies. There is also some correlation with increasing population densities.

Where we find the least permanent settlement and physically most direct technologies, we have cultivation systems that fallow the land not by rotating crops but by rotating land use. We call this type of horticulture *shifting cultivation*, because after people have grown crops, and fertility declines, and yields start to fall (these cultivators not using any fertilizer to supplement the soil's nutrients), they abandon the plot

to the forest and move elsewhere to clear a new garden on fresh land. Secondary regrowth, meanwhile, recolonizes the abandoned area, which is left fallow for tens of years to allow nature to restore its fertility; following which it may be cleared and planted again in the next generation. Shifting cultivation is labor intensive, featuring hand tools, such as axes, machetes, hoes, and pointed digging sticks. We find a sexual division of labor, orchestrated into a joint effort. Men usually do the heavy axe-related work. They fell the trees and clear the forest. They also enclose the area to be gardened with rough fencing if this is necessary to keep out animals. The subsequent burning off of the dry and dead vegetation cleared from the plot is often done by both men and women working together. This burning is an important step, reducing standing vegetation to ash, which is readily mixed with the soil, liberating locked up nutrients in a form more available to planted crops. The release of nutrients (such as nitrogen, potash, phosphorus, and so on) through burning has led to the coining of the term 'swidden' to describe this type of cultivation. (Swidden is an Old English word meaning to burn.) Following clearing and burning off, women usually take over and are responsible for breaking up the soil, planting crops, weeding, and finally, harvesting the plot. People living around the world in Asia, Africa, the Pacific, and Latin America grow a large variety of crops using this cultivation technique: for example, grains such as corn, millet, and sorghum; roots such as manioc, yams, and sweet potato; and fruits such as bananas, pawpaws, and melons.

Many Amazonian Indian populations practice shifting cultivation, horticultural crops supplying the bulk of their food regardless of the time spent gathering and hunting in the surrounding forest (Watters 1971). Among the Yanomamo, plantains and bananas are the staple crop. They select well-drained sites, relatively clear of thorny underbrush. They do not attempt to burn large tree trunks, left strewn plots in a jumble, serving as boundaries between patches, the crops planted there belong to those who cultivate them. Newly established gardens yield crops in cycles, the rapidly growing ones such as maize coming first, followed by others including manioc, taro, sweet potato, and mapuey. The Yanomamo also grow chewing tobacco, cotton for hammock yarn, drugs for shamanistic rituals, and many fruits including papaya, avocados, gourds, and hot peppers. A garden produces constantly as it matures, but a regular supply of food demands careful management. Gardens have direction, moving little by little as people gradually abandon older areas as thorny underbrush encroaches. They constantly clear adjacent land and transplant secondary plantain suckers as they appear. Sometimes villages are obliged to establish new gardens elsewhere. This is usually a political decision, communities moving when threatened by raids from enemy villages. It requires a large effort to

establish a new garden some way off, to transport needed cuttings and seeds. New gardens also produce sporadically at first, and people may face hunger, whereas established 'rolling gardens' offer predictable subsistence.

At some ill-defined point, agronomists distinguish *bush fallow* systems. These are broadly similar to shifting systems with regard to technology and cropping strategies, but with a reduced fallow interval and longer periods under cultivation. Instead of one or two years under cultivation followed by two or more decades under fallow forest, these horticulturists may farm land for 5–10 years with a fallow interval of similar duration under bush or savanna vegetation. Stock may graze on the fallow, cattle, goats, sheep, and so on. Settlement is increasingly stationary, and land holdings are usually more clearly defined with agreed field boundaries. These fallow systems sometimes evolve from shifting regimes with increasing population densities. They may demand management of soil fertility through the application of manure or fertilizer, otherwise yields will decline over time. Degradation of the natural resource base may occur with increasing population pressure and demand to grow cash crops.

Again, at some ill-defined point, we distinguish *ley* systems. These are ones in which farmers systematically use the land to pasture livestock during the non-arable phase. At one end are unregulated leys where people agist their animals on unmanipulated natural regrowth of grasses and herbs. They have communal grazing rights, and practice little pasture management. At the other end are regulated leys where farmers manage the grazing vegetation, frequently putting down grasses and legumes as fodder. They maintain individual pastures which they may fence off. They may graze meadows directly or use them to produce hay or silage. At this point we usually think they have evolved into agricultural regimes.

Bush fallows and unregulated leys are common in interlacustrine East Africa (Allan 1967). Lugbaraland, for example, comprises fields and homesteads scattered across open upland country. Homesteads comprise compounds, clusters of family huts and granaries, under which are ghost shrines and magical plants. Fields surround them. Each homestead cultivates three types of fields. Men do the heavy work of opening the land, women weed and harvest. Both sow, depending on the crop, men handling more cash crops. They intercrop in all. Postharvest care and use of crops is the responsibility of women. The 'riverine fields', irrigated by channels from streams, are highly fertile and need only short fallows, they support sweet potato, maize, sugar cane, and bananas. The 'home fields', fertilized with ashes and manure, support nutrient-demanding crops such as beer-brewing white sorghums. The 'outside fields' support staple eleusine, together with sorghum, simsim, and pigeon

pea, cultivated for two or three years, after which they are left under bush fallow to restore fertility. People allow unregulated grazing of cattle and goats on fallow. They recognize different fallows: from recent and regaining fertility; a few years old, the presence of certain plants showing restored fertility; cleared land left for a few months before hoeing; through to uncultivated land. Each woman in a homestead should have areas in all fields, of equal fertility. If not, quarrelling is likely. The fields of a homestead are likely to be scattered, due to differences in soil and water. This sets a limit on the maximum size of farming groups. A household short of certain farmland may move and take up residence with kinsmen elsewhere, usually a wife's or mother's brother.

It is generally agreed that with the invention of the plough we approach the realm of *agriculture*. The plough allows people to harness either the strength and energy of draught animals or engine-powered machines to assist in their preparation of land for the planting of crops. The result is that one person, together with their team of oxen or whatever, can accomplish considerably more work alone, releasing others to follow different occupations. We have the emergence of increasingly specialized labor, a move from so-called organic to mechanical solidarity. We find the practice of crop rotation and occasional fallowing to maintain soil fertility with the plough and associated agricultural machinery, together with the increasing use of amendments such as manure, fertilizer, biocides, etc.. In regions that suffer water deficits, people may have irrigation technologies. In some places they may have plantations of perennial commercial tree crops. The upshot is permanent farming, with clearly demarcated fields. While it is inappropriate to go into the growth of the first civilizations among the early cultivators of the fertile crescent in the Middle East, of Mesoamerica and of the Far East, we should note some of the consequences of these developments, founded on a settled agricultural way of life (Sauer 1969). They allowed for greater population densities, which, combined with the relative permanence of settlement that results with agriculture, led to the emergence of wider-scale political groups than those based on the family or tribe. These developments opened the way over millennia to the evolution of industrial-urban societies, sometimes with associated peasantries.

Before turning from the agronomic aspects of horticultural societies to consider the social orders associated with them, it needs to be stressed that while the foregoing regimes have been presented with an evolutionary dimension, it would be wrong to consider them as discrete steps leading from shifting cultivation to mechanized agriculture. This typology is no more than a low-level generalization by which we can usefully classify cultures. When we look closely we find that many societies do not fit comfortably into any one

category, but span two or more, as the previous East Uganda example illustrates. In the Baliem valley of New Guinea too, where sweet potato is the staple and people herd pigs, we find three sorts of cultivations. The largest are the permanent plots on the valley floor, some of which the Dani recultivate immediately upon harvest and others they leave fallow for months, even years. These gardens feature elaborate ditch systems which drain away/store water, delineate and protect cultivations from pigs, and serve as mulching basins supplying organic rich mud for slopping over beds to ensure continued fertility. Other gardens men clear in a classic shifting mode on the mountain slopes, burning off plots and planting for a year or two. The third and smallest are kitchen gardens maintained adjacent to houses, supporting a wide range of valuable crops such as tobacco, sugar cane, and bananas, continually fertilized with household waste. Households commonly have several different widely separated fields at different stages.

3. *Sociocultural Orders*

We now turn briefly to look at the gross nature of the social orders found associated with horticulturists. It is difficult to distinguish between horticultural regimes according to political economy (how people distribute resources, etc.). They occur in one of three broad categories: egalitarian with balanced reciprocity, chiefdoms with redistribution systems, or peasantries in nations with markets. There is some correlation between permanence of settlement, cultivation regime, and polity, with shifting cultivators frequently living in egalitarian orders and ley farmers in chiefdoms.

The *egalitarian societies* featuring balanced reciprocity are characterized by groupings commonly called tribes. These are relatively large groups of people (that is, in comparison to hunter-gatherer bands), who occupy demarcated territories, to which resources they lay specific claim and rights. Characteristically these societies recognize all individuals as equals and place no persons above others, with authority and power to rule over them. They are what we call stateless or acephalous, and have evolved various strategies to maintain social order without formal government, judiciary, and so on; employing, for instance, descent and age in Africa, and ceremonial exchange in Melanesia. The productive group is not the tribe, but usually the family, with some help from extra kin in occasional large cooperative ventures. Under this household mode of production farmers consume most of their produce, although they distribute some to others. The formal distribution of food and goods is likely to be significant, taking place predominantly in reciprocal transactions. Relatives and friends who give things to one another keep a careful account. They give, not with the expectation of receiving an immediate return gift (or payment), but

with the expectation of an equal return sometime later. There is often a competitive element in these transactions, those doing best winning higher status. They sometimes constitute grand institutions and are attended with some ceremony. Exchange is a facet of social and political relations and may exist independently of material wants and needs. This takes us away from subsistence and horticulture towards socio-political issues.

In Melanesia, ceremonial exchanges of balanced reciprocity are central to the maintenance of social order. New Guinea highlanders live in an egalitarian society. Each family supplies its own food and provides its own shelter. It occupies a compound often comprising several related families and friends, with men's and women's houses, and pig sty. Sometimes friends and neighbors make up a cooperative work party to garden or build a house. But there are no leaders. The Dani combine for conviviality, each person doing the same thing, the output comprising the sum total of their efforts (it is more fun mudding gardens together, for example, even though this is a one-man job). Feuding is common, clans fighting with bows and arrows and spears. Social order is promoted through exchange, primarily of pigs, which are only killed on ceremonial occasions. The giving and receiving of pigs constantly refurbishes the social network, people are bound to one another through their lifetimes by the exchange of hundreds, even thousands, of pigs. Clan affiliation determines access to land, all have equal rights. These are rights of usufruct, not land ownership. Men do the heavy, spasmodic garden and construction work, and are more involved in public activities such as politics, warfare, and rituals. Women undertake routine cultivation work and domestic responsibilities, herding pigs, and tending family needs. There is little call for distribution of goods with this minimal sexual division of labor. There is some trade with people elsewhere for a few imported goods.

The *chiefdoms* with redistribution systems are hierarchically organized societies, where members are ranked one above the other. In the top rank are the rulers, commonly called chiefs. These persons have authority vested in them, often sanctioned by some supernatural connection, and govern those living in their chiefdom, kingdom, tribe, or whatever. Everyday rule is usually delegated to lower rank persons, who are locally responsible for day-to-day government, administration of justice, and so on. These chiefdoms are often feudal in nature, with these local leaders owing allegiance to the chief and supplying a military force if required by him. Societies organized in this way exploit raw materials on a larger scale. They do this, for example, by territorial conquests (as epitomized by the Zulu under their king Shaka) and through extensive trading networks (for example, the Aztecs controlled mining activities as far away as northern Mexico). These societies can also organize

larger productive groups through the authority of their rulers, who by so doing not only assist people but also provide some sort of rationale for the existence of their power (for example, the farming terraces, irrigation works, storehouses for produce, and so on, constructed by the Inca). Redistributive systems predominate in these societies, where those of lower rank give food and goods to those of higher rank in the form of tribute. The chief will rearrange everything he receives and then redistribute it to his subjects (usually via local-level officers in his government). He may add to it any surplus goods which his probably superior productive position supplies (i.e., from his large, communally-worked gardens).

The chiefdoms of South Africa are good examples of this political order. The horticulture practiced is broadly similar to East Africa, the main crops being maize and millet, together with ground nuts, gourds, sugar cane, and pumpkins. Farming is seasonal, dependent on the summer rains. One source of rulers' political authority is the belief that they can control the advent of the rains. People may have a precarious existence, food supplies fluctuating annually between plenty and scarcity bordering on famine. The Swazi, for example, talk of lean summer months as the time 'to swallow the pickings of the teeth.' Horticulture is not a prestigious occupation and is left primarily to women, whose main tool is the iron hoe. Except, that is, for ploughing, which involves highly valued oxen handled by men, and the cultivation of cash crops, notably tobacco and cotton. Households cultivate large fields using ox-drawn ploughs. The power rulers wield also relates to their right to allocate land to their subjects, who depend on it for their livelihood. The Swazi say that their political overlords 'serve' them the land, securing their rights by allegiance and usage. Women are allocated garden areas by their husbands on their marriage. Homestead plot size depends primarily on supply of resident labor. People use grazing lands communally. They value pastoralism highly, having the so-called African 'cattle complex': these animals have great symbolic value, being exchanged to ratify marriage, sacrificed to propitiate ancestors, and paid in tribute to rulers. They call the king the 'Bull' of the nation, and the royal herd far exceeds any other, supplying animals redistributed to subjects at national events and sacrifices. In addition to sex and age, pedigree also structures the division of labor. Men and women cooperate in agriculture, man's work is heavier and more spasmodic, woman's routine and more continuous. Aristocrats do not engage in manual labor to the same extent as their subjects, they are responsible for successfully organizing their efforts, supervising work parties and arranging for specialists to doctor land and seed. The rulers have several 'gardens of kingship' in different localities, of which local headmen arrange communal cultivation. Homesteads rely on kinsmen and neighbors to assist at bottlenecks, customarily organized

into two competitive work parties they spur each other on in songs, rhythmically coordinating their work through music. The size of communal work parties reflects status: they enhance prestige, being rewarded with beer and food at the host's home.

The *peasantries* associated with markets are also incorporated into hierarchically organized societies. They are usually encapsulated within nation states where they occupy marginal and low positions, relatively powerless and commonly exploited. These are horticultural communities in peripheral, under-privileged situations, frequently taken advantage of, even abused by the dominant society. They usually feature extensive poverty. The larger political formations which rule significant aspects of their lives may supply them with certain services. Peasants depend in some regards on economic and political institutions beyond their local control. They may maintain informal reciprocal exchange networks within their communities, but outside they are obliged to participate in impersonal commodity markets. While they supply their own subsistence needs (similar to tribespeople, from whom many of the Third World's peasants have descended in recent times), they are obliged also to cultivate a surplus to sell on outside markets to earn needed cash. In addition to using this money to purchase goods manufactured elsewhere, they need some cash to pay the taxes levied on them by the colonial/national governments to which they are subject. They may also need to purchase outside inputs, such as inorganic fertilizers and biocides, to maintain their yields, especially if their farming system is under increasing demographic pressure, perhaps resulting in increasing environmental degradation. This may contribute to growing poverty. What peasants receive financially in return for their surplus horticultural produce is on the whole unfair, the elite higher up the social hierarchy, controlling access to imperfect markets and the arrangements for the distribution of produce, make a disproportionate profit to maintain their privileged position and life-style.

The Mayan Indians of Mexico have occupied a peasant status increasingly since the Spanish conquest (Wilken 1987). They sell crops surplus to their subsistence needs, largely maize and beans, and trade salt from the Ixtapa works at fiesta day markets. In turn they purchase goods such as coffee, sugar, fish, liquor, and bread from markets. They have been involved in marketing for centuries, historical evidence showing that they traded with Aztecs in prehispanic times. Maize is their staple, believed to have an 'inner soul' in the ear, together with beans, squashes, chillies, chayotes, and fruits such as peaches. They keep chickens and pigs, sheep for wool woven into *chamaras*, blankets and shawls, and mules for carrying heavy loads. The Mayans cultivate three types of land. Small, individually owned garden plots located near highland homes, their ancestral patrimony. Larger *ejido* plots

acquired during the 1940s agrarian reform program, allocated by local committees to households. And plots in the lowlands rented from wealthy *Ladino* landowners by patrilineal groups, which they divide equally among themselves. They use centuries' old swidden techniques, working with axes, machetes, bill hooks, and hoes. After cutting and burning vegetation, they plant using pointed digging sticks. In old fields they cut and rake maize stubble into piles for burning, and then hoe sheep manure into the turned topsoil. They prepare fields for planting at the onset of the rainy season. Ritual attends planting, a critical task in which a shaman offers candles, incense, liquor, and prayers to the Earth Owner, who controls wind and clouds. People cultivate fields for varying periods of time, depending on elevation and soil quality, before allowing brush to grow again. They store threshed maize in granaries or indoor grain bins prior to sale.

Again this sociocultural typology, like the previous agronomic one, is only gross, the elements constituting approximate cultural sets which have proved useful in organizing our ideas over many years. It continues to structure our thoughts in a preliminary fashion. There is some broad correlation between peoples' horticultural arrangements, that is how they produce food and other items necessary for life, and how they are socially organized, both to effect production and to achieve distribution of its fruits. But this is not to imply, as some writers argue, that mode of production determines the nature of social arrangements.

4. Future Directions

Several questions remain to be answered about horticultural societies. Many aspects are still poorly understood, and insight sometimes blinkered by orthodoxies. The Baliem Valley, for example, supports one of the highest population densities in New Guinea (~160 persons per km²), with no evidence that it is pushing against the environmental limits. How can the region's intensive horticulture system support such a high population density without any outside fertilizer amendments? The accepted shifting cultivation model which pertains to this part of the world predicts evidence of environmental strain, of the kind commonly associated with overpopulation. Yet the sophisticated horticultural regime does not seem to exhaust the soil (Sillitoe 1996).

A major contributor to our understanding of horticultural societies has been 'farming systems research' conducted under the aegis of international development agencies (Shaner et al. 1982). This involves multidisciplinary terms, using survey techniques largely, to detail the ecological, technical, and socioeconomic aspects of horticultural regimes and identify constraints on production amenable to scientific research. It was initially associated with 'modernization,' research intended to advance the development

of horticultural societies into agricultural ones, to enmesh them in commercial farming and specialized production for the market place. It was thought that this would alleviate poverty, leading to increased production of a food surplus necessary to support increasingly urban populations specializing in industrial, administrative, and service sectors. To this end, agricultural research institutes worldwide embarked on programs to breed new 'high-yielding varieties' of crops and develop associated technologies to increase production. The scientifically resoundingly successful 'green revolution' diminished the threat of famine. Nonetheless, it increasingly became evident that while the 'revolution' had benefited resource-rich and wealthy landowners, it had largely passed poor farmers by, increasing wealth differentials. It also worryingly increased dependency on outside manufactured inputs (inorganic fertilizers, fossil-fueled machinery, chemical pesticides, and herbicides) and gave rise to concern about long-term sustainability with evidence of increasing environmental pollution, susceptibility to mutated pathogens, insecure supply of needed inputs, and so on. The move towards cash cropping also put farmers at the mercy of market fluctuations, sometimes causing their families considerable hardship, further increasing resistance to modernization and adoption of commercial production. We become aware that 'modernization' not only scarcely helped poor households farming in marginal and fragile, resource-poor environments, but may have made some wealthier ones vulnerable too.

The realization that not only were some small-scale subsistence-focused horticultural societies proving very resistant to change as envisioned by modernization, but that other communities were increasingly exposed to serious perturbations beyond their control in attempting to accommodate its interventions, prompted a rethink of development priorities in the 1980s. It was increasingly acknowledged that poor people need to be involved in the planning and implementation of any development interventions intended to assist them, with the consequences of what international bankers euphemistically called economic restructuring taking effect (a dramatic instance of outside market forces impacting negatively on farmers' fragile commercial enterprises, as their nations' burgeoning debts were rescheduled). The 'participation' approach to development came of age. This promises to advance understanding and the interests of horticultural societies in the future, particularly with the concomitant emergence of 'indigenous knowledge' research, which represents the coming together of applied farming systems research and academic disciplines such as anthropology, geography, and ecology which have long esteemed understanding of horticultural societies (Warren et al. 1995). The assumption is that any development assistance needs to be sympathetic to local sociocultural and environmental contexts and to accommodate

peoples' aspirations. Understanding these implies their cooperation. It also furthers meaningful appreciation of the complex relations that inform natural resources management, as understood by local farmers, those who contend daily with them—the collapse of many interventions has been attributed to a failure to comprehend the complexity of their livelihood systems. These changes in research and development agendas bode well for furthering understanding in the future, and promoting the interests of horticultural societies *along their own lines*.

Hospitals and Health: Psychosocial Aspects

During the second half of the twentieth century, the dominant mode of health care delivery in the United States has evolved from individual, patient–physician

relationships to care provided by organizations (Starr 1982). At the same time, social scientists have moved from examining hospitals as closed systems, which operate independently of their environment, to seeing them as open systems, both affected by and responding to external forces (Scott 1998). This perspective assumes that structural forms and organizational behavior in the healthcare sector are influenced by factors such as regulation, change in professional power, competition among providers, and mutualistic behavior among different types of providers. The context in which hospitals operate has been described as having two essential components: the technical environment and the institutional environment. The technical aspects of an organization's task environment involve the production of products and services and the market forces that reward the efficient and effective production of those products and services. Institutional environments encompass the rules and requirements to which organizations must conform if they are to receive the social and political support and legitimization needed to survive.

Organizations in the health care sector have traditionally been subject to both strong institutional and strong technical pressures. These forces have operated in separate but parallel fashion to shape the practices and structures of hospitals (Alexander and Scott 1984). For example, hospitals traditionally maintained very loose control over physician staff as a reflection of strong professional requirements for autonomy. At the same time, they were accountable for the 'technical' quality of care through legal and quality assurance controls. Recently, market forces have played a more visible role in shaping national policy debate concerning healthcare access, quality, and costs. In view of this, some have argued that the influence of traditional institutional structures and practices, such as regulation, professional norms, and local control, have weakened and are now subordinated to the technical demands of the market. However, there is sustained evidence that historical institutional forces have not been eliminated, but instead are interacting with the new 'market' ethos to constrain and shape the structures and practices of hospitals, including those originating in the corporate sector. These interactions have given rise to a unique set of changes and practices that differ from both those common to the corporate sector and those common to hospitals in more institutionally dominant eras.

1. Institutional Environment of Hospitals

Institutional environments feature elaborate rules and requirements to which individual organizations must conform if they are to receive support and legitimacy. Attention is directed away from control and coordination of technical processes and towards conformity to externally defined requirements or regulations. The more institutionalized the environment of an

organization, the more its structures and procedures are governed by external controls. This control requires specific arrangements in the organization that are independent of contributions to technical performance (Scott 1995). For much of the twentieth century and up until today, hospitals and other healthcare organizations have been subject to strong institutional pressures, including a broad array of governmental regulations and requirements. Further, numerous professional specifications have governed what types of personnel might be hired, how tasks are distributed among them, and what procedures must be followed in performing these tasks.

The healthcare field in the US has long been characterized by institutional pressures that are both strong and heterogeneous (Stevens 1989). All branches of the federal government make decisions centrally that affect the entire healthcare sector. Local and state governments also exercise authority to regulate health care. This fragmented structure of authority makes it possible for various actors to pass laws to meet particular needs, and regulations are therefore uncoordinated, at best, and inconsistent or conflicting, at worst. Further, a long tradition of volunteerism in American hospitals has complemented the inculcation of professional norms into the institutional structure of these organizations. The notions of local control, community accountability, and philanthropic support of hospitals have served to keep decision-making from becoming overly centralized. At the same time, this has discouraged the formation of a cohesive, integrated healthcare system.

2. Technical Environment of Hospitals

Notwithstanding the institutional demands on hospitals, the technical requirements of modern medicine are considerable and often require tight internal controls and careful coordination if performance is to be effective. Hospitals have also increasingly been pressured to improve efficiency in the use of resources. Retrospective cost reimbursement was singled out as the primary explanation for both rising costs and inappropriate utilization. Critics also identified professional specialization and hospital-based care as major contributors to rising costs. Growing specialization and fragmentation in delivery rendered services increasingly impersonal, while the predominance of inpatient services threatened accessibility and provision of comprehensive, family-oriented care.

Historically, political attention had focused on expanding access to health care, as exemplified by the passage of legislation in the 1960s extending health insurance coverage to many of the elderly (Medicare) and the poor (Medicaid). The 1980s, however, marked the beginning of a new era that shifted the focus to controlling costs (Scott et al. 2000). Several years of

double-digit increases in prices threatened the economic interests of actors who paid for health care; in response they initiated policies and practices to control costs. In 1984, the federal government's Medicare program became the first major payer to attempt to control hospital costs by paying a fixed fee for each service, rather than the 'usual and reasonable' fees that hospitals routinely charged. This key change in payment policy had significant financial and market effects for hospitals. The resulting reductions in payments to hospitals and other organizational providers cut their budgets and contributed to cash flow problems. Hospitals and other providers tried to compensate by increasing their patient and service volume. In turn, this created more competition for patients.

A series of remedies have been proposed to deal with the cost escalation crisis. The solutions imposed have often clashed with the historical institutional functions of hospitals, namely, providing care to the community, running on a voluntary basis and engaging in philanthropic enterprise. Direct regulatory approaches to containing costs in the 1970s have shifted to greater emphasis on legal, budgetary, and market responses to addressing these issues. Taken as a whole, these remedies fall under the general rubric of a competitive approach to controlling costs, even though all involved substantial government oversight and occasionally intervention. Such approaches are consistent with a general societal shift toward privatization and market solutions to larger social problems. While recently court rulings have relaxed some regulations stifling collaboration among doctors and organizational providers, new regulations have reduced price-fixing and other forms of anticompetitive behavior. Together these rulings have provided both inducements and constraints on organizational behavior, such as severe limitations on hospital acquisitions and mergers.

Budgetary remedies have been applied at both the federal and state levels. At the federal level, the government has budgeted a fixed reimbursement for each inpatient admission based on diagnosis. States have also enacted rate-setting programs that prospectively set reimbursement levels for hospitals and other providers. These budgetary interventions have forced healthcare providers to attend to efficiency and have raised the level of competition among these providers. Finally, market remedies have included the introduction of so-called 'managed care' strategies, designed to reduce utilization and thereby costs (see *Managed Care*). Examples of these strategies have included competitive bidding and selective contracting in government programs and the use of preferred providers and risk-based financial incentives by private insurance firms. Both state and federal governments have begun to publish information on the performance of healthcare providers, aimed at redressing the traditional asymmetry of information between providers and consumers of health care.

As expected, these interventions have lowered healthcare costs and decreased utilization (Robinson 1996). But there have also been other, unanticipated effects. At the field level, the 1990s have witnessed an increasing number of entries and exits of new and existing organizational forms into the healthcare system. Although most hospitals and other organizational providers that have closed have tended to be primarily inner-city and rural institutions and have done so for primarily technical/rational reasons, many others have remained operating despite financial losses and technical inefficiencies. The survival of so many marginal institutions in the face of increasing pressures from a market-based system clearly reflects the importance of local/community support for these institutions, and the salience of legitimacy in organizational survival (Rohrer 1989). This illustrates well the complex combination of technical and institutional forces that shape organizational life in the healthcare sector.

3. Hospital Responses to Hybrid Environments

A fundamental question becomes, how do organizations operating within such hybrid environments accommodate different environmental demands that are often diametrically opposed to each other? The convergence of traditional institutional and new technical forces impinging upon hospitals has created new organizational, strategic, and survival challenges for healthcare providers. Neo-institutional theory suggests that organizations functioning in sectors that are highly developed both institutionally and technically will develop more complex and elaborate administrative systems and will experience higher levels of internal conflict (Scott 1995). Historically, we know this to be true for many organizations in the healthcare sector. Hospitals, for example, have typically operated within a dual hierarchy of control, represented on the one hand by hospital administration and on the other by hospital medical staff and physicians. These dual lines of control operate in parallel with each other but rarely have intersected in such a way as to disrupt the relative spheres of influence over issues related to control, resource allocation and professional prerogatives.

Conflict has been expressed in hospitals largely through increasing parity between managerial and professional logic and ideologies. The emphasis of managerial ideology on rational systems and cost-effective care has increasingly conflicted with the professional orientation toward individual doctor/patient relations and the micro delivery of specific medical services (Goodrick et al. 1997). Conflicting claims to the right way to deliver health care, the presence of alternative rationales for organizing work (professional vs. managerial), and the inherent conflicts between technical and institutional pressures in

the healthcare sector have eroded the legitimacy of hospitals. This has opened the way for a number of new organizational forms, practices, and strategies, particularly those that have symbolically represented the new ethos of privatization and corporate rationality. For example, health organizations are increasingly lobbying government and engaging in marketing campaigns in order to influence legislation and public opinion. Rather than being passive recipients of institutional changes in the broader environment, they seek actively to shape societal beliefs toward health care and the way health care is organized.

4. Organizational Heterogeneity

Health care delivery has been dominated traditionally by hierarchical organizations such as hospitals and healthcare systems. However, as competitive pressures and the demands of managing care under limited resources have increased over the past decade, a wide variety of new organizational forms have emerged (see *Health Care Delivery Services*). These range from managed care organizations, physician-hospital arrangements, and physician practice management companies, to diagnosis-specific service contracts with specialized providers, such as home health care and rehabilitation firms.

As traditional institutional norms and practices have eroded and have been replaced by a stronger corporate rationality, we have observed greater heterogeneity among organizations in the healthcare sector. This new ethos suggests there is no one best way to organize in order to achieve technical efficiency and positive performance in the marketplace. More variation in organizational forms is exhibited as hospitals become less concerned with mapping the characteristics of the institutional environment onto their own structures, and more concerned with achieving technical efficiencies and buffering their technical cores from environmental disturbances.

A clear response to the new market forces in health care has been the adoption of structures and practices from the corporate sector (Burns 1990). These structures include multidivisional organizational designs, parent holding-company arrangements, contract management of facilities, and vertical integration across a number of different service lines. While these practices clearly have gained popularity during the 1990s, there is limited evidence that they actually improve the quality or lower the cost of care. Neo-institutional theorists have argued that whereas early adopters of these corporate structures may have done so for technical/rational reasons, later adopters may have viewed them as the prevailing institutional practices under the new market-based health care environment.

5. Hospital Governance

Historically, most nonprofit hospitals were overseen by autonomous governing boards composed largely of representatives of the communities the hospitals served. This type of governance arrangement reflected a longstanding institutional belief that the control of nonprofit hospitals should be vested in local communities. However, during the 1980s and 1990s, two developments have altered this traditional governance model of nonprofit hospitals, both of which are part of a larger trend toward the so-called 'corporatization' of health care. One development is the consolidation of over 40 percent of US hospitals into complex health-care systems. In such systems, the locus of control for member hospitals is shifted to varying degrees outside local communities to system-level governing boards and corporate offices (Toomey and Toomey 1993). Another development is corporate restructuring of hospitals where hospital assets and decision-making authority are transferred to multiple corporate entities that may include a parent/holding company and various subsidiaries. Such restructuring often entails the creation of multiple governing bodies that can attenuate the decision-making authority of the provider's community-based board.

Under a traditional model of governance, nonprofit hospitals resemble consumer cooperatives in that community representatives are in a position to determine hospital policies. As such, a traditional form of governance is arguably a constraint on hospital price inflation, since community representatives have an incentive to resist price increases that they ultimately will incur in the form of higher insurance premiums. Also, form of governance may impact the accessibility of hospital services since a community-based board may be inclined to invest resources to expand the accessibility of hospital services to its own community (e.g., through the provision of uncompensated care). Policymakers have expressed concern that system membership and corporate restructuring are diminishing the role of communities in the control of nonprofit hospitals, and government agencies that have oversight responsibilities for nonprofit hospitals are currently examining alternatives (see *Health Care Organizations: For-profit and Non-profit*).

6. Physician–Organization Structures

As managed care and competitive pressures have compelled hospitals to consolidate and provide services along a broad continuum of care, the need to integrate formerly loosely coupled elements of these organizations has increased. Perhaps the most problematic aspect of such integration is the alignment of incentives and strategic goals between delivery organizations and physicians. Hospitals seek to engage in

strategic relations with physicians in order to: (a) protect against the risks of agency from physicians who have traditionally borne little risk for the care of patients, (b) reduce transaction costs by developing economies of scale and integrating physicians into the structure of the delivery organization, (c) achieve market power both up and down stream over suppliers and customers respectively, and (d) develop capabilities that differentiate systems from competitors in the areas of innovation, technology, and quality. While these market-driven reasons are clearly critical to hospitals and healthcare systems, the alignment of economic and strategic interests between organizations and physicians is difficult given the differences in cultural context, socialization, orientation to patient care, and economic incentives.

As managed care organizations and health care regulators have recognized the need to align the economic incentives of providers with the goals of cost containment and high quality, they have changed methods of provider compensation from simple discounting to risk sharing (e.g., capitation, *per diem*, or per case reimbursement for hospitals). Providers under these systems assume actuarial and utilization risk and reward. In principle, risk sharing promotes appropriate behavior, since high utilization and costs will result in deficits for either the physician group or its physicians. In practice, the physician group's form of compensation, incentives, and governance moderate these effects. For example, the incentives inherent in risk sharing can be lost if individual physician compensation is not strongly linked to holding costs below the group's fixed budget. Alternatively, if physicians feel they have no say in the formulation of incentives in compensation systems, they may be less willing to abide by them. These examples suggest that the incentives created by risk sharing are effective only under certain conditions. Several authors have recognized that the effects of such payment mechanisms may partially depend on organizational factors such as type of governance, physician leadership, information dissemination, sanctions, and organizational culture (Kralewski et al. 2000, Alexander et al. 2000).

Physicians and organizational healthcare providers recognize the need to work together to acquire managed care contracts and to manage risk. To facilitate such contracting, avoid institutionalized constraints inherent in hospital-medical staff relations, and develop the administrative infrastructure necessary for managing service delivery, many healthcare systems have established market-based organizational arrangements that link the delivery organization with one or more physician groups. Market-based arrangements are different from internal hospital structures in that they tend to be formally structured, contractual in character, corporate in organization, and include physicians outside the formal membership of the medical staff.

Given fundamental differences between methods of organizing by physicians and delivery organizations, however, it is highly questionable whether structural solutions to achieving greater integration between physicians and delivery organizations can be completely effective. There is only limited evidence to suggest that structural solutions work and considerably more evidence that self-selection by physicians into closely aligned structural arrangements may account for more of the explained variance in alignment than structure itself. Hospitals' attempts to integrate and align with physicians have not always rationalized the delivery of health care, but instead in many cases have made it more complex. Physicians and their interests vary widely, and hospitals have discovered that no one structural vehicle best accommodates the interests of all physician subgroups. Consequently, it is not uncommon for multiple market-based arrangements to exist within a single organization. This makes the coordination of care and alignment of incentives at least as difficult, if not more so, as it has been under the traditional medical staff model.

7. Organization of Work in Hospitals

Largely as a result of increasing competitive pressures and external emphases on cost containment, the organization of work within hospitals has shifted. Two trends are particularly in evidence: (a) the use of teams to perform managerial and clinical work, as opposed to performing such work individually, and (b) the use of contracts to obtain labor externally rather than to hire employees.

Because of demands by managed care firms and integrated healthcare systems to provide comprehensive care to patients and/or enrollees in health plans, there is growing recognition that patients need comprehensive care in order to address their multiple problems effectively. Given the broad spectrum of knowledge necessary for comprehensive care, there is growing belief that teams of practitioners with complementary roles and skills are best suited to providing high quality, cost-effective patient care (Fried and Rundall 1994). Teamwork in the clinical round is also perceived as an antidote to fragmentation in services, a traditional problem in healthcare delivery. For example, repeated patient assessments by various healthcare providers add unnecessary costs to patient care, when one combined assessment would suffice. Advocates of team-oriented care cite studies that consistently show that collaboration among physicians, nurses, and other healthcare personnel enhances the quality of care and patient satisfaction (Nikolaus et al. 1999, Le et al. 1998).

Team-based care stands in marked contrast to the traditional hierarchical work relations in most hospitals, which accord the physician a role of absolute

autonomy and control over patient-care processes. The growing emphasis on prevention, wellness, and cost-effectiveness in care delivery make this hierarchical structure outmoded. Flatter structures and more collegial relations among providers appear to be the developing norm. For example, many nurses advocate a collaborative relationship with physicians where nurses have primary responsibility for health maintenance, prevention, and diagnosis and treatment of routine cases, while physicians retain responsibility for the diagnosis and treatment of complex cases and the prescription of medications.

Contracting for labor services as an alternative to employment stems from the need for more flexibility in an increasingly competitive environment. Hospitals need to be able to make rapid changes in their workforce in response to demands from a volatile market. Rather than staffing to accommodate periods of peak demand with attendant down time for slack periods, hospitals have increasingly adopted a contingent approach to staffing, responding to the particular needs of the organization at a given time (Katzman 1999, Rizzuto et al. 1999). Contracting typically occurs in housekeeping, business, and clinical services. Proponents argue that contracting frees top managers to concentrate on core services, brings specialized expertise to the organization, improves flexibility through the ability to terminate contracts, reduces supply costs through superior purchasing power, and promotes the recruitment of specialists who may be in short supply. Critics argue, however, that the contract-management firm and the contracting organization may fail to clarify performance goals or that contracted staff may have difficulty working with other departments and full-time personnel. Perhaps most importantly, some believe that contracting for a wide variety of services without a clear strategy risks damaging organizational coherence and control (D'Aunno et al. 1996).

8. Quality of Care in Hospitals

Another illustration of the organizational response to technical and institutional pressures lies in the area of healthcare quality. On the one hand, decline in public support and trust for hospitals has reduced their impetus to assure quality and discipline members of their organizations for lapses in quality. Responsibility for quality has begun to shift to the payers of health care and their agents (e.g., managed care organizations), as well as to the courts which adjudicate an increasing number of malpractice suits against hospitals and physicians. These trends reflect a growing tendency to think of health care as a commodity rather than an entrusted service provided by professionals and professional organizations. On the other hand, there is greater emphasis placed on quality

improvement systems within organizations as a counterbalance to external controls over quality and as a response to market pressures to increase the efficiency and effectiveness with which care is delivered. Again, this duality of external control vs. internal control is a juxtaposition based in the competing demands placed on hospitals by institutional and technical forces.

Hospitals, in particular, are being challenged by increasingly competitive markets and regulatory changes to produce high quality care without raising costs. Given the multiple pressures and problems associated with healthcare quality, hospitals face the additional challenge of developing policies, procedures, and incentives to improve quality within a domain that has traditionally been the province of highly autonomous professionals. Quality improvement (QI) practices have emerged in recent years partially as an alternative to quality assurance and as a reaction to the shortcomings of outcome-based control. With mounting pressure to maintain or improve quality in the face of reduced resources, hospitals have begun to look to process improvements as a mechanism to provide high quality care while containing healthcare costs. While the adoption of QI appears to be an internally generated response to changing market conditions, for the most part, accrediting bodies such as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) have also encouraged hospitals to adopt QI.

Given the traditional emphasis on provider-patient relations, individualized approaches to improving quality have received the vast majority of attention to date. Although the knowledge and practices of individual physicians are important for high quality care, increasingly clinicians practice within groups or systems of care. As such, the quality of care delivered depends critically on the ability of these groups or systems to prevent errors, coordinate care among settings and practitioners, and ensure that relevant, accurate information is available when needed.

One of the most promising recent developments is the effort to institutionalize quality improvement in hospitals as a coordinated, organization-wide approach to care strategies (Berwick et al. 1990, Gaucher and Coffey 1993, Carman et al. 1996). These practices, collectively, are designed to systematically examine and improve processes of care and care support in organizational settings. Typically, these quality improvement efforts are strongly rooted in evidence-based procedures and rely extensively on data collected from hospitals about care processes and patient outcomes.

9. Hospital Behavior in Other Nations

The focus of this article has been to associate change in hospital structure and behavior to change in the broader market and institutional contexts in which

these organizations operate. The United States has been prominently featured in this discussion because of the somewhat unusual combination of strong technical and institutional pressures to which hospitals must respond. Other countries, however, may diverge markedly in the degree to which either institutional or market forces play a role in shaping hospital behavior. For example, in countries where healthcare delivery is highly centralized and funded exclusively by the government, we would expect to find much more structural homogeneity among hospitals, in marked contrast to the increasing diversity and differentiation among US hospitals. In other nations, where privatization and multiple sources of healthcare funding predominate, hospitals are more likely to resemble in their structure and behavior other commercial vendors of services to the market.

Recent trends in OECD countries would seem to indicate that they are facing technical pressures for increased efficiency similar to those in the United States (Normand 1993). Significant reductions both in the number of hospital beds per 1,000 and in average length of hospital stay have resulted, particularly in Scandinavian countries. In the countries of the former Soviet Union, on the other hand, average length of stay has not dropped, despite mounting financial strain due to economic instability. One potential explanation for this is lingering institutional norms regarding appropriate clinical practice (Hensher et al. 1999). This may illustrate how specific institutional beliefs about health and health care in a given nation may shape hospital behavior in ways that differ substantively from the ways in which institutional forces shape hospital behavior in the US. For example, in Taiwan, the deeply seated belief that family is the primary care giver is reflected in the hospital practices of incorporating family members in patient education, extended visiting hours, and even boarding with the patient during the hospital stay. Cross-national differences in hospital structure and behavior are thus likely to be a reflection of both the structure and content of the broader environment from which hospitals obtain patients, critical resources, and legitimacy.

J. A. Alexander and M. E. Comfort

Hotelling, Harold (1895–1973)

Harold Hotelling (1895–1973) was one of a handful of statistical researchers who in the first half of the twentieth century developed the solid intellectual foundations of the then newly developing discipline of statistics. In addition, he was also an important contributor to several areas of mathematical economics. His academic career includes: professorships at Stanford University, Columbia University, and the University of North Carolina at Chapel Hill, and his professional leadership involved major statistical and economic societies. He is perhaps best known for his statistical work in multivariate analysis, introducing the concepts of principal components, canonical correlations and Hotelling's- T^2 . In mathematical economics, he contributed to natural resource economics, spatial economic competition, and introduced the welfare equilibrium proposition.

1. Early Life

Born on September 29, 1895 in Fulda, Minnesota, Harold Hotelling, whose parents were Clair Hotelling and Lucy Rawson, was the oldest of six children. Having moved with his family to Seattle at age nine, Hotelling studied journalism at the University of Washington, taking time from his studies to work on a weekly paper. In 1919, he received his BA in Journalism, graduating Phi Beta Kappa. Encouraged, in part, by the mathematician and well-known historian, Eric Temple Bell, he went on to graduate study in mathematics at the University of Washington, receiving an MA in 1921. It was during this time that he married Floy Tracy in 1920. He received his Ph.D. in Mathematics in 1924 from Princeton University, doing dissertation research on dynamic topology with Oswald Veblen, although his original intent was to study mathematical economics. His interest in economics took root while growing up and in his belief in

‘the importance ... of a study of economics [in] that [it] might possibly impress some people to the point of making some changes in the institutions with which they had become familiar [and] which I [Hotelling] was already prepared to condemn vigorously.’ Alternatively, he ‘couldn’t escape the lure of mathematics’ and notes that he ‘hoped and [it] appeared that the mathematics would be extremely prolific of new economic theorems and ideas if followed out’ (Hotelling 1963).

2. Beginning at Stanford University

Invited to join the Food Research Institute at Stanford University, Hotelling was a research associate there from 1924 to 1927, following which he was an associate professor in Stanford’s Department of Mathematics (1927–31). An early indication of the breadth of his intellectual interests is illustrated by the fact that in 1927 he taught courses on mathematical statistics, differential geometry, and analysis situs (a forerunner of topology), and in that year published papers on the application of the latter to statistics, and on differential equations subject to error. While working in the Food Research Institute, he was introduced to the work of R. A. Fisher (five years his elder), and through their mutual correspondence they became friends. In fact, Hotelling wrote the book review in the *Journal of the American Statistical Association* (Hotelling 1927) of the first edition of Fisher’s *Statistical Methods for Research Workers* (and also did subsequent reviews there of the Second through Seventh Edns.). After the planned visit of Fisher to Stanford in the summer of 1928 was abandoned, Hotelling visited Fisher at the Rothamsted Experimental Station during the second half of 1929. Their connections continued and at the outbreak of World War II, Hotelling, along with three others, wrote to Fisher volunteering to care for Fishers’ six daughters in the United States during the war. However, a last minute cancellation kept the Fisher children in Britain (Box 1978, p. 377).

While at Stanford, Hotelling wrote a number of path-breaking papers in statistics and in mathematical economics. The most notable among these statistical results was his generalization of Student’s t -ratio to handle multivariate response data (Hotelling 1931). This generalization remains known as Hotelling T^2 . His paper with Holbrook Working (Working and Hotelling 1929) on modeling and linear prediction first demonstrated that the standard error of the estimate of a linear regression depended on the independent variable’s value, thereby giving rise to the well-known Working–Hotelling curved simultaneous confidence regions for a linear regression. His research contributions to mathematical economics were equally notable. His 1929 paper provided a game-theoretic solution given by two differential equations to a problem of price and location competition between

two entities in a spatial setting. His 1931 paper on the economics of exhaustible resources is recognized as the seminal paper in the field of natural resource economics. In that paper, Hotelling demonstrates that in an equilibrium setting, prices of exhaustible natural resources will tend to rise over time at a percentage rate equaling the interest rate.

3. Columbia University and the Statistical Research Group

Hotelling moved to Columbia University in 1931 as a Professor of Economics, having been recruited to further the development of mathematical economics, and also to initiate mathematical statistics. Throughout his career at Columbia and later at the University of North Carolina at Chapel Hill, Hotelling was superlative at both attracting outstanding researchers and mentoring young researchers destined for stardom. The Nobel-prize winning economist, Milton Friedman, was among the earliest mentored by Hotelling, spending 1933–4 at Columbia learning mathematical economics from him. Later mentoring Kenneth Arrow, another Nobel-prize winning economist, Hotelling was also instrumental in attracting Abraham Wald, W. Allen Wallis, and Jacob Wolfowitz to the statistics facility at Columbia. As a teacher, Hotelling was perceived to be organized and comprehensive, interweaving theory with application. Importantly, an appreciation of research was imparted to his students, and he was able at an interpersonal level to instill in his students their own confidence to be successful at research (Madow 1960).

Hotelling was one of three original voting fellows of the Institute of Mathematical Statistics on September 12, 1935, and was President of that Institute in 1941. He began his association with the Cowles Commission, participating in its first Summer conference in 1935, and served as President of the Econometric Society during 1936–7. In 1939–40, he was a Visiting Lecturer at the Indian Statistical Institute and was President of the Indian Statistical Congress (1940).

Along with Wallis and Wolfowitz, Hotelling was a charter member of the Statistical Research Group (SRG), at Columbia, for which Wallis was appointed Director of Research. The SRG, founded on July 1, 1942, and in existence until September 30, 1945, was an extraordinary research group of statisticians whose goals were to provide research support and analyses for the armed forces in furthering the quality and accuracy of their war efforts. The origins of sequential analysis stem from Wald’s work for the SRG, and among Hotelling’s contributions were techniques for control charts for multivariate data (Kruskal 1980). (A detailed history of the SRG is provided by Wallis 1980).

Early in Hotelling’s career at Columbia, his wife, Floy, died in 1932, leaving behind two small children.

In 1934, Hotelling married Susanna Edmundson and together they had six children, five sons and a daughter (who died in her infancy).

Hotelling, during his prewar years at Columbia, continued to produce ground-breaking research in statistics and economics. His 1933 and 1936 papers introduced and lay the groundwork for principal component analysis as a multivariate statistical technique for simplifying the structure of large numbers of correlated measures (Hotelling 1933, 1936a). In 1936, he extended notions of multiple correlation to canonical correlations in order to measure and study the relationships between two dependent sets of correlated responses (Hotelling 1936b). In the field of economics, his 1935 paper provided a consistent theory uniting demand and utility by means of a constrained optimization problem and his presidential address to the Econometric Society in 1938 (Hotelling 1938) introduced a welfare equilibrium proposition which leads in certain societal settings to the argument that goods be priced at their marginal costs. In 1940, his innovative and insightful paper on the teaching of statistics in universities was published (Hotelling 1940). In this prescient paper, Hotelling observes the inevitability of the increased demand for statisticians, and argues that the teaching of statistics in universities would be best done solely by statisticians in separate departments of statistics (a quite novel idea in 1940!). With regard to this article, Jerzy Neyman (1960) later wrote ‘in my opinion the establishment of the excellent departments of statistics in such universities as Chicago, Columbia, Harvard, North Carolina, and Stanford is due to a considerable extent to the publication of Hotelling’s article.’

4. Career at University of North Carolina

After the war in 1946, Hotelling was recruited by Frank Graham, President of the University of North Carolina at Chapel Hill to start the Department of Mathematical Statistics there upon his arrival. In addition to being appointed professor of mathematical statistics and professor of economics, he was named Associate Director of the Institute of Statistics (directed by Gertrude Cox), which was constituted with Chapel Hill’s department and the Department of Experimental Statistics at North Carolina State, as well as related groups in psychometrics, social sciences and biostatistics. It is notable that when Hotelling was planning to go to Chapel Hill, he proposed that Wald join him there. In order to entice Wald to remain at Columbia, a Department of Mathematical Statistics was promptly proposed and officially approved in December 1946 (Hoxie 1955). As at Columbia, Hotelling attracted outstanding statisticians to the Chapel Hill faculty including R. C. Bose, Wassily Hoeffding, P. L. Hsu (who had been at Columbia with Hotelling), William Madow, Herbert Robbins, S. N. Roy, and Walter Smith. Hotelling relinquished the chairman-

ship to George Nicholson in 1952, and devoted the remainder of his career there to his research and his students.

His research at North Carolina involved, on the whole, elaborations and in-depth further study of some of his earlier research. Noteworthy among these is his work in 1947 and 1951 on hypothesis tests related to multivariate analysis of variance, which lead to the testing criterion referred to as the Lawley–Hotelling trace. He formally retired in 1966, but continued to be active in the department. He was elected to the National Academy of Sciences in 1970, and received a number of other academic honors during this period. Subsequent to a serious stroke in mid-1972, Harold Hotelling died in Chapel Hill, North Carolina on December 26, 1973.

5. Hotelling’s Contribution to Multivariate Statistical Analysis

One of the origins of statistical hypothesis testing is a test that the mean μ of a normal distribution has a specified value μ_0 . The resultant Student’s t -test, obtained in 1908, remains as one of the most used statistical procedures. The t -statistic is

$$t = \sqrt{N}(\bar{x} - \mu_0)/s$$

where $\bar{x}$ and s , respectively, represent the mean and standard deviation of a sample of size N . Hotelling recognized that many experiments will have correlated measures $x_1, \dots, x_p$, which arise from a multivariate normal distribution, and he provided the Hotelling’s T^2 test to handle the means of multiple measurements (Hotelling 1931). For a sample of size N let $\bar{x} = (\bar{x}_1, \dots, \bar{x}_p)$ denote the sample mean vector and $S = (s_{ij})$ represent the sample covariance matrix.

The T^2 -statistic is

$$T^2 = N(\bar{x} - \mu_0)' S^{-1}(\bar{x} - \mu_0)$$

where $\mu_0 = (\mu_{10}, \dots, \mu_{p0})$ is the specified mean vector in the hypothesis. When the hypothesis is true, $(N-p)T^2/p(N-1)$ has an F -distribution with p and $N-p$ degrees of freedom.

Analogous to Student’s t -test, the T^2 -statistic can also be used to test for the equality of the mean vectors of two normal distributions that have the same unknown covariance matrix but unequal means, μ and ν . Now the statistic becomes

$$T^2 = \frac{N_1 N_2}{N_1 + N_2} (\bar{x} - \bar{y})' S^{-1}(\bar{x} - \bar{y})$$

where $\bar{x}$ and $\bar{y}$ are mean vectors from samples of size N_1 and N_2 , respectively, and S represents the pooled sample covariance matrix. Although there are many parameters in this model, under the null hypothesis the

distribution of $(N_1 + N_2 - p - 1)T^2/p$ has an F -distribution with p and $N_1 + N_2 - p - 1$ d.f.

The T^2 -statistic additionally arises as a linear discriminant, as noted by Fisher, and is the sample analog of the Mahalanobis squared distance.

Quite remarkably, Hotelling noted that for the two-sample problem, the T^2 statistic is invariant under the transformation $\bar{x} \rightarrow \bar{x}A$, $\bar{y} \rightarrow \bar{y}A$, where A is any nonsingular matrix. This anticipated a general theory of statistical invariance developed much later. In particular, the T^2 -test has a number of optimal properties among invariant tests: (a) the T^2 -statistic is the only invariant function of the sufficient statistics $\bar{x}$ and S ; (b) as a test statistic it is the uniformly most powerful test among all invariant tests; and (c) the noncentral distribution depends on the scalar parameter $(\mu - \nu)\Sigma^{-1}(\mu - \nu)'$, which is the only invariant of the parameters.

Large data sets either in exploratory data analysis, data mining, or model building are accompanied by a large number of variables. The reduction of numbers of variables is often a first step in trying to uncover patterns in the data. Because multivariate measures $x_1, \dots, x_p$ are related, there is the need to disentangle the correlational structure. To accomplish this, Hotelling (1933, 1936a) introduced the p principal components $z_1, \dots, z_p$, which are linear combinations of the underlying measures, namely $z_k = \sum_{i=1}^p a_{ki}x_i$, $k = 1, \dots, p$, where the coefficients are normalized by $\sum_{i=1}^p a_{ki}^2 = 1$. The first set of coefficients $a_{11}, \dots, a_{1p}$ is chosen so as to maximize the variance of z_1 . The second set of coefficients $a_{21}, \dots, a_{2p}$ is chosen to maximize the variance of z_2 subject to the constraint that z_1 and z_2 are uncorrelated. At each step the variance is maximized, but with the additional constraints that each z_k be uncorrelated with $z_1, \dots, z_{k-1}$. Their ordered variances $\text{Var}(z_1) \geq \dots \geq \text{Var}(z_p)$ turn out to be the characteristic roots of the population covariance matrix.

In effect, principal components provide transformed coordinates that are uncorrelated, thereby disentangling the measures. Because the principal components are ordered according to their variances, this permits the researcher to focus on a subset of principal components that contributes substantially to the total variance. In multiple regression, the predictor variables often are closely related, and the problem of multicollinearity results. Principal components is one important procedure that introduces orthogonality and reduces dimensionality, thus removing multicollinearity.

To build a hierarchy of correlational measures one can start with the ordinary Pearson product moment correlation between x and y . With multiple measures $x_1, \dots, x_p$ and y one generates the multiple correlation of y and the linear combination $y^* \equiv \sum a_i x_i$, which is the maximum correlation between y and y^* . Suppose now there are multiple measures $x_1, \dots, x_p$ and $y_1, \dots, y_q$. To analyze the relation between these two

sets of variates, Hotelling (1936b) defined canonical correlations between u_k and v_k , which are the correlations of linear combinations $u_k = \sum a_{kj}x_j$ and $v_k = \sum b_{kj}y_j$ where $k = 1, 2, \dots, K \equiv \min(p, q)$. The coefficients are normalized so that the variances of u_k and v_k are 1, and are chosen so as to maximize the correlations, and such that $u_1, \dots, u_k$ are mutually uncorrelated and $v_1, \dots, v_k$ are mutually uncorrelated $k = 1, \dots, K$. The new variables u_k and v_k , $k = 1, \dots, k$ are called the canonical variables; furthermore, it turns out that u_i and $v_j (i \neq j)$ are uncorrelated. The discovery of the corresponding matrix factorization is quite remarkable. A special case of this factorization leads to the singular value decomposition, which is a very important representation in numerical linear algebra.

As a result of this decomposition, one can transform the original variables to new coordinates $(u_1, v_1), \dots, (u_K, v_K)$, that exhibit a simple structure: (a) the pairs are uncorrelated; (b) the pairs are ordered decreasingly in accordance to their correlations (which are non-negative); that is, (u_1, v_1) are maximally correlated; and (c) the variances of the u_k 's and v_k 's are normalized to be one. In a 1935 paper, Hotelling had earlier focused on the first pair (u_1, v_1) , and he called u_1 the most predictable criterion and v_1 the best predictor.

Principal components and canonical correlations can be viewed in terms of roots of a determinantal equation and estimated from their sample analogues. It was this context that opened an entire area of statistical research on the distribution of the roots of random determinantal equations. In 1939, a number of papers appeared simultaneously in the statistical literature in which the central distribution of the roots were obtained. From then until the present, there is a continuing flow of theory concerning the noncentral distributions of roots of sample determinantal equations.

Hotelling's training as a mathematician provided him with a warehouse of tools that he applied to statistical problems. Among his first papers was a presentation in 1926 to the American Mathematical Society on the use of topological principles in the derivation of distributions. Many of his later results were obtained with geometrical arguments. He was able to exploit asymptotic theory to obtain normal approximations and limiting results. Hotelling, in 1930, was the first to attempt to state precise conditions for the consistency and asymptotic normality of the maximum likelihood estimator. With Lester Frankel in 1938, he obtained expansions for the distribution of Student's t -statistic, thereby leading to a useful normal approximation.

With his interest in relations between variables, Hotelling recognized that the required normality assumptions may be unrealistic. This led him to study the nonparametric version of the product moment correlation. Together with Margaret Pabst, Hotelling

studied the Spearman rank correlation coefficient and they showed that for large samples it approximately follows a normal distribution. In 1953, Hotelling continued his analysis of correlations and obtained expansions of Fisher's z -transformation of Pearson's product moment correlation. This work remains among the definitive results in this area.

Hotelling wrote on matrix calculations and developed methods that still stand. His work on weighing designs led to a number of combinatorial generalizations. Although Hotelling had a mathematical focus for his research, he was not averse to working on applied problems. The range of his applied papers include results concerning the physical state of protoplasm, duration of pregnancy, causes of birth rate fluctuations, anthropomorphic measures of Southwest Indians, and effects of pregnancy on dental caries.

Harold Hotelling's originality and imagination is seen in both the genius of his research that produced innovative methods that stimulated whole areas of modern statistics and in his prescient leadership in the discipline of statistics. Further details concerning Hotelling, including his complete bibliography, can be found in Olkin *et al.* (1960), in Pfouts (1960), and in three articles appearing as 'Three papers in honor of Harold Hotelling at 65' in *The American Statistician* (14), published in 1960 (pp. 15–25).

Household Archaeology

1. Introduction: The Emergence of Household Archaeology

Household archaeology emerged in the late 1970s and early 1980s as a late development of social archaeology on both sides of the Atlantic. The aim of household archaeology is to create a context in which a humanized reconstruction of the past may be nurtured, through the study of intrasettlement relations. Such an investigation at the microscale involves the intensive recording of archaeological observations and detailed excavation of an area broad enough to include architectural and other features of the built environment. The criticism of such an effort is that it produces an isolated picture of one part of a social group—perhaps only one household—that does not provide a statistically valid extrapolation to the rest of a settlement, or from one settlement to the regional scale.

Household archaeology developed both as an extension of and a reaction, by both processual ('new') and Marxist-oriented archaeologists to the social evolutionary features of social archaeology. Social archaeology provided data and inferences for explanations of change and variation of past cultural systems, focusing on intersettlement relations, especially in terms of the interaction of political leaders on a

regional basis within the parameters of ecological features such as distance and resource distribution. Marxist-oriented studies added the dimensions of ideology and power relations in production and distribution.

A criticism of the macroscale models of social change has been that, in identifying the longer-term evolutionary trajectory of, for example, resource control, hierarchical social relations, and population growth, and in establishing the general social form of a group, the context of shorter term changes and variability is given a lower priority in explanation. In this way a dehumanization of the past has been created in order to 'write history (or prehistory) large.'

Household archaeology developed in the 1980s and 1990s as the result of a growing interest in intra-settlement relations, but it is a sub-discipline that is neither unified, organized, nor recognized within archaeology. The aims and agendas of the archaeologists who carry out studies that are termed 'household archaeology' are as variable as are the theoretical strands of archaeology itself.

2. *Household Archaeology: Archaeology at a Small Scale*

When it was initially developed in the late 1970s the study of households aimed at filling in the most detailed level of settlement pattern and activity analysis, which could then be extrapolated to make more general statements about demographic trends, specialized production, class structures and so on (Flannery and Winter 1976). Later, in the important volumes edited by Wilk and Rathje and Wilk and Ashmore, the importance of households as 'fundamental elements of human society' was emphasized (Ashmore and Wilk 1988, p. 1, Wilk and Rathje 1982). At this time it was suggested that, since households are the level at which social groups articulate directly with economic and ecological processes, their study would offer a chance for archaeologists to examine social adaptation (in a functionalist sense) with direct reference to the empirical details of the archaeological record. It was assumed this would be done within the methodological framework of scientific logical positivism. In other words, household analysis would allow archaeologists to 'bridge the existing 'mid-level theory gap' in archaeology' (Wilk and Rathje 1982, p. 617). Thus household archaeology developed alongside the empirical theory-building in archaeology, known also as middle range research, that lies at the heart of the history of processual archaeology at the end of the twentieth century.

It is clear that household archaeology in the 1980s implied examining and analyzing social change at a microscale as a complement to analyses of social and economic change at a broader scale of regions and

continents. Household archaeology served to provide a richness of detail, but was not an end in itself. The ultimate target was to understand social evolutionary change.

3. *Sources of Inspiration for Household Archaeology*

The explicit inspiration for household archaeology comprised the studies of households and multiscalar histories written by historians (including historians of the so-called Annales school) (Braudel 1972), and by anthropologists, especially those interested in historical demography and historical anthropology (Arnould and Netting 1982, Laslett and Wall 1972, Netting et al. 1984), (Hammel and Laslett 1974, p. 76). It is the latter who coined the term 'co-resident domestic group,' as a way to bring together the enormous diversity of the minimal social group—family, household, houseful and to use a term that was not subject to 'cultural bias' and would have value for 'objective scientific analysis.' The "'co-resident domestic group'" consists of those who share the same physical space for the purpose of eating, sleeping and taking rest and leisure, growing up, childrearing and procreating' (Hammel and Laslett 1974, p. 76).

Archaeologists envied the historians and social anthropologists their knowledge about the kinship relations and the demographic composition of the members of a domestic group that allowed them to explore the 'co-resident domestic group' in terms of variability in their size and kinship composition, and the cooperative activities of their members. Traditional scientific archaeological methodology puts limitations on the investigation of the social composition of or relations within the domestic group. In view of the dangers inherent in using architectural features or any other archaeological data to identify a 'household' on a prehistoric site, Wilk and Rathje pointed out that it was more productive for archaeologists to investigate questions such as what co-residents of a domestic group (households) do, rather than what their social form is (who lives there and how they are related) (Wilk and Rathje 1982). Thus, for example, it was argued that to understand transformations in the social relations of production in Neolithic Southeast Europe, it was not essential to be able to identify 'households' in the historical and anthropological sense of the term (Tringham 1990, p. 603). It was sufficient to be able to investigate changes in co-residence and the cooperative activities of kin-based co-resident domestic groups.

It is not surprising that the impetus for household archaeology came from archaeologists who had focused on the excavation and interpretation of well-preserved architectural remains. Architecture—more broadly, the built environment—provides the essential

context of co-resident domestic groups. Archaeologists working in prehistoric Mesoamerica led the field (Ashmore and Wilk 1988, Wilk and Rathje 1982). Simultaneous and parallel developments were occurring in the Southwest US with archaeologists working with spectacular Pueblo architecture, such as Grasshopper Pueblo (Ciolek-Torrello 1986), and in Europe and the Near East with archaeologists working in Neolithic architectural contexts (Bogucki 1988, Tringham 1990, Tringham 1991). The Chacmool conference on Household and Community provided a welcome synthesis of the diverse routes to household archaeology in place by 1989 (MacEachern et al. 1989).

4. *Modeling Household Activities in Archaeology*

In modeling the economic and social role of co-resident domestic groups, participants of 'household archaeology' have followed social anthropologists in their models of the domestic mode of production (Chayanov 1966 (reprinted 1986), Netting et al. 1984, Sahlins 1972). These models characterized self-sustaining agriculturists and horticulturists who live in permanent villages and carry out relatively small-scale production. Such studies have emphasized the importance of the function of households as the organizing units of cooperative labor, production, consumption and sharing of resources, the transmission of property and rights from one generation to another, and the creation and maintenance of ties and alliances with other units through marriage and other forms of exchange. These same essential features of social reproduction became the objects of investigation of household archaeology (Ashmore and Wilk 1988, Wilk and Rathje 1982).

The study of 'what households do' has been enriched by the Marxist focus on ideology, power and social inequality. In the domestic mode of production the pattern of domination and inequality between and within different households of a settlement and between different settlements, although temporary and flexible, is thought to comprise a crucial variable in stimulating and enabling larger-scale transformations such as the intensification of production, the increase of the labor supply, and the increase in cultural complexity (Meillassoux 1978).

Inequalities certainly exist, along with innumerable variations, between households and are the result of differences in the cycles of demographic and economic evolution through which households pass—cycles in which they expand, accumulating wealth, power, property, and members, and then contract. Thus, at any one time the households of a settlement will demonstrate differences in membership, the composition of the labor force, and the structure of dominance within the co-resident group and within

the settlement as a whole. They will demonstrate differences in relations with groups outside the village, and, most importantly, differences in access to the products and processes of production. This concept of small-scale social inequality is the basis of a number of archaeological models that use the emerging importance of households as the unit of social reproduction to explain larger social and economic transformations (Rathje and McGuire 1982, Tringham 1990).

These differential patterns of social and economic relations reflecting social inequalities, however, have such a low archaeological visibility that these societies have traditionally been regarded as 'egalitarian.' The difficulty in recognizing inequality in 'egalitarian' societies is due to the fact that it is ephemeral and not cumulative. An additional significant factor, however, is that inequality in such societies is not based on such criteria as the ownership of land and other material property, which are easily definable or easily recognizable in the archaeological data. Control of labor—not land, capital or property ownership—is the crucial variable on which inequality is based in precapitalist self-sustaining societies. Thus, those who control the circulation of labor and its products, control the social reproduction of society. At the scale of the domestic unit or household, this may be an individual within the household, or it may be 'senior' households who control the labor of 'junior' households. It has been argued that inequality at this scale creates tensions in numerous spheres and is a crucial variable in the process of socioeconomic transformation that can be observed in the archaeological record (Tringham 1990, p. 608).

5. *Archaeological Evidence of Household Inequality*

The primary requirement for the examination of the social context of production and economic life at an archaeological site (in other words, of household archaeology) is that a number of domestic architectural units be exposed by excavation. This will enable a comparative view of co-resident domestic groups across the settlement at any one time. This information is enhanced by the provision of such a picture through time. Only when a large number of domestic structures is exposed is it possible to tell whether, for example, all the structures in a given excavated occupation horizon represent residences or parts of residences; whether the differentiated units of co-residence can also be differentiated as units of cooperative production; whether all the domestic structures were occupied at the same time; whether they all became part of the archaeological record at the same time or whether they were destroyed or abandoned at different times, and, finally whether they appear to be in a parallel stage of their use-lives at the

time of destruction or abandonment or whether some seem to have been more recently established than others. The study of archaeological architecture in terms of the use-life of the buildings has greatly enhanced these efforts for the purposes of household archaeology (Tringham 1994). In this way the context and nature of the construction, maintenance, occupation, modification, and abandonment/destruction, and replacement of a residence all become objects of knowledge. Traditionally, they would have comprised elements that were subsumed under the formal features of the building. The investigation of a building through different stages of its use-life, brings to light many important aspects that would otherwise have been ignored; for example, modifications such as the addition or removal of rooms during the cycle of growth and decline of a domestic unit; efforts to prolong the use-life of a building by repairs and renewals; symbolic emphasis placed on particular use-life stages such as re-plastering, the destruction of old houses (for example by fire), or founding of new houses (Tringham 1994).

Inequalities within and between domestic units are manifested archaeologically by the spatial differentiation of the production process (that is, in the production, consumption, and distribution of food and nonfood resources). In each case the pattern of economic activity (and inequality) should have a distinctive appearance, demonstrating differential access to the materials, means, process, and products of production. The expectation is that different households will show differential access not only to the products of exchange with other groups but also to the raw materials, techniques, and equipment for making use of resources, such as food items, minerals, and ceramics. Such a differentiation of economic activity is frequently, but not necessarily, accompanied by specific styles of material elaboration, such as ceramic decoration.

6. Trends in Household Archaeology

For many years household archaeology remained marginal to the mainstream of processual (new) archaeology. In his review of Ashmore and Wilk's edited volume on *Household Archaeology in Mesoamerica*, David Freidel noted that for the interest in and impact of 'household archaeology' to be sustained, it would need to be incorporated into a more ambitious theoretical program in archaeology (Freidel 1989). Its incorporation into Marxist models of power and social inequality certainly helped in this respect. The theoretical basis that has contributed most to sustaining interest in household archaeology, however, has been that of feminist anthropology and theories of social practice (Bourdieu 1977, Moore 1988). A common theme of these diverse post-structural theories has been their development beyond

neo-Marxian models of power and labor control to models of how ideologies of gender, class, labor, production, identity, etc., are constructed, maintained and transformed. They focus on domestic arenas and the contexts of daily practice as being the most significant places where these negotiations between social agents take place. During the later 1990s these models have also come to characterize the many faces of post-processual archaeology, one of which is an archaeology of households that has transformed into an archaeology of gendered places (Tringham 1994).

In the archaeology of gendered places, the archaeological record is not only analyzed and observed at a microscale, but also interpreted at a microscale. It challenges the search for the universal category of 'kin-based co-residential domestic group' and embraces the richness of the diversity of the social context of domestic action that has been forefronted in social anthropology for many years (Moore 1988). It lifts the household domain out of its previous position of 'assumed general knowledge' and as marginal to the 'great events' of history. It provides a richly-based, multiscalar theoretical framework to consider the role of the labor of players in prehistory: women, men and children (Tringham 1991).

The theoretical basis of feminist anthropology and social practice theory obviously creates some serious epistemological challenges to the scientific logical positivist methodology that characterizes mainstream processual (new) archaeology. It is as difficult to identify 'gender' in archaeological architecture as it is to find 'households' and 'families.' Responses to this challenge have been articulated in many publications (Hodder 1999, Wylie 1992). They are based in a celebration of the ambiguity of archaeological data, a critical awareness of the scientific process of inference, and a richly researched utilization of sources for interpretation—ethnography, history, art and literature. Above all in the post-processual epistemological framework, archaeology is identified as an interpretive discipline rather than a hypothetico-deductive search for true (pre)history. Thus in order to think about the prehistoric construction and practice of gender ideologies and dominance relations within or between households, a researcher may interpret the archaeological data and their meaning in many ways. It is not required to identify gender or 'domestic unit' in the archaeological record.

The database for an archaeology of gendered places remains especially but not exclusively in the record of the built environment. Along with the nature of household archaeology itself, however, the excavation and interpretation of archaeological architecture has changed. According to post-processual concepts, the built environment can be thought of as both a passive container that has a use-life and reflects social action and as an 'active' arena or medium for and symbolic expression of social actions. Thus social actions, practices, negotiations, and dominance ideologies of

whoever passes through a building are constrained and channeled by the materiality of that building. (Tringham 1994). In practice this has led to the necessity of retrieving a highly detailed microstratigraphic record of the traces of human activity, in which the sequence of every depositional event is recorded and interpreted. It is time-consuming, expensive, but immensely rewarding (Hodder 1999, Tringham 1994).

Along similar lines, household archaeology in the late 1990s has embraced the ambiguities recognized by practice theory anthropologists about kinship categories, including 'family' and 'household.' In their view, it is the meaning and cultural value ascribed to a relationship that are significant rather than some set of biological ties (Gillespie 2000). The enactment of kinship often involves the negotiation of identity and the identification of relationships through particular places on the landscape—buildings and sets of material culture (Joyce 2000).

At the beginning of the twenty-first century, 'what households do' is still a focus of household archaeology, but the 'doing' is far more complex than physical action. Moreover, a 'co-resident domestic group' is no longer a faceless economic category, but comprises the complex life-histories of many people as well as buildings and places. Finally, household analysis is no longer a step along the ultimate goal of understanding social evolutionary change. It plays an essential role in the creation of a multiscalar history that considers such questions as how—in practice—was a sense of place created; how was social memory about this group maintained; what were the myths about garbage; what would the walls of a house say if only they could speak (Tringham 2000).

R. Tringham

Household in Anthropology

Anthropologists use the term household loosely to refer to a residential group whose members cooperate in some activities of production, consumption, or child rearing. They have distinguished the household from the family by defining the former as a residential unit and the latter as a kinship unit. Close scrutiny of this distinction reveals key assumptions that have shaped the way anthropologists and other social scientists have conceptualized and studied not only households, but *families*, *kinship*, and *domestic groups*.

1. Problems in Defining the Household

The grounds for analytically separating families and households lie in the broader claim that kinship and locality are two distinct principles of organization (Keesing 1958). This claim, in turn, derives from the discipline's focus in the nineteenth and early twentieth centuries on the principles organizing social groups and relations in nonstate societies. Kinship, which was assumed to be universally defined on the basis of genealogical linkages rooted in biological reproduction, was considered the most important among these principles. As a key mode of recruiting members to (and limiting membership in) politically important groups such lineages and clans, kinship (genealogical propinquity) was distinguished from *locality* (spatial propinquity), which defined residential units such as hamlets and villages. As anthropologists expanded their range of ethnographic research to include peasant communities, they drew on the distinction between kinship and locality to differentiate family from household. The family as a corporate kin group was distinguished from the household as a collection of kin and sometimes nonkin who share a common residence. The corporate character of the peasant family was viewed as rooted in its jural rights to property, usually land, which its members held in common. Family members supposedly retained these rights regardless of whether they were members of the same household. Hence, family and household, it was argued, are both 'logically distinct' and 'empirically different' (Bender 1967, p. 493).

Actual usage of the term household in the anthropological literature, however, calls into question both the logical distinction and the empirical difference between families and households. For one, residential units composed of individuals who are not genealogically linked, such as orphanages, college dormitories, men's houses (in societies where gender segregation among adults is practiced), convents, and army barracks, usually are not considered households. At the same time, however, families whose members move between residential units that are located on different continents are referred to as 'transnational households' (Basch et al. 1994). In other words,

anthropologists attach the term household only to groups of people sharing both a common living space and activities that are identified as *domestic*. *Domestic activities* include those activities related to food production and consumption or to reproduction, including childbearing and child rearing. As these are the very same activities that are considered the functional basis of the 'family,' in practice, households are identified using both 'kinship' and 'residence' criteria. Thus, the claim for the logical distinction and empirical difference between family and household is not affirmed by scholarly practice.

Because 'domestic' activities are sometimes carried out by groups of people who do not reside together, some anthropologists (Bender 1967) have suggested that it would be better to employ alternate terms in our ethnographic descriptions. Among the alternatives that have been suggested are 'co-residential group,' 'budget unit,' and 'domestic group.' Less important than the terms employed, however, is the need for ethnographers to describe precisely the composition, organization, activities, and functions of these units. In addition, the cultural meanings people attach to these units need to be explicated. In the absence of this knowledge, anthropologist and others are likely to project their own cultural meanings and expectations on them.

The difficulties of identifying households are illustrated by innumerable cases (see Segalen 1984) which demonstrate that neither the boundaries nor the functions of household are easily discerned. Questions have been raised as to how to treat residential groups that move through a seasonal cycle of dispersal and concentration, how to handle the movement of people between dwelling units, whether to define as a single household the huts or houses that share a common yard or those that share a common stove, and whether to include servants, apprentices, boarders, lodgers, and nonkin in the household. More recently, studies of transnational migration (Rouse 1991, Basch et al. 1994) have raised the question as to whether residential units located in different nations and even on different continents constitute a single household. Studies of gay and lesbian kinship (Weston 1991), on the other hand, have challenged the assumption that heterosexual marriage and parenthood are the universal, natural core of families and households.

2. Problems in the Classification of Households Types

Much of the literature on households has been concerned with explaining variations among households that are distributed over time and space. In describing this variation, most scholars have focused on the character of the genealogical links between members of the household as its defining feature. Terms such as 'stem family household,' 'nuclear family

household,' and 'patrilateral extended household' are based on the configuration of genealogically-defined kin types included in the household—in other words, its *household composition*. In addition, the most genealogically 'close' members of the household are assumed to form its structural core. For example, if a household contains two adult brothers, their wives and children, it is labeled a fraternal-joint household. The assumption here is that the relationship between the brothers constitutes the structural core that shapes the relations of all the members of the household. Accordingly, studies of household change over time track changes in the genealogical composition of the household.

The classification of households on the basis of their genealogical composition rests on the shaky assumption that people who are similarly linked genealogically will have the same or greatly similar social relations. In other words, it is assumed that the labeling of a household as a 'stem-family household' captures its organizational structure and function. But a stem-family household found at one time and place does not necessarily share the same organizational dynamics as a stem-family household at another time and place. A household, or any social unit, is much more than the sum of its genealogical links. It is the negotiated outcome of the culturally meaningful actions and relations of its members. The actions and relations of household members with identical genealogically defined links can differ radically. Even households with the same genealogical composition in the same community may have significantly different structures of authority and divisions of labor (Yanagisako 1984).

3. What Explains Variation among Households?

A key question that has fueled comparative studies of households by anthropologists, historians, demographers, and other social scientists is what explains variations among them. Two related questions have been asked of variations observed in household composition. First, why do a significant proportion of the households in a society differ from what people report to be the ideal type of household? Second, irrespective of these ideals, what explains the distribution of household types within and between societies? Three types of variables have been offered to answer both these questions: demographic variables, economic variables, and social stratification variables.

3.1 Demographic Variables

Demographic variables affect the size and composition of households, thus acting as constraints on the attainment of the culturally ideal household type. Age at marriage, life expectancy, and fertility shape the composition of households at any given time in a population. The economy of the household is also shaped by demographic processes. Among peasants

for whom the household is the unit of production, changes in the demographic structure of the household as it moves through the developmental cycle entail changes in the ratio of consumers to workers (Chayanov 1966).

Fortes's (1958) model of the developmental cycle of domestic groups draws on these demographic processes to explain the varieties of domestic groups found in a society. Fortes hypothesized that the variety of household types found in a community or society at any point in time are merely different phases in the developmental cycle of a 'single general form.' As all households pass through different stages of the developmental cycle at different times, a census taken at a particular point in time will catch only a few in the ideal, complete phase. Hence, an ideal household type such as the patrilineal stem family household of Japan (which includes a married couple, their adult son and his wife and children) is better regarded as 'a transitory state in the development of the household, rather than as a form' (Hammel 1975, p. 142).

Fortes's model has been useful in helping us understand the impact of events such as birth, marriage, and death on the composition of households. It cannot account for all the observed variation in households, however, because other cultural and social forces (see below) are also involved. Fortes himself later (1978, p. 18) conceded that a model of a uniform developmental cycle could not explain why the actual histories of different families entail different developmental sequences. The model may also blind us to historical shifts wherein more recently formed households embark on a different trajectory than older ones. In addition, while demographic factors undoubtedly shape households, it is a mistake to treat them as exogenous, biological constraints on the composition and economy of households. To do so confuses social replacement with biological reproduction and overlooks the strategies people actively employ to control household size and composition, including their 'kinship' practices of marriage, fosterage, adoption, timing and spacing of births, and timing of family division. The collection of longitudinal data on households, whether by utilizing historical sources or through retrospective oral histories, is necessary for understanding both continuity and change. Cohort analysis is an effective tool for helping ascertain similarities and differences in the household histories of members of successive cohorts, defined on the basis of year of birth, marriage, or other historically significant events experienced by the members of a community.

3.2 Economic Variables

Economic variables are also adduced to explain cross-societal variation in household composition and organization. In some cases a mix of 'economic' and

'ecological' factors, including labor needs of production, defensive needs, care of children, taxation, and conscription practices of the state, are identified as the functional basis for the prevalence of certain household types. In others, the labor requirements of a particular productive activity are singled out as the primary determinant of household type. In their cross-societal analysis of 60 randomly selected societies, Pasternak et al. (1976) conclude that labor requirements are the most powerful determinant of the formation of extended family households. They hypothesize that in societies where work outside the home makes it difficult for a mother to tend to children and other domestic tasks or when the outside activities of the father make it difficult for him to perform his subsistence work, extended family households will prevail. Although they are able to demonstrate a correlation between activity requirements and presence of extended family households, they lack diachronic data to support the hypothesized causal relation between their independent variable (activity requirements) and their dependent variable (presence of extended family households). Consequently, they must resort to arguing that it is more plausible that activity requirements cause extended family households rather than vice versa. However, it is even more plausible that household composition and productive activities do not lie in a simple, unidirectional causal relation but rather shape each other.

Attempts like that of Pasternak et al. to identify the determinants of household composition and structure through statistical analysis of cross-societal comparisons have declined significantly over the past 30 years as the inherent problems and limitations of such studies have been increasingly recognized. Among these problems is that of discerning whether the units that have been selected for comparison are appropriate. As all societies contain different frequencies of a range of household types, it is misleading to classify entire societies into those with 'extended family households' vs. those with 'independent family households.' A better understanding of the relation between household composition and 'economic' factors may be gained by investigating the ways in which diverse types of households in a society articulate with one another, rather than by reducing the entire society to a single household type.

Labor requirements are often used to explain the frequency with which a particular household type appears in a society or section of society. Netting (1974) cites several ecological studies as demonstrating that household composition among horticulturalists and agriculturalists varies with the type and amount of labor required for effective crop production. His own study attributes the differences between the large, extended families of shifting cultivators and the nuclear family households of intensive agriculturalists in the same Nigerian plateau environment to different labor requirements (Netting 1965).

A shaky assumption underlies both cross-societal and intrasocietal studies that seek the determinants of household variation in productive labor requirements. In all of them, it is assumed that once having identified the subsistence activity or primary productive activity of the household, researchers can ascertain the labor requirements of that activity and proceed to show how the household efficiently meets them. In doing so, however, they overlook the fact that it is not simply technological requirements that necessitate a household type, but the entire manner in which production is socially organized. In other words, a productive activity can be accomplished by a variety of household types depending on how that production is socially organized, including the division of labor by sex and age, the use of hired labor, cooperation between households in productive tasks, and the exchange of labor between households. In assuming that the household is a self-contained labor unit, researchers fail to sufficiently investigate the existence of other forms of labor organization. But the social units engaged in production may not be the same at different phases of the productive cycle. For example, different social units may work together in the planting, weeding, and harvesting of crops. To attribute household composition to labor requirements begs the question, because it assumes the prior existence of an entire social organization of production. In order to overcome this narrow focus on technical requirements of production, the interplay of a wider range of cultural, political, and economic forces shaping productive relations within and between households needs to be considered.

3.3 Social Stratification

Differential access to resources, in particular differences in ownership and control of the means of production, also shape household variation in both peasant communities and among urban, industrial populations. A past tendency to neglect inequality in studies of households and other domestic groups can be attributed to the assumption that the communities studied by ethnographers were basically homogeneous. When anthropologists have studied peasant communities, for example, the implicit contrast with the landowners—who were generally not studied—led them to overlook significant differences among the peasants. Consequently, there has been a tendency to dismiss stratification as a significant factor in the analysis of household variation among peasants. Yet peasant communities are nowhere homogeneous, but are always internally differentiated. Differences in wealth among peasants are also overlooked because they are often obscured by idioms of kinship that bind the landed to the landless and the land-rich to the land-poor. Significant wealth differences may exist, however, between the smaller co-residential units of a single kin-based compound or between brothers who head

the main and branch households of a family. In other words, ideas and ideologies of family and kinship may obscure stratification among kin.

4. *Changes in Households over Time*

Anthropological studies of household and family change over time have focused generally on the effects of industrialization, urbanization, and the increasing integration of communities into capitalist market relations. Many of these studies challenge or argue for the refinement of the prevailing sociological theory that family, household, and kinship decline in importance as a society 'modernizes' and becomes increasingly urbanized and industrialized. They demonstrate that in some cases urbanization and industrialization have strengthened the extended family rather than weakened it and that new functions are assumed by extended families and extended family households. For example, urban migration may contribute to the maintenance of extended family households. While these studies provide an important correction to the theory of modernization and kinship decline, they are marred by the inconsistent use of ambiguous terms, including 'extended family household.' The argument over whether extended families have declined with urban-industrialization is in part the result of differences in the way in which researchers define and conceptualize household type. Quite often it is assumed that people who live in extended family households pursue common strategies and cooperative actions under the direction of a central authority—the head of the household. This not only gives undue weight to centralized authority as the defining feature of the extended family, but it also overlooks the heterogeneity in the goals and strategies of the members of a household.

5. *Recent Critical Approaches to Household*

The adaptationist, utilitarian approach to households that prevailed in much of the anthropological literature up until the 1980s has been challenged by new theoretical approaches that have had an important impact on the discipline in general. Among these perhaps the most significant has been feminist theories of gender.

In the 1970s, one of the first questions feminist anthropologists raised in rethinking the anthropological analysis of women's status and roles was whether ethnographers had overlooked women's goals, strategies, and forms of action, especially in the 'domestic sphere.' M. Wolf's (1972) study of Taiwanese joint family households, for example, revealed that family and household division was brought about as much by women's attempts to advance their own goals and those of their 'uterine family' as it was by conflicts among brothers. Collier (1974) argued that this process occurs commonly in

societies where men gain power by holding together large bodies of co-resident kin, but where women (especially younger women) gain power by breaking up such units. By attending to the informal power women often wield in societies where men are granted formal authority, feminist anthropologists alerted us to the tensions and conflicts and, therefore, the complex processes shaping households and other domestic groups. Likewise, investigations of women's relations with kin and others outside their household demonstrated that it is not just men who link mother-child units to larger institutional structures. The involvement of women in informal exchange networks between families and households had been overlooked by androcentric studies that had equated male relations with the 'public sphere.' Once studies showed that the female and male members of households—as well as the young and the old, those born in the household and those who had married into it—often do not share the same goals and strategies, it was no longer possible to retain the naive concept of a unified 'household strategy.' Finally, by calling into question the presumed universality and immutability of gender identities and the gender division of labor, feminist anthropologists denaturalized gender systems and called for the study of its historical and cultural production. They revealed the gender assumptions embedded in concepts of the 'public' and 'private' spheres (Reiter 1975), in definitions of the 'domestic sphere' and 'domestic groups,' including family and household (Yanagisako 1979) and in theories of kinship (Yanagisako and Collier 1987).

6. *Rethinking Households*

Functionalist analyses of 'household adaptation' reified the household, treating it as a social actor endowed with human consciousness and motives. Households were described as having goals, fashioning strategies, and adapting to the changing pressures of a modernizing society. Such language demonstrates the ease with which an analytic construct can be made into a social actor. The imputation of consciousness and will to households is rooted in the assumption that those who live together share a collective motive and will—in other words, a unified household strategy. It obscures the complex social processes through which people negotiate the relations that produce households, despite different and sometimes conflicting goals, strategies, and ideas about what it means to 'live together.'

Neither the composition nor the dynamic structure of households can be understood without a thorough understanding of the cultural meanings and sentiments that shape the social actions and relations of the people who live in them. This does not mean that households cannot be compared across societies, but rather that the comparative study of households must include an explication of the culturally specific and

heterogeneous meanings and motives shaping peoples' residential preferences and relations. Such an expanded strategy of research and analysis will enable anthropologists to move beyond crude comparisons of distributions of genealogically defined household types within and across societies to understanding households as the negotiated outcomes of culturally meaningful action.

Household Production

Household production is the production of goods and services by the members of a household for their own consumption, using their own capital and their own unpaid labor. Goods and services produced by households for their own use include accommodation, meals, clean clothes, and childcare.

The process of household production involves the transformation of purchased intermediate commodities (e.g., supermarket groceries and power-utility electricity) into *final consumption commodities* (meals and clean clothes). Households use their own capital (kitchen equipment, tables and chairs, kitchen and dining room space) and their own labor (hours spent in shopping, cooking, laundry, and ironing). The total economic value added by households in household production has been aptly named Gross Household Product (GHP) (Eisner 1989, Ironmonger 1996).

1. The Use of Labor and Capital in Household Production

In the language of economics, labor and capital are the two factors of production. However, labor, the time and effort provided by household members, is really the use of human capital; the second factor of production, capital, is the use of physical or tangible nonhuman capital (the services provided by land, dwellings, vehicles, and equipment). Economics conceptualises the production process as the use of capital (human and other) together with energy, to transform raw materials and 'unfinished' commodities (intermediate inputs) into finished goods and services ready for use by people (final consumption).

As countries industrialize, a large part of household production of food, clothing, furniture, and housing is transferred to business organizations and then purchased by households. Nevertheless, even in a world

apparently dominated by the market, a large amount of household production is necessary. Households need to add further value to put purchased commodities in the possession of ultimate consumers in the right place and at the right time.

2. Household Production in Contrast to Market and Subsistence Production

2.1 Market Production

While the market economy produces goods and services not produced by households (television sets and battleships), in many cases the market and the household are in direct competition, (restaurant meals vs. home prepared meals, and taxis vs. self-driven owned cars). Restaurants and taxis usually require immediate payment, if not by cash, then by credit card. In households, users do not pay each other by cash or credit card for meals served or transport provided.

Four separate modes of production are possible depending whether the household or the market provides the capital or the labor. Household production occurs when the household provides both its own capital and its own labor. However, the market can provide either one or both of these two factors of production. For example, a housekeeper could be employed to prepare meals, clean the house, and do the laundry. This paid housekeeper's time would be the use of 'market labor' in conjunction with 'household capital'—the kitchen, dwelling, and household equipment. Again, a household could rent a dwelling and a vehicle (market capital) but do its own cleaning, cooking, laundry, and driving (household labor).

In many countries, the use of paid domestic servants has almost disappeared; servants have been replaced by the household's own labor combined with more and better household capital and equipment. Many recent developments, such as supermarkets and automatic banking machines, involve a mode of production with households providing the required unpaid labor in lieu of the paid labor of shop assistants or bank tellers.

2.2 Subsistence Production

In developing countries many millions of households use their own capital and unpaid labor by way of fishing, collecting wood and water, growing vegetables and other food, building shelter, and making clothing. Thus, subsistence production fits the definition of household production when the goods produced are used within the household that produced them.

However, the wood, water, food, fiber, and clothing outputs from subsistence production could be sold on

the market to other households or to business enterprises. When such commodities are in fact sold, the value added in their production conceptually becomes part of market production.

3. Household Production and the Household Economy

The household economy describes the collective economic activities of households. Often the household economy is called the household sector as distinct from the business, government, and foreign sectors. However, the household sector is large enough to deserve the term household economy. The rest of the economy can then be called the market economy. Thus, the transactions between the household and the market are perhaps more akin to international trade between two economies than transactions between different industrial sectors of a single economy. The two major types of inter-economy trade are the sale of labor time by the household and the sale of household goods and services by the market.

3.1 Households as Producers

With few exceptions, economic textbooks focus on households as consumers and fail to discuss households as producers using their own labor and capital.

One of the earliest writers about the process of household production was Charlotte Perkins Gilman (*Women and Economics*, 1898) who questioned the traditional gender division of labor. She proposed moving even more household production to the market. This would yield gains from greater specialization and economies of scale and enable women to choose their work on the basis of inclination and talent.

Margaret Reid (*Economics of Household Production*, 1934) played a significant role in the development of household economics as a discipline, particularly for curricula in some North American universities. She held that, although the household is our most important economic institution, the interest of economists was concentrated on 'that part of the economic system which is organized on a price basis.' Reid is regarded as the first writer to specify the often-used third person criterion to distinguish between productive and nonproductive (consumption) activities. Her test was: 'If an activity is of such character that it might be delegated to a paid worker, then that activity shall be deemed productive' (Reid 1934). Thus, preparing a meal is productive work but eating it is nonproductive consumption or leisure. Of course eating and other consumption activities are productive in the sense that they are necessary for the continuation and re-invigoration of life. Another problem with this criterion is that student educational activities are

classed as unproductive since you would not learn to play the piano by paying someone to take the lessons for you.

A further problem is that production almost always requires a contribution from capital as well as from labor. The criterion needs to be extended to include services that might be obtained from rented capital as well as from a paid worker. Thus, accommodation services provided by a household's own dwelling are production; so are the transport services provided by a household's own vehicles and the entertainment services provided by a household's own sound and vision equipment. This extends the range of household production considered by Reid in 1934 and mostly since then by other writers. The expanded market alternative criterion would be 'An activity shall be deemed productive if it is of such a character that it might be obtained by hiring a worker or by renting capital equipment from the market.'

Gilman and Reid had little impact on mainstream economics. Economic theory continued to portray households as places only of consumption and leisure, with production of goods and services occurring only in business or public enterprises.

3.2 *The New Household Economics*

In the mid-1960s a major theoretical development took place, known as the 'new household economics' (Becker 1981, Ironmonger 1972, Lancaster 1971). In this theory the household is regarded as a productive sector with household activities modeled as a series of industries.

In this new approach, households produce commodities that are designed to satisfy separate wants such as thirst, hunger, warmth, and shelter. The characteristics, or want-satisfying qualities, of the commodities used and produced can be regarded as defining the production and consumption technology of households. With changes in incomes and prices, households still alter expenditures as in the earlier theory. However, in the new theory, households adjust their behaviour as they discover new commodities and their usefulness in household production processes.

The activities approach derived from the theory of the new household economics readily combines with the earlier input-output approach of Leontief (1941) to establish a series of household input-output tables as the framework for modeling household production.

4. *Measuring the Household Economy*

The measurement of the household economy emerged as a focal point for many researchers once the household was recognized as a major centre of production, not just consumption.

4.1 *Importance of Measuring the Household Economy*

In the 1970s a number of writers drew attention to the macroeconomic magnitude of the household economy. Boulding (1972) conceptualised households not only as the main driving force for the market economy, with household purchases covering about 60 percent of GNP, but also as the most important agent in the grants economy. This is the economy of one-way transfers, grants, or gifts, given mainly within households from those earning money incomes to other members, children, spouses, and dependants not earning a money income. Dependants receive clean, serviced accommodation, cooked meals, and clean clothes; the transfers are of transformed commodities purchased from the market which embody value added by household capital and labor.

In a perceptive book, *The Household Economy*, the American writer Scott Burns (1977) observed that 'the hours of work done outside the money economy rival those done inside and will soon surpass them.' Burns saw the household as the strongest and most important economic institution—healthy, stable, and growing. Alvin Toffler (1980) took a similar optimistic view of the household economy in his classic *The Third Wave* where he describes the many ways in which tasks are being driven back from the market to the household.

The pressure to transfer paid labor costs from the market to the unpaid labor costs of the household leads to the development of self-service petrol stations, automatic bank tellers, and Internet shopping. It also leads governments to support unpaid household-based care of sick, disabled, and elderly people instead of professional care in hospitals and nursing homes. Taxation of paid labor helps drive these technology and policy changes.

4.2 *Deficiencies in the National Statistics of Work and Production*

During the latter half of the twentieth century an almost unrecognized statistical revolution took place. At its heart was the System of National Accounts (SNA) that provides the framework for estimating GDP. Governments now spend millions of dollars collecting and publishing regular quarterly statistics of GDP and of the numbers employed in this production. These data permit comparisons of economic performance through time and between countries.

Statistics of GDP and employment are not only the common discourse of economists but have been elevated universally as major tools of economic and social policy including those operating at the international level through the International Labour Office, the International Monetary Fund, and the World Bank.

In the 1980s a number of writers exposed the deficiencies in statistics of work and production. Among these are Luisella Goldschmidt-Clermont (1982) and Ann Chadeau (1985). Perhaps the most strongly advanced reason for measuring household production is to make women's work visible as exemplified by Marilyn Waring's books *Counting for Nothing* (1988) and *Three Masquerades* (1996). Throughout the world, women provide most of the labor needed in household and subsistence production. All of this work is unpaid. On the other hand, in spite of increasing participation of women in paid jobs, most paid work is still done by men.

With few exceptions, the national statistics of work and production continue to ignore the unpaid labor and economic output contributed by women (and men) through household production. At least two-thirds of the work and economic production of women, half of the world's adult population, is excluded. Discussion of public issues such as gender equality, labor market policies, wages, and income policies, to name a few, is statistically misinformed. The point is made frequently that the increase in women's participation in paid work leads to overstatement of the increase in measured economic activity, because the reduction in household production is not counted (Nordhaus and Tobin 1973, Weinrobe 1974).

The SNA definitions used to measure production cover market transactions only. They exclude household production and make no allowance for the destruction of natural resources.

These omissions have been much criticized by the women's and environmental movements. Consequently, the UN Statistical Commission, in the 1993 revision of the SNA, has recommended that national statistical offices prepare accounts for economic activities outside the presently defined production boundary. 'Satellite' accounts separate from, but consistent with, the main SNA accounts of the market economy can be prepared to show the use of natural resources or the extent of economic production by households.

Demands for the full recognition of women's economic production culminated in the Platform for Action adopted in September 1995 at the Fourth World Conference on Women in Beijing. It enjoined 'national, regional and international statistical services and relevant governmental and United Nations agencies' to develop a more comprehensive knowledge of all forms of work and employment by:

Improving data collection on the unremunerated work which is already included in the United Nations System of National Accounts' and developing methods for 'assessing the values, in quantitative terms, of unremunerated work that is outside national accounts, such as caring for dependants and preparing food, for possible reflection in satellite or other official accounts (Platform For Action, Fourth World Conference on Women, Beijing, 1995).

As statistics currently used to measure work and valuable production are incomplete and misleading, new measures are required to produce more accurate statistical pictures.

4.3 *Methods of Estimating the Household Economy*

Some of the earliest estimates of the value of household services were those made for the United States (by Mitchell for 1919 and Kuznets for 1929) and for Sweden (by Lindahl, Dahlgren, and Korb for 1929 and earlier years); they simply multiplied the total number of households in rural and urban areas by the corresponding annual cost of hiring a domestic servant (Hawrylyshyn 1976).

The statistical offices of Denmark, Norway, and Sweden included household production in their national income estimates prior to World War II. Norway's estimates, started in 1912, were quite elaborate, valuing the unpaid work of married women on average wage income for unmarried women and widows in various age groups. They were discontinued in 1950 when the United Nations recommendations were adopted (Aslaksen and Koren 1996).

The Scandinavian view that the real economic production of goods and services included all goods and services produced by households, whether for their own use or for others, was unable to prevail in the debates about the initial standards for national income and product accounting. The market-based approach to GDP estimates continues. However, the way is clear through satellite national household accounts for separate estimates to be made of the value of household production, Gross Household Product (GHP).

The initial information base for such estimates is provided by surveys of the use of time on various household activities (Vanek 1974). International comparability of statistics of the uses of time was given a great boost by the cross-national time budget study in 12 countries conducted in the 1960s under the sponsorship of UNESCO and the International Social Science Council (Szalai 1972). Since then national statistical offices in many OECD countries have followed the Szalai methodology collecting diary-based national surveys of time use from representative samples of households.

The results show that the present statistics of employment greatly understate the volume of economic work needed. Surveys across 12 OECD countries covering various years from 1985 to 1992 show that the mean time spent in paid work was 24h per adult per week. The mean average unpaid work in the household economy was 26h per adult per week (Goldschmidt-Clermont and Pagnossin-Aligisakis 1995, Ironmonger 1995).

The representations of work provided by official statistics of employment are thus at variance with those from official statistics of work from time use surveys. In the main, official statisticians still report an

Table 1
Household productive activities, Australia, 1975–76 \$million

INPUT	Intermediate inputs		Factors of production		Total
	Materials	Energy	Labor	Capital

Source: Ironmonger D S (1989).

outmoded view that unpaid domestic work is somehow not ‘work’—only those working in the monetized market sector are counted as being ‘economically active.’

Three methods of imputing a value to the time used in household production have been used, all taking a wage per hour from the market economy. The first is the ‘opportunity cost’ wage that a person could be paid for doing an extra hour of work in a market job rather than an hour of unpaid household work. The cost of an hour of household work is the forgone opportunity to earn in the market. This method is usually rejected since it yields different values depending on who performed the task. The second method uses the wages of specialist paid workers who come to the household, e.g., a cleaner, a cook, a nanny, a gardener, to value the same tasks performed by household members. This ‘specialist replacement cost’ method can be criticized because these workers work more efficiently than a usual household member can, taking less time to perform the same task. Finally, a ‘generalist replacement cost’ method of valuation uses the wage rate for a generalist worker or housekeeper. This is regarded as more appropriate since the working conditions and range of activities are similar to those of household members.

Time-use surveys provide only one source of information about household production since they omit the contribution from nonhuman capital (the land, dwellings, and equipment owned by households). A more complete national accounting approach to measuring and modeling the household economy is required to cover all factors of household production, all intermediate inputs, and all the principal outputs.

5. National Household Accounts and Modeling the Household Economy

5.1 Extended National Accounts

A number of scholars have suggested that national

accounts needed extending to cover missing non-market household production. Essentially, they viewed household production as a missing part of the estimates, not a separate economy. Robert Eisner and co-workers at Northwestern University conducted the most extensive work on these lines in the 1980s. Their research culminated in the book *The Total Incomes System of Accounts* (1989). Eisner’s estimates for the United States make clear the greatly expanded role, in total economic product, of households. United States GHP in 1981 was put at \$1709 billion, 37.5 percent of the extended GNP of \$4560 billion.

5.2 Household Input–Output Tables and Satellite Household Accounts

Household production is best considered as the production of goods and services by a separate economy, complementary to and competitive with the market economy. Every country can be analyzed as two linked economies. The household sells labor to the market; it uses the money income to purchase intermediate commodities from the market which it transforms into items of final consumption through the use of its own unpaid labor and its own capital goods.

The household economy can be studied as a set of six industries providing accommodation, meals, clean clothes, transport, recreation, and care in competition with parallel market industries. Activities such as shopping and cleaning are simply ancillary activities to the principal final outputs of the household economy.

The input–output approach to measuring and modeling the industries of the market economy associated with the work of Leontief (1941) has been applied to measuring and modeling the industries of the household economy. This was started in Australia for Australian households (Ironmonger 1989). Input–output tables showing the uses of labor, capital, energy, and materials in each of the main and ancillary industries of the household economy have now been

prepared for Australia, Canada, Finland, Norway, and the United States.

How the household economy uses time, materials, energy, and capital can be seen from the Table 1 adapted from the first published household input–output table. This is for the Australian household economy. The household input–output tables are exactly the satellite accounts that have been recommended in the 1993 revision of the SNA and in the resolution of the Platform for Action of the 1995 Beijing Women's Conference. The world statistical agencies need to establish standardized methods of estimating GHP.

6. Household Production and a World of Binary Economies

The major scientific achievement of this field has been the measurement of the magnitude of household production through surveys of the uses of time. Household production is now recognized as an alternative economy to the market; in many countries the household economy absorbs more labor and at least one-third the physical capital used in the market economy.

In future, national statistical organizations will produce regular estimates of GHP. Data on outputs of household production—accommodation, meals, clean clothes, and the care of children and adults—will complement data on inputs of unpaid labor and the use of household capital.

Proper recognition of the household economy will have arrived when national household accounts are published each quarter alongside national accounts for the market economy. These data will enable greater scientific research on the organization of household production, the interactions with the market economy, the role of households in building human capital, on the effects of household technology, alternative social and economic policies on gender divisions of labor, and on family welfare.

Housing Economics

Housing has a set of characteristics which together make it different from all other commodities.

(a) *Necessity*: Housing satisfies a basic human need, shelter.

(b) *Importance*: Most households spend more on housing than on any other class of commodity.

(c) *Spatial fixity*: Most housing units are rooted to a particular location. Living in a particular housing unit, a household therefore consumes not only the characteristics of the housing unit *per se*, but also the characteristics of its *location*—its neighbors and neighborhood, its accessibility to other locations, its taxes and public services, and its locational amenities and disamenities.

(d) *Durability*: Housing is the most durable of major commodities. If built soundly and maintained well, a housing unit will last virtually indefinitely.

(e) *Heterogeneity and complexity*: To describe a housing unit reasonably accurately requires enumerating very many characteristics (complexity). Also, housing units exhibit considerable heterogeneity in characteristics, and households considerable heterogeneity in tastes.

(f) *Housing as an asset*: Because housing is durable and the expenditure share on housing high, the housing stock constitutes a substantial proportion of a nation's wealth and of most households' portfolios. The demand for housing therefore combines consumption and asset motives.

(g) *Housing and the macroeconomy*: Since housing is durable, modest fluctuations in housing demand translate into large fluctuations in housing investment. Due to the importance and volatility of housing investment and the magnitude of the wealth effects generated by movements in housing values, the performance of the housing market has a major impact on the macroeconomy.

The interactions of these characteristics cause the economics of housing to be significantly different from the economics of other commodities. Section 2 will examine the supply of housing and Sect. 3 the demand. Section 4 will discuss how supply and demand interact to determine equilibrium in the housing market. Section 5 will look at the housing market from the perspective of real estate economics. Section 6 will consider the role of government with respect to housing.

1. Housing Supply

Before discussing how housing is supplied, a quantifiable definition of 'housing' is needed. The appropriate definition depends on context. In some contexts, highly aggregated definitions that ignore housing heterogeneity—the number of units or total floor area—are most useful. In other contexts, each housing unit is usefully viewed as a bundle of many characteristics. In yet other contexts, intermediate levels of aggregation are most helpful. The definition employed strongly influences the way the market is conceptualized and housing supply and demand described.

Most housing economics is conducted at a high level of aggregation. A nation's monetary authority is interested in the value of the nation's housing stock and the level of housing investment, not in where housing units are located within cities or how many units have two bedrooms. Similarly, the government's housing ministry is principally concerned with housing affordability, crowding, sanitary facilities, and structural soundness, and not in how many units have fireplaces.

At the highest level of aggregation, a housing unit is described simply by the flow of housing services it provides, which can be measured by its rent. Holding its characteristics fixed, an increase in the unit's rent corresponds to a rise in the price of housing services. A housing supply curve may then be defined relating the units of housing services supplied to the price of housing services. Because housing is durable, the elasticity of the housing services supply curve depends on the time horizon. Within, say, a month, the housing supply curve is almost vertical; little can be done beyond maintenance to increase the quantity of housing services supplied. As the time horizon increases, the housing services supply curve becomes increasingly elastic; within six months, a rise in the price of housing services will induce some rehabilitation; within a year, some new housing will be constructed; etc.

In many situations, the analyst is concerned with the interaction between particular housing submarkets. For example, the government might be interested in the effects of a subsidy on owner-occupied housing. To analyze this policy, the housing market would be divided into owner-occupied and rental submarkets. The two submarkets would interact on both the supply (the subsidy would encourage the conversion of housing from rental to owner occupancy) and demand (the subsidy-induced fall in the consumer price of owner-occupied housing services would cause a decrease in rental housing demand) sides. Other divisions of the housing market into submarkets are appropriate in other contexts. If the government is concerned with the living standards of the poor, the housing market is usefully divided into quality submarkets; if it is concerned with downtown revitalization, a division into downtown and suburban submarkets is suitable; etc.

The discussion thus far has treated the supply for housing services—a flow. Lurking in the background is the supply of housing stock. The two are related through the user cost of capital, which is the ratio of the annualized cost of employing a unit of capital to its supply price, and equals the interest rate plus the rate of depreciation plus the maintenance cost rate plus the effective tax rate on capital less the rate of capital gain.

In the short run, rent adjusts to clear the market for housing services. This translates, via the user cost of capital, into the equilibrium asset price or market value of housing. If this exceeds construction cost, new

construction is triggered, which increases the supply of housing stock and of housing services, causing rent to fall. This process continues until a long-run equilibrium is attained where the market-clearing rent equals construction cost times the user cost of capital.

The above conceptualization of the housing market is especially well-suited for aggregate analysis. The remainder of the section reviews several alternative conceptualizations, each of which has its particular domain of application.

The focus of the Mills–Muth model (see Mills (1972) and Muth (1961, 1969), and Brueckner (1986) for an integrative treatment) is on urban spatial structure—how housing density (the ratio of floor to land area), housing rent, and land rent vary with location. Ignore the spatial fixity and durability of structures, so that static analysis can be applied. A landowner adds capital to his land until marginal cost equals marginal revenue. Under competition land rent equals the corresponding producer's surplus. This analysis relates land rent and housing density to housing rent at a particular location. Now turn to the market. Housing rents adjust so that in equilibrium at each location the quantity of housing supplied equals the quantity demanded, with more attractive and accessible locations commanding higher rents. Then from the relationship between housing rent and housing density, the equilibrium urban spatial structure is obtained.

The Mills–Muth model ignores the durability of structures. A related class of models, reviewed in Brueckner (2000), examines the spatial structure of a growing city, accounting for durability. A developer who owns vacant land then faces the decision of *when* to build as well as at what density. The relationship between predevelopment land value and postdevelopment housing value and density can be straightforwardly derived. Normally vacant land is developed from the center outwards. Subsequently, there are successive waves of redevelopment. Each wave entails construction at higher density with the time between waves depending on the city's growth rate. This process is evident in some cities but in others has been curtailed by redevelopment restrictions.

The Mills–Muth model and dynamic durable housing models treat location, housing density, and unit size. Housing units also differ in quality. If two housing units of the same size at the same location command different rents, the higher-rent unit is presumably of higher quality. Since the poor typically live in low-quality housing, quality differentiation is particularly important to consider when evaluating policies aimed at improving low-income housing. Models of housing quality differentiation examine the filtering process (Grigsby (1963)). An urban location goes through a life cycle. Housing is of high quality when constructed but depreciates with age, and as it does so is occupied by successively poorer households. Eventually, rehabilitation/renovation or redevelopment of the site at higher density becomes profitable, and the cycle

repeats. Since the typical neighborhood was initially developed in a short time span, the filtering process gives rise to neighborhood cycles too.

More recent filtering models (Sweeney (1974), Arnott et al. (1983), and Rothenberg et al. (1991)) view the housing market as a hierarchy or continuum of quality-differentiated submarkets. At any instant, the housing market is described by the housing stock at the various qualities. Rent as a function of quality adjusts to clear the market. Construction occurs at those qualities where housing value equals or exceeds construction costs. Maintenance is carried to the point where the last dollar spent increases housing value by one dollar, and a housing unit's price is the present discounted value of rent less maintenance expenditures. These models can be enriched to treat land, as well as housing differentiation by unit size, location, and density (Anas and Arnott (1991)).

Filtering models provide a strong conceptual basis for policy analysis and are intuitively appealing, accommodating all the standard housing conversion processes—construction, maintenance, rehabilitation, upward and downward conversion (combining and subdividing housing units), abandonment, and demolition and reconstruction. Despite their popularity among academic housing economists, filtering models have not yet been widely adopted by the housing policy community.

Working with detailed descriptions of housing units is normally distracting, but in measurement is essential. The minister of housing may be uninterested in whether the poor have fireplaces (as long as they receive heat), but will be interested in whether the average quality of low-income housing has increased. This requires obtaining a quality index, an aggregate of many housing characteristics—including fireplaces. Investors, housing policy analysts, and macroeconomists are all concerned with the time trend of housing prices, which requires developing price indices. And for property tax purposes, housing values need to be estimated accurately, which necessitates detailed description. Hedonic analysis utilizes such detailed description. The market values (or rents) of housing units are regressed against a long list of their characteristics (including public services, neighborhood and neighbor characteristics, accessibility measures, and environmental variables). The regression coefficients are interpreted as implicit market prices for characteristics (Rosen (1974)). Hedonic analysis has proved very useful not only in housing valuation and housing price and quality index construction, but also in inferring the market's valuation of various neighborhood characteristics, public services, air quality, etc. But the implicit conceptualization it employs—separate markets for each of hundreds of housing characteristics—is unwieldy for most housing policy analysis.

Industry studies focus on market organization—industry concentration and the form of strategic interaction between firms. The conventional wisdom

that the housing market is competitive or monopolistically competitive, while inadequately researched, appears sound.

2. Housing Demand

The previous section indicated that how housing supply is described depends on how housing is conceptualized. The same is true of housing demand. Most housing demand studies employ the housing services conceptualization. Accordingly, there is a vast empirical literature estimating the income and price elasticities of demand for housing services. Excellent reviews are provided in Goodman (1996) and Olsen (1986). Muth, whose classic *Cities and Housing* (1969) provides the foundation of modern housing analysis, has argued that since the housing expenditure share has shown remarkable stability over time and location—about 25 percent of after-tax income—the long-run price and income elasticities of housing must be close to unity. Most empirical studies, however, estimate significantly lower price and income elasticities. How can the results of these empirical studies be reconciled with Muth's observation?

The literature has concentrated on four classes of explanations.

(a) With high moving costs (including psychic costs), a household does not instantaneously change its housing when its income or the price of housing changes; rather, housing decisions are long-term. This explains why experiments investigating how households alter their housing consumption under temporary rent subsidies have found a generally price-inelastic response. Relatedly, the demand for housing should depend more on permanent than on transitory income.

(b) That many moves are triggered by demographic change (e.g., marriage, births, retirement, and divorce) makes it more difficult to identify the economic determinants of housing choice.

(c) Tenure choice with borrowing constraints (e.g., Jones (1993), Ortalo-Magné and Rady (1999)). The typical household starts its lifecycle by renting, often under-consuming housing to save up for a down-payment. Having saved up enough, it moves into a starter home, aiming to trade up when it can afford to. The timing of these moves depends on the realization of the household's uncertain income prospects and demographic changes and on the evolution of housing prices, interest rates, and down-payment requirements.

(d) The asset or portfolio demand for housing. When deciding how expensive a home to buy, a household considers how much housing it would like to include in its wealth portfolio. A household's demand for owner-occupied housing achieves a balance between its consumption and portfolio demands. Households adjust the discrepancy between these

demands through tenure choice, customization and furnishing (Henderson and Ioannides (1983)). A household whose asset demand exceeds its consumption demand may purchase a large home but spend little on decoration, or may purchase additional housing units and rent them out. A household whose asset demand falls short of its consumption demand may choose either to own a cheaper house and decorate it nicely or to rent.

Estimating price and income elasticities accounting for all these complications, as well as the tax treatment of housing, is indeed a daunting task. Despite these difficulties, considerable progress has been made in the empirical analysis of housing demand, reflecting advances in data collection, computing power, applied econometrics, and housing economic theory, and the use of controlled experimentation. Regrettably, however, little work has been done on estimating filtering models (Rothenberg et al. (1991) is a notable exception), which has impeded their use in policy analysis.

3. Housing Allocation and Markets

Throughout history, most consumer goods have been allocated through markets. The twentieth century witnessed a sharp rise in the size and scope of government. The communist countries adopted central planning, which entailed government construction, operation, and direct allocation of housing. Elsewhere too, government intervention in the housing sector increased. The pendulum has started to swing in the opposite direction, but by historical standards government intervention in the housing sector remains high. Even in the United States, with the most free-market of western economies, much low-income housing continues to be allocated outside the market, and the allocation of market housing to be deliberately influenced by a myriad of government policies.

Why have governments everywhere doubted the ability of markets to allocate housing? Textbooks in microeconomic theory give a standard list of (classic) market failures or inefficiencies—public goods, natural monopoly, and technological externalities. None is important in the context of housing. The primary motive for extensive government intervention vis-à-vis housing has rather been to improve equity. Some believe that the income distribution generated by the free market is just but most do not. How then is equity to be achieved within a generally market-oriented economy? There are two broad approaches. One is income redistribution, general egalitarianism; the other is effective redistribution through the taxation/subsidization or nonmarket allocation of specific commodities, specific egalitarianism. Most economists favor general egalitarianism because it respects consumer sovereignty. But most governments evidently favor specific egalitarianism. They—and the person

Figure 1
Equilibrium bid-rent curves

on the street—feel that the consumption of some goods (basic housing, clothing, food, education, and medical care) is more meritorious than others (alcohol, cigarettes, drugs, and luxuries). Many governments have favored the nonmarket allocation of housing over subsidization, because it permits more refined targeting and is administratively simpler. There has been remarkably little modern economic analysis of nonmarket housing allocation (Anas and Cho (1988) is a notable exception). The rest of the section will therefore consider market allocation under competition.

The relevant economic theory was developed by Alonso (1964). He asked: How does the market determine the pattern of household location within a city? Suppose that there are two household groups, rich and poor, that each household derives utility from only other goods and housing floor area, and that locations differ only in accessibility. In equilibrium, all rich households achieve the same utility level, U^R . Associated with this utility level is the equilibrium housing bid-rent curve for the rich, which indicates the housing rent (per unit floor area) payable by the rich at different locations consistent with this utility level. Similarly, in equilibrium, all poor households achieve the same utility level, U^P , associated with which is their equilibrium housing bid-rent curve.

Two basic principles apply: (a) A housing unit goes to whomever bids the most for it; and (b) rent equals the bid rent of whomever bids the most for it. The top panel of Fig. 1 plots the equilibrium bid-rent curves for the two groups as a function of accessibility, a . Applying the two principles implies that housing between accessibility levels a' and a'' goes to the rich and that between a'' and a''' to the poor, and that housing rent as a function of accessibility is given by the 'upper envelope' of the equilibrium bid-rent curves. The lower panel of the figure shows the stock of housing available at different accessibility levels. The equilibrium utility levels are determined by the conditions that, for each group, the quantity of housing

demanded equals the quantity of housing supplied. The slope of a group's housing bid-rent curve is the premium that group is willing to pay for improved accessibility. As drawn, the poor outbid the rich at more accessible locations because they are willing to pay a higher premium per unit floor area for improved accessibility. This result has been used in explaining the post-World-War-II suburbanization of wealthier US households.

The accessibility-rent tradeoff is central in determining the pattern of household location. The above analysis can be extended to treat other factors, such as the relative value different groups attach to amenities, disamenities, public services, and neighborhood composition. Each group has an equilibrium bid-rent surface over all locations within the metropolitan area, and lives where it outbids all other groups. Groups may differ not only in income but also in demographic status, race, job location, etc. Extending the analysis to account for taste heterogeneity within groups yields the probabilities that a particular location is occupied by a household in a particular group. The same competitive allocation mechanism operates with respect to other housing attributes. A household group occupies housing of a particular quality, for example, if it outbids all other household groups.

The asset value of a housing unit is the discounted present value of expected future rents minus expected costs, adjusted for uncertainty. The volume of construction depends on profitability, as measured by asset price minus supply price; similarly, the volume of rehabilitation depends on the gain in asset price through rehabilitation minus the cost; and maintenance expenditure depends on how steeply housing value rises with quality.

The above discussion indicates how a perfectly competitive housing market works. In actual housing markets, housing units and households exhibit multi-dimensional heterogeneity. To find a unit that suits its tastes, a household undertakes costly search over vacant units. The friction of search confers market power on landlords, who are consequently price-setters rather than price-takers. With entry and exit close to free, actual housing markets are therefore more accurately described as monopolistically competitive, with excess capacity taking the form of vacant units. Furthermore, housing markets are matching markets, with market tightness (the ratio of searching households to vacant units) playing an important role in the market adjustment process (Anglin and Arnott (1999)). Down-payment requirements on mortgages and credit restrictions on developers also significantly affect the market's operation.

Whether the gain in accuracy from treating the housing market as monopolistically rather than perfectly competitive justifies the increased analytical complexity is an empirical issue and depends on context. Normally little is sacrificed in using perfectly competitive models to analyze the positive effects of

specific housing policies. But imperfectly competitive models should be used to provide microfoundations for housing macroeconomics since nonprice adjustment is important, and to evaluate welfare changes from housing policies.

In the frictionless world of perfect competition, and without taxes, a household would be indifferent between renting and owning. That tenure choice is in fact important indicates that it should be considered from the perspective of imperfect competition. Though often treated in the context of housing demand, tenure choice is an aspect of market equilibrium since it concerns the contractual form through which housing services are exchanged. Rental and single-family owner occupancy are the most common contractual forms; others include condominium ownership (under which common areas are jointly owned) and cooperative ownership (under which a resident is essentially a shareholder in the building).

4. Real Estate Economics

Real estate economics is superbly surveyed in DiPasquale and Wheaton (1996). How does residential real estate economics differ from traditional housing economics? Both are concerned with the housing sector, but real estate economics regards it from an investment perspective, housing economics from a policy perspective. At the beginning of the twenty-first century much of the best research on the economics of housing is being done under the rubric of real estate economics.

One important development has been the extension of real estate investment theory to treat uncertainty satisfactorily. Because real estate investment decisions are made under uncertainty and are largely irreversible, they are usefully viewed as the exercise of real options (Titman (1985), Capozza and Li (1994)), to which the theories of options valuation and irreversible investment can be applied.

Most housing economics is microeconomics applied to the housing sector. But housing macroeconomics is important too. Housing macroeconomics is concerned with the relationships between housing macroeconomic variables (stock, starts, completions, vacancy rates, average rents, etc.), and with how fluctuations in economy-wide variables affect the housing sector, and vice versa. Most large-scale macroeconomic forecasting models of the 1960s contained a housing module. After a period of inactivity, housing macroeconomics has reappeared on the research agenda—in real estate economics, as the study of residential real estate cycles. Current work (e.g. Stein (1995)), and DiPasquale and Wheaton (1996)) suggests that the amplitude of fluctuations in residential real estate values and investment is sensitive to the severity of borrowing constraints and the form of expectations.

Real estate economists have also explored the interlinkages between the real and financial sides of

residential real estate markets, and the design of optimal contracts, considering incentive, selection, and risk-sharing effects, between banks and borrowers, developers and contractors, landlord and tenants, and between the sellers and buyers of houses and real estate agents.

5. Housing Policy

Housing policy debates tend to pit economists against planners. The divisions between the two groups are social philosophical. Since economists value individual freedom to choose, they hesitate more than planners in imposing their vision of the good life on others. Also, economists generally emphasize efficiency and believe it is best achieved via markets, with government enforcing property rights and intervening minimally to mitigate market failure, while planners tend to be suspicious of markets and to object to the inequities and apparent disorder they generate. For all these reasons, planners almost invariably favor more government intervention than do economists.

The planner's view dominated housing policy in western Europe from the 1920s through to the 1980s, especially in the Scandinavian countries where housing markets were largely supplanted by government allocation. The objective of decent and affordable housing for all was largely achieved, but at the cost of considerable inefficiency. During the last decade, these countries have been dismantling the Byzantine allocative and regulatory structures which had evolved, and moving to increasingly free housing markets. Thus, the economist's view is currently in the ascendancy.

Economists' belief in the efficiency of markets is at least well-reasoned. Two central results in microeconomic theory are the First Theorem of Welfare Economics, which states that under perfect competition a market equilibrium is efficient, and the Second Theorem, which states that (under convexity conditions) any efficient allocation can be achieved as a competitive equilibrium with appropriate lump-sum redistribution. If, therefore, an economy satisfies the Theorems' conditions, efficiency and equity can be simultaneously achieved if the government only enforces property rights and redistributes income appropriately, leaving everything else for markets to do, and almost all government intervention in the housing sector is harmful. Whether real world economies come close to satisfying the Theorems' conditions is clearly crucial in determining the appropriate role of government in housing provision, and therefore needs to be considered very carefully.

In the 1960s most neoclassical economists believed that, since buyers and sellers are many and entry and exit free, housing markets are almost perfectly competitive. Most housing economists in the late twentieth century would disagree. Housing markets have many

characteristics which violate the assumptions of perfect competition: housing is a heterogeneous good; transactions costs are important; asymmetric information is endemic; and insurance and futures markets in housing are highly incomplete. As well, because the government cannot observe an individual's 'need' but must instead infer it from a signal (e.g., income) which she can manipulate, all redistributive policies are distortionary. Equity is then most efficiently achieved through a portfolio of policies, including perhaps housing assistance for the poor. Since the optimal portfolio is sensitive to details of the economic environment, housing economists nowadays tend to base their policy advice as much on the results of controlled experiments and empirical studies as on *a priori* reasoning. While consideration of market imperfections expands the scope of potentially ameliorative government intervention, the political economy literature warns that government, too, is highly imperfect.

Government withdrawal from the housing sector has been especially pronounced in direct housing provision. The current view is that low-income housing projects were a mistake. They led to the alienation and ghettoization of the poor, and were excessively costly (since it is efficient for the poor to live in filtered-down housing). Low-income housing policy in the United States today encourages household mixing by race, ethnicity, and income, through subsidizing the nonpoor to live in the projects and the poor to move into middle-income neighborhoods. Other countries are experimenting with selling project units for owner occupancy.

A classic debate in housing economic policy is whether intervention is more effective on the demand or supply side of the market. Generally speaking, housing demand policies can achieve better targeting, but may drive up rents in the short run until the lagged supply response kicks in.

Virtually all housing policies apply to either rental or owner-occupied housing but not both. Most policy makers encourage homeownership, believing it to foster social behavior, civic responsibility, and commitment to neighborhood. The empirical evidence is, however, weak since controlling for the effect that responsible and well-functioning households are more likely to choose homeownership is difficult. Homeownership is encouraged through subsidized and guaranteed mortgages, mortgage interest deductibility under the income tax, tax inducements for first-time homeownership, and subsidies for home improvements.

There are several other elements common to the housing policy debate in most countries.

(a) *Rent control*: (reviewed in Arnott (1995)) Economists have been virtually unanimous in their opposition to traditional (now termed 'first-generation') rent controls, which impose ceilings on rents below market-clearing levels. Almost all jurisdictions which have had first-generation rent controls have either dismantled them or replaced them with second-generation pro-

grams which stress tenant security rather than rent reduction.

(b) *Tax policy*: Most countries use tax policies to achieve housing policy goals.

(c) *Eviction rights vs. security of tenure*: The nature of the landlord-tenant relationship bears the seeds of conflict. Policy concerning eviction for nonpayment of rent entails a classic tradeoff between risk sharing and incentives. Predictably, relative to the United States, European jurisdictions favor the tenant.

(d) *Zoning, building codes, and density and height restrictions*: These significantly affect the spatial pattern of rents and hence household location by income-demographic group. In many cities, height and redevelopment restrictions have forced up downtown property values, driving many poor households previously resident there to surrounding locations. Also, affluent North American suburbs have used minimum lot size zoning and other regulations to exclude the poor.

(e) *Antidiscrimination*: Housing audits have been used in the United States to identify discrimination. A pair of individuals, one of whom belongs to a potentially discriminated-against group, are paid to pose as prospective tenants or prospective homebuyers and are given the same resumé; differences in their treatment are then attributed to discrimination. Also, recent empirical research has attempted to identify discrimination by banks in mortgage lending.

(f) *Homelessness*: In most western countries, homelessness is now a very visible housing problem. While many causes are sociological—the weakened bonds of family and community, higher mobility, deinstitutionalization of the mentally ill, and increased drug use—economic causes are important too (O'Flaherty (1996)). The withdrawal of governments from the housing sector has caused low-quality housing rents in many cities to rise so much that homelessness is a rational response for some very low-income individuals and households.

Human Behavioral Ecology

Human behavioral ecology (sometimes referred to as evolutionary ecology) is the application of evolutionary biological models to the study of behavioral variation in humans. Evolutionary approaches to the study of human behavior fall under a variety of names such as sociobiology, biosociology, biocultural or biosocial science, human ethology, socioecology, and

evolutionary psychology (Cronk 1991, p. 25). While some of these names are synonyms others represent different emphases that will be described below. Human behavioral ecology attempts to explain behavioral diversity as a consequence of environmentally contingent responses made by individuals in their attempts to maximize their inclusive fitness. Critical to this goal is the specification of environmental factors that constrain an individual’s attempt to maximize fitness. As a consequence, individuals develop behavioral strategies designed to solve a variety of adaptive problems set by nature such as producing food, mating, investing in offspring, and managing social interactions between offspring, mates, kin, and unrelated individuals.

1. Origins and Early History of the Field

Behavioral ecology is a relatively new discipline and, for the most part, it is practiced by anthropologists. The publication of E. O. Wilson’s *Sociobiology* (1975) along with the earlier work of biosocial anthropologists such as Robin Fox and Lionel Tiger (Cronk 1991) and evolutionary biologist Richard Alexander (1974) were critical in stimulating interest in applying Darwinian approaches to the study of human behavioral diversity. Very quickly Wilson’s sociobiological approach was found to be limiting because it was largely based on older ethological approaches which posited relatively simple, general, and rigid models of the relationship between genes and human behavior (Winterhalder and Smith 1992, p. 9). This was especially apparent in his final chapter of *Sociobiology* (1975, pp. 547–75) where he considered humans. Here he suggested that certain behavioral traits such as territoriality among foraging peoples were universal (1975, pp. 564–5). This claim and the approach that generated it was shown to be limited in a paper by Dyson-Hudson and Smith (1978), a paper which represented perhaps one of the earliest applications of behavioral ecology to the study of human behavioral variation. Using a cost-benefit model developed by the avian behavioral ecologist J. Brown, they showed that territoriality was variable among tribal populations and was determined by specific environmental factors consistent with evolutionary theory.

As will be more fully described below, environmental cost-benefit approaches in the context optimization models is at the core of much of behavioral ecology. It is vital to understand that behavioral ecology is a branch of evolutionary biology and the core of evolutionary biology is about changes in the frequencies of genes through time. However, behavioral ecology is agnostic about the causative role of genes in the study of human behavioral variation. This position was clarified by Alan Grafen (1984) with his notion of the phenotypic gambit. Phenotypic variation

is shaped by an individual's genotype interacting with a variety of cultural, developmental, environmental, and other non-genetic factors. The degree to which variation in any trait is a consequence of genetic variation is not directly relevant to the formulation or evaluation of behavioral ecological models. This approach is consistent with analyses in non-human behavioral ecology (Alcock 1989).

1.1 Relationship to Other Fields Using Evolutionary Approaches to the Study of Human Behavioral Variation

The new field of evolutionary psychology (Barkow et al. 1992), and, to some extent, its congener human ethology, is often inappropriately confused with behavioral ecology and sociobiology, and it is useful to distinguish between these complementary Darwinian approaches to the study of human behavioral variation. Behavioral ecology attempts to develop hypotheses regarding variation in behavioral strategies that individuals employ to maximize their inclusive fitness. In many studies the central focus is on the reproductive consequences of behavior. In contrast, evolutionary psychologists are interested in elucidating the cognitive mechanisms (or mental modules) that evolved in humans in the 'environment of evolutionary adaptedness.' This concept stresses the fact that all adaptations are to historic environments and whether traits developed in the past are adaptive in current environments is problematical. As a consequence, evolutionary psychologists seek to uncover those mental modules that were designed by natural selection to solve problems such as: What criteria do people use to select mates? How does mate selection criteria differ between the sexes? What factors induce individuals to continue or abandon mating relationships? From this perspective, the reproductive consequences of behavior are not of concern. Other differences distinguishing these fields include behavioral ecology's reliance on naturalistic fieldwork in contrast to questionnaire survey and laboratory experiment, and the relationship between behavior and fertility. Winterhalder and Smith (2000) should be consulted for a more detailed examination of the assumptions, methods, and goals of these fields.

Dual inheritance theory (Boyd and Richerson 1985) is founded on the realization that cultural traits or memes are in some sense identical to genes because both are replicators that use vehicles (bodies) to transmit themselves across generations and are subject to selective forces. Cultural traits differ from genetic traits in their mode of transmission: they may be transmitted from mind to mind through natural selection of carriers of the trait (the trait has a positive effect on fitness), through emulation of high status people who exhibit the trait, by coercion, or by psychological

mechanisms that make the trait desirable or habit forming (e.g., various addictions). In addition, cultural traits may be transmitted laterally within generations instead of lineally through generations allowing them to spread more rapidly. Compared to behavioral ecology and evolutionary psychology little empirical work has been done employing dual inheritance models.

1.2 Relationship to Traditional Social and Behavioral Sciences

Behavioral ecology is distinguished from traditional anthropological and social science theory in its emphasis on the individual as the unit of selection and the idea that much of the content of culture is a consequence of decisions by individuals to enhance their inclusive fitness. Ever since its founding as a discipline, anthropologists have argued that individuals sacrifice themselves to enhance the integration or survival of the social systems in which they participate or are much like puppets or robots manipulated by culture (Cronk 1991). Furthermore, any attempt to reduce or link cultural behavior to lower levels of analysis was specifically condemned. Human behavior was believed to have emergent properties irreducible to the facts of psychology and biology. While it is clear that some dimension of human behavior are not usefully reduced to underlying psychological or biological processes simple observation tells us that humans are biological and psychological entities and some of the behavioral diversity can be usefully linked to underlying levels of analysis.

1.3 Theoretical Armamentarium

Behavioral ecology is strongly informed by a series of theoretical breakthroughs that developed in the early 1960s and 1970s in the evolutionary analysis of social and foraging behavior. These include inclusive fitness (or kin selection, Hamilton 1964), reciprocal altruism (Trivers 1971), sexual selection and parental investment (Trivers 1972), sex biasing in parental investment (Trivers and Willard 1973), optimal foraging theory (Winterhalder and Smith 2000), and, most recently, life history theory (Stearns 1992). These papers clearly demonstrated that behavioral variation was an apt subject for investigation from an evolutionary perspective consistent with the modern synthesis and a gene centered view of evolution. Early on in the development of behavioral ecology there was considerable expectation that kin selection would inspire considerable research especially in the areas of food exchange and other forms of cooperative behavior. As will be evident below, few studies have made kin selection a central focus of investigation.

2. Areas of Application

2.1 Foraging Theory

Human dietary selectivity has been a fundamental area of interest for anthropologists because of its strong implication for the structuring of social relations among hunter-gatherers, group size, mobility patterns, and our understanding of economic dimensions of human evolution. One of the earliest applications of behavioral ecological research came with the application of optimal foraging theory (OFT) in the study of hunting, fishing, and gathering (or foraging behavior) among modern hunter-gathers and foraging horticulturalists. OFT allows researchers to develop a large set of fundamental hypotheses that predict which food resources foragers will pursue when encountered during a search (diet breadth), or where foragers will travel to search for resources (patch choice models) and how long they will stay in these places before moving to other areas (marginal value theorem). These models assume that foragers have a goal, which is to maximize their net rate of return while foraging because by doing so they are ultimately able to maximize their fitness. The rate of return is indexed by a currency such as calories or another attribute of food value (e.g., Hill 1988). This assumption is reasonable because food resources are fundamental to survival and reproduction for one of two reasons. When the environment is poor, humans can be said to be 'resources limited.' Therefore, maximizing one's net rate of return allows foragers to acquire the greatest amount of food while foraging. On the other hand, when the environment is relatively rich, humans may be 'time limited' such that efficient acquisition of food resources leaves foragers with more time to engage in alternative fitness enhancing activities such as child care (Winterhalder and Smith 2000).

There have been a number of qualitative and quantitative tests of optimal foraging models applied to the problem of diet breadth (Hill and Kaplan 1992). Qualitative tests predict directional tendencies in prey choice by showing that diet breadth (the number of different species that will be pursued upon encounter), for example, will expand or contract depending on the encounter rates of highly profitable species (Winterhalder and Smith 2000). Quantitative tests predict the precise number of species a forager will pursue under a variety of environmental conditions (Hill and Kaplan 1992), which species will enter or drop out of the optimal diet breadth, and the exact rank-ordering of species in the diet breadth. Most studies of diet breadth show a division of labor between men and women, and children and adults (Hill and Kaplan 1992) which seem to be based on game versus vegetable products for the former and skill and strength levels for the latter.

Although OFT was designed to account for foraging behavior in animals and then later extended to human foraging, recent applications have been made in the areas of the origins of agricultural and pastoral food production with considerable success (Winterhalder and Smith 2000). It has rekindled anthropological interest in the problem of conservation among native peoples. Thus far, research indicates that true conservation is rare among native peoples but even more importantly researchers are attempting to specify the conditions under which conservation is likely to emerge and an adaptive strategy.

2.2 Group and Resource Transfer

The movement of goods, and, to some extent, services, between families and individuals has received considerable attention by behavioral ecologists. Traditionally such research is subsumed under the terms of exchange or reciprocity. Behavioral ecologists term such activities transfers because it more neutrally characterizes resource movement between groups and/or individuals compared to traditional terms such as exchange or reciprocity (which assume that the transfer of good or services between individuals will be returned in some material form at some point in time). In the analysis of transfers, one assumes that giving or yielding a resource that one has acquired will be done such that acquirer of the resource gains something in return or avoids a cost in defending that resource. As a consequence, models of transfer assume that the benefits of giving are greater than the costs of monopolizing the resource. The models of transfer developed thus far include (a) scrounging (or tolerated theft); (b) risk minimization; (c) trade or exchange; and (d) the show-off hypothesis.

At one extreme, coercive models of scrounging or tolerated theft assume that the resource acquired cannot be easily or effectively defended against those who lack resources and that the benefit of giving or yielding a portion of the resource presents a higher payoff than the cost of defending it against another who are in greater need and thus more willing to contest the resource. At the other extreme are models of sharing, which assume that individuals give resources to others contingent upon an expectation that something of value will be returned to the giver in the future. For example, when resources cannot be predictably acquired (especially true in hunting) risk minimization or pooling strategies are employed through the mechanism of reciprocal altruism. Individuals who acquire resources share with those who have been unlucky in the hunt with the expectation that in the future should they return home without game others who have acquired game will share with them. Kin selection models have been used to explain why resource transfers tend to be biased toward close kin; sexual selection models (e.g., 'show off hypothesis') argue that actors attempt to acquire large but

high-variance resource packets (e.g., large game animals) to demonstrate their desirability as a mate; and trade models suggest that transfer occurs through specialization via the mechanism of reciprocal altruism.

2.3 Mating Strategies

Models of mating or marital strategies, in one form or another, are largely founded on the polygyny threshold model (Winterhalder and Smith 2000, p. 64). This model is relevant when males differentially control resources necessary for successful reproduction. The polygyny threshold model predicts that females will select mates according to the quantity of resources they control. In this situation, polygyny will emerge among those males who can offer more resources to females than unmarried or monogamous males. In short, wealthy males are much more likely to mate polygynously than poor males. In most cases, ownership of material resources (e.g., agricultural land) or high productive productivity (e.g., ownership of large herds) is what differentiates poor from wealthy men. However, in some societies where economic stratification is absent, some men are nevertheless exceptionally productive (e.g., excellent hunters) or have achieved political power or status (e.g., distinguished warriors, leaders, or shamans) and this may be the differentiator between polygynous and monogamous men.

The polygyny threshold model assumes female choice in marital affairs. In some cases this assumption is clearly suspect and male coercion may determine a woman's marital fate. At the same time, some researchers have identified counter strategies that females use to deal with coercive male mating tactics (Winterhalder and Smith 2000, pp. 60–1). Equally troubling is the fact that in some cases female fertility declines under polygyny (this is especially true for junior wives). At this point it is clear that polygyny will nearly always enhance a man's fertility but it frequently impairs a woman's. This latter issue is leading researchers to seek factors that could compensate for lowered fertility. For example, it may be the case that although a woman may bear fewer offspring under polygyny she may produce more grandchildren. This would be true if her sons were polygynous, married earlier than average, or married women with high reproductive value.

Although polygyny is permitted in nearly three-quarters of all anthropological populations, monogamy and the rare case of polyandry (a woman having more than one husband simultaneously) are being investigated through modified versions of the polygyny threshold model. In the case of monogamy it is becoming clear that extramarital mating (concubinage, affairs) and remarriage following divorce (serial monogamy) is more common among wealthy males. Although such systems are officially monogamous,

from a reproductive point of view they produce the high male reproductive variance characteristic of polygynous systems.

2.4 Reproduction: Mating, Parenting, and Life History Strategies

Given that the costs of reproduction vary greatly between males and females, they face fundamentally different trade-offs between the allocation of mating and parental effort in reproduction. The higher costs of reproduction for females limit the number of offspring they can produce and pursuit of additional males through mating effort will have little impact on the quantity or quality of offspring they can produce. As a consequence, they are concerned with the genetic quality of their mates (e.g., ability to deal with pathogens) since these qualities will be passed to offspring, and their ability and willingness to invest in offspring given the fact that humans require some degree of biparental care.

Studies of parental effort have focused on the issues of birth spacing, differential investment in offspring, and the interaction between mating and parenting. The ornithologist Lack was the first to recognize the trade-off between offspring number and offspring quality (or the ability of offspring to thrive and eventually reproduce). Since parental resources are limited, more offspring, through a shortening of the birth interval, will mean less investment per offspring and the potential for reducing each offspring's fitness. This trade-off suggests that there will be an optimal number of offspring that maximizes a parent's fitness and this number will vary with environmental circumstances. In general, one would predict that where parental resources are abundant birth intervals should be short and where parental resources are scarce birth intervals should increase. The crosscultural evidence from natural fertility traditional societies strongly supports the relationship between parental resources and reproductive success: wealthy parents or culturally successful parents have higher fertility than poor parents.

Paradoxically, the association between cultural success and fertility is absent in modern contraceptive societies. The situation has led behavioral ecologists to reexamine the demographic transition that began in Western countries during the eighteenth and early nineteenth centuries, which has now spread to developing nations. During this transition fertility fell faster than mortality rates fell yielding smaller families while family wealth increased. One solution to this paradox has been to investigate whether parents are investing more in children (e.g., education) thereby creating 'higher quality' children who will be able to compete successfully in highly competitive labor markets. At the same time, these children are delaying reproduction as they pursue higher education and gain entry into high status occupations, which require

further delays in reproduction as they work hard to achieve secure occupational niches. This theoretical perspective derives from life history theory described in Sect. 2.4.3.

In a seminal article, Irons (1979) suggested that there ought to be a correlation between cultural and reproductive success. Cultural systems are structured so as to encourage individuals to achieve certain kinds of culturally valued statuses. These achievements vary culturally depending on local environmental constraints. Both in traditional and in a number of recent societies, which have not entered the most recent demographic transition, culturally valued statuses are achieved through hunting prowess, religious rank, herd ownership, political leadership, occupational status, or land holdings. At this point there are nearly 20 studies showing in nearly all cases a positive correlation between cultural achievement and fitness (either fertility or survivorship of offspring) or factors strongly associated with fitness (number of wives, frequency of extra-pair copulations). However, it is very important to note that this relationship is demonstrated for male but not female reproductive success. Significantly, attributes that lead to high male fitness such as polygyny decrease female fitness at least over the short-term but perhaps not the long term.

2.4.1 Parental investment. In general the amount of investment an offspring receives from parents depends on (a) the relatedness between parent and offspring; (b) the effect of investment on the offspring; and (c) the effect of investment on parents' future reproduction and survival. These hypotheses have been positively evaluated using crosscultural and ethnographic cases studies. For example, the probability of infanticide, abuse, and neglect has been shown to be strongly sensitive to these factors. Infants who are unrelated to a woman's current husband ((a) above), or who have congenital defects ((b) above), or who are born in times of economic privation ((c) above) receive little or no investment. The thinking explicit in this approach is that parents adjust their investment in children according to their perceptions of a child's quality, paternity, current environmental conditions, and the needs of other offspring. Further investigations into differential parental investment have been inspired by the Trivers and Willard (1973) model where sex of offspring may influence investment. This model predicts that wealthy parents will invest more in the sex that has greatest variance in reproductive success (usually males) while poor parents will invest more in offspring with least reproductive variance (usually females). Research on societies as diverse as hunter-gatherers, pastoralists, to eighteenth-century Germany and nineteenth-century India has demonstrated the predicted differential investment by sex and distortions in sex ratios.

2.4.2 Parenting as mating effort. Providing care and giving food to children are conventionally seen as kinds of parental effort by males. However, recent research reveals that care and food provisioning are sometimes allocated to children who are unrelated to males. Consequently, such behavior may be fruitfully viewed as attempts to create or maintain a mating relationship. Essentially males are attempting to demonstrate their ability to invest in offspring and therefore convince a female that they would be a valuable partner.

2.4.3 Life history. Life history strategies deal with age specific schedules of mortality and fecundity and the traits that are directly a result of these schedules (Hill and Kaplan 1999, p. 397). It deals with important developmental events such as age at first and last reproduction, growth rates, birth intervals, and senescence. The theory is based on the assumption that effort allocated to somatic effort (growth, development, and maintaining the body) cannot be allocated to reproductive effort (e.g., mating and parenting). Formal research in this area is relatively new and has focused on the peculiar human trait of menopause, inter-birth intervals among foragers, and demographic transition theory.

The grandmother hypothesis attempts to explain the evolution of menopause, a life history trait that is exceptionally rare among mammals and well documented in humans. The model predicts that women will cease reproduction prior to death in order to insure required investment in current dependent offspring and to assist their children in the rearing of grand offspring. Although attractive, the model does not, as yet, show that continued reproduction until death is not a superior alternative.

Throughout history, humans have passed through a number of demographic transitions beginning with a high mortality and high fertility regime to today's worldwide transition to a low mortality and low fertility regime. A central issue behavioral ecologists are confronting is the apparent paradox between fertility and wealth. In tribal and in many state-level historical populations there is a consistent positive correlation between fertility and wealth. This means that the traditional human pattern was to convert wealth into reproduction. However, at the end of the twentieth century there is a global tendency for parents to reduce reproduction where wealth increases. Several explanations are offered for this trend. An initial set of explanations suggested that parents are now concerned with maximizing the number of offspring over more than one generation by reducing risk through an increase in heritable wealth. The 'human capital' perspective notes that in the current environment there is an increased requirement of parental investment needed to make children competitive in a modern

labor market where earning capacity is determined by parental investment in such things as education. Finally, more recent resolutions of the paradox focus on risk sensitive strategies that seek to lower the variance in expected completed family size. An important point evolutionary psychologists make in this problem is that, for the first time in human history, we possess safe and effective means of contraception, an alternative that humans did not previously have as they made their reproductive decisions. This has led to research demonstrating that there is a kind of correlation between wealth and reproductive success, at least for men. This research shows that wealthy men have greater numbers of premarital and extramarital unions than poor men. This lends some credence to the perspective that some of the adaptations we currently possess cannot be easily understood by looking at the reproductive consequences of behavior.

3. Summary

Human behavioral ecology is a young and explicitly Darwinian approach to the study of human behavioral variation. It redresses an absence of evolutionary considerations in the analysis of human behavior and social organization in the social and behavioral sciences. Since its inception in the late 1970s it has spawned the development of new journals and academic specialties explicitly devoted to training students to query the evolutionary bases of behavior. Its penetration into academic life has been uneven. It is most prominent in those disciplines such as anthropology and psychology where human evolution is considered relevant for a holistic understanding of human behavior or in economics where self-interest, methodological individualism, and maximization are key elements in modeling behavior. It has been resisted in departments such as sociology and political science where the findings on human evolution are either ignored or regarded as irrelevant.

Human Capital: Educational Aspects

The notion of ‘human capital’ is an economic concept, based on the distinction between two types of economic activity: investment and consumption. Economists use the term ‘investment’ to refer to an activity or use of resources which will generate income in the future, in contrast with ‘consumption,’ which produces immediate satisfaction or benefits, but does not create capacity to earn future monetary

income. Traditionally, economic analysis of investment and capital tended to concentrate on measurement of physical capital, namely buildings, machinery, or other equipment, which generate income by creating or enhancing productive capacity. More than 200 years ago classical economists, notably Adam Smith in *The Wealth of Nations* (1776), pointed out that education could be regarded as a form of investment, since it is likely to improve the productive capacity of workers, and thus increase their lifetime earnings, just as investment in physical capital, such as building a factory, or buying a new machine, will generate monetary income in the future.

This analogy between investment in physical capital and investment in human capital was recognized by several eighteenth- and nineteenth-century economists, but not fully developed until the 1960s when US economists such as Schultz and Becker published a series of influential works, notably *Investment in Human Capital* (Schultz 1961) and *Human Capital* (Becker 1964), which explored the idea and implications of investment in human capital by attempting to measure, for the first time, the rate of return to investment in education and training. This new emphasis on empirical analysis of human capital, described by another US economist, Mary-Jean Bowman (1966), as 'the human investment revolution in economic thought' proved to be a powerful influence, not only giving rise to a whole new branch of economics—the economics of education—but also affecting education policy in both industrialized and developing countries in a number of ways. This contribution summarizes research and literature on educational aspects of human capital, discusses ways in which estimates of rates of return and the links between education, employment, and economic growth have influenced education policy, particularly on the financing of education, and examines a number of criticisms of the concept of human capital, including the idea that education often represents a 'screening device,' rather than a genuinely productive form of investment, and the more recently developed concept of 'social capital,' which challenges narrow definitions of human capital (see *Education and Economic Growth; Education and Employment; Education and Income Distribution*).

1. Measuring the Rate of Return to Investment in Education

The notion that education is investment in human capital represents more than a simple analogy between education and investment in physical capital. It implies that it is possible to measure the returns to investment

in education, and to apply cost-benefit analysis to decisions about education expenditure, in the same way as rates of return are used to analyze the profitability of investment in conventional physical capital. Cost-benefit analysis is designed to express the costs and benefits of a project in monetary terms, and to calculate its expected profitability, or rate of return, by comparing all future benefits with the total costs of the investment. As noted above, there were several early references to the idea of human capital in eighteenth- and nineteenth-century economic literature, but the first serious attempts to measure the economic costs and benefits of education, and compute rates of return, were in the USA in the 1960s. (Schultz 1961, Becker 1964). These were followed quickly by estimates of the rate of return to education in many other countries. Psacharopoulos (1973) presented international comparisons of rates of return to education, both as a social and as a private investment, in 32 countries, and subsequently published several attempts to update and summarize estimates of rates of return around the world, including more than 50 industrialized and developing countries (see, for example, Psacharopoulos and Woodhall 1985, Psacharopoulos 1994).

Such estimates of the rate of return to educational investment for the individual (the private rate of return) or to society as a whole (the social rate of return) rest on several crucial assumptions. Cost-benefit analysis of education assumes that the economic benefits of education can be measured in monetary terms by using the average earnings differentials between more and less educated workers as a measure of their superior productivity. Workers with higher levels of education have better employment opportunities, and therefore higher average lifetime earnings, than those with less education, and these additional earnings, after various statistical adjustments, are used by economists as a proxy measure of the direct economic benefits of education, and compared with the private and social costs of education (including costs of tuition and earnings forgone by students in school or university). Most rate of return estimates concentrate on these direct monetary benefits, and either ignore or sidestep the problem of measuring the indirect benefits to society (sometimes called 'spillover' benefits or 'externalities') of investing in education. More attention has been paid recently to indirect benefits, but most rate of return estimates still rely mainly on the direct monetary benefits of investment in human capital.

International comparisons of rates of return to education (for example Psacharopoulos and Woodhall 1985) reveal certain general patterns:

(a) Social returns are consistently lower than the private rate of return.

(b) Social and private rates of return to primary education tend to be higher than rates of return to secondary or higher education.

(c) The rate of return to education is higher in developing countries than in developed countries.

(d) The rate of return to investment in education is higher than the average rate of return to physical capital in developing countries, though not necessarily in developed countries.

2. Implications of Rates of Return for Education Policy

Analysis of costs, benefits, and rates of return on investment in human capital raises important implications for both economic and education policies. The idea that education contributes to economic growth by developing and disseminating knowledge, and by improving the quality and productivity of the labor force, is now widely acknowledged and has influenced the economic strategies and educational planning of many individual governments, as well as international agencies and multilateral agencies such as the World Bank. For example, a study for the World Bank (Psacharopoulos and Woodhall 1985, p. 3) notes that:

Education, like other forms of investment in human capital, can contribute to economic development and raise the incomes of the poor just as much as investments in physical capital, such as transport, communications, power, or irrigation. The World Bank ... has long recognized the importance of investment in education and has been active in this field since 1962. When the Bank was first established in 1944, however, education was not counted among the productive purposes for which it was authorized to provide investment capital. This attitude prevailed right through the 1950s, when official statements of Bank policy took the view that the Bank should concentrate its lending on projects designed to make a direct contribution to the productive capacity of its members, rather than finance projects such as the construction and equipment of schools, colleges and universities. Even though such projects were considered essential to the development of a country, the Bank's proper role, as a bank, was said to be confined to providing loans for the more directly productive sectors of the economy. Gradually, this attitude changed, however, both within the World Bank and in the world at large.

More recently, the 1998–9 World Development Report (World Bank 1999), devoted to *Knowledge for Development*, emphasized that 'knowledge is crucial for development,' arguing that education as a form of investment in human capital was a 'key ingredient' in the economic growth and success of East Asian economies such as Hong Kong (China) the Republic of Korea and Singapore (sometimes called the East Asian Miracle economies). (See also *Education and Economic Growth* for a more extended discussion of this topic.)

Policies determining investment by governments, lending by agencies such as the World Bank, and aid policies of bilateral and multilateral agencies have been influenced not only by the assumed and often

demonstrated relationship between education and economic growth, but also by the consistent finding that the rate of return to primary education is the highest among all educational levels, particularly in developing countries. Studies of the economic benefits of primary education were influential in building support for the World Conference on Education for All at Jomtien in 1990, and for the subsequent emphasis on achieving universal primary education as an economic as well as an educational goal (see Colclough and Lewin 1993).

Rate of return estimates also have important implications for policies on education finance. The fact that private rates of return to educational investment are higher than the social rate of return, particularly for higher education, has been used to justify the introduction of tuition fees or student loans at the university level in several countries. For example, when the UK government first announced the introduction of student loans in 1988, the Department for Education and Science (1988, p. 10) presented estimates of social and private rates of return and argued that:

the return on the individual graduate's personal investment in higher education ... in recent years has been in the region of 25 percent, taking all subjects together. The same analysis shows that the return to society on its investment in the graduate's higher education has been much lower: between 5 percent and 8 percent. The individual graduate benefits more than the community as a whole from the latter's investment in the former's higher education. The division of costs, on the other hand, goes the other way. That is why there is scope for the individual student to bear more of the cost of the investment.

Critics argue that such arguments ignore, or at least tend to underestimate, the indirect benefits of education, which accrue to society as a whole as much as (or even more than) the individual. These include the inter-relationships between education, family health, fertility and child mortality, which are now recognized as crucial components of the benefits of education for girls and women in developing countries. An early attempt to analyze differences between rates of return for males and females, (Woodhall 1973) emphasized that 'human capital' should not be interpreted as 'investment in man,' being just as relevant to women as to men, but there was little progress in developing measures of social or indirect economic benefits of education until the 1990s, when a study of *Women's Education in Developing Countries* (King and Hill 1993) included estimates of the returns to women's education which demonstrated clearly the importance of social as well as monetary returns to education for women and girls. This led Larry Summers, then chief economist of the World Bank, to declare, in a Foreword to his book 'I have become convinced that once all the benefits are recognized, investment in the education of girls may well be the highest return investment available in the developing world.'

(Summers 1993, p. v). This has crucial implications for policies to improve equity by reducing barriers to female participation in education.

3. *Objections to Human Capital Theories: Education as a 'Screening Device'*

Although the concept of human capital has a long history in economic theory it remains a controversial idea, when applied to education, and there have been many objections and criticisms to the notion of measuring the rate of return to educational investment. The earliest discussions of human capital suggested that education or training raised the productivity of workers, and hence increased their lifetime earnings, by imparting useful knowledge and skills. However, this assumption was challenged by critics who argued that the earnings of educated workers reflected their superior ability, rather than the specific knowledge and skills acquired during their education. Moreover, critics argued that highly educated workers were more likely to come from higher social or income groups, to work in favored occupations and in urban rather than rural areas. Many estimates of rates of return to education now adjust the observed earnings differentials of educated people to allow for the observed influence of other factors, such as ability or social class background, on earnings, or in the absence of suitable data, they simply assume that 60 percent, rather than the full 100 percent of observed earnings differentials, are due to education, rather than ability or other factors (an adjustment that is often called the 'alpha coefficient' in the literature on the economics of education).

Many critics go further, however, and suggest that education does not improve productivity by imparting knowledge and skills, but simply acts as a 'screening device,' which enables employers to identify individuals of high innate ability or with certain personal characteristics, attitudes, or motivation, which employers value and which they therefore reward by means of higher earnings. This objection to theories of human capital, often called the 'screening hypothesis,' has attracted considerable controversy. Dore for example, in *The Diploma Disease*, an influential critique of the effects of education in developing countries, (Dore 1997, p. 93), presents many criticisms of what he calls the 'rate of return argument,' culminating in the assertion:

We observe people who have certain kinds of education subsequently (on average) getting higher levels of income than other people with less education. But how do we know that this enhanced earning power is *because* of their education (implying on a broader scale, that more education in a society would make that society more productive)? Is the 'investment' metaphor genuinely justified? Is it true that the education

changes a man, *enhances* his capacity to work and in this way alters the price at which he can sell his labours?

Dore gives numerous examples of educational qualifications being used as a 'screening device' or 'filter' in selecting job applicants—an aspect of what he calls the 'diploma disease'—and contrasts the 'screening hypothesis' with 'traditional "human capital theorists" who persist in believing that people earn more because their education has *changed* them and that the "investment" assumptions of their rate of return analysis are correct' concluding that 'different institutional practices, different social structures, different educational traditions and degrees of equality of opportunity make the intervening mechanisms between schooling and earnings levels very different in different countries.' (Dore 1997, pp. 94–5)

Such criticism was challenged, however, on the grounds that while a 'weak' version of the screening hypothesis is undoubtedly true, since employers may well use educational qualifications as a proxy for other characteristics when selecting their work force, there is no evidence to support the 'strong' version of the hypothesis, that education has no direct effect on productivity. The fact that employers continue to pay educated workers more than the uneducated throughout their working lives refutes this.

Even so, the idea of education as a screen or filter has been important in influencing theories of human capital. Blaug (1976, p. 850) in a review which he describes as a 'slightly jaundiced survey of the empirical status of human capital theory' predicts that:

in time, the screening hypothesis will be seen to have marked a turning point in the 'human investment revolution in economic thought,' a turning point to a richer, still more comprehensive view of the sequential life cycle choices of individuals.

4. *Concepts of Social and Cultural Capital*

Just as economists now recognize that the concept of human capital must be enlarged to take account of the effect of education on individual attitudes and motivation, as well as knowledge and skills, and that the indirect benefits (externalities) of education may be even more important than the direct economic and monetary benefits, sociologists and scholars from other disciplines now emphasize the complementarities between human capital, social capital and other forms of investment. Bourdieu (1986) argued that 'capital can present itself in three fundamental guises: as *economic capital*, which is immediately and directly convertible into money and may be institutionalized in the form of property rights; as *cultural capital* which is convertible, on certain conditions, into economic capital and may be institutionalized in the form of

educational qualifications, and as *social capital*.' (Bourdieu 1986, p. 47). At about the same time Coleman (1988, pp. 14–15) argued that analysis of the purely economic effects of human capital is deficient and needs to take into account social structures and relationships in the family and community as well as effects of investment on the individual: 'norms, interpersonal trust, social networks, and social organization are important in the functioning not only of society but also of the economy.' (Coleman 1988, reprinted in Dasgupta and Serageldin 2000, p. 14).

More recently the concept of 'social capital' has attracted considerable attention, including a new study for the World Bank (Dasgupta and Serageldin 2000) that emphasizes the complementarities between human capital and social capital, and between concepts from sociology, anthropology, and political science as well as economics, in analysis of the effects of investment and social action. The overwhelming conclusion of this review is that educational aspects of human capital must also be included in such a 'multifaceted perspective.'

M. Woodhall

Human Cognition, Evolution of

Human cognition is the way it is, in large part, because it evolved the way it evolved. Unfortunately, for science, however, the key evolutionary processes took place long ago and cognition does not fossilize. This means that scientific investigations of human cognitive evolution must rely on a variety of more-or-less indirect sources of data. Among the most important of these are: (a) the cognition of nonhuman primates; (b) the fossils and material artifacts left behind by humans at various periods of their evolution; and (c) the cultural-cognitive processes at work in modern human populations.

Following common practice in the various branches of comparative biology and psychology, it may be assumed that if all the species of a given evolutionary taxon possess a certain physical trait or behavioral propensity, then the common ancestor for that taxon also possessed that trait or propensity. In the case of humans, the taxon of direct relevance is primates, with special attention to *Pan troglodytes* and *Pan paniscus* (referred to collectively as chimpanzees), because human beings shared a common ancestor with them a mere 6 million years ago. The cognitive processes common to chimpanzees and human beings thus represent the best evidence we have for the cognitive processes of the very first hominids.

For most of the day, every day, primates forage for food, quite often for patchy resources such as fruits and new leaves and buds (which only grow on some

plants at some times of the year), and sometimes for insects or other animal prey who can move freely on their own. In order to forage efficiently, therefore, primates must:

- (a) remember 'what' is 'where' in their local environments, for example, which fruits are in which trees at what times;
- (b) take creative detours and shortcuts to get to the food as quickly as possible;
- (c) track the visible and sometimes invisible movements of prey and other objects;
- (d) recognize and categorize different foods and objects on the basis of perceptual features;
- (e) quantify relative amounts of foods on the basis of perceptual features; and
- (f) use insight in problem solving, for example, in extracting food from substrates.

A variety of empirical studies—both observational in the wild and experimental in captivity—demonstrate that virtually all anthropoid primates have all of these cognitive skills (see Tomasello and Call 1997 for a review). Primates also must use sophisticated cognitive skills to deal effectively with their social environments. Among the most important of these (again, see Tomasello and Call 1997, for a review) are the abilities to:

- (a) recognize individuals within the social group;
- (b) form social relationships with group mates based on such things as kinship, friendship, and dominance rank;
- (c) recognize the 'third-party social relationships' of other group mates based on such things as kinship, friendship, and dominance rank;
- (d) predict the behavior of individuals based on such things as their emotional state and their direction of locomotion;
- (e) use many types of social and communicative strategies to outcompete group mates for valued resources;
- (f) cooperate with conspecifics in problem-solving situations and in forming social coalitions and alliances; and
- (g) engage in various forms of social learning from conspecifics.

Indeed, the fact that the primate social environment presents such a wide array of cognitive challenges has led some theorists to posit that the truly unique features of primate cognition—involving such things as understanding and dealing with relational information—have come from their adaptations not to the physical world but to the social world (Humphrey 1976, Tomasello and Call 1997). Empirical work on primate cognition—coupled with the working assumptions of comparative biology—has thus established that by the time hominids set out on their own evolutionary pathway some 6 million years ago, they already possessed a plethora of cognitive skills, derived mainly from adaptations in the context of foraging for food and dealing effectively with group mates. In brief,

they already conceptualized a sensory-motor world of permanent objects—arrayed in a representational space and categorized and quantified in some fundamental ways—and a social world of animate conspecifics with whom they could cooperate and compete in various complex ways.

However, if we compare contemporary chimpanzees and human beings there are still some cognitive skills that are unique to humans and that therefore must have arisen after the human–chimpanzee divergence 6 million years ago. Most important, in the physical world human beings, and only human beings, understand the causality of events; that is, they understand events in terms of the unobservable 'forces' that explain why they happen in the way they do (Visalberghi and Tomasello 1998). Understanding causality enables individuals to interact with their physical words in much more flexible ways, for example, by creating or blocking key antecedent events in order to produce a desired consequent. Analogously, in the social world human beings, and only human beings, understand the intentionality of behavior; that is, they understand behavior in terms of the unobservable mental 'forces' (thoughts, beliefs, desires) that explain why individuals behave the way they do (Visalberghi and Tomasello 1998). Understanding intentionality enables individuals to interact with conspecifics in much more flexible ways, for example, by attempting to manipulate their knowledge or motivational states so that they will act in desired ways. But perhaps even more importantly, understanding conspecifics as intentional agents constitutes the social–cognitive foundation for human culture, which gives human cognition its species-unique social–collective dimension (see Sect. 3).

1. Hominid Material Artifacts

For the first 4 million of its 6 million years of existence, the human lineage consisted exclusively of one or another species of australopithecine. Australopithecines were small in stature, bipedal, with ape-sized brains, and no stone tools; many modern paleo-anthropologists thus refer to them as 'bipedal apes.' Although we know little of the behavior of these earliest hominids, there are no clear indications that they cognized the world in anything other than the typical great ape manner.

With the birth of the genus *Homo* some 2.5 to 2 million years ago, the human lineage began to show signs of some unique cognitive adaptations. Most important, humans began to make stone tools in ways that required at least some degree of planning and causal understanding of the way rocks could be modified and used instrumentally (Schick and Toth 1993). Thus, early in this period *Homo habilis* made Oldowan (pebble) tools, which required some understanding of how rocks break when struck in certain

ways, and which were often made in one location and then carried to another for subsequent use. Later, *Homo erectus* made Acheulean hand axes (bifaced and symmetrical), which showed a clear ability to hold in mind a definite end product during the process of manufacture and in addition an ability to understand some of the basic causal forces at work in stone tool making. During the early parts of this period (especially from 2 to 1.5 million years ago), the brains of hominids expanded in size by about one third, perhaps because of the cognitive demands of making and using these complex technological products.

A second major brain expansion about 500,000 to 200,000 years ago increased hominid brain size by a factor of one third once again, basically to its modern size. This took place in a set of hominids known collectively as archaic *Homo sapiens*, followed soon by modern *Homo sapiens*. These hominids invented some new techniques for making stone tools, initially the Levallois technique in which a large stone core is specially prepared so that smaller flakes of a special type may be systematically struck off, and later the technique of making blade tools (in much the same way) whose great length to width ratio made them much more multipurpose. Following this in many populations were specialized microlith tool industries, with all kinds of highly specialized tools for highly specialized purposes (each made in a specialized way). Interestingly, some of these flakes, blades, and microliths were hafted onto wooden or bone handles, which made them even more efficient cutting tools. Of special importance from a cognitive point of view, manufacturing these hafted tools required their makers to understand, before the manufacturing process began, that different parts of the tool had different instrumental functions. These so-called composite tools may thus indicate the ability of archaic and early modern *Homo sapiens* to understand and plan for the different causal roles of the different components of a tool.

Another feature of hominid tool use suggests something of how individuals learned to make and use their tools. Both Oldowan and Acheulean types of tools showed great uniformity of use at particular historical periods across all groups of hominids who used them, no matter how far apart from one another they may have lived. In the case of the Oldowan tools of *Homo habilis* (and relatives), this uniformity was confined to Africa and lasted for hundreds of thousands of years. In the case of the Acheulean tools of *Homo erectus*, this uniformity extended all over Africa, Western Europe, and the near East and India, and lasted for over one million years. But with the rise of the more modern techniques of tool making and use, especially the blade and microlith technologies uniquely associated with modern humans, different populations of human beings began to make and use their tools in population specific ways. This new pattern of distribution among social groups suggests the possibility of the cultural

transmission of tool making and using techniques in the different populations, in much the manner of contemporary human populations.

We cannot know much about the social lives of the earliest modern humans because we have so few fossils and artifacts. But if indeed truly cultural organization emerged only with modern humans, then it is reasonable to suppose that there was some change in social cognition that led to this new form of social organization. The main reason to believe this is that before nine months of age human infants are 'acultural' creatures in the sense that they are not yet able to appropriate the cultural artifacts and practices of those around them actively. Soon a major change in their social cognition occurs and they begin to understand other persons as intentional beings like themselves, with mental states like their own. This is indicated by the emergence a whole suite of new behaviors such as:

- (a) following the gaze direction and pointing gestures of adults;
- (b) engaging in shared attentional interactions with adults;
- (c) imitating adult actions on external objects; and
- (d) directing adult attention through pointing and other gestures, all of which indicate a new understanding that other persons have intentional relations to the world (Carpenter et al. 1998).

Because of this new understanding, infants begin to acquire in earnest the tools, linguistic symbols, and other cultural artifacts and activities of their social groups (Tomasello et al. 1993). (Note that children with severe autism never develop this social cognitive ability and they, in a sense, remain acultural individuals; Hobson 1993.) If we assume this same relationship between social cognition and cultural learning in human evolution, we can use the artifactual evidence for the emergence of human cultures to infer that a change in social cognition occurred with modern humans.

2. Culture and Cognition

With the advent of modern humans and their cultural organization, human cognition took on a radically different character. First, with the advent of skills of cultural learning and teaching (resulting from the social-cognitive ability to understand others as intentional and mental agents), human beings began to create artifacts and social practices that accumulated modifications over time. Thus, the so-called 'cultural explosion'—which took place in some, but not all, human populations at about 40,000 years ago—was characterized by many new technological inventions and very rapid changes and improvements in existing technologies. Tomasello et al. (1993) hypothesized that this kind of cumulative cultural evolution, in which the complexity of material and symbolic artifacts ratchets up very quickly over historical time, is

only possible with the human form of cultural learning in which the learner understands the intentions of another individual in the sense that she understands what the behavior is 'for.' The need for this kind of understanding is clearest in the case of tools and symbols since both of these artifacts clearly point to things beyond themselves: the tool to its instrumental function in modifying the physical world and the symbol to its communicative function in modifying other people's attention and behavior.

Once this kind of cultural learning was operative, human populations could, in effect, pool their cognitive resources in a way unique in the animal kingdom. Chimpanzees and other nonhuman primates benefit from observing the activities of their conspecifics, but because they do not understand the intentions of others, what they learn from these observations is limited (Tomasello 1996, see also Kummer and Goodall 1985). Human beings, on the other hand, are able to acquire relatively faithfully many of the tools, symbols, and social practices of others, so that inventions spread relatively rapidly and are preserved in the group effortlessly until some new and improved innovation comes along, which is then acquired faithfully, and perhaps modified further, by another generation. An important result of this ratcheting up of cultural inventions over historical time, is that human children are born into a world of artifacts and social practices that embody something resembling the accumulated wisdom of their entire social group throughout its entire cultural history (Donald 1991).

When children acquire the use of a material or symbolic artifact, or learn to engage in a conventional social practice in their culture, they internalize the intentional states of the adult inventors and users of the artifact or social practice (Vygotsky 1978). This internalization process is of special importance when children acquire linguistic symbols, because a human language embodies all of the myriad ways that the people of a social group have found it useful to categorize and construe their worlds for purposes of communicating with one another. Because the same entity may be construed in many different ways linguistically—this object is a dog, an animal, a pet, or a pest—in acquiring a natural language children are induced to take multiple simultaneous perspectives on entities in the world, with some of these perspectives being common to all languages and some of them being unique to particular languages. When internalized by the child, then, the process of linguistic communication creates in each individual a species-unique form of perspectively based cognitive representation, commonly known as symbolic representation (Tomasello in press).

As a way of highlighting the cognitive importance of processes of cumulative cultural evolution over historical time and their interaction with processes of cultural learning and internalization over ontogenetic

time, we may imagine a human child raised on a desert island in isolation from all other human beings, with a normal brain, body, and sense organs, but with no access to tools, other material artifacts, language, graphic symbols, writing, Arabic numerals, pictures, people who could teach her things, people whose behavior she could observe and imitate, or people with whom she could collaborate. It is likely that as an adult this child's cognitive skills would look very little like those of contemporary human beings (Tomasello in press). The point is thus that modern human beings have the cognitive skills they do because they inherit things from their progenitors both biologically and culturally (cf. the Dual Inheritance Model of Boyd and Richerson 1985, Durham 1991). They inherit biologically the ability to understand conspecifics as intentional agents—and the cultural learning processes that this enables—and these abilities then in turn open the way to the cultural line of inheritance and children's internalization of the ways of understanding the world embodied in their culture's accumulated artifacts and social practices.

3. Conclusion

Much of this account, in common with other accounts of human evolution, is necessarily speculative. But it is based on a solid body of research demonstrating precisely how human cognition is similar to and different from that of nonhuman primates, and on a relatively straightforward search for the two most important species-unique aspects of human cognition in the human artifactual record. First, the earliest humans some 2 million years ago began to demonstrate some new skills of causal understanding in the context of complex tool manufacture and use. Second, and even more important, the earliest modern humans some 150,000 years ago began to demonstrate some new skills of social cognition—understanding conspecifics as intentional and mental agents—that fundamentally changed the process of human cognitive evolution because they enabled uniquely powerful processes of cultural learning and cumulative cultural evolution. These cultural processes, in turn, transformed the ontogenetic niche in which human cognition developed ontogenetically from a social into a truly cultural niche including artifacts, symbols, and social practices with accumulated histories. The ability to pool cognitive resources in these ways may even have been the competitive advantage that modern humans had over other contemporaneous hominids. The ultimate outcome of these evolutionary and cultural processes in humans today is a form of cognition that is culturally and symbolically constituted in ways unprecedented in the animal kingdom.

M. Tomasello

Human Development and Health

Both 'health' and 'human development' are broad terms, covering a lot of conceptual and empirical ground. Both will be defined quite broadly here. Health will encompass the broad range of indicators of physical and mental illness, as well as disability and mortality. Human development is associated with two relevant bodies of scholarship (see Lerner 1998 for extensive discussions). One view, seen most often in

the early history of growth-oriented child development, defines human development as the unfolding of characteristics and capacities as one ages. A second view, used more often in current-day developmental psychology and by social scientists, defines human development as the patterns of skills, attitudes, and behaviors that emerge over the life course. These definitions are not discordant; what distinguishes them most are the assumptions and theoretical contexts on which the definitions rest.

Except for the field of developmental psychopathology (Cicchetti and Cohen 1995), the dominant psychological view is a developmental one that focuses on the patterns typically observed across individuals who are not subjected to unusual traumas or disruptions. Generally it is assumed that developmental processes and outcomes are characteristic of the species; hence, variability is expected to be modest, although both personal experiences and the broader social and cultural contexts can affect the nature and timing of developmental phenomena to a limited extent. The strongest and most generalizable developmental patterns are observed in the early years of life when it is possible to predict with considerable accuracy developmental milestones such as walking, talking, and the capacity for abstract thinking. There has been less interest in and study of developmental changes during adulthood, which are fewer in number, less dramatic, and less consistent across individuals. In fact, it was the fields of lifespan psychology and psychological gerontology that made a major contribution to reorienting developmental psychology to a fully contextual view (see *Lifespan Development, Theory of*, Schaie 1996).

In line with a contextual view of development, social scientists expect substantial variation in the ways in which skills, attitudes, and behaviors are patterned across individuals and the life course. Although they do not discount the possibility of universal or nearly universal laws of development, life course scholars assume that social and cultural forces are the primary determinants of human behavior—and that those forces will exert strong influences on the timing and nature of even those behaviors that are characteristic of the species. Because of dramatic differences in social systems and cultural traditions, wide individual and group variations in patterns of behavior over time are expected. Even when confronted with patterns of behavior that are strongly associated with age, social scientists will tend to view those patterns as the result of strong cultural proscriptions and/or the influence of powerful social forces (Elder 1992).

1. The Link Between Health and Human Development

Scholars studying developmental processes first became interested in illness as a threat to normal

development. Serious illnesses and/or disabilities can constrain the individual's ability to master developmental tasks and/or the timing of mastering them (e.g., Cicchetti and Cohen 1995, Newacheck and Taylor 1992). Moreover, failure to master early developmental tasks can disrupt the achievement of later ones, resulting in a snowballing pattern of developmental disadvantage. Although early research focused largely on disruptions to highly specific developmental tasks (e.g., cognitive development, motor skills), recent research casts a wider net, including, for example, studies of how severe childhood illness can delay or disrupt the development of social skills, self-esteem, and academic achievement (e.g., Gortmaker et al. 1990).

Another research tradition examines the relationships between health and human development from the opposite point of view: how patterns of development influence subsequent health. In this tradition, successful accomplishment of developmental tasks (be they biologically driven or socially/culturally prescribed) is viewed as a form of resource accumulation (human and social capital) that affects health later in the life course. A broad body of research now documents the links between early achievements—including intelligence, educational achievement, self-esteem, feelings of self-efficacy, and the social skills required for successful social relationships—and health in middle and later life (e.g., Clausen 1993, Elder 1999).

Although these are distinct research traditions, both are part of a broader and deeper intellectual transformation of how health and illness are understood by both scientists and the larger public. From the middle of the nineteenth century until the middle of the twentieth century, the *medical model* dominated our understanding of the nature and causes of illness. The medical model views illness as biological dysfunction caused by the failure of the organism's biological defenses to prevent damage or disturbance. It is a complex model, recognizing that threats to the body's integrity can be generated from either external forces (injuries, viral and bacterial antagonists) or internal dysfunctions (congenital deficits, cellular dysregulation). But it is a purely biological model that ignores potentially health-relevant social, psychological, and cultural factors.

Since the 1950s a multidisciplinary model, sometimes called the *biopsychosocial model* of illness, has become the dominant perspective on illness among both scientists and the larger public. The major tenet of this model is that illness is a product of the complex and interacting effects of biological, psychological (including behavioral), social, and cultural factors. An important corollary of this model is that biological intervention alone typically cannot prevent, cure, or manage illness. Both the causes of and appropriate interventions for illness and premature mortality occur at multiple levels. Research on the reciprocal and

complex links between human development and health has been one important illustration of the utility of the biopsychosocial model of illness.

2. Current State of Knowledge

2.1 The Effects of Health on Development

A broad body of research documents the fact that childhood illness, especially chronic illness, is associated with increased risk of developmental problems. This has been demonstrated for a variety of physical illnesses including epilepsy (Hermann et al. 1989), juvenile onset diabetes (Hoare 1984), and cystic fibrosis (Thompson et al. 1994), to name but a few. Problems and delays are observed most frequently for cognitive development and learning, emotional control and maturity, the ability to form successful attachments with peers, and behavioral problems at school and at home. Mental illness during childhood is associated with similar developmental problems (Rutter and Rutter 1993). Although the number of studies that examine the consequences of childhood chronic illness on long-term developmental outcomes is small, research to date suggests that developmental problems tend to multiply over time, supporting psychologists' predictions that early developmental disruptions bode poorly for mastery of later developmental tasks.

There also is strong evidence that childhood mental illness is associated with poor *adult* outcomes. Turnbull et al. (1990), for example, report that the onset of major psychiatric illness before the age of 16 is associated with lower levels of educational attainment, lower occupational attainment and income, and higher rates of separation and divorce. Family formation is also affected by childhood mental illness. Forthofer et al. (1996) report that childhood and adolescent mental illness is associated with earlier, but less stable marriages.

The effects of chronic childhood physical illness on adult achievements are less clear and appear to vary across illnesses. Children suffering from illnesses that can be managed effectively typically attain levels of education, occupation, and income similar to those of their healthy peers (Newacheck and Taylor 1992). In contrast, illnesses that result in frequent incapacity and/or threats to survival (such as cystic fibrosis) and those that involve the brain (such as epilepsy) are associated with poorer adult socioeconomic outcomes.

Although childhood physical and mental illnesses are associated with developmental problems in a number of domains, cognitive problems, especially learning disabilities, have the most severe consequences for both short- and long-term outcomes, as demonstrated in studies comparing children who did

and did not experience learning disabilities as a result of epilepsy (Hermann et al. 1989). Children with epilepsy who did not have learning disabilities resembled healthy children with regard to social competence, depression, and behavior problems at school and at home. In contrast, children who experienced learning disabilities as a result of epilepsy exhibited developmental problems in a wide range of areas. Relative to other developmental problems, learning disabilities also are most strongly related to low levels of socioeconomic achievement during adulthood.

There is also an intergenerational component to the effects of health on development during childhood and adolescence. A broad body of research consistently reports that children who live with a parent who suffers from chronic physical illness, chronic or intermittent mental illness, and/or disability are at increased risk of developmental problems or delays (e.g., Hirsch et al. 1985). Indeed, the effect sizes for parental illness are as great as, and sometimes greater than, those for childhood illness. Again, a variety of developmental problems are observed, including cognitive and learning problems, behavior problems at school and at home, general social competence, and the ability to make successful attachments to peers.

Given the strong evidence that chronic illness (of self or parent) places children and adolescents at risk of developmental problems, recent research appropriately focuses on the processes and mechanisms that account for these relationships. This is a highly complex issue because there are multiple pathways by which illness affects development. For children who are chronically ill, characteristics of the illness, its *sequellae*, and the nature and efficacy of medical management all play a role in helping to protect against or, alternatively, increasing the risk of developmental problems. As noted above, some illnesses have direct effects on developmental outcomes (e.g., when diseases cause cognitive problems or constrict the child's ability to form bonds with peers). Illness severity has an impact on development beyond the symptoms and impairments generated by the disease. For example, the greater the level of absence from school as a result of illness, the more severe the developmental problems (McCubbin 1988). Medical treatments also play a role in developmental outcomes. Some medications have side effects that place the child at risk of developmental obstacles (e.g., inability to concentrate); other treatments (e.g., chemotherapy) can impair functioning in multiple domains. Finally, the stigma associated with chronic illness (Hermann et al. 1989) can lead to rejection from peers and discomfort in public places (e.g., diabetic children require special diets and cannot participate in many 'normal' childhood activities).

Beyond the constraints of the illness and its treatment, the family plays a strong role in increasing or lessening the ill child's risk of developmental problems. Quality of parenting and the parents' methods of

coping with a chronically ill child are especially important (McCubbin 1988). The entire dynamic of family life is changed by the presence of a chronically ill child. Parenting requires more time, special skills, and maintaining a delicate balance between 'normalizing' the child's life as much as possible, while also providing high levels of supervision and medical management. Demands change over time as the illness waxes or wanes and as the child ages. Providing care to a chronically ill child over long periods of time is draining and affects all areas of parent's lives (e.g., the marital relationship, relationships with other children, labor force participation, financial security) (Avison et al. 1991).

Family dynamics also appear to explain the conditions under which children experience developmental problems when a parent is chronically ill. Two processes seem to be especially important in this regard. First, if parental illness is accompanied by high levels of marital discord, the likelihood of developmental problems in the children is greatly increased (e.g., Mann and MacKenzie 1996). Second, the risk of developmental problems increases exponentially if the parent's illness is associated with being 'emotionally unavailable' to the child (e.g., Wootton et al. 1997). Indeed, developmental delays can be observed by the age of 2 when the parent is emotionally estranged or distant from the child (Radke-Yarrow et al. 1985).

3. The Effects of Development on Health

There also is impressive evidence that developmental outcomes during childhood and adolescence have strong effects on health in middle and late life. There are three primary pathways by which early developmental outcomes exert persisting effects on health: socioeconomic achievements, social integration, and social support.

Of all the social factors related to health, socioeconomic status (SES) is the most consistent and powerful (House et al. 1994, Link and Phelan 1995). SES typically is operationalized as a combination of income and education, and sometimes occupation as well. All three SES components are related to health and longevity, although they seem to operate in somewhat different ways. The relationship between income and health is multifaceted, for example, income is related to access to and quality of healthcare, and to goods and services that promote health (e.g., safe housing, adequate nutrition). Occupation is, of course, a primary determinant of income, but also affects health via prestige and greater autonomy and control in occupational settings (e.g., Link et al. 1993). Education typically exhibits the strongest relationships with health outcomes, in part via its effects on occupation and income, and more directly via better health habits and increased knowledge and use of

information about health and healthcare (Ross and Wu 1995). SES during adulthood is strongly related to early development. As noted earlier, school performance and educational attainment are major developmental outcomes during early life.

Social integration refers to the attachments individuals sustain with the larger society and are typically measured in terms of occupational, organizational, and community roles. A broad body of research, beginning with Durkheim's classic work on suicide, has documented strong links between social integration and health and longevity (House et al. 1988). Again, early developmental outcomes are linked directly to social integration during adulthood. Sustaining social integration requires social competence, reasonable intelligence, and the self-discipline required for adequate role performance—all of which are developmental outcomes that are established, in large part, during early life.

There is impressive evidence that health is related robustly to social relationships. The effects of social ties on health operate in a variety of ways. First, high-quality relationships with family and friends are directly related to better health and longevity (e.g., House et al. 1988). Second, close relationships are the foundation from which social support emerges during times of stress. Social support takes a variety of forms ranging from consolation and reassurance to the provision of information and tangible assistance. High levels of social support help to protect against the onset or exacerbation of illness and facilitate recovery from illness (de Leon et al. 1999, George et al. 1989). The ability to form appropriate attachments and the social skills needed to sustain social bonds are established early in life.

Thus, early development sets the stage for subsequent health in a variety of ways. Moreover, the benefits of successful development tend to increase over time, whereas the disadvantages that result from unsuccessful development also spiral over time. This pattern, known as cumulative advantage/disadvantage (Ross and Wu 1996), results in diverging levels of health across adulthood, until very late life when biological factors may act as 'levelers,' narrowing the differences between the advantaged and disadvantaged.

Health in middle and late life is affected by both proximal and distal factors. Unquestionably, proximal and contemporaneous factors are typically more powerful predictors of morbidity and mortality than are distal patterns. Nonetheless, life course research has added to the knowledge base in two ways. First, sometimes, early events and experiences have persisting demonstrable effects on health and longevity, even when more proximal factors are taken into account. Second, the indirect effects of early events and experiences often help to elucidate the selection processes that result in more proximal antecedents of morbidity and mortality.

4. Methodological Challenges

A variety of methodological issues complicate efforts to better understand the links between development and health; two especially important ones are considered here. First, adequate depiction of the complex and time-dependent relationships between development and health requires longitudinal data collected over a significant portion of the life span. Such studies are especially important for identifying the effects of development on health because it is not until middle age that a significant proportion of the population exhibits health problems. Few studies to date assess developmental and health outcomes over the appropriate age range (i.e., from childhood/adolescence until at least late middle age). Such studies are very expensive in both time and money, making a substantial increase in the future unlikely.

Selective mortality also poses a serious threat to our understanding of the links between development and health, both of which are related strongly to mortality. Extant research is based on survivors, which has two important implications. First, it is likely that research findings *underestimate* the effects of developmental outcomes on subsequent health because the most unhealthy are likely to have died. Second, selective mortality may account for some of the observed patterns among survivors. For example, the narrowing of SES differences in health during late life may be due to earlier mortality among low SES persons rather than a 'biological leveling' at the end of life (Bartley and Plewis 1997). There is no way to overcome this problem. However, given longitudinal data covering large segments of the life course, the effects of selective survival can be estimated. The possible effects of selective survival should be considered in the interpretation of all empirical findings.

5. Future Directions

Future research on the links between health and human development is likely to focus on two major topics. First, efforts will continue to trace the specific pathways and mechanisms by which development and health affect each other. Although extant research has made important contributions to this issue, substantial components of these processes remain unknown and replication of findings to date is especially important because of reliance on cross-sectional and short-term longitudinal research designs. Second, future research will address the extent to which and ways in which developmental and health problems in early life can be compensated for or reversed. Some contributions to this issue will result from naturalistic research that identifies compensatory factors that permit early disadvantage, in either development or health, to be overcome or minimized. Other contributions will result from research in which interventions designed to

prevent developmental or health problems or to compensate for them are evaluated in terms of feasibility, cost, and effectiveness. Given the complex web of factors associated with early developmental and health problems, the challenges of arresting or reversing trajectories of disadvantage will be great, but the benefits will be great as well.

L. K. George

Human Development, Bioecological Theory of

The bioecological model, together with its corresponding research designs, is an evolving theoretical system for the scientific study of human development

over time. Within the bioecological theory, development is defined as 'the phenomenon of continuity and change in the biopsychological characteristics of human beings, both as individuals and as groups. The phenomenon extends over the life course, across successive generations, and through historical time, both past and future.' The term 'future' raises a question: How is it possible to investigate scientifically phenomena that have not yet taken place? The question, of course, is hardly new; indeed it pervades every field of scientific endeavor. However, we are the only species that has, over historical time, developed the capacity to engage successfully in scientific inquiry, and thereby, in many respects, has been able to change the nature of the world in which we live. As a result, within certain limits, we humans have altered the nature and course of our own development as a species (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998).

To place the bioecological theory of human development into a larger context, it is important to recognize that many of the general perspectives advanced and elaborated in this theory, are also parts of other related lines of theoretical and empirical inquiry into human development. Examples are lifespan psychology (Baltes et al. 1999), cultural psychology (Cole 1995), Magnusson's developmental theory of contextual-interactive holism (Magnusson and Stattin 1998), and, especially, the work of Robert Cairns, who through communications and publications extending over three decades, has played a major role in the evolution of the four defining properties of bioecological model: process-person-context-time. Cairns is of course best known as the founder and principal protagonist of developmental science. Examples of his books and articles that have been most relevant to the evolution of the ecological model are cited in the bibliography (Bergman et al. 2000, Cairns 1970, Cairns and Cairns 1994). The specific profile of the theory of Bronfenbrenner and his colleagues is its comprehensive interdisciplinary and integrative focus on the age periods of childhood and adolescence and its explicit interest in applications to policies and programs pertinent to enhancing youth and family development.

1. Defining Properties of the Bioecological Model

The term 'evolving' highlights the fact that the model, along with its corresponding research designs, has itself undergone a process of development over its own 'life course.' Another defining property of the bioecological model specifies that it deals with two closely-related but nevertheless fundamentally different developmental processes, each taking place over time. The first defines the phenomenon under investigation: namely, that of continuity and change in the bio-

psychological characteristics of human beings. The second focuses on the development of the scientific tools—the theoretical models and corresponding research designs required for assessing the continuity and change.

These two tasks cannot be carried out independently, for they are the joint product of emerging and converging ideas, based on both theoretical and empirical grounds—a process called 'developmental science in the discovery mode' (Bronfenbrenner and Evans 2000, pp. 999–1000). In the more familiar 'verification mode' the aim is to replicate previous findings in other settings to make sure that the findings still apply. By contrast, in the discovery mode, the aim is to fulfill two broader but interrelated objectives:

(a) Devising new alternative hypotheses and corresponding research designs that not only call existing results into question, but also stand a chance of yielding new, more differentiated, more precise, replicable research findings and, thereby, producing more valid scientific knowledge.

(b) Providing scientific bases for the design of effective social policies and programs that can counteract newly emerging developmentally disruptive influences. This has been an explicit objective of the bioecological model from its earliest beginnings.

A major challenge to today's bioecological model is to discover how such new working hypotheses and corresponding research designs can be developed for the future. One answer lies in the possibility that, despite historical change, some elements of the model, and their inter-relationships, may remain constant across both time and space. From this perspective, today's model has several distinctive defining properties that become the foundation for the rest. Some are of relatively recent origin; others date back to the model's earliest formal beginnings (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998, for reviews). Each is expressed here in the form of a Proposition.

1.1 Proposition I

An early critical element in the definition of the ecological model is experience. The term is used to indicate that the scientifically relevant features of any environment for human development include not only its objective properties but also the way in which these properties are subjectively experienced by the persons living in that environment. This equal emphasis on an 'experiential' as well as an 'objective' view springs neither from any antipathy to behaviorist concepts, nor from a predilection for existential philosophical foundations. It is dictated simply by a hard fact. Very few of the external influences significantly affecting human behavior and development can be described solely in terms of objective physical conditions and

events (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998).

A critical term in the foregoing formulation is the word 'solely.' In the bioecological model, both objective and subjective elements are posited as driving the course of human development; neither alone is presumed sufficient. Moreover, these elements do not always operate in the same direction. It is therefore important to understand the nature of each of these two dynamic forces, beginning on the phenomenological or experiential side. Both of the underlined terms are relevant because, while related to each other, they are typically applied to somewhat different spheres. The former is more often used in relation to cognitive development and pertains mainly to changes in how the environment is perceived at successive stages of the life course, beginning in early infancy and proceeding through childhood, adolescence, adulthood, and, ultimately, old age.

By contrast, 'experience' pertains more to the realm of feelings; for example, anticipations, forebodings, hopes, doubts, or personal beliefs. These too, emerge in early childhood, continue through life, and are characterized by both stability and change. They can relate to self or to others, and especially to family, friends, and other close associates. They can also apply to the activities in which one engages; for example, those that one most or least likes to do. But the most distinctive feature of such experiential qualities is that they are 'emotionally- and motivationally-loaded', encompassing both love and hate, joy and sorrow, curiosity and boredom, desire and revulsion, often with both polarities existing at the same time but usually in differing degrees. A significant body of research evidence indicates that such positive and negative subjective forces, evolving in the past, can also contribute in powerful ways to shaping the course of development in the future (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998).

But these are not the only powerful forces at work. There are others that are more objective in nature. This does not mean, however, that they are necessarily either more or less influential, mainly because the two sets of forces are interdependent and affect each other. Like their subjective counterparts, these more objective factors also rely for their assessment on corresponding theoretical models and associated research designs that have evolved over time. These more objective relationships are documented below in the form of two propositions (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998). The first specifies the theoretical model, and provides concrete examples; the second foreshadows the corresponding research designs for their assessment.

1.2 Proposition II

Over the life course, human development takes place through processes of progressively more complex

reciprocal interaction between an active, evolving biopsychological human organism and the persons, objects, and symbols in its immediate external environment. To be effective, the interaction must occur on a fairly regular basis over extended periods of time. Such enduring forms of interaction in the immediate environment are referred to as proximal processes. Examples of such processes include feeding or comforting a baby; playing with a young child; child-child activities; group or solitary play; reading, learning new skills; athletic activities; problem solving; caring for others; making plans; performing complex tasks; and acquiring new knowledge and know-how.

For the younger generation, participation in such interactive processes over time generates the ability, motivation, knowledge, and skill to engage in such activities both with others and on one's own. For example, through progressively more complex interaction with their parents, children increasingly become agents of their own development, to be sure only in part.

In sum, proximal processes are posited as the primary engines of development. The next defining property speaks to the corresponding research designs.

1.3 Proposition III

The form, power, content, and direction of the proximal processes producing development vary systematically as a joint function of the characteristics of the developing person (including genetic inheritance); the environment—both immediate and more remote—in which the processes are taking place; the nature of the developmental outcomes under consideration; and the continuities and changes occurring in the environment over time, through the life course, and during the historical period in which the person has lived.

Propositions II and III are theoretically interdependent and subject to empirical test. An operational research design that permits their simultaneous investigation is referred to as a Process-Person-Context-Time model (PPCT).

In the corresponding research designs for the bioecological model, the element of time has special importance. To show that development has actually occurred, the research design must demonstrate, or at least make plausible, that the elements in the design, and their dynamic relationships to each other, have influenced the 'biopsychological characteristics of the developing person over an extended period of time.'

For example, a rich data archive generously made available by Small and Luster (1990) from their state-wide studies of youth at risk in Wisconsin has made possible some reanalyses of working hypotheses derived from the newly-emerging formulations.

Figure 1 depicts the results from a reanalysis of the effects of parental monitoring on the academic

Figure 1
Parental monitoring and high school grades by gender: mothers with more than a high school education

achievement of high school students living in one of the three most common family structures found in the total sample of over 2500 cases. The students were between 14 and 16 years of age. The participants were also differentiated by gender, and stratified by two levels of mother's education, with completion of high school as the dividing line. The figure shows the results only for the high school graduates.

Parental monitoring was defined as 'the effort by parents to keep informed about and set limits on their children's activities outside the home.' Levels of parental monitoring, ranging from 0 to 12, are shown on the horizontal axis, and grade point average (GPA) appears on the vertical scale. The markers to the right of each curve record the average GPA for each of the six groups.

The data were fitted to a curve with a declining slope, rather than simply with a straight line, based on the following considerations derived from the bioecol-

ogical model: Higher levels of academic performance require mastery of progressively more complex tasks, and hence are more difficult to achieve. As can be seen in Fig. 1, the relation between parental monitoring and school grades does indeed show a declining curvilinear trend. This effect, however, is far stronger for girls than for boys, particularly in the most advantaged ecological niche—families with two biological parents in which the mother had some education beyond high school.

Both of these results are consistent with two working hypotheses derived from the bioecological model. The first stipulates that proximal processes (in this instance, parental monitoring) are likely to have greater impact in two-parent families than in those in which the mother is a single-parent or the father is a step-parent. The second hypothesis posits a stronger and longer-lasting influence of the family on the development of females than of males.

In addition, a distinctive feature of the pattern for girls is a marked flattening of the curve at higher levels of monitoring, and, in the case of daughters of single-parent mothers, even becomes a turnaround. This finding suggests that under such circumstances, the demands on the girls may become so great that the existing proximal processes are not equal to the task, and as a result, bring fewer educational returns. Finally, an analysis (not shown) of data on students whose mothers had no more than a high-school education revealed a similar pattern, but the constructive influence of monitoring was appreciably weaker, and its greater benefit to girls was reduced. Nevertheless, daughters of mothers with less than a high-school education both in single parent and in stepfather families still had higher GPA scores than did sons. Moreover, within each level of mothers' education statistically significant differences by family structure were found in school achievement, with students growing up in two-parent families receiving the highest grades and those from single-parent families the lowest.

To turn to a related issue: although proximal processes function as the engines of development, the energy that drives them comes from deeper sources that take us back to the experiential world of Proposition I (Bronfenbrenner and Evans 2000, Bronfenbrenner et al. 1996, Bronfenbrenner and Morris 1998). Both the subjective and the objective forces exert an especially strong influence on development during the formative years (from early infancy to young adulthood). A substantial body of research over the past century indicates that, two or three decades ago, these forces lay mainly within the family, with parents acting as the principal caregivers and sources of emotional support for their children, and with other adult family members living in the home being next in line. To a lesser extent, other relatives, family friends, and neighbors also functioned in this role.

However, there has been a marked change in this pattern over the past three decades. Parents, and other adult family members as well, have been spending increasing amounts of time commuting to and working at full-time jobs (in which overtime is increasingly often required or expected).

The nature of this trend and its relevance for human development are conveyed in the Propositions that follow. (For brevity's sake, the term 'child' is used below to encompass the entire period from infancy through young adulthood.)

1.4 Proposition IV

In order to develop—intellectually, emotionally, socially, and morally—a child requires, for all of these, the same thing: participation in progressively more complex activities, on a regular basis over an extended

period of time in the child's life, with one or more persons with whom the child develops a strong, mutual emotional attachment, and who are committed to the child's well-being and development, preferably for life (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998). The prerequisites stipulated in Proposition IV then lead to the developmental consequences described in the next Proposition.

1.5 Proposition V

The establishment of a strong mutual emotional attachment leads to internalization of the parent's activities and expressed feelings of affection. Such mutual ties, in turn, motivate the child's interest and engagement in related activities in the immediate physical, social, and—in due course—symbolic environment that invite exploration, manipulation, elaboration, and imagination. The next Proposition broadens the family circle.

1.6 Proposition VI

The establishment and maintenance of patterns of progressively more complex interaction and emotional attachment between parent and child depend to a substantial degree, on the availability and involvement of another adult, a third party, who assists, encourages, spells off, gives status to, and expresses admiration and affection for the person caring for and engaging in joint activity with the child. It also helps, but is not absolutely essential, that the third party be of the opposite sex from that of the other person caring for the child, because this is likely to expose and involve the child in a greater variety of developmentally-instigative activities and experiences (Bronfenbrenner et al. 1996). Where this is an attachment to two or more parent figures, each can serve as a third party to the other.

The research evidence for this Proposition came mainly by default. It was produced by demographic data documenting a rapid rise in the proportion of single-parent households. The trend began in the 1980s, and then continued at an even faster rate through most of the 1990s. The overwhelming majority of such homes were those in which the father was absent and the mother bore primary responsibility for the upbringing of the children.

A large number of investigations of developmental processes and outcomes in families of this kind have since been conducted across a range of cultural and social class groups. In general, the findings lead to two complementary conclusions:

(a) Even in families living in favorable socio-economic circumstances, children of single-parent mothers, or of fathers, for whom no other person is

acting reliably in a 'third party' role are at greater risk for experiencing one or more of the following developmental problems such as: hyperactivity or withdrawal; lack of attentiveness; difficulty in deferring gratification; poor academic achievement; school misbehavior; and frequent absenteeism.

(b) At a more serious level, there is the so-called 'teenage syndrome' of behaviors that tend to be associated together: dropping out of school; involvement in socially-alienated or destructive peer groups; smoking, drinking, frequent sexual experience, adolescent pregnancy, a cynical attitude toward work, and—in the more extreme cases—drugs, suicide, vandalism, violence, and criminal acts. Most of these effects are more pronounced for boys than for girls (Bronfenbrenner et al. 1996).

Not all single-parent families, however, exhibited these disturbed relationships and their disruptive effects on children's development. Systematic studies of the exceptions have identified what may be described as a general 'immunizing' factor. For example, children of single parents were less likely to experience developmental problems especially in families in which the mother (or father) received strong support from other adults living in the home. Also helpful were nearby relatives, friends, neighbors, members of religious groups, and, when available, staff members of family support and child care programs. What mattered most was not only the attention given to the child—important as this was—but also the assistance provided to the single parent or by others serving in the supportive roles cited in Proposition VI. It would seem that, in the family dance, 'it takes three to tango.'

But dancing is not the whole story. By the 1980s, theory and research in the ecology of human development had documented an accelerating trend toward greater permissiveness in styles of child rearing in American families. At the same time, successive scientific investigations had revealed progressively greater developmental advantage for strategies that placed increased emphasis on parental discipline and demand. The interpretation that emerged from analyses of the available data suggested that widespread application of these research findings would serve as an effective response to the developmentally disruptive changes taking place in contemporary society.

At this point, it is important to mention two other bodies of research that contributed significantly to the development of bioecological theory and its corresponding research designs. The first is now of long standing. In 1974 the sociologist Glen H. Elder, Jr., in his classic volume *Children of the Great Depression* (1974, 1999), extended the concept of development beyond the formative years to encompass the entire life course.

The second addition has yet to be fully exploited. Bronfenbrenner and Ceci (1994), taking the bioecological model as their point of departure, suggested an empirically testable alternative for the established

scientific paradigm used in behavior genetics. The proposed alternative model: (a) allows for nonadditive synergistic effects; (b) employs direct measures of the environment; and (c) proposes proximal processes as mechanisms of person–environment interaction through which genotypes for developmental competence are transformed into phenotypes. The model predicts that: (a) estimates of heritability (h^2) for developmental competence increase markedly with the magnitude of proximal processes; (b) heritability measures the proportion of variation in individual differences that are attributable only to 'unactualized' genetic potential, with the degree of 'unactualized' potential remaining unknown; (c) actualized genetic potential (h^2) will vary with the quality of the environment, and will increase as that quality is improved (for example, through providing job opportunities, health services, and intervention programs in low-income neighborhoods).

The authors also suggested that high levels of such patterns of parental behavior as 'neglect, abuse, or domination' could serve as powerful mechanisms for actualizing genetic potentials for developmentally maladaptive behaviors that both disrupt proximal processes and produce developmental disarray.

1.6.1 The bioecological model in the discovery mode: future perspectives. This section is based on Propositions and working hypotheses derived from the bioecological model for which, as yet, there are few empirical data. The section begins with future prospects for addressing the second stated goal of the bioecological model: that of 'providing needed scientific bases for the design of effective social policies and programs that can counteract newly-emerging developmentally-disruptive influences.'

In accord with the latter objective, the section begins with an unorthodox proposal. By and large, thus far, theory and research on human development have been concerned with the influence of the older generation on the development of the younger. In the Proposition that follows, the direction is reversed. (It should be noted that the basic idea underlying this Proposition is not new, and is foreshadowed both in the theory of Vygotsky (1978), and in the contemporary 'action' theory of Brandtstädter (1998, 1999).)

1.7 Proposition VII

The psychological development of parents is powerfully influenced by the behavior and development of their children. This phenomenon occurs through the life course; is more evident during the formative years when most children are living at home in the care of their parents; and often becomes especially pronounced during adolescence, when the young begin to

strive for independence both as individuals and as members of peer-groups. Such behavior is particularly likely to occur amongst those adolescents or youth who have comparatively little contact with their parents or other caring adults earlier in life. Although many studies have focused on the development of such alienated young people, the impact of the latter's behavior on the subsequent development of their parents has yet to receive the systematic investigation that it deserves. The converse of the foregoing Proposition—the influence of the successful transition of children through adolescence and young adulthood on the constructive development of their parents—has regrettably received even less scientific attention.

1.8 Proposition VIII

Over the life course, the process of attachment exhibits a turnaround. In the beginning, it is the children who are the beneficiaries of the parents' irrational commitment, whereas toward the end the roles are reversed. Then it is the elderly parents who receive the love and care of their now middle-aged children. If, however, there was no attachment at the beginning, there may be no attachment at the end.

In this regard, developmental science has yet to address a curious omission both with respect to theory and research design. Resort to search engines in psychology and related fields has thus far failed to identify any investigations of the influence of parent-child attachment on the future development of the parent in contrast to that of the child.

This is not quite the case, however, for the next proposition in the discovery mode. The theoretical model, the corresponding research design, as well as half of the necessary empirical data are already available. The only problem is to find or conduct a study that meets the requirements of this model.

1.9 Proposition IX

If an investigation conducted in the past meets the requirements of the bioecological model, including assessment of developmental outcomes 'over an extended period of time,' then replication of the study at a later point in time would reveal whether the processes under investigation were still valid or had been nullified or superseded by subsequent historical changes. When the latter occurs, the investigator is confronted with the challenge of proposing alternative working formulations for explaining the observed phenomena.

At the conclusion of this article, we move from the domain of theory and research design to the world of reality and action. In the bioecological model, these two worlds have never been far apart. Especially from

1970 to 2000, these two worlds have become ever closer to each other. At a more general level, the findings from both domains reveal what has been referred to as 'growing chaos' in the lives of children, youth, families, schools, the world of work, and the ever-greater commuting in between (Bronfenbrenner and Evans 2000, p. 1022). The most recent report of this phenomenon appears in an article by Bronfenbrenner and Evans (2000). It contains the following summary about the nature of 'chaos' and its developmental consequences.

'Chaos integrates the various elements involved, and foreshadows the role [of chaos] in the bioecological model in terms of what is called 'chaotic systems.' Such systems are characterized by frenetic activity, lack of structure, unpredictability in everyday activities, and high levels of ambient stimulation. Background stimulation is high, and there is a general lack of routinization and structure in daily life. The environment is also a major source of interruption of proximal processes in the form of residential noise, crowding, and classroom design' (p. 121).

At the turn of the century, we are left with a troubling question: From the perspective of the bioecological model, what is the prospect for the future development of our species? The answer to that question lies with the willingness of the USA and other economically developed countries to heed the emerging lessons of developmental science. At the moment, it is difficult to know what the answer will be. The future could go either way.

Given this alternative, then surely it becomes the responsibility of developmental science to communicate such knowledge as we possess, and to do so in words that can still find an echo. Here is a first draft.

In the USA it is now possible for a youth, female as well as male, to graduate from high school, or university, without ever caring for a baby; without ever looking after someone who was ill, old, or lonely; or without comforting or assisting another human being who really needed help. The developmental consequences of such a deprivation of human experience have not as yet been scientifically researched. But the possible social implications are obvious, for—sooner or later, and usually sooner—all of us suffer illness, loneliness, and the need for help, comfort, and companionship. No society can long sustain itself unless its members have learned the sensitivities, motivations, and skills involved in assisting and caring for other human beings.

Human Development, Successful: Psychological Conceptions

From its outset human development is dependent on the presence of essential and beneficial conditions in the physical and social environment. Some of these conditions are fundamental and the same for all human beings (oxygen, water, food), while others are more complex and necessary to varying degrees (e.g., support of caregivers, language education, culturally specific competencies). Human beings also differ from one another in their psychological and physical needs: congenital and acquired vulnerability and deficiencies need special support and encouragement, some of them may even require specialist intervention or preventive treatment (e.g., specialized diets in the case of inherited metabolic disturbances such as phenylketonuria). At any event, there needs to be a minimum degree of fit between the individual and his or her environment before development can actually take place. Within these bounds, however, a very wide range of human development can unfold: An individual's predispositions and qualities encounter an immeasurably vast range of diverse environmental influences (socialization, critical and non-normative life events, historical influences, etc.). These influential factors operate throughout an individual's ontogenesis (Baltes et al. 1998). Human development never reaches completion, is multidirectional and seldom irreversible, while at the same time features a high degree of interindividual variability and intraindividual plasticity (Baltes 1987, Baltes and Baltes 1990). Moreover, there is now a broad consensus that human development does not take place uniformly in an irreversible sequence of different stages and phases, but is a process that individuals themselves actively influence in substantial ways (Brandtstädter 1998).

In view of this broad range of possibilities, the question of how and under what circumstances human development can succeed proves to be complex in several respects. The purpose of this chapter is to deal with two questions. The more important, of course, is the question of what makes development successful: which are the prerequisites of an 'art of life' (Staudinger 1999)? To answer this question, however, the term 'successful' needs to be clarified.

1. What is 'Successful' Development? The Problem of Criteria

Since the work of David Hume (1978), many have argued that while empirical sciences like psychology may, for reasons of principle, apply criteria which are value judgments, they cannot justify or legitimize the use of such criteria. According to this view, no matter how good science may be, it can only describe and explain the world, but it cannot judge it. Is the question of 'successful' development hence unanswerable from the start, at least from the viewpoint of an empirical science?

Actually, the relationship between empirical description and explanation on the one hand and value judgments or normative standards on the other is in fact more complex than that. Even if empirical facts do not constitute sufficient conditions for making evaluations, as a rule they are nevertheless necessary ones (Brandtstädter and Schneewind 1977). Any decision or action is predicated not only upon preferences and value judgments but also upon expectations which take account of empirical facts. For instance, the demand for a juvenile who commit crimes to be 'educated' by a punishment assumes that punishment actually serves to influence his future actions. This is an assumption that can, and indeed must, be empirically tested. In this respect science plays a key role in answering the question of successful development, even if the criterion for measuring 'success' has had to be determined on a prescientific basis.

Yet it is open to question whether assessments of human action and biographies really are as completely arbitrary as is suggested by a Humean perspective. Without wishing to become involved in the finer points of the philosophical debates surrounding the 'deducibility' of normative statements from descriptive ones, it can nevertheless be said that all positions purporting to offer proof of the inherent distinction between 'is' and 'ought' in fact tend to presuppose this 'gap' of principle rather than to prove its existence (Mavrodes 1968). In search for firm foundations for value judgments as well as for empirical descriptions, the last line of defense is the practice of simply not calling certain statements into question because the grounds for doubting them appear more dubious than the statements themselves.

So although we can forget any prospect of finding 'the' best biography *per se* in the foreseeable future, indisputably negative examples can easily be identified within the variations realized. For instance, there is no doubt that a person who persistently and repeatedly violates others for no reason, leads a less 'productive' life than one who shows reasonable consideration for others' interests and needs when taking his or her actions and decisions. Likewise, one can hardly describe an old age marred by illness and loneliness, causing distress particularly to the aged person but also to his or her relatives and friends, as 'successful'

without arousing the suspicion that this is an artificial, academic discussion or simply cynicism. The details of examples such as these will be controversial, and here too particular constellations will lead to changes in our assessments. Nevertheless, such examples show that in many cases value judgments ('better'-'worse') are scarcely more doubtful than the 'brute' facts.

However, the search for universal criteria of successful development which can be applied to all people irrespective of their individual, cultural and historical circumstances, is likely to be fruitless, because it follows from the actional perspective of human development that people's 'success' depends to no small degree on what they themselves consider to be successful. Within the development-regulating normative rules and developmental tasks of a culture, which incidentally are themselves subject to cultural development processes, the individual organizes ways of shaping his or her own life, looking for and construing orientations which give meaning to his or her personal development (Brandtstädter 1998).

These considerations point toward a solution to the question of criteria. Beyond the fulfillment of the fundamental conditions essential for life, the prerequisites for successful development are clearly those meta-competencies and meta-resources which ensure that individuals can make use of opportunities and encouragement, can compensate for deficiencies and vulnerabilities, can choose and realize their own developmental goals, and thus can actively shape their development within the framework defined by immediate and potential possibilities (Brandtstädter and Schneewind 1977). This metaperspective implies a multicriteria approach on the one hand, and the integration of subjective and objective criteria of 'success' on the other (Baltes and Baltes 1990).

2. What Makes Development Successful?

If human development is basically the product of culture and, at the same time, the result of individual action, an essential prerequisite for successful development is the capacity to act, i.e., to choose developmental goals, to make decisions, to form intentions and to put them into practice, and also to overcome resistance and to revise strategies where necessary. Acting successfully entails first the precise competencies needed to carry out a particular action in practice. Additionally, an adequate representation of these competencies and potentials in the person's self-concept is a prerequisite for an appropriate and autonomous choice to be made from among the possible developmental options. Thus, processes of self-regulation perform an integrating, 'orchestrating' function for human development (Staudinger et al. 1995).

Self-regulating processes can essentially be classified into two modes (Brandtstädter and Greve 1994). In the assimilative mode, goals are maintained even

against resistance, and strategies are pursued tenaciously until they are achieved. Obviously, development can only succeed if people are sufficiently willing and capable; anyone who always gives up immediately will achieve neither essential tasks nor those of his or her choosing. In the accommodative mode, when faced with goals that are truly or are perceived to be unachievable, or with irreversible losses and deterioration, preferences and orientations are adapted in a way that avoids meaninglessness and depressive tendencies, and preserves subjective well-being, but at the same time brings new, achievable goals into view, which revive the capacity and motivation to act. These aspects are illustrated with examples from the research fields of juvenile delinquency and successful aging.

2.1 Autonomy and Social Integration: The Sample Case of Juvenile Delinquency

Although difficulties of coping with developmental tasks occur throughout the lifecourse, juvenile delinquency serves as a good example with which to illustrate such difficulties. Challenges such as physical changes and sexual maturation, the need to develop interpersonal skills (e.g., for relationships with the opposite sex), acquiring education and, in particular, forming a personal and social identity are not just the storms to be weathered during adolescence; these challenges are vitally bound up with laying the groundwork for successfully solving the tasks and meeting the demands of adult life (Crockett and Crouter 1995). In particular, social developmental tasks play a particularly prominent role during the years of youth (Petersen and Leffert 1995). Especially at a juvenile age, the dualism involved in social integration is patently evident: at one and the same time, social integration is an aim in itself and a prerequisite for successfully fulfilling the developmental task of preparing adulthood. However, both the necessity and the opportunity to change and challenge social contexts are characteristic features of adolescence too. Since the dividing line between creatively transgressing the social rules and a deviant or pathological disregard for social limits can be a fuzzy one, these dilemmas of individuation vs. integration and of autonomy vs. adaptation may serve as a background for the explanation of juvenile delinquency (Coie and Dodge 1998). Delinquent juveniles, in particular those whose deviance is 'adolescence-limited' (Moffitt 1993), have evidently not managed to cope successfully with these tasks (Petersen and Leffert 1995). Thus, personal resources of coping with discrepancies between the social demands on the one hand and the personal goals, desires and competencies on the other gain a key function in explaining juvenile delinquency and, as a consequence, successful juvenile development. In particular, the goodness of fit between

the individual and his or her social environment thus becomes an important precondition and, at the same time, a central criterion for developmental success of adolescence.

2.2 Resources of Resilience: The Sample Case of Successful Aging

Going yet another step further, human development in general can be regarded as a hierarchical, interactive sequence of micro- and macroscopic coping processes. While current coping processes and resources are shaped by developmental conditions, coping reactions can also act as forces in creating future development. That leads on to the investigation of developmental constellations of individual and social resources that make an individual either resilient against or vulnerable to new strains as they arise. The discussion of the conditions under which people cope successfully with aging illuminates this aspect very well. Numerous studies have shown that people's ability to function and their sense of well-being are not greatly impaired as they grow old, if at all. Indicators of overall psychological status such as self-esteem, general sense of well-being, or being convinced of having control over one's own life are variables which, taken together, do not show any substantial covariance with age (e.g., Brandtstädter et al. 1993, Staudinger et al. 1995). As a consequence, the stereotype of aging being a process strongly characterized by deficiencies and loss has gradually gone out of favor as being too one-sided and incomplete, to be superseded by a more multifaceted view of 'productive' and 'successful' aging (Baltes and Baltes 1990). These findings are most surprising when set against the well-documented fact that, whether in terms of cognitive development, changing sensory functions or morbidity, aging does entail a real increase in the losses and impairment people suffer (Bond et al. 1995).

This apparent contradiction between the growing strains and losses on the one hand and the stability of the self and well-being on the other is resolved once the personal constellations of 'resilience' (Rutter 1990) are made the focus of the theoretical perspective (Baltes and Baltes 1990, Brandtstädter 1998, Staudinger et al. 1995). In addition to the model of developmental self-regulation already mentioned (Brandtstädter et al. 1993), the main model providing important insights that help to explain resilience in old age is that of 'selective optimization with compensation' (Baltes and Baltes 1990). As losses occur, they can be partly cushioned or alleviated by way of selective improvement (training, expertise), and compensated for as people reorient their lives or change their strategies. Against the background of the actional conception of development, it is important to point out that resilience is not just a reactive quality, but is often brought to bear proactively, before the troubling event

actually occurs or the degenerative tendency sets in. For instance, the fact that people have less chance of becoming crime victims as they grow older is partially explained by an increasing tendency to behave more cautiously (Greve 1998).

3. Conclusion: Courses and Conditions of Successful Development

In terms of cognitive functions, social integration, and self-regulation, human development features a considerable amount of plasticity (Baltes et al. 1998), which not only makes up the core prerequisite for the dynamics of resilience and the coping processes discussed here, but indeed is also a general precondition for the very possibility of lifespan development. Self-regulation processes are both a central criterion for adaptation processes on the one hand and they substantially control them on the other.

Personal well-being and psychological health, and social integration can only be maintained and improved if the individual can be protected against unfavorable conditions by resilient resource constellations, if personal and social coping resources can help to cushion and compensate for the crises and losses that will inevitably occur, and if the individual capacity to act is largely maintained, whether by stabilizing the required conditions or by finding a new orientation toward achievable objectives. Actually, all of these aspects can be seen both as the products and the producers of successful development.

Development essentially consists in upholding and implementing the individual's capacity to adapt to the discrepancies in new situations and developmental tasks as he or she seeks (via assimilation or accommodation) to attain a solution to, or dissolution of, the discrepancies that are generating a crisis or creating a burden, if these are unavoidable in the long run. Thus, successful development implies a progressive adaptation which simultaneously maintains or indeed expands this plasticity and adaptivity. As far as we know today, this is possible—and usual—at least up to the latest years of very old age (Baltes 1997). That leads to the somewhat tautological-sounding statement that successful development essentially means ensuring that development, i.e., progressive adaptation, will always be possible and really will occur.

The emerging perspective of adaptivity and activity as the roots of successful human development suggests essential new research perspectives focusing on sources of resiliency and vulnerability at any stage of human development. Moreover, even if the preconditions and processes are known which provide successful development, the ways to improve the individual's capacity to acquire or to use them are still to be investigated. Thus, studies in applied developmental science are needed in order to discover techniques and

strategies of individual and social improvement of both of these core conditions, with respect to special interventions, e.g., in the case of juvenile delinquency, as well as with respect to primary prevention of developmental crises, e.g., in the case of successful aging in very old age.

Human Ecology

Human ecology addresses the relationships of humans to their environments. This demarcation concept unites an array of otherwise unconnected scholarly traditions. The traditions are distinguished by their different interpretations of ecology itself, by the different theory frames they employ for the study of human ecology, and by their respective objects of explanation or problematics. This article begins with the different interpretations as a preview for sorting and examining the different theory frames and their problematics.

1. Interpretations of Ecology

Interpretations of the concept and substance of ecology differ according to the unique vantage points provided by independent scholarly traditions.

1.1 The Biological Interpretation

Ecology was originally given a biological interpretation in 1866 when Ernst Haeckel defined the science in accord with the work of Darwin, who had attempted to explain evolution in terms of the adaptations of organisms to the biotic and abiotic features of their environments. A generation later another foundation concept appeared: since evolutionary studies indicated there was an ecology of living organisms before humans evolved, and humans themselves are living organisms, there must therefore be a human ecology. On the biological interpretation, humans are part and parcel of the natural world, and are subject to the same biophysical dynamics that govern the organization of other living communities. For most of the twentieth century, however, although gradually shifting in the last couple of decades, biologists took only a passing interest in the scientific study of the ecology of humans *per se*.

1.2 The Metaphorical Interpretation

Social scientists, by contrast, were quick to seize on the idea of a human ecology with independent investigations begun in the 1920s, in India, by Radhakamal Mukerjee, who followed the biological interpretation, and in the USA by Robert Park, whose students did not. Aware of theories of community succession that their biological colleagues were then developing for natural communities, in which society was used as a metaphor to understand natural organization, some early US sociologists came to use nature as a metaphor to understand social organization. Setting aside the rhetorical uses of ‘ecology’ as a synonym for ‘contextual’ or ‘environmental,’ two variants of metaphorical interpretation can now be found in social science. The first applies bioecological concepts to the study of human communities *per se*, reasoning by analogy. Here, institutional or organizational settings are taken as contexts or environments for humans within their groups, populations, or societies, which are supposed to be organized parallel to natural communities. This variant generally overlooks the fact that natural communities contain multiple species and humans are a single species, preferring to finesse this by elaborating biological species and evolutionary analogies for societal divisions of labor. The second variant, discussed in Sect. 2.3, treats ecological knowledge as a social construct. Left unaccounted for in the metaphorical interpretation are biological connections between human societies and other natural systems. The metaphorical interpretation is a blueprint for the study of the internal workings of society through the adaptations of its populations or groups by means of their social organizations and shared cultural knowledge (see *Biology's Influence on Sociology: Human Sociobiology*).

1.3 The Ideological Interpretation

With the reawakening of the modern environmental movement worldwide and its growth in the last decades of the twentieth century, an ideological interpretation of ecology has appeared. In this, the biological and metaphorical interpretations of ecology are freely interwoven and supplemented with value judgments gauged against standards supposedly congruent with ecological science. Some versions of the ideological interpretation use nature as an ideal to evaluate and reform social and political organization, economic practice, and personal conduct, while others try to frame environmental ethics so as to integrate ecological science with politics, economics, philosophy, education and various religions and cultures. The ideological interpretation is neither monolithic nor uniform, but its advocates generally fall to the left of ideological spectra. The common thread is that ecology is more than science or metaphor: It is a world view with ethical implications for personal, cultural,

and institutional change (see, for example, Evernden 1992, Oelshlaeger 1994, Orr 1992).

2. Theory Frames for Human Ecology

The multifarious research traditions of human ecology may be understood in terms of the different theory frames they have employed, which reflect their respective interpretations of ecology. Different theory frames address different problematics.

2.1 The Evolutionary Theory Frame

The evolutionary theory frame assumes that ecological forces act on genetic and cultural variation among individuals and populations so as to effect a selective survival and reproduction. Using this assumption, neo-Darwinian principles of natural selection are applied to understand how individuals adapt to their natural environments, how different social species reflect common principles of social organization in response to ecological contingencies, and how populations and cultures are affected by pathogenic disease.

Individual behavior and social organization are classic problematics in social science. The application of evolutionary theory attempts to provide a fuller explanation of these. One strand of theory develops a human evolutionary ecology patterned on the behavioral and evolutionary ecology of the biological sciences. In this, an adaptive design is assumed to be the product of the elemental behavior of individuals, such as foraging, territorial defense, time allocation and mate selection, all of which are presumed to satisfy economic cost-benefit principles (Smith and Winterhalter 1992). It has yet to be demonstrated whether neo-Darwinian evolutionary-economic models have application beyond the case of hunter-gatherers. Because organic traits (such as brain size, bipedalism, and vocal chords) underlie cultural capabilities, and culture is understood as a human adaptation, some evolutionary models assume the co-evolution of biological and cultural traits in ecological context (Boyd and Richerson 1985, Durham 1991). Another strand of theory focuses on problematics of social organization among different species, with a view to discovering common principles but without presuming that the properties of social organization can be reduced to the summed behavior of individuals. In addition to comparisons with social primates, a research tradition of long standing, Machalek's (1999) transpecific sociology enables the comparison with humans of the demographic constraints, division of labor, and homeostatic mechanisms that appear in colonies of social insects, and of common strategies of environmental exploitation across social species (see *Cultural Evolution: Overview; Human Ecology*).

Problematics of epidemiology, ancient, and contemporary, fall within an evolutionary theory frame inasmuch as most scholars consider pathogens to be the principle agents of natural selection operating on humans since sedentary lifestyles were adopted 10,000–12,000 years ago. The most startling and horrible example of the human ecology of disease is the cultural and demographic extirpation of untold millions of native Americans in times of post-Columbian exploration, due to epidemic pathogens imported by Europeans and their African slaves, and from which the tribes had no inherited or acquired immunities. In modern times, medical authorities are again sounding alarms about the development and spread of epidemic pathogens, old and new, because normal genetic mutations eventually produce drug-resistant variants of old as well as new, and now dangerous, variants of formerly benign organisms. Since microbic pathogens are part of the living environment of all humans, human culture and society have to adapt to ever-changing conditions of pathogenic disease just as pathogens adapt to humans—an inherently ecological condition. The incidence of pathogenic diseases is known to be affected by agricultural practices, dietary customs, migration patterns, population densities, climate alteration, cultural hygiene practices, lack of potable water, sexual mores, modern transportation that transcends normal environmental barriers, and technological methods of intervention (see Ewald 1994, Kipple 1997).

Intervention methods typically disrupt population equilibria that might normally exist between pathogens and humans, thus preventing natural environmental controls from exerting themselves. Instead of stabilizing natural environments, technology implemented through the social organization of medicine and public health rather attempts to control pathogens so as to stabilize their relationship to humans. This method in itself, by intervening to change natural biota, provides a stimulus for microbic evolutionary adaptation. The general principle is that changed environments bring changed frequencies of microbic pathogens, human intentions notwithstanding. Some scholars (Mascie-Taylor 1993) have tended to conceive human ecology entirely in these epidemiological terms, however, this has not been predominant.

2.2 The Environmental Theory Frame

The environmental theory frame dominates modern research traditions of human ecology. It too presumes a biological interpretation of ecology, but in some cases substantially supplemented by considerations of social science targeted to problematics of subsistence and sustainability.

Anthropologists and geographers have a long tradition of investigating how human behavior, culture, traditions, settlements, built environments, spatial

location, territory, and humans' sense of place are affected by efforts to procure subsistence from natural—typically regional—environments. Research programs investigating cultural ecology, ecological anthropology, environmental geography, and environmental history consistently demonstrate how the development of culture and society vary with settlement patterns, technology and means of material resource acquisition, and how natural environments are modified by sociocultural variations in subsistence practices. A cultural materialism, which viewed culture and its symbolism as epiphenomenal, was implicit or explicit in many of these classic approaches, as was a dualistic construal of nature and culture. Modern approaches, especially political ecology, are different (see Biersack 1999, Scoones 1999). They focus on the interaction of spatial and temporal environmental dynamics with people situated in political, social, institutional, and cultural context, and emphasize the effects of human agency within the push-pull parameters of social, economic and political inequalities, on the one hand, and local or regional environmental transformations, on the other. Political ecology conceives human-environment interactions as mutual, thus linking human ecology to political economy and crossing from problematics of subsistence to those of sustainability (see *Feminist Political Ecology*).

No problematic has so dominated modern environmental discourse as the question of limits to growth, specifically, whether industrialism is sustainable into the indefinite future as it is adopted round the world. Biologists began the debate in the 1960s by importing from population ecology concepts of carrying capacity limits, and they averred that cascading world population growth augured for environmental catastrophe. Some social scientists amplified this neo-Malthusian argument, noting that industrialism is not a population but a way of life, one which produces too much consumption not just too many consumers.

Attentive to anthropogenic environmental degradation (aquifer depletion, biodiversity loss, deforestation, ozone depletion, global warming, etc.), the new social science tradition of examining environmental interfaces with human production and reproduction is now secure with the appearance of numerous textbooks and treatises on environmental sociology, environmental psychology, and ecological economics (see Costanza et al. 1997, Harper 1996). These specialties tend to conceive human-environment interactions within the existing theory traditions of their established disciplines. Recently, ominous neo-Malthusian analyses have been challenged by more optimistic theories of ecological modernization (Spaargaren and Mol 1992).

Theory aside, problematics of sustainability are routinely encountered as matters of practice in the concerted effort to promote sustainable development in economically less secure nations of the world. Specifically promoted by the United Nations, sus-

tainable development is taken to mean eliminating world poverty while not compromising local environmental stabilities (Brundtland Commission 1987). In fact, sustainable development as practiced has promoted the transfer of industrial technology to promote economic growth. Where the ideal has succeeded, and by consensus it has not much, in effect sustainable development programs have promoted further industrialization—thus rekindling the question of the long term sustainability of human-environment interactions as local, regional, and global environmental degradation compounds, interactively cascading from industrialism's increased energy capture and waste disposal. The concern over environmental degradation directs the problematic of sustainability, which currently is targeted more towards local than toward global applications (see *Human-Environment Relationships*).

2.3 The Analogic-Symbolic Theory Frame

The analogic-symbolic theory frame works with a metaphorical interpretation of ecology, with different variants selectively emphasizing analogies or symbolic constructs as central to theory development. Generally speaking, the theory frame takes biological ecology just seriously enough to borrow some of its content (sometimes merely its words) so that nature can serve as a metaphor to understand society, thus advancing social science. In the classic sociological tradition, 'environment' usually had no biological referent, and neither does 'community' or 'ecosystem,' which are favorite analogs in modern sociological human ecology. As noted earlier, US sociology provided the first sustained research tradition of human ecology, something of an urban geography, concerned as it was with spatial relations in cities, that beginning in mid-twentieth century the influential Amos Hawley gradually transformed into an ecological demography. In this, territorially circumscribed human populations are characterized by technologically based organizational adaptations in the sustenance producing activities of populations within their social, political, and economic environments. These orienting concepts have not changed in more than a generation (see Micklin and Posten 1998). They reflect a social and demographic, but not a biological, materialism in the conception of purely sociological problematics. Direct descendants, such as organizational ecology, and distant cousins, such as family ecology, likewise depend on theoretical analogies to biological phenomena in order to relate social entities to social environments (see *Population Ecology*).

A wholly independent and more recent set of problematics relating society and environment applies a social constructionist interpretation to environmental social science, counterweighting its biological interpretation. In this, natural environments become

material for the analysis of symbolic meanings and understandings by which social groups perceive and define environmental events as real and respond to them collectively. One-to-one theory analogs with bioecology are not sought, but the metaphorical interpretation of ecology runs deep because symbolized realities are accorded primacy over biophysical realities. Natural environments are taken to have significance only as people socially construct, perceive, define, and negotiate them as real, and make contestable claims about them. The problematics address social responses to natural environments insofar as environmental issues are defined through shared meanings (Hannigan 1995).

Theory variants that are exclusively analogic or symbolic usually seek to separate not integrate human ecology and bioecology, so as to strengthen social science *per se*. Implicitly, sometimes explicitly, many variants reflect the species prejudice that nonhuman organisms represent 'lower' forms of life and the cultural prejudice that Western industrialism represents the 'highest' form of social progress. These two prejudices are explicitly criticized in many variants of the interactive theory frame.

2.4 The Interactive Theory Frame

The interactive theory frame for human ecology is the newest, most diverse and most numerous in its scholarly problematics. Its growing traditions may only be listed here. They include assorted environmental ethics, such as deep ecology, the land ethic, and animal rights; assorted spiritual ecologies, including native US land wisdom, Christian-based ecological process theology, and strains of Buddhist, Taoist, and Jainist thought; some applications of complexity theory for evolving interactive systems; Gaian ecology; politically grounded approaches, such as social ecology and green Marxism; ecofeminism; and more (see, for example, Bookchin 1995, Benton 1996, Callicott 1994, Tucker and Grim 1993, Warren 1996).

All of these assume some variant of the ideological interpretation of ecology, reflecting a wish to integrate ecological knowledge with selected priorities in human affairs. Some are based in science, while others are based in philosophy, politics, religion, or tradition, but almost none maintains a hard and fast distinction between objective and subjective knowledge. Almost all take a holistic rather than reductionistic approach to their problematics, in which the traditional boundaries of scientific disciplines, and even the classic boundaries between science and the humanities, are regarded as anachronistic. Most reject any nature-culture dualism, and many disavow anthropocentrism. Multiple distinct problematics are defined, depending on the point of view. The overriding theme construes human ecology as knowledge of the complex interactive connections that integrate human activities with

environmental contexts. The overall result is an eclectic combination of biological, environmental, moral, and even esthetic, approaches to human ecology (see *Nature, Concepts of: Environmental and Ecological; Ecology, Deep; Feminist Political Ecology*).

3. Conclusion

Human ecological scholarship on the biological, environmental, and ideological interpretations, with their derivative problematics, is now being increasingly writ into the curricula of educational institutions. Calls for 'green education' are being implemented internationally, programs in environmental science that include a human component are expanding, and one US undergraduate institution of higher learning, the College of the Atlantic, devotes its curriculum entirely to human ecology. While still stymied by the traditional boundaries of academic disciplines, and sometimes by parochial scholarship, human ecology—the subject, not the name—is experiencing dynamic growth, as befits the coming century of the environment.

L. Freese

Human Ecology: Insights on Demographic Behavior

1. Introduction

Human ecology is the ‘the study of the form and the development of the community in human populations’ (Hawley 1950, p. 68, Hawley 1971) for which the unit of analysis ‘is not the individual but the aggregate which is either organized or in the process of being organized’ (Hawley 1950, p. 67) and where the concept of ‘community’ is defined as a ‘territorially based system of functional interdependencies that results from the collective adaptation of a population to its environment’ (Berry and Kasarda 1977, p. 12). Human ecology proposes that populations adapt to social, economic, political, and biophysical environments through organizational innovations, and that systems grow ‘to the maximum size and complexity afforded by the technology for transportation and communication’ in reducing the time cost of maintaining the accessibility and exchange required by interdependent populations (Hawley 1986, p. 7). It is important to recognize that it is this theoretical framework, not the mere fact that aggregate data are used, that places research in the human ecological tradition.

2. Contemporary Human Ecology

The intellectual lineage of human ecology traces from the emergence of plant and animal ecology in the late nineteenth and early twentieth centuries and its application to human populations in the work of Park and Burgess (1921), McKenzie (1933), and other scholars at the University of Chicago. The approach of these scholars, while innovative, was ultimately limited in scope. Perhaps most limiting was the initial insistence that cultural variables be excluded from the purview of human ecology in favor of a focus on spatial patterns resulting from a process of unplanned competition. By contrast, the insights into demographic phenomena described herein depend almost entirely on *contemporary human ecology* (hereafter, *human ecology*) which denotes the body of theory and research that began with the publication in 1950 of Amos H. Hawley’s *Human Ecology*, a landmark volume which led to a major reorientation of the field. Hawley’s work dramatically shifted the focus from the description of physical features of the city and mapping of social phenomena to ‘the ways in which human populations organize in order to maintain themselves in given environments, thus relegating spatial analysis to a minor though still useful position in the discipline’ (Hawley 1986, p. 3). It is not spatial arrangements themselves, but rather the social relations often reflected in spatial patterns and processes, that are of interest to human ecologists (Frisbie and Kasarda 1988 for further discussion).

Albeit something of an oversimplification, the human ecological paradigm can be thought of as encompassing four broad categories of variables: population, organization, environment, and technology—codified by Duncan (1959, 1964) as the ecological complex bearing the acronym POET. It is crucial to recognize that, in human ecology, population is defined generically to mean ‘a number of units sharing one or more given characteristics... (which acquires) operational significance only when clothed with a set of institutions and located in a space-time context’ (Hawley 1998, pp. 11–12). At least since Hawley’s redirection of the field (1950), the primary unit of analysis for human ecology has been the organized population, not the individual units comprising populations. In addition, human ecology places a much heavier emphasis on analysis of the social and economic environment, as compared to the biophysical environment (Hawley 1998). This distinguishes (but does not isolate) human ecological concerns from those which characterize bioecology and the environmental movement.

The term ‘demographic behavior’ is used broadly here to refer, not only to the basic processes of fertility, mortality, and migration, but also to *social demographic* phenomena, with social demography defined as ‘the analysis of how general social and cultural factors are related to population structure and pro-

cess' (Ford and De Jong 1970, p. 4). In this context, an impressive range of human ecological insights into a large number of demographic issues might be identified. This article primarily emphasizes contributions to the study of the systemic attributes and processes involved in population growth and societal development, the distribution and redistribution of population, and intra- and interurban morphology. While this selectivity is logical in light of human ecology's emphasis on systems, it warrants mention that the well-known contributions of human ecology to research on social networks and residential segregation are given little attention inasmuch as these are the subjects of other articles included in this volume (see *Social Networks and Fertility* and *Residential Concentration/Segregation, Demographic Effects of*, respectively). Further, while much of the present discussion concentrates on research conducted in the US, human ecology has been drawn upon rather extensively in cross-national research (Frisbie and Al-Khalifah 1998).

3. Human Ecology's General Theoretical Contribution to Macrolevel Demography

It is clear that human ecology has contributed substantially to the preservation and advance of macrolevel theory in the social and behavioral sciences, generally, and in demography, in particular (Poston and Frisbie 1998). However, in the mid-twentieth century, two events combined to diminish the interest of demographers and other social scientists in macrolevel analysis. The first was the publication of work dealing with what came to be known (erroneously) as the 'ecological fallacy.' Robinson (1950) argued that results of research in which aggregates are the units of analysis cannot be used to infer relationships among individuals and that a large proportion of research that employs aggregate data does so only because information on individuals is not available. The second was actually a sequence of events involving the emergence of modern techniques of sampling and survey analysis which greatly enhanced the opportunity for rigorous microlevel studies (Linz 1969). For a time, demography listed far toward reliance on individual-level research, even in the face of warnings by renowned scholars that the discipline was ill-served by a fixation at the microlevel (e.g., Ryder 1980).

A more balanced view prevails, partially due to the efforts of 'ecological demographers' both early on (Schnore 1961) and later (Namboodiri 1988). As it turned out, Robinson's thesis was only partially correct. The problem identified by Robinson is not 'ecological' in nature, but rather an issue that arises whenever cross-level generalizations of any kind are contemplated. Moreover, many of the central tenets of human ecology are inherently macrolevel constructs

devoid of any counterpart at the individual level. For example, the concept of the division of labor makes sense only when applied to groups. Analogous reasoning applies to many demographic variables. Individuals are born, they die, and in between they may migrate, but only groups, not individuals, have birth, mortality or migration rates.

A signal contribution of human ecology has thus been the development of a theoretical framework for a wide range of demographic studies of organized aggregates. Examples include investigations of the relationship between commodity exchange and position of cities in the US metropolitan hierarchy (Eberstein and Frisbie 1982), as well as in the world-wide system of cities (Meyer 1986), the effects on the volume and rate of migration, of functional niche and extent of the division of labor (Murdock et al. 1992, Poston and Mao 1996), changes in the social stratification of suburbs (Guest 1978, Krivo and Frisbie 1982), segregation of racial and ethnic populations (Massey and Denton 1989), and the 'birth' and 'death' rates of formal organizations (Carroll 1984, Hannan and Freeman 1977). Such work, in turn, offers a substantive grounding for multilevel analyses, in which, e.g., the behavior of individuals is partially explained in terms of the social or ecological context in which they exist.

4. Specific Insights on Demographic Phenomena

4.1 Population Growth

Perhaps no demographic issue has seized and held the attention of scholars, policy makers, the media, and the general public as that of rapid population growth. Interest in the 'population explosion' intensified circa 1970 in the wake of publications which predicted exhaustion of resources and irremediable environmental pollution if population and economic growth continued unchecked (Erllich 1968, Meadows et al. 1974). A wide range of less apocalyptic, but still highly disturbing, publications focused attention on less developed countries (LDCs) and the actual or anticipated deleterious consequences of rapid population growth for development and increases in the standard of living in these nations—effects epitomized by the piling up of excess rural populations in peripheral slums of huge cities (Davis 1975).

Early on, some scholars challenged the view that continued rapid population growth spelled worldwide collapse (see Davis 1990 for a summary of the position of 'alarmists' and 'skeptics'). Regardless of whether one tends toward pessimism or optimism, it is evident that demography has to come to grips with the Malthusian contention that population growth will inevitably be limited by exhaustion of natural and/or nonrenewable resources. Before one can meaningfully discuss its utility for better understanding population

growth, it is necessary to recognize that, in human ecological theory, population is regarded as a necessary, but not sufficient, condition. An important analytical implication is that population

cannot operate independent of organizational circumstances. In and of itself it cannot cause war, resource exhaustion, or environmental pollution, as Malthusians have argued. Such outcomes are explained as due to maladaptations or malfunctioning of organization (Hawley 1986, p. 26).

Human ecologists have also called attention to certain errant assumptions that are perhaps more apt to be found in popular or 'vulgar' interpretations than in Malthus' work itself (Keyfitz 1982). Among the most troublesome of these is the naïve perspective that the concept of manageable population size can be operationalized as a 'simple ratio of organisms to units of a resource or resources'—naïve because it fails to take into account 'the manner in which the population is organized to use the resources' (Hawley 1950, p. 151). This flaw apparently underlies the conclusion that concepts such as 'carrying capacity' and 'limits to growth,' have failed to provide either 'analytic power, or foresight, instead of hindsight' (Davis 1990, p. 13).

Constructive insights are found in the human ecological model of system change, growth, and equilibrium. In *system* terms, growth refers to 'maturation ... through the maximization of the potential for complexity and integration implicit in the technology for movement and communication possessed at a given point time' (Hawley 1986, p. 52). This perspective has direct roots in Boulding's (1953) theory of nonproportional change which suggests that a limit to growth occurs, not when some ratio of organisms to resources is reached, but when the communications and transportation costs involved in maintaining the coherence of a system become prohibitively high. Growth of systems can be expected to take the form of a logistic curve which describes a period of rapid growth which gives way to slow or no growth. Equilibrium in this view is a *temporary* state, and population increase will resume in combination with system expansion as additional organizational and technological inputs allow breaking through the upper asymptote imposed by the costs of movement and coordination of activities (Hawley 1986, 1998).

Applied specifically to demography, this insight might be translated as follows:

As to demographic growth, its initial acceleration is a natural byproduct of...economic transformation since, predictably, the fruits of economic improvement are in part used for obtaining better health and lowered mortality. Malthusian outcomes, however, need not be the inevitable result of rapid population growth. Such growth is transitory: given economic success, the spontaneous onset of "demographic transition" can be confidently expected. Pressure built into the reward mechanisms of modern industrial society induce behavioral

changes that eventually lead to low fertility, hence to low or no population growth (Demeny 1990, p. 417).

Recent worldwide fertility declines are consistent with this perspective. A 1999 United Nations publication shows that the world total fertility rate (TFR = the number of children a female surviving to the end of her reproductive life would bear given prevailing age-specific fertility rates (Keyfitz and Flieger 1990, p. 16)), after hovering around 5.0 during the period 1950–70 had fallen precipitously to 2.93 in 1990–95, with an expected TFR = 2.71 for 1995–2000 (UN 1999). By 1975–80, fertility in developed nations was already below replacement level (TFR = 1.91; for replacement, TFR is approximately 2.1, allowing for mortality of children). In LDCs, the rate for 1990–95 was 3.27, but this represented a rather astonishing decline from TFR = 6.00 in 1965–70. Based on its medium variant, the UN (1999, pp. 520–1) projects that average fertility among today's LDCs will fall to bare replacement level within the first four to five decades of the twenty-first century.

Of course, even with this major slowdown in population growth, 50 years into the twenty-first century, the world will still have a population much larger than today's roughly six billion (UN 1999, US Agency for International Development 1999). Some scholars (e.g., Bongaarts and Feeney 1998) have argued that current low fertility rates are, at least in some contexts, temporarily, rather than permanently, depressed to below replacement, while others believe the contemporary trend is likely to be permanent or at least rather persistent (Lesthaeghe and Willens 1999).

5. Urbanization

The concentration, deconcentration, and organization of urban populations have been central to ecological theory and research. As noted, Hawley defined human ecology as the study of the form and development of the community, of which urban places are a prime example. Although neither the *highly stylized spatial* models of urban form and growth developed by Burgess and Park, nor those of other scholars, have remained central to urban studies, these heuristic representations had a basis in analytical constructs that are important building blocks for ecological theories of the distribution and interaction of populations in both intraurban and interurban systems.

5.1 Intraurban Systems: Land Use and Population Distribution

Among the most directly relevant of human ecological insights for understanding *intrametropolitan* systems are those having to do with land use and population concentration/deconcentration. Of special interest is

Burgess' notion of geographical gradient as a basis for the hypothesis predicting an inverse relationship between intensity of land use by a population and distance from center to the periphery of cities (cf. Hawley 1971). This relationship, formalized by Colin Clark (1951), can be expressed in the form of natural logarithms as

$$\ln d_x = \ln d_o - bx \quad (1)$$

where d_x is the density of population at distance x from the center, d_o is the central density, and b is an empirically derived density gradient. Reflected in this equation is a theory of land use which begins with the premise that functional differentiation and interdependence of populations and organizations in a city require mutual accessibility. Since, *ceteris paribus*, the center of a city is the point most accessible to all other parts of the city, there will be competition for core location, thereby driving up the cost of land at or near the center which, in turn, requires that more intensive use must be made of space. As ease of access declines with distance from the core, so too does the cost of land and the intensity of its use (Berry and Kasarda 1977, Hawley 1971, Turner 1994). The magnitude of the insight afforded by the human ecological theory of urban land use for demographers and others interested in the distribution and redistribution of population is seen in the fact that the validity of this model has been demonstrated by research using data covering a period of over a century and a half and for more than 100 cities (Frisbie and Kasarda 1988, p. 634).

Ecological theory also predicts that reduction in the friction of movement of population, materials, and ideas over time and space will cause the slope of the gradient to become less and less steep. As modern means of transportation developed and dramatic advances were achieved in accumulating, processing, and disseminating information, simple models based on a core-to-periphery gradient in a monocentered city have become progressively less relevant as metropolitan areas have increasingly become multinodal. But, because it is the systemic relationships reflecting the need for mutual accessibility of functionally interdependent populations, not spatial patterns, *per se*, that are central to the theory, the relevance of the ecological perspective remains in the face of rapidly changing urban systems. To illustrate, in the 1970s, as documented by numerous scholars and summarized by Edmonston and Guterbock (1984), several factors seemed inimical to the continuation of the rapid pace of suburbanization. Transportation costs had risen dramatically due to the reduction of petroleum supplies by major producing nations, while income growth in constant dollars slowed notably and housing prices soared—all of which raised the cost of moving to, and commuting from, the urban periphery. In addition, demographic composition had shifted such

that the types of families that had traditionally fueled movement to suburbs, i.e., larger households headed by couples of prime child-bearing age, became proportionately fewer. Taking the coefficients of Clark's equation as dependent variables for more than 200 metropolitan areas, Edmonston and Guterbock demonstrated that mean central densities of cities continued to decline over a 25-year time span and that 'the density gradient dropped consistently' (1984, p. 918). That is, the initial concentration at the core of cities occurred due to the need for accessibility. The large negative sign of the density gradient reflected the less developed transportation and communications technology available during the early stage of city building, but the slope flattened as technological innovations emerged. When the cost of movement over time and space rose sharply in the 1970s, the deconcentration of population nevertheless continued because, by that time, jobs and market outlets (industrial parks and shopping malls), recreational facilities, and utilities had also expanded well into the urban periphery (Berry and Kasarda 1977, Edmonston and Guterbock 1984). Thus, in the face of altered social and economic conditions, the human ecological paradigm continues to be a reliable guide for research on population distribution and redistribution. The reason, in part, is due to the conceptualization of space as a time-cost variable. What organized populations seek to minimize is not *distance* between interdependent entities, but the cost in time, effort, and other resources required for regular interaction (Stephan and McMullin 1981).

Another crucial aspect of intraurban population distribution in the US is residential segregation by race and ethnicity. As mentioned above, this topic is addressed in detail later in this volume. However, a brief discussion is in order here because it is demographic analysis that has most fully documented segregation, and a substantial portion of the explanation for these findings has been provided by human ecological theory. A prime example is seen in the work of Massey and colleagues who, over many years, have traced the sharp separation of African Americans from whites (and the lower levels of separation of Latinos and Asians from whites), taking into account variation in socioeconomic status, nativity, and other factors (Massey 1979, Massey and Denton 1989, 1993, Farley and Frey 1994). Based on an examination of segregation in the US and five other nations, Massey concluded that 'the operation of common processes of *ethnic* concentration and dispersal are well-summarized by the ecological model' (Massey 1985, p. 315; emphasis added), especially as the model pertains to chain migration, invasion, and succession of populations, the urban economy, and the housing market. Although human ecological theory is much less helpful in accounting for black-white segregation, Massey and Eggers (1990) have usefully addressed this phenomenon in research on 'the ecology of inequality.'

5.2 Interurban Systems: National and World Patterns

A useful point of departure for many demographers interested in *intermetropolitan* organization has been the classification of cities according to horizontal and vertical dimensions. The horizontal dimension refers to functional specialization of cities in various goods and services at various stages of production for the market, as operationalized in terms of types of industrial activities (Duncan et al. 1960, Frisbie and Kasarda 1988). The vertical dimension refers to the level of dominance exercised by cities in a metropolitan hierarchy as measured by performance of coordinative functions, including financial services and organization of the market (Duncan et al. 1960, Eberstein and Frisbie 1982, Wanner 1977) on a scale that may be regional, national, or international in scope (Frisbie and Kasarda 1988, Wilson 1984).

Moving down the ladder of abstraction leads to a crucial hypothesis, viz., that a positive association will exist between the performance of higher-order functions and extensiveness of involvement in the urban web of interdependence. An empirical test (Eberstein and Frisbie 1982), using data on 171 US urban centers, with metropolitan function defined as performance of financial, commercial, administrative, and distributive activities and extensiveness of interdependence measured in terms of volume and variety of trade flows and number of exchange linkages among urban centers, provided considerable support for this hypothesis. In a study of the world system of cities, Meyer concluded that '(t)he hypotheses of ecological dominance were confirmed' (1986, p. 553). Specifically, Meyer found that, with a focus on the key functions of banking and finance, world core cities (e.g., New York, London, Tokyo) 'dominate the peripheral metropolises of South America, and within the core the upper level metropolises exert even greater dominance than the lower level metropolises' (1986, p. 553). In addition to the general support provided for ecological theory, such findings reinforce the social demographic point that 'while all metropolises are large cities, not all large cities are metropolises. Population size is a concomitant; function is the keynote' (Vance and Sutker 1954, p. 115).

6. Migration

'Change without movement is impossible' (Hawley 1950, p. 324). Based on this tenet, human ecology views migration (whether within or across national boundaries) as a means through which something approaching a balance between population size and life chances may be *temporarily* achieved. Many of the most fundamental concepts employed in migration research are rooted in human ecological theory, including the recognition that, because migration

involves a destination as well as a place of origin, it is necessary to consider both 'push' and 'pull' factors. Recently, human ecological models, which also include population size and distances between origin and destination as predictors, have been able to account for well over half the variation in migration streams of interstate migration in the US (Poston and Mao 1996) and interprovincial migration in China (Poston and Mao 1998). The ecological view of the push of 'overpopulation' as an impetus to migration refers not only to an excess of population to land, food, or some other natural resource, but more generally to availability of ecological niches in the form of job opportunities, especially as these are generated by the movement of capital (Hawley 1950).

Another contribution is seen in the notion of 'chain migration,' a phenomenon to which classical ecologists called attention. Chain migration means that 'migrants do not select destinations randomly, but follow social networks... to specific jobs in particular neighborhoods of selected cities' (Massey 1985, p. 318). The concept has enhanced our understanding of how residential segregation occurs and of how migrants adapt at destination through drawing on 'social capital' provided by co-ethnics (Massey 1985, 1991).

Clearly, the human ecological perspective must be supplemented by other theories of migration (Portes and Fernandez-Kelly 1989). One problem with the 'push—pull' model is that it cannot explain, '(g)iven the same set of expelling forces and factors of attraction, why is it that some individuals leave while others stay' (Portes 1991, p. 76). This weakness is inherent in the macrolevel approach of human ecology. Microlevel studies essentially seek an answer to the question 'Who moves and why?' By contrast, for human ecological studies of migration, the central question is 'Where do people go and why?'

While ecological theories of migration involve much more than a simple 'push—pull' hypothesis, there is, nevertheless, a certain tendency to neglect population movements that are forced or 'impelled' by political agents at origin (Petersen 1958). An analogous gap is evident at destination due to the lack of attention paid by ecologists to the impact of immigration policies instituted by receiving countries seeking to restrict, and/or influence the composition of, immigration flows (Freeman and Bean 1997). Further, despite the importance attributed by Hawley to capital flows as a determinant of immigration (1950, p. 330), research in human ecology seems to have failed to appreciate fully the importance of the penetration of capital for the creation of economic imbalances that stimulate immigration (Portes and Fernandez-Kelly 1989).

The theoretical contributions of human ecology to this line of research did not cease with the appearance of Human Ecology. Hawley has extended his own ideas concerning the spatial movement and redistribution of population, particularly with respect to urban-oriented migration (1971, 1986). More recently,

as part of a comprehensive theory of 'assembling of human populations' that involves geopolitical as well as ecological processes, Turner has set forth a set of propositions that envisions the rate of net immigration as 'a positive and additive function of: (a) the level of transportation and communication technologies, (b) the rate and extent of contact with external populations, (c) the differentiation as well as volume and velocity of markets, (d) the diversity of the population, and (e) the size of population settlements' (Turner 1994, p. 88). Coupled with the notions of chain migration and population flows preceded by capital flows, Turner's formulation seems highly pertinent to many of the international population flows that have characterized the twentieth century.

7. Summary

Contemporary human ecology has sustained and helped extend the theoretical foundation of macrolevel demography. It has also contributed in numerous ways to the understanding of specific demographic phenomena, as illustrated by reference to research on population growth, urban form and process, and migration, with brief attention given to residential segregation by race and ethnicity. While other examples could have been employed, it is palpable that human ecology provides a paradigm that, in spite of certain weaknesses and oversights, greatly facilitates comprehension of how populations grow and distribute themselves within, and adapt to, the natural and social environments.

P. Frisbie

Human Evolutionary Genetics

Human evolutionary genetics is the inference of human history and evolution through the study of genetic variation. While much biological variation among humans is readily observable, variation at the DNA level typically is hidden. Only in the last decades of the twentieth century, with the development of molecular biological techniques, has this variation become detectable. The hidden patterns of human genetic variation have been shaped by events and processes of the past. For instance, the differing long-term census sizes of the human and chimpanzee species have led to dramatically different levels of genetic diversity within the two species. Chimpanzees are more genetically diverse, indicating that the species has undergone less severe bottlenecks than has the human species. While genetic data may not indicate why the human species went through a bottleneck, they provide at least a partial solution to the puzzle that is human evolutionary history.

The field of human evolutionary genetics is built on the premise that one can infer evolutionary history through the analysis of human genetic variation in the context of relevant theory and nongenetic data. Patterns of genetic variation are considered to be the outcome of a set of processes that can be modeled, primarily according to population genetics and molecular evolutionary theory. The goal is to ‘undo’ the process, in a sense, in order to infer the past. The extent to which nongenetic data are incorporated, either explicitly or implicitly, cannot be overstated. Geographic, linguistic, archaeological, demographic, historical, and climatological data, along with findings from other areas in biology, are incorporated to varying degrees as human evolutionary geneticists draw conclusions from the genetic data.

1. *Two Directions within Human Evolutionary Genetics*

The study of genetic variation provides two categories of insight into human history and evolution. Each category reflects an emphasis on one set of evolutionary processes. While the pattern of variation of some DNA segments may reflect both sets of processes, one set is often presumed to have predominated.

1.1 *Phenotypic Evolution*

A longstanding focus of human evolutionary genetics is phenotypic evolution, including changes in morphology, physiology, and behavior. By comparing patterns of genetic variation of humans and closely related species, for example, researchers can infer the processes that led to the current human phenotype (to the extent that this phenotype has an inherited genetic basis). Also included in this category is the study of the evolution of susceptibility to disease. To date, most findings regarding phenotypic evolution have been in this area. The more general question of what, at the DNA level, distinguishes humans from other species has only recently reached the forefront of research in human evolutionary genetics but promises to be an exciting research direction. Critical in this area of research is an understanding of the relationship between the variation at the DNA level and the variation at the phenotypic level.

1.2 *Population Processes and Events*

A second category, exemplified by the human–chimpanzee comparison above, includes population processes and events. Researchers attempt to infer, for example, population sizes of the past, rates of migration between groups, and the timing of population movements. This was a primary focus of the field during the latter half of the twentieth century, and remains so into this century. A central question has been the timing and location of the origin of anatomically modern humans.

2. *‘Population’ and ‘Group’*

Essential to the practice of human evolutionary genetics are definitions of the terms ‘population’ and ‘group.’ The less precisely defined term, ‘group,’ is used here to mean any collection of individuals. In a theoretical framework, the term ‘population’ is defined very precisely, as a set of individuals constituting a mating pool. All individuals of the appropriate sex in the population are considered to be equally available as potential mates. Groups of humans rarely, if ever, fit this definition of a population. The boundary between one population and another is obscure. In

practice, therefore, human evolutionary geneticists delineate populations along linguistic, geographic, sociopolitical, and/or cultural boundaries. A population might include, for example, all speakers of a particular Bantu language, all inhabitants of a river valley in Italy, or all members of a caste group in India.

3. *‘DNA Segment’*

The term ‘DNA segment’ is defined here as any length of DNA that is passed intact (without recombination of paternal and maternal DNA) from parent to child. Under this definition, any single nucleotide constitutes a DNA segment, as does the entire non-recombining portion of the Y chromosome. The entire mitochondrial (mt) DNA genome can also be considered an independently evolving DNA segment. Essential to this definition is the consistency of history across the nucleotides of a DNA segment. That is, without recombination, all nucleotides of a given individual’s DNA segment have been inherited via the same set of ancestors (e.g., father, paternal grandfather, etc., for the non-recombining portion of the Y chromosome). Success in inferring human evolutionary history depends in part on the extent to which we can infer the history of a particular DNA segment. It also depends on the number of independently-evolving DNA segments studied, as discussed below.

While there are, as exemplified above, stretches of the human genomes (nuclear and mitochondrial) that fit the above definition of a DNA segment, most stretches of the nuclear genome have the potential to undergo recombination. When human evolutionary geneticists analyze DNA sequences such as the Human Leukocyte Antigen (HLA) region on chromosome 6, they must either assume that recombination has occurred rarely enough to be ignored, or bring recombination into their analytical framework.

4. *Summarizing Genetic Variation*

In summarizing genetic variation, initially researchers count the number of copies of each genetic variant in each group under study. For instance, frequencies of the variants A, B, and O (also called alleles) of the ABO blood group system, one of the earliest polymorphic (variable) genetic systems studied, have been estimated for thousands of human groups around the world.

4.1 *Within Group Genetic Diversity*

Gene diversity (heterozygosity), defined as the chance that two DNA segments drawn randomly from a

group are different, summarizes within-group variation and is estimated from allele frequencies. Other measures of diversity take into account additional information, such as the number of differences between two DNA segments (nucleotide diversity), or the total number of variable positions along a DNA segment (number of segregating sites), within a group. Molecular evolution and population genetic models allow the interpretation of such diversity estimates in terms of mutation rates, population size changes, natural selection, and migration.

4.2 Among and Between Group Diversity

Human evolutionary geneticists often condense information regarding the genetic variation among a set of human groups into a single measure, typically called F_{ST} (Hartl and Clark 2000). Estimates of F_{ST} and similar statistics lie behind the oft-mentioned finding that the greatest proportion of the total genetic variation in the human species lies within human groups rather than among them. This has been interpreted as evidence for a relative lack of isolation among human groups. While F_{ST} summarizes variation among groups, genetic distances summarize the genetic difference between a pair of populations (Hartl and Clark 2000). Relatively small genetic distances are considered to be evidence that two groups have been less isolated from one another than have other pairs of groups. Differences in population sizes, however, strongly influence estimates of genetic distance.

5. Patterns of Variation for Different Segments of the Human Genome Evolve Independently

At each segment of the human genome, variation is introduced through mutation and subsequently modified through natural selection, random genetic drift, and gene flow between groups. The current pattern of variation of each such segment tells a story. Closely linked segments (those near one another on a chromosome that undergoes recombination, or on the same non-recombining chromosome) are likely to tell a similar story, at least going back a short time. In general, however, segments of the human genome evolve independently and therefore have different histories. The most recent common ancestor (MRCA) of all contemporary representatives of a particular DNA segment (e.g., the non-recombining portion of the Y chromosome) existed in a particular place at a particular point in time. The MRCA of another, independently evolving DNA segment (e.g., the mitochondrial genome) is likely to have existed in quite a different place, at a different point in time.

In the absence of natural selection, the pattern of variation at a particular segment reflects population sizes and movements of people. Even if each DNA

segment evolves independently and therefore has its own history, population size and migration influence the variation at all segments of the biparentally inherited parts of the genome similarly. Human evolutionary geneticists, therefore, combine the information from multiple DNA segments to draw conclusions regarding population processes. This consideration of multiple gene histories increases the robustness of conclusions (Mountain 1998).

An important consideration is the rate of mutation at each genomic location. DNA repair mechanisms that influence the rate of mutation differ between nuclear and mitochondrial DNA. Furthermore, DNA segments that include repeated elements (e.g., CACACACACACA) tend to mutate more rapidly than do nonrepetitive segments. Indeed, even within a short DNA segment of one hundred nucleotides, mutation rates may vary by an order of magnitude. The rate of mutation strongly influences the time depth over which a DNA segment is informative. A slowly mutating segment, for instance, will be uninformative over a short timescale. Mutation rates are very difficult to measure or estimate, primarily because mutation typically is rare (usually far fewer than 1 mutation per 10,000 nucleotide sites per generation).

With respect to gene flow, it is important to distinguish between interspecific and intraspecific questions regarding history and evolution. For questions regarding multiple species (e.g., the Hominoids), it is typically assumed that gene flow between species is essentially nonexistent. One consequence of a lack of exchange between groups is a greater chance of observing fixed genetic differences. That is, all individuals of one group are of one genetic type, while all individuals of another group are of a different type. Intraspecific questions must be approached differently in that gene flow may have occurred between groups below the species level. The current paucity of fixed differences between human populations reflects, among other factors, a great deal of genetic exchange between populations. There is a great deal of debate regarding the precise nature of genetic exchange between human populations. Migration models typically include a constant rate of gene flow over time. While such a model is likely to apply to human history at some level, more appropriate models include changing rates of gene flow and the possibility of rare but influential major migration events (Fix 1999).

When natural selection has a stronger influence on genetic variation than random genetic drift, the pattern of variation within and among groups is affected. Natural selection has clearly played a strong role in generating human genetic variation, especially in constraining the observable variation. While an environmental factor such as average temperature may influence variation at a number of loci simultaneously, and in a similar direction, other factors may influence only one or two loci. This provides one

way of distinguishing between a model of natural selection and a model involving population processes alone; the latter are expected to influence all loci, while environmental factors influence only a subset. Incorporating natural selection in addition to population processes into evolutionary models greatly increases the total number of models under consideration, so that demonstrating the impact of positive natural selection (i.e., new alleles arise within an individual and provide that individual with a selective advantage over other individuals) is a serious challenge. One thoroughly investigated case of natural selection influencing human genetic variation is that of the rise of lactose tolerance in adults (Durham 1991).

6. Development of the Field

As currently practiced, research in human evolutionary genetics builds upon over a century of the development of a theoretical framework, of technical tools (data analysis and biological), and of collections of data. Prior to 1900 there was essentially no research in the realm of human evolutionary genetics. The latter half of the nineteenth century was critical, however, in that C. Darwin, G. Mendel, and their contemporaries provided the basis for a theoretical framework with an emphasis on variation and natural selection. This continued into the twentieth century with the classic work of G. H. Hardy and W. Weinberg in 1908 (Provine 1971). Independently, they described the simple but elegant relationship between the frequencies of an allele and the frequencies of resulting genotypes (in a population, with individuals mating at random with respect to genotype).

6.1 Development of Tools and Theory: 1900–50

The first half of the twentieth century saw the development of some of the essential elements in the field—technical tools and population genetic theory. Serological (blood typing) techniques, developed by 1900, made possible the genotyping of the ABO locus and led to a decrease in the risk associated with blood transfusions. Initial studies of the ABO locus focused on the variation among United States' soldiers. The resulting data are recognized as the first population data for what are now called 'classical genetic markers': Blood groups, and protein and enzyme polymorphisms. The discovery of blood groups and protein polymorphisms continued slowly during this period.

Other dramatic developments relevant to the field of human evolutionary genetics prior to 1950 lay in the area of population genetic theory, 'the quantitative synthesis of Mendelism and Darwinism' (Provine 1971, p. 129). As early as the 1920s Sewall Wright, Ronald

A. Fisher, and J. B. S. Haldane were publishing in the field. Fisher's *The Genetical Theory of Natural Selection* (1930), Wright's 'Evolution in Mendelian Populations' (1931) and Haldane's *The Causes of Evolution* (1932) are part of a proliferation of theoretical work of this period. They were joined by Theodosius Dobzhansky, whose *Genetics and the Origins of Species* (1937) was just one of several major contributions. Together, these authors outlined the theory behind the roles of natural selection, mutation, migration, and random genetic drift in the genetic evolution of populations (see Provine 1971, for an accessible history of the origins of theoretical population genetics). These theoreticians continued contributing well into the second half of the century.

By 1950, a number of classical genetic markers had been studied across human populations (Cavalli-Sforza and Bodmer 1971). Variation within the Rh genetic system, discovered in 1939, was considered in light of population genetic theory, as researchers attempted to explain the existence of alleles that are clearly deleterious to individuals under certain conditions. While studies often focused on the health impact of genetic variation, there was also an anthropological component: Researchers sought to measure and explain the genetic differences among human groups. The elevated frequency of Rh—individuals among Basques, for instance, was initially seen as evidence that they were descendants of the earliest modern humans in Europe. In 1948, Linus Pauling and colleagues described the role of the different forms of hemoglobin in sickle cell anemia, developing a revolutionary technique called electrophoresis to distinguish the different forms. At about the same time, J. B. S. Haldane put forth a hypothesis to explain the high frequency of another hemoglobin disorder, alpha thalassemia. He suggested that the blood cells of individuals heterozygous (having two different alleles) at this locus were more resistant to attack by malarial protozoa. This hypothesis was subsequently extended to sickle-cell disease. The story of the advantage of the sickle cell allele in malarial regions remains one of the most convincing examples of the population genetic phenomenon known as heterozygote advantage. For a succinct summary of the research see Durham (1991).

6.2 Development of the Field: 1950–75

The third quarter of the twentieth century saw rapid development in several dimensions of human evolutionary genetics. In the mid-1950s, Mourant published his first *Distributions of Human Blood Groups* (1954) with tables of population frequencies for nine blood groups and the sickle cell trait. In the mid 1960s, Harris, Hubby, and R. Lewontin (see Lewontin 1974, for references) discovered that a large fraction of

proteins show variation within a species. This discovery led to a dramatic increase in the number of informative polymorphic systems typed across human populations: by the early 1970s, Cavalli-Sforza and Bodmer (1971) list 27 such systems. In 1972 Lewontin (1972) published a seminal article concluding that most human genetic variation is found within local human populations. Remarkably, today's more sophisticated techniques and larger data sets consistently confirm this original finding.

A number of research groups carried out detailed studies of nonWestern populations of particular interest to anthropologists at the time. J. Neel and colleagues focused on South American populations, particularly the Yanomama of southern Venezuela, beginning in the 1960s. They were surprised by the extent of genetic differentiation between Yanomama villages, attributing this to the small size of groups founding the villages. For details of this and other regional studies conducted during the 1960s, see Crawford and Workman (1973).

During this period new numerical methods, phylogenetic methods, and computer simulation were introduced and were immediately applied to the burgeoning set of data on classical genetic markers. In the early 1960s, L. Cavalli-Sforza and A. Edwards developed several methods for generating trees from population genetic data, and applied these to data for five blood groups for 15 human populations from around the world. While their initial results are not entirely consistent with results from larger, subsequent data sets, many of the features of that initial tree can be found in recent analyses as well. One surprising finding was that genetic and anthropometric traits (physical dimensions) gave very different pictures of differentiation among human groups. While anthropometric traits indicated a similarity between Africans and Australians, genetic traits (blood groups) indicated then, and still do, that these geographically distant populations are genetically distant as well.

Meanwhile theoretical population geneticists, particularly P. A. P. Moran and his students, as well as M. Kimura, continued to extend and develop models relevant to the field of human evolutionary genetics (Ewens 1979). In the context of new understanding about DNA and mutation, Kimura (1969) argued that most mutations, or variants, found in living individuals provide neither a survival/reproductive disadvantage nor advantage to the individuals whose genomes include these mutations. Instead, he claimed, these mutations are neutral, or nearly so. If most variation is neutral, then patterns of variation are to be interpreted in terms of population history rather than in terms of natural selection. During this period, statistical methods were developed to test the null hypothesis of no natural selection. The subsequent finding that the null hypothesis was difficult to reject (Lewontin 1974) had a direct impact on the field of human evolutionary genetics. It reinforced the idea

held by some geneticists that random genetic drift (random changes in allele frequencies over time) plays an important role in microevolution (see Kimura 1983, for discussion of controversy). While drift was certainly recognized as a powerful evolutionary force prior to Kimura's work, his 'Neutral Theory' of molecular evolution combined with the results of tests for natural selection led to a pendulum swing, with increased emphasis on drift (Weiss and Buchanan 2000). This was particularly the case for recently derived variation such as that found within the human species.

A number of research developments in biology, such as the discovery of the structure of DNA by J. Watson and F. Crick in 1953, had a significant impact on the field only much later, after DNA sequencing became sufficiently routine for population studies. The development of the clarifying concepts of cladistics by W. Hennig during the 1950s and 1960s had a much more immediate impact within systematics than within human evolutionary genetics. Nonetheless, Hennig's work has clearly had an influence in recent years, as phylogenetic methods using parsimony criteria have been applied to human DNA sequence data. In 1960, L. Pauling and E. Zuckerkandl introduced the concept of mutations occurring regularly enough at a particular nucleotide site to be considered 'clock-like.' To the extent that evolution at the molecular level is clock-like, researchers can infer dates, at least relative dates, given the number of mutational differences between DNA sequences.

6.3 Development of the Field: 1975–90

By the early 1980s, new techniques for assessing genetic variation supplemented serological and protein typing. Restriction enzymes were used to cut DNA segments at very precise locations. The sizes of the resulting DNA fragments varied depending on the underlying DNA sequence of an individual. Gel electrophoresis, introduced much earlier (1948), enabled researchers to compare and estimate fragment sizes. This approach led to an explosion in the number of known human polymorphisms during the 1980s. These were initially ascertained for medical genetic research (in the search for genes associated with disease), but were immediately recognized as valuable for human evolutionary genetics research. While thousands of polymorphisms were discovered, only a few hundred were actually studied in a geographically broad set of human populations.

During the 1980s DNA sequencing began replacing restriction analysis as the tool of choice within human evolutionary genetics. The initial focus was on the most highly variable regions of the mitochondrial genome, with its large number of copies per cell. The comparison of mtDNA sequences from numerous individuals throughout the world brought public

attention to the field. The public was captivated by the notion of 'the mother of us all,' as the mtDNA ancestor was labeled. Many people were also surprised by the interpretations of the patterns of mtDNA variation: That the common ancestors of living members of the human species lived relatively recently (less than 200,000 years ago rather than 1–2 million years ago (Klein 1999)) and that these ancestors probably lived in Africa.

7. Human Evolutionary Genetics at the Turn of the Millennium: Population Processes and Events

7.1 Human Genome Project

The rapid development of human evolutionary genetics over the final decade of the twentieth century owes a great deal to the Human Genome Project. Much of the technology developed under the auspices of that project (e.g., improved speed and accuracy of DNA sequencing methods) is currently applied in the field. In 1991, a group of human evolutionary geneticists led by L. Cavalli-Sforza proposed that the Human Genome Project be extended to include consideration of variation among individuals. Almost immediately, the proposal encountered criticism from groups concerned that geneticists might exploit individuals contributing DNA samples. Nonetheless, a subsequent Human Genome Project plan did include consideration of variation across individuals as a major goal. New methods of detecting variation among individuals were developed. The result is hundreds of thousands of nucleotide sites known to be polymorphic in humans across the entire human genome. Very few, however, have been studied in a broad set of human populations.

7.2 DNA of Ancient Peoples

Under some conditions (e.g., low temperature, aridity) DNA persists relatively intact within bones and teeth for thousands, if not hundreds of thousands, of years (Wayne et al. 1999). During the 1980s human evolutionary geneticists began to take advantage of this preservation of genetic information of the past. DNA from the bones of Neanderthal specimens, for example, has been compared with that of living humans in order to address the question of whether Neanderthals and anatomically modern humans interbred on a large scale within the last 100,000 years. The DNA from early anatomically modern humans promises to provide even further insight into human evolution during this time period (Relethford 2001). With respect to more recent human evolution, ancient DNA of Native Americans living prior to 500 years

ago has demonstrated no evidence of a dramatic loss of genetic variation in the intervening period, despite a dramatic reduction in the number of Native Americans (O'Rourke et al. 2000).

7.3 DNA of Living Peoples: Inferences Across a Range of Time Scales

While the DNA of ancient peoples has great potential to provide insight into human evolution, the DNA of extant peoples has been studied much more extensively (Cavalli-Sforza et al. 1994). The DNA of living people retains the signatures of events and processes at various time depths ranging from hundreds of thousands of years down to tens of years. Autosomal, Y chromosomal, and mtDNA of living people has shed light, for instance, on the peopling of Europe over the last 40,000 years. Researchers have estimated the relative contributions of Paleolithic and Neolithic Europeans to the present-day European gene pool. Independently evolving segments of the human genome are consistent in supporting the hypothesis of a relatively large contribution by Paleolithic Europeans to today's European gene pool, while Neolithic peoples from the Near East appear to have contributed roughly a quarter of that gene pool (Lell and Wallace 2000).

Two examples illustrate the potential for making inferences on a shorter time scale (a few thousand years at most). The social structure of the Hindu caste system, for instance, has been investigated using a combination of Y chromosome and mtDNA. Human evolutionary geneticists have compared the relative rates of male and female movement between castes, concluding that the caste system is driven by the social mobility of women (Bamshad et al. 1998). As a second example, oral traditions have been examined in light of DNA variation. According to oral history, the Lemba, a Bantu-speaking people of southern Africa, descend from Jews who moved from the Middle East to Yemen and then to southern Africa within the last 2,700 years. The finding that Lemba Y chromosomes are similar to those common amongst Jews and rare amongst the Lemba's African neighbors supports this tradition (Owens and King 1999).

7.4 New Theoretical Tools

While much of the population genetic theory and many of the data analysis tools relevant to human evolutionary genetics were developed prior to the 1990s, valuable new tools have been introduced more recently. Among these are Markov Chain Monte Carlo (MCMC) methods (see, for example, Griffiths and Tavaré 1995), and coalescent-based approaches (Kingman 1982). MCMC methods make possible

estimation of effective population size, population growth rate, migration rate, and mutation rate. The coalescent approach to inference involves considering the history, or genealogy, of a sample of present-day genes. The approach has been most valuable in efforts to date events of gene histories such as the age of the MRCA of all human Y chromosomes (Thomson et al. 2000). Most applications of the genealogical approach have been in the context of lengthy, non-recombining segments of the genome (i.e., mtDNA and the non-recombining portion of the Y chromosome). A major goal in the field today is to apply the same approach to a large number of segments of the autosomes and X chromosome.

8. Human Evolutionary Genetics at the Turn of the Millennium: Phenotypic Evolution

For an unknown number of segments of the human genome, current variation among human beings or among primates reflects the impact of natural selection. In these cases, while population processes and events have played a role, differences in fitness between individuals with different alleles have had greater influence. The most readily detected evidence of selection is in the context of disease, as exemplified above in the case of sickle cell anemia, malaria, and the hemoglobin genes. The field of human evolutionary genetics overlaps with medical genetics in that researchers in both fields seek to understand the origins of any genetic variation that appears to influence disease. The history of the gene associated with cystic fibrosis, for example, has been explored extensively.

A current focus of human evolutionary genetics is phenotypic traits other than disease, such as locomotion, dentition, and skin color (Weiss and Buchanan 2000). While little is known about the genetic diversity underlying skin color, variation at one gene, the melanocortin-stimulating hormone receptor gene, is known to be associated with red hair and fair skin that burns easily. Genetic diversity at this locus is significantly higher than the average nucleotide diversity in human populations and is likely to be an adaptive response to variation in environmental factors such as the availability of sunlight (Owens and King 1999).

Recently, researchers within human evolutionary genetics have begun focusing their attention upon the question, 'What makes us human?' Primate evolutionary geneticist Morris Goodman (1999) and others have argued for a 'Human Genome Evolution Project.' The goal is to identify features unique to the human genome that influence such traits as cognition, the form of the hind limb, and susceptibility to disease. There are approximately 40 million nucleotide differences between the human and chimpanzee genomes amongst the roughly 2×10^9 base pairs of non-

repetitive DNA. While most of these DNA level differences appear to confer no difference at the phenotypic level, a subset clearly does. The challenge is to identify that subset.

Known differences between humans and chimpanzees include chromosomal inversions and fusions, gene duplications, and repetitive element insertions (Varki 2000). Changes in the regulation of gene expression, however, are expected to be a more common source of phenotypic change (Varki 2000, Weiss and Buchanan 2000). Goodman and colleagues have described one example, wherein γ globin genes went from being expressed only within the embryo to being expressed primarily during the fetal stage. This change correlates with an evolutionary trend towards prolonged fetal life in the anthropoid primates (Goodman 1999). The search for other such changes is likely to occupy human evolutionary geneticists for the foreseeable future.

9. The Human Evolution Puzzle: Genetics Provides Some of the Pieces

The study of human evolution takes place within a broad range of academic disciplines. These include the fields of paleoanthropology and archaeology (Klein 1999), as well as such seemingly disparate fields as linguistics, developmental biology (Weiss and Buchanan 2000) and paleoclimatology (Hewitt 2000). Only within the context of findings in these fields can the study of genetic variation provide insight into some of the many details that constitute the evolutionary history of the human species. Human evolutionary geneticists face an exciting challenge as they attempt to integrate their findings regarding human evolution with those of counterparts in these linked disciplines.

J. L. Mountain

Human Genome Diversity and its Value

1. Introduction

The era of modern genetics began with the rediscovery of Mendel's laws in 1900. However, long before this rediscovery, Charles Darwin (1859) recognized that variation in characteristics among individuals provided the basis of origin of species. Evolutionary biologists and population geneticists have long been interested in studying such variations, especially those that have genetic bases, and their origins and maintenance. Genomic diversity of a population is the raw material for its evolution by natural selection. Genomic diversity of a population can be measured in several ways. The most commonly used measure is the probability that two genes at any particular position of the chromosomes chosen randomly from the population are different. Of course, it is not practically possible to choose genes, since at any position of the chromosomes, two genes remain in combination in an individual. The above probability is equivalent to the probability that if an individual is drawn at random, this individual will possess a combination of two different genes at the chromosomal location under consideration. The different gene variants at any chromosomal location (locus) are called alleles. The combination of two alleles at a locus in an individual is called the genotype of the individual. When the genotype comprises the same two identical alleles, it is said to be homozygous; otherwise, heterozygous. The higher this probability, the greater is the genomic diversity. When all individuals of a population have identical genes, this probability attains the value of zero indicating that there is no genomic diversity in the population at that locus.

1.1 The Beginning of Human Genome Diversity Studies

The fact that individuals can differ in inherited traits was first clearly established with the identification of the ABO blood group system by Landsteiner in 1900. Soon after World War I, the Hirschfelds (1919) first discovered that human populations differ in frequencies of ABO blood group types. This finding marked the beginning of human genome diversity

studies. Subsequently, the development of biochemical- and molecular-genetic techniques have provided greater understanding and more refined estimates of human genome diversity.

1.2 The Importance of Genetic Diversity

It is crucial for any population to be genetically diverse. Humans, like many other species, are susceptible to various infections, many life-threatening. There is an increasing realization from recent research that genetic factors are involved in conferring susceptibility/resistance to most such infections. If all individuals in a population were to be genetically the same, then in the event of an outbreak of a new infection, it is possible for the entire population to be easily wiped out by the infectious agent if no individual carries genes conferring resistance to this agent.

2. Human Genomic Diversity at Various Levels

The development of starch gel electrophoresis by Oliver Smithies in 1955, permitted genomic diversity to be estimated at the level of proteins. Electrophoretic surveys of a variety of serum proteins and red-cell enzymes indicated extensive polymorphism among humans (Harris 1966). He showed that about 30 percent of human proteins are polymorphic, however, the genomic diversity estimated on the basis of such polymorphisms averaged between 10 percent and 20 percent. What this means is that at loci that determine various proteins and enzymes, there is more than one allele present in roughly 30 percent of such loci, however, at these loci, only about 10–20 percent of individuals are heterozygous on the average. Since electrophoresis can only detect such genomic variation that result in electrical charge change, and since only about 25 percent of genomic changes result in charge changes of the corresponding protein molecules (Nei 1975), this technique can only detect a small fraction of genomic changes. Hence, estimates based on data of such polymorphisms necessarily provide an underestimate of the true genomic diversity. There are, however, large differences in estimated diversities using different human proteins. These differences are, in part, due to differences in the degree of functional constraint of various proteins (Nei 1987). Not all proteins are functionally equally important. Changes in genes determining such proteins that are functionally important are generally more detrimental to the individual than changes in genes determining functionally less important proteins. Random changes, known as mutations, in genes create new alleles and enhance genomic diversity. Since mutations in genes of functionally important proteins are more detrimental, the new alleles created by such mutations

are quickly removed from the population by natural selection. Hence, genomic diversity is related to functional constraint.

The development of the Southern blotting technique in 1975, allowed polymorphisms to be studied directly at the DNA level. The first DNA variants using this technique were detected in the late 1970s as restriction fragment length polymorphisms (RFLPs). Such length polymorphisms are due to cleavage or noncleavage of DNA at particular sites, commonly caused by single nucleotide polymorphisms (SNPs), that are detectable using specific restriction endonucleases. RFLP data also showed significant genomic diversity in human populations. Nucleotide sequencing, however, is the most direct method to investigate genomic changes. While systematic nucleotide sequencing studies involving large segments of the human genome and a large number of individuals are just beginning, from the limited data that are already available it has been estimated that the average level of diversity per nucleotide varies between 0.0001–0.005 (see Chakravarti 1999 for a summary of recent results). Thus, in every 10,000 nucleotide positions along the human chromosomes, between 1 and 50 positions are estimated to differ between any two copies of that chromosome. This remarkable 50-fold difference in nucleotide diversity is again in part due to the fact not all regions of the genome are functionally equally important. Accumulation of mutations is tolerated in the functionally less important parts of the genome, but strongly selected against in the more important parts of the genome.

3. The Value of Human Genome Diversity in Understanding Human Evolution

With the passage of time, a population splits into subpopulations because of various cultural, economic, demographic, and ecological reasons. For example, after a period of demographic expansion of a population, subgroups of individuals may be compelled to move to another locality because of depletion of resources in the original habitat. Subsequent to this move, the original group and the newly founded subgroup may cease to have any genetic contact that is realized through exchange of mates. Generally, such subgroups are founded by a limited number of individuals, which impacts upon the genomic diversity of the subpopulation. When several such subpopulations are formed and remain isolated from one another so that individuals of one subpopulation do not exchange mates with other subpopulations, genomic diversification of the subpopulations is hastened. (Fusion of populations also occurs, but is possibly much less common than fission, especially in expanding populations.) Admixture, or the exchange of genes, increases the genomic similarity between two

populations. The primary barriers to admixture are cultural and linguistic differences and geographical distance. Thus, one expects genes, cultures, and languages to evolve in tandem. Indeed, genomic diversity depends on demographic size and history of a population. Recent advances in molecular and statistical techniques have shown, for example, that pairwise comparisons of sequence differences among people within a population can reveal past demographic patterns of the population (Slatkin and Hudson 1991, Rogers and Harpending 1992, Thomson et al. 2000).

3.1 Some Important Evolutionary Inferences

The above facts have been used to make important inferences on human evolution. By examination of worldwide human genetic variation, Cavalli-Sforza et al. (1994) have found a major concordance between language similarities and genetic affinities. Their studies have also revealed that the spread of agriculture was by human migration, rather than through the spread of customs and knowledge. The most interesting, and perhaps the most controversial, inference derived from genome diversity data has been that all anatomically modern humans evolved in a single geographical region, Africa. If one considers a segment of the genome on which the possibility of any strong effect of natural selection may be negligible, and if by comparing the nucleotide sequences of this segment in two individuals, one finds them to differ by a certain number of nucleotides, then it is possible to easily estimate the date of their common ancestor if the mutation rate (the rate at which nucleotide changes take place per year) is known and can be assumed to be constant over time. Based on nucleotide sequence data and several other lines of genetic evidence, it has been inferred that (a) modern humans are a relatively young population, (b) Africans are genetically the most diverse group of humans, (c) the largest genetic divergence among Old World populations is between Africans and non-Africans, and (d) modern humans arose in Africa between 200,000 and 100,000 years ago and dispersed throughout the Old World to replace archaic human species completely (Stoneking 1993, Nei 1995), although some geneticists (Ayala 1995) do not believe in complete replacement or even in the single-origin scenario for anatomically modern humans (Wolpoff 1999, Relethford 1995).

3.2 Human Genome Diversity Studies Can Answer Some Central Biological Questions

The nature and extent of genome diversity depend on various evolutionary forces, such as, mutation, natural selection, random genetic drift, admixture, and recombination. The relative importance of the various evolutionary forces in determining and maintaining

diversities within and between human populations remains poorly understood. However, from past studies of human populations with diverse structures, it is clear that random genetic drift (genetic events dictated primarily by chance that result from the small size of local groups) and the flow of genes from one population to another through migration or mate exchange are responsible for much of the patterning within human populations. No reliable estimate exists of the fraction of the human genome which is under the direct effect of natural selection. Put differently, how much of the observed variation in the human genome has a direct bearing on the fitness of individuals is largely unknown.

With the clearer understanding of the features of the human genome that is now emerging, thanks to the Human Genome Project, it will soon become possible to answer some of these central biological questions. For this, it will be necessary to carefully partition the genome into different equivalence classes of segments based on particular features, such as function, tissue specificity, gene density, distance from chromosome centromere or telomeres, etc., and then estimating within- and between-population diversities separately for each of these classes.

4. Human Genome Diversity and Molecular Medicine

The practice of medicine today focuses on 'treatment after disease onset'; the promise of molecular medicine is 'prevention before disease onset.' The hope for this promise is that genetic bases for most diseases will be discovered as a result of the spectacular advances in molecular genetics. Genes for diseases will be mapped on chromosomes; mutations precipitating clinical conditions will be identified. These discoveries will permit delineation of genotypes that are predisposed to specific diseases. Knowledge of the genotype of an individual will allow prediction of risk to disease. Preventive measures, that will not only include lifestyle modification but also genotype-specific therapy, will be undertaken for high-risk individuals.

4.1 Genome Diversity Studies Can Lead to Gene Discovery

Genomic diversity data on human populations can be used successfully in localizing on chromosomes the genes that cause inherited disorders, identifying predisposing/susceptibility factors to various diseases, and estimating relative roles of genetic and environmental factors in disease causation. In a large population, alleles at a pair of loci generally combine randomly into possibly genetic types. Thus, in a large population, there is usually no association between loci, unless they are physically very close on the same chromosome. However, in small isolated populations

or in recently admixed populations, strong associations between alleles at different loci are expected. Put differently, in such cases genetic loci behave non-independently in a statistical sense. This phenomenon is known as linkage disequilibrium. Disequilibrium decays every generation at a rate dependent on how far apart the genes are on the chromosome, which is measured by the rate of recombination between the genes. By examining patterns of linkage disequilibrium between diseases and genomic markers, especially in small isolated populations, it is possible to map loci controlling diseases. For example, in recently admixed populations, disequilibrium can be observed over chromosomal areas as large as 5–10cM, which is about 2–5 percent of the estimated linkage length of an average human chromosome (Morton 1991). These estimates, in turn, help identify mutations that cause various genetic disorders. Thus, genome diversity studies can lead to gene discovery.

Variations at the DNA level among individuals that occur, on an average, once in every 500–1000 base pairs (bp) along the 3 billion bp human genome can result in a wide range of susceptibility or resistance to diseases. Polymorphisms in different regions of the genome can interact among themselves and/or with the environment in conferring susceptibility/resistance. By DNA sequencing of appropriate genomic regions (e.g., those that are involved in detoxification pathway, signal transduction, etc.) in individuals exposed to various levels of pathogens and environmental toxins and correlating the information thus obtained with clinical outcomes, it is potentially possible to identify specific alleles as well as environmental exposures that precipitate disease. Genome diversity research will enable more precise identification of the interaction of genomic polymorphisms with environmental agents in disease causation. Such research can lead to implementation of public health programs for protecting susceptible populations and for targeting genetic screening to groups at greater risk to disease. Indeed, the focus is shifting from gene discovery to gene diversity.

4.2 Risk Assessment via Genome Diversity

One of the primary values of genome diversity research is that it will help define genetic polymorphisms and gene products that can predict development, progression, and severity of disease. While for rare diseases, single mutations with large effects are generally involved in the precipitation of disease, for common diseases, perhaps common variations in several genes are involved. These common variations singly do not significantly enhance the risk to a common disease, but jointly precipitate the disease condition. So the estimation of frequencies and effects of common genetic polymorphisms, particularly single nucleotide polymorphisms (SNPs), in defined populations, are expected to play an integral role in

molecular medicine. These estimates may, one day, enable high-risk patients to be diagnosed at a very early stage of disease and be treated with effective therapies that reverse the disease process or even prevent disease from occurring. Drugs can be targeted specifically to those genotypically defined patients who will respond well to the drug with no adverse side effects.

5. Debunking the Myth of Race

Humankind is a reproductive community, all members of which are connected by ties of mating and parentage. Yet, any two individuals, identical twins excepted, carry different sets of genes. To systematically study this enormous genomic diversity, biologists and anthropologists have described and named complexes of organisms to identify for themselves, and to let others know, what they are talking and writing about. Thus, classifying and giving names to classes began as a convenience-tool of science. Human biologists too have named classes of populations as ‘races.’ For example, Garn (1965) recognized nine ‘geographical races’ and 32 ‘local races’ of man. Most such racial classifications were based on visible characteristics, such as skin color, nose height, etc. Such characters are generally adaptive to environmental conditions. Further, such characters also influence mate choice. Therefore, racial differences that are recognized by such characters are really the products of natural and sexual selection. Darwin (1871) noted ‘Although the existing races of man differ in many respects ... yet if their whole organization be taken into consideration they are found to resemble each other closely in a multitude of points.’ Studies on human genome diversity have gradually made the ineptitude of typological approaches evident to increasing majorities of anthropologists. Yet, racial classifications are often used in sociopolitical debates in which certain races are claimed to be ‘genetically superior’ to others. Past studies on genetic diversity have shown that there is usually much greater intra-populational genetic variation than interpopulational variation (Lewontin 1972, Nei 1975, Barbujani et al. 1997). This means that a pair of individuals from a so-called ‘genetically superior race’ may be genetically more different than when one of them is compared with another from a ‘genetically inferior race.’ This is clearly in contradiction to the notion of genetic ‘superiority.’ Indeed, genome diversity studies have provided further evidence that has helped debunk the myth of races. Through their analyses of data compiled from genetic studies in global populations, Cavalli-Sforza et al. (1994) have shown that frequencies of genes often form geographical gradients, which make the task of drawing lines on a map to divide the regions of different races nearly impossible. Thus, race boundaries are never sharp. Worse still, gradients of frequencies of different genes often criss-cross on a

geographical map. When boundaries of gene frequency gradients are steep, they often correspond with linguistic boundaries or other similar cultural barriers to gene mixing. Thus, observed genetic differences among populations have no relation with genetic 'superiority' or 'inferiority.' Such differences are primarily the results of natural selection, barriers to genetic intermixture and also chance effects (random genetic drift). Human genome diversity studies have been valuable in debunking the myth of race.

Human Genome Project: German Perspective

1. The Human Genome Project

The Human Genome Project differs from any previous biological or medical project in size and cost. Its ambitious goal is the deciphering (sequencing) of all 3 billion building blocks of our genetic make-up—the so-called DNA—by 2005, the identification of all genes encoded in that DNA, and the understanding of the role of these genes in health and disease. The knowledge of these genes and their function is crucial for basic biological research as well as for the improvement of prevention, diagnostics, and therapy of disease. It is the prerequisite for a targeted design of pharmaceuticals and for novel approaches like gene therapy. This knowledge poses hope to millions of affected people and contains also an immense economic potential.

The Human Genome Project was started in the USA in 1990, James Watson, the codiscoverer of the DNA structure being its first co-ordinator. It was clear from the beginning, due to the estimated cost of US \$ 3 billion and the immense amount of work involved, that the Human Genome Project had to include many countries. The Human Genome Organization (HUGO), an independent international organization of genome scientists, was established to co-ordinate the duties. The US Human Genome Project started off with considerable public funding (US \$ 87 million in 1990) and was soon followed by the UK and France. Between 1991 and 1996 France contributed a comprehensive genetic map of the human genome. It is noteworthy that this work was predominantly financed by private money from a patients' association. The British Wellcome Trust for its part set up the world's largest sequencing facility, the Sanger Centre. Smaller initiatives later emerged, for instance in Japan and Canada. No such activity, however, was seen in Germany until 1995. By 2001 a nearly complete 'working draft' of the human genome has been presented by the publicly funded Human Genome Project, including a significant German contribution. The complete sequence will be available in public databases some time ahead of schedule, probably by 2003. In 1998 an emerging competition to the Human Genome Project by private companies, namely by

Craig Venter's Celera, had speeded up the deciphering of the human genetic code tremendously. But the knowledge of our comprehensive genetic make-up is not considered as a benefit for mankind by everybody. Profound ethical issues are raised by the possibilities inherent in this knowledge. This had been realized by the founders of the project and therefore, about 3 percent of the budget was dedicated to exploring the ethical, legal, and social implications of the Human Genome Project. In most countries participating in the Human Genome Project, an extensive discussion took place about the opportunities and risks attached to these novel technologies. In Germany a parliamentary committee was established to elucidate the topic. But the discussion was much more polarized in Germany than in other countries.

2. Cutting Edge Technology is Considered a Necessity for Germany's Industrialized Society

Germany is a strongly industrialized country. Due to its lack of raw materials, its economy is heavily dependent on export-oriented manufacturing industries. To reach and maintain its high standard of living, and to survive on the world market, Germany is in permanent need of cutting-edge technologies. Traditionally Germany's strength lay in the engineering and chemical industries. Other fields like agriculture and coal mining have undergone deep structural crises and are nowadays only viable on the basis of high subsidies. This is particularly true for rural areas or areas that have been focused on one industrial branch for generations. German labor law and the strong position of German trade unions protect employees from unemployment and provide broad social protection, but on the other hand slow down structural changes. Revolutionary technical developments can give a well-developed industry an opportunity to solve structural problems and to gain new markets. During the 1970s and 1980s, progress in microelectronics and computer technology constituted such a revolution. But neither industry nor academia realized this development in time so that it was subsequently missed in Germany. During this time, future prospects for highly qualified young scientists became increasingly worse. Germany had to face a severe 'brain drain,' predominantly to the United States. The structural problems dramatically deteriorated following German reunification—the entry of the Five New *Länder* (states) of the former German Democratic Republic to the Federal Republic of Germany, which became known as 'German Disease' in the 1990s. The economic recovery—the so-called *Wirtschaftswunder*—of West Germany after World War II, often promised to East Germans after reunification by West German politicians, was not easy to repeat. The resulting increasing economic pressure led to a resumption of the debate about the

pros and cons of biotechnology in general. After the end of the Cold War, other ethically controversial economic sectors such as the arms industry became less significant. Up to this time there had been no co-ordinated funding for biotechnology research, let alone any participation in the Human Genome Project, although the scientific basis was established and many technical developments pointed the way ahead. Though among a few scientists discussions on the need for genome-wide analysis had started in Germany around 1980, leading up to a proposal to sequence the entire genome of the bacteria *Escherichia coli* or even human chromosome 21 at the European Molecular Biology Laboratory in Heidelberg where much of the early technology had been developed, both the German scientific community, as well as funding agencies were at this point by and large not able to recognize the immense potential of genome-wide analysis.

While a large number of new powerful biotechnology companies emerged in the United States during the 1980s, recombinant pharmaceuticals had to be imported to Germany. The first version of the German Genetic Engineering Law was very restrictive and bureaucratic. It took the Frankfurt-based company Hoechst (now Aventis) years to get the approval to produce recombinant human insulin in their brand-new facilities. As a consequence, most large German pharmaceutical companies transferred their research departments to locations in the United States. Politicians realized very late the immense economic damage caused by this development. To take countermeasures two large co-ordinated research programs were started by the Federal Ministry of Research—the German Human Genome Project (DHGP) in 1995 and the BioRegio Competition in 1996.

3. Genomic Research Against the Background of German History

To fully understand the assessment of and the reservation about genetics in German society, it is helpful to take a closer look not only at economic aspects but also at intellectual history and the National Socialist period.

3.1 The Idea of Eugenics

At the beginning of the twentieth century various political and intellectual movements in search of a new order existed in Germany. As in many other countries at that time many of these were characterized by strong nationalism and/or antisemitism. Some of them had their roots in German romanticism or naturalism: movements like the *Wandervögel*—a rambler's association and precursor of a new German youth movement expressing a strong love of nature.

This milieu, in combination with vague Darwinian ideas, ushered in the idea of improvement of the human race and prevention of its degeneration under the overwhelming influences of a modern and industrialized world: the idea of eugenics originally introduced by Galton in the 1870s. Many of these movements were infiltrated by National Socialists and forced to take the party line during the *Gleichschaltung* after the Nazis had seized power in 1933. Fragments of these simplistic ideas were soon adopted by the Nazis. When the philosopher Nietzsche talked about the 'overman,' a superior human, it was interpreted that an inferior human was the conclusive consequence. Eugenics was not a purely German affair. Many countries, including the United States, had a strong eugenics movement during that time. In none of these countries, however, was eugenics used as a justification for profound discrimination, leading to the Nuremberg Laws of 1935 and eventually the extermination of some 6 million Jews by 1945.

3.2 The Role of German Physicians and Geneticists During the National Socialist Period

The role of German physicians and geneticists during the Nazi period is complex and exceeds by far the scope of this article. It should be sufficient to illustrate their influence by some examples. After the rediscovery of Mendel's Rules many scientists were worried that mental diseases like schizophrenia or idiocy, or the mixing of the white 'race' with individuals considered to be inferior (e.g., members of ethnic groups from the former colonies) would lead to a decline of European culture. Already during the first two decades of the twentieth century, the superiority of the white race to other humans and the destruction of so-called 'life unworthy to be lived' was discussed openly even in international scientific circles. Eugen Fischer, a scientist at the University of Freiburg, published a book in 1913 in which he addressed 'the problem' of mixed marriages between white men and Hottentot women and considered the progeny of such marriages as nonviable without protection by a superior race. Many of the racist ideas of Fischer and others were ingested in the emerging National Socialist ideology at that time. In 1927 Fischer became the director of the newly founded Kaiser Wilhelm Institute (KWI) for Anthropology, Human Heredity, and Eugenics in Berlin; in 1939 he was elected president of the University of Berlin. In this latter position he was responsible for signing the dismissal notices of his Jewish colleagues. A motivation for most of the scientists was an almost paranoid anxiety of the decline of their own culture and 'race.' In many cases, personal advantages that derived from the dismissal of their Jewish colleagues might have encouraged this development. Scientists supporting the National Socialist idea of racial hygiene like Fischer, Rüdin of the KWI of Psychiatry, Hallervorden of the KWI of Brain Research, or von

Verschuer, Fischer's successor as the director of the KWI for Anthropology, were welcomed by the leaders of the Nazi party. Most of the scientists involved, however, considered themselves as being apolitical. From their point of view they supported the system for the sake of science. Eugen Fischer wrote in a German newspaper: 'It is a rare and special good fortune for theoretical science to flourish at a time when the prevailing ideology welcomes it and its findings can immediately serve the policy and the state' (*Deutsche Allgemeine Zeitung*, March 28, 1943). Since most of these scientists did not have an official post in the Nazi administration and were not actively involved in the killing of people, only a few had to flee from Germany after the end of World War II. Josef Mengele, known as the 'Angel of Death' of Auschwitz, managed to escape to Brazil where he lived unmolested probably until 1979. Those who had deliberately worked with human experimental material like eyes, brains, etc., gained from concentration camps or psychiatric hospitals or had asked for this material from their co-workers, mostly avoided prosecution.

3.3 Germany Dealing with its Difficult Past

After World War II the faith of society in a detached and neutral science was profoundly disturbed. Genetics came under special suspicion because its advocates had provided 'scientific' basis for the National Socialist racial hatred. Scientific terminology had been adopted and occupied by the Nazis. As the Nobel Prize laureate Christiane Nüsslein-Volhard puts it quoting the term 'selection,' 'Scientists think of Darwin's fundamental theory of the origin of species while German society even today is reminded of the gas chambers of Auschwitz.' The reasons for this are diverse and many. Most geneticists did not differentiate themselves properly from the National Socialists. The borderline between fanatic followers and murderers like Josef Mengele, opportunists who profited from the system like Eugen Fischer and Otmar von Verschuer (who was Mengele's superior in Berlin), and those who had remained in their positions with tacit permission, remained hazy. After 1945 no genuine reappraisal of the role of physicians and geneticists during the Nazi period occurred. Directly after the war, Germany was too busy working on its economic recovery to ask questions about guilt. Many members of the intellectual elite had either emigrated or had been killed during the Nazi period. But many key proponents of the genocide reappeared in important academic positions. Otmar von Verschuer became professor of genetics at the University of Münster where in 1954 he even rose to the position of Dean of the Medical Faculty. The Kaiser Wilhelm Society was renamed Max Planck Society (MPS), and Adolf Butenandt, the Nobel Prize laureate of 1939 who was sometimes criticized for not differentiating himself clearly from the Nazi regime, became its first president.

Many of the experiments that were committed in Auschwitz and elsewhere were financially supported by the Kaiser Wilhelm Society or the Deutsche Forschungsgemeinschaft (DFG), the national German Research Council. It was, however, not before the late 1990s that DFG and MPS initiated an independent review of their own role during the NS period.

Because many natural sciences had fallen into disrepute after 1945, public discussion was completely dominated by intellectuals of the social sciences. This was in sharp contrast to the period from the turn of the century until 1933 when, for instance, physicists like Einstein, Heisenberg, and Planck were actively involved in the social and political debate, and disputes among artists, philosophers, theologians, and scientists were common. After 1945, genetics had not become common knowledge in Germany even in intellectual circles. Instead, a vague fear of genetic reductionism and determinism remained. This led Robert N. Proctor, a US historian of science, to state: 'The legacy of Nazism influences the attitudes many Germans show towards genetics today and is probably responsible for the absence of a prominent science-oriented intellectual elite. Where are the Goulds, Hawkings and Dawkins of Germany?' The polarization between social scientists and natural scientists who were mainly seen as technocrats still persists. The seizure of power by man over himself created the fear that humanity could be the first victim.

3.4 The German Human Genome Project

During the 1980s the tremendous successes of genetic engineering boosted the biotechnology industry in the USA and provided the prerequisite for the idea of the Human Genome Project. While in the US, companies like Amgen turned over more than US \$ 1 billion per year, the production of recombinant pharmaceuticals was still hampered in Germany. At the same time, recombinant pharmaceuticals and vaccines had to be imported into Germany. One of the first dedicated centers for genome research in Germany, the *Genzentrum* in Munich had bulletproof windows installed in fear of an attack. The international Human Genome Project was started in 1990 without any German participation. But increasing economic pressure forced Germany to a rethinking of genome research. After a thorough investigation of the issue by a parliamentary commission, two programs of the Christian Democratic-Liberal coalition started in the mid-nineties. The BioRegio Competition aimed at exploiting the synergy of self-organization of whole regions as centers of excellence for biotechnology and was unexpectedly successful. The German Human Genome Project (DHGP), integrated into the international effort to decipher the human genome, was thematically much more focused. It was strongly

industry-oriented and a special infrastructure was to guarantee the effective transfer of the knowledge gained to industry. Initial efforts to raise half of the budget from the German pharmaceutical industry failed. Subsequently, the whole budget of DM 40 million per year was granted by the Federal Ministry of Education and Research. To safeguard the interests of industry, a Patent and Licensing Agency (PLA) was established whose task was to screen the results of the projects granted within the DHGP and to guarantee a patent application if applicable. The patent is granted to the inventor at no cost. In turn, the Industry Association gets the right of first refusal on the patent.

The agreement also gave the Industry Association the right to screen the data produced in the German DNA sequencing centers—a clear infringement of the so-called Bermuda Principles—an agreement between all academic sequencing centers worldwide making all data immediately publicly available without any restrictions. The Industry Association waived their claims only after massive pressure from the international scientific community.

The DHGP has had a profound effect on the German biotechnological industry. Contrary to the expectation that the big pharmaceutical companies would exploit the scientific results, licensing of patents was sparse. Instead, many researchers preferred to start their own companies, a tendency up to then only rarely found in German academia. The success of the DHGP initiative led to Germany exceeding the United Kingdom in the number of biotech companies by the year 2000.

Initial concerns among scientists that funding of genome research would be cut after the change of government to a coalition of Social Democrats and the Green Party were groundless. Not only has the DHGP been maintained, but also a plant genome project—initiated by the prior administration—as well as a microorganism genome project were started, assisted by additional projects on bioinformatics and proteomics. In 2000, a long-expected concept document was released by the Federal Ministry of Education and Research. This paper draws up a long-term perspective for genomic research in Germany and safeguards the existence of central infrastructure units (resource centers) for genomic research. At the same time, boosted by the announcement of the draft version of the human genome, a tremendous increase in funding was approved that eventually brought Germany in line with genomic funding in countries like Japan, UK, and France.

The economic success as well as the prospects of new diagnostic and therapeutic possibilities has very much changed the German attitude towards human genetics. Medical genetics is now much more accepted than it was a few years ago. In contrast, due to concerns about health as well as to the aggressive marketing strategies of certain agrochemical biotech companies, plant genetic engineering has met with

deep disapproval in Germany. However, the fatalistic attitude in Germany towards fundamental natural sciences has somewhat changed. The former lack of discussion in society that permitted simplistic arguments to gain predominance has been overcome. The majority of the German intellectual elite has realized that an informed discussion within society is needed to solve the problems stimulated by genome sciences.

Human Genome Project: Japanese Perspective

The Japanese Human Genome Project (JHGP) was initiated in 1988. The project experienced some difficulties in the initial stages, such as scarcity of resources and the perception that genome research was not hard science. As a result the JHGP was unable to follow the specific aims of sequencing DNA of the human genome. This article explains how the JHGP adopted strategies to overcome these problems and how it became an effective contributor to the international human genome project.

1. History of the Human Genome Project in Japan

The drive toward an international approach to the Human Genome Project began in 1985. In 1988, as a response to this development and the progress of the human genome project activities in the United States and Europe (see *Human Genome Project: German Perspective*), the Japanese human genome project (JHGP) conducted a feasibility study. The study was supported by a general research grant from the Ministry of Education, Science, Sports and Culture (ESSC: MONBUSHO). As a result of this study, the research council of MONBUSHO proposed the formulation of a special human genome research grant and a five-year plan for the promotion of genomic research.

The genome research supported by this special grant had a project-like characteristic, and because of this was confronted by criticism from various sources. There was a strong belief among certain groups that this kind of project was not 'hard research' but rather mere routine work. Moreover, difficulties were experienced in relation to the scarcity of technicians skillful in this area who could support the genome researchers and also in the reluctance shown by the government and private institutions to invest heavily in a single project. As a result of these difficulties

a The Institute of Physical and Chemical Research Japan. b STA, Japan.

JHGP could not follow the specific aim of sequencing the DNA of the human genome.

Instead, JHGP adopted the strategy of developing excellent genome-related research. By this strategy, JHGP successfully contributed to the construction of human genome physical maps, the development of full-length cDNA construction techniques, and the making of cDNA expression maps, leading to an enhancement of human genome research in Japan. However, JHGP was far behind the United States and Europe, particularly in the field of genetic disease analysis based on human genome mapping. More specifically, as most of the major human genome projects were still in their infancy, JHGP was behind in terms of planning rather than the research itself.

Although, for Japan, this predicament was partly due to some researchers failing to recognize the

importance of the human genome project, the main reason was the failure to establish a single human genome research center coordinated by the relevant ministries and institutions. For instance, JHGP was planned independently by two ministries and a government agency. These bodies included the MONBUSHO, comprising many University researchers, the Ministry of Health and Welfare (MHW) supervising medical activities, and the Science and Technology Agency (STA) supporting various large-scale projects. As a result of the lack of collaboration between these government organizations, talented researchers, useful materials, and research money were unnecessarily dispersed. Moreover, because of the slow response of bioindustries to the human genome project, government agencies were unable to formulate a collaborative liaison with them in Japan.

Figure 1

Contribution of the three geographical areas to the DDBJ/EMBL/Genbank International Nucleotides Database (January 1996–January 1999)

These problems were essentially based upon the political and social infrastructures within Japan; however, in spite of these difficult situations, several success stories emerged from JHGP. For example, seven research groups in Japan successfully contributed to the completion of the *Bacillus subtilis* (*B. subtilis*) genome sequence by determining the nucleotide sequences of its shared region of 1.3 Mb. The complete genome sequence of *Synechocystis* sp. was determined by the Kazusa DNA Research Institute, which was established by Chiba prefecture and industries. The Ministry of Agriculture, Forestry and Fisheries of Japan (MAFF) launched the rice cDNA project, which is currently leading international research on the rice genome. In 1998, the *Escherichia coli* (*E. coli*) genome project team in Japan successfully completed three quarters of the *E. coli* genome sequence, although the American team completed the whole *E. coli* sequence in the same year.

Genome Informatics was initiated from scratch because there were no major research activities which could act as a focal point, except the DNA databank of Japan (DDBJ) within the National Institute of Genetics (NIG). In particular, the recruitment of talented researchers, education and training of research students, installment of a computer network for genome research, and the establishment of a DNA database had to be done within a short period of time. Although these were successfully dealt with to some extent, there were still some problems to be solved such as intimate collaboration among the different institutions in charge of various bioinformatics activities.

2. The Present Situation of the Human Genome Project in Japan

As genome research advances internationally, there has been increasing recognition that genome research constitutes the necessary foundation for the future development of biology, medical research, and biotechnology. In particular, the necessity of establishing a large-scale genome-sequencing center has been accepted widely. However, the realization of this plan has been difficult because of budget limitations.

Since the basic law of science and technology development was passed in 1997, the budget limitations have, to some extent, disappeared under the national goal that Japan should become a country of creative science and technology. Because of this basic law, the government invested approximately \$US 200 million in the genome research project in the 1998 fiscal year alone. Presently, various activities in JHGP are conducted under the initiative of governmental organizations and private industries. MONBUSHO successfully established the Center for Information Biology in NIG to support DDBJ and the newly established Human Genome Research Center in Tokyo University. The Ministry of International Trade and Industry (MITI) and the MHW coordinated a promotion business venture of genome-related enterprise and the STA created the genome science center in Yokohama. Moreover, large research grants were made to many genome research groups through various funding mechanisms. However, not all of these activities are along the lines of well-planned strategies of genome research.

The general focus of JHGP is toward the determination of large-scale genome sequences and a functional analysis of the genes that will be discovered by sequence determination. JHGP is placing more emphasis on the areas of genomic structure, function, and information. As for genome sequence determination, Kitazato University, Japan Marine Science and Technology Center, and STA and the Product Evaluation Center under MITI are pushing the genome sequencing of microorganisms by producing 122 Mb each year. In 1995, the Japanese Science and Technology Corporation initiated the human genome-sequencing project. The subgenomic segments such as HLA, immunoglobulin variable, Down's syndrome, and oncogene-related regions, have been determined for about 15 Mb by Kitazato University, Cancer Institute, Keio University and Tokai University.

In total, the sequence production in Japan is about 5 Mb per year, which is one order of magnitude smaller than that of the Sanger Center in the United Kingdom and the Sequence Center at Washington University in the United States. Therefore, JHGP has great expectations of the role of the newly established Genome Science Center, which is planned to produce 30–50 Mb per year. Kazusa Research Institute is producing several Mb genome sequences of *Arabidopsis* per year.

Moreover, the genome project team supported by MAFF has a ten-year plan of sequence determination of the complete rice genome of 400Mb, producing 20Mb per year for the initial several years. In summary, the sequencing capacity of genomes in Japan has so far been 15–20Mb per year. Judging from recent increases of the number of genome research groups focusing on bacteria, fungi, lower organisms, insects, and fish and the enhancement of genome research on humans and the mouse, 200Mb sequence production per year is expected in the near future.

JHGP has a slight edge over other countries in the field of functional genomics. In particular, the Osaka University genome team was the first to analyze a cDNA expression profile of human genetic data (called 'body mapping') and other genome teams have quickly developed a full-length cDNA determination technique. Although these activities were not directly connected to a bioindustry as they are in the United States, MITI recently pushed the utilization of these technical advances to industry. Moreover, human genome diversity has become recognized as important for disease gene analysis and functional analysis. In particular, the so-called 'complex diseases' such as multi component diseases are becoming important targets of the human genome diversity project (see *Human Genome Diversity and its Value*). This project will require a lot of genetic data concerning the Japanese population, in particular a large amount of polymorphism data from several thousand people (see *Race: Genetic Aspects*).

Several preliminary research projects have already started in Japan. The cDNA project of *Caenorhabditis elegans* (*C. elegans*) genome has been conducted by NIG in cooperation with the Sanger Center and Washington University. The *B. subtilis* and *E. coli* genome teams have already begun functional analysis of all genes contained in their respective organisms. Many researchers are participating in these genome projects by conducting bioinformatics research and constructing databases. Thus, JHGP has resumed its original goals in a more integrated and coordinated way.

3. The Future Challenge of the Human Genome Project in Japan

In Japan, the aim of the human genome project was redirected to not only sequence the human genome but also to include the functional analysis of genes as well as the elucidation of protein tertiary structures. Although this redirection has successfully eased various criticisms, the main focus of the human genome project has been diffused to a considerable extent, leading to an ambiguity of the Japanese contribution to the international effort of human genome sequencing. Given the expectation that human genome sequencing

has been achieved mainly by the United States and Europe, the Japanese human genome project will be successful if it orients its major effort towards the promotion of functional genomics, comparative genomics, evolutionary genomics, and genomic diversity analysis, along with the development of DNA chips or microarrays.

Conducting functional genomics requires analytic technologies that are capable of dealing with a large number of genes and proteins. Toward meeting these requirements, genome researchers in Japan have started contributing to the development of differential display, DNA chips and the identification of variant DNA. In the near future, these efforts should be connected to advancement of industrial technologies to produce unique and significant methodologies useful to functional genomics.

For genome informatic research, DDBJ at CIB/NIG, the Human Genome Research Center at Tokyo University, the Chemistry Institute at Kyoto University, and other research groups are making efforts to incorporate information science into genome research, in the belief that 'genome science is virtually information science.' There is no doubt that informatic aspects are extremely important to genome research. In particular, the elucidation of gene networks will be crucial for understanding the development and evolution of organisms, and in this sense, bioinformatics will play a crucial role. Another aim of JHGP is the allocation of talented bioinformatics and the education of students who understand both biological and information sciences. This will be an important component of the future activities of the JHPG.

Human Resource Management, Psychology of

Human resource management (HRM), as practiced in work organizations, includes five broad activities that together constitute the HRM system: staffing, retention, development, adjustment, and managing change (Cascio 1998). *Staffing* comprises the activities of (a) identifying work requirements within an organization, (b) determining the numbers of people and the skills mix necessary to do the work, and (c) recruiting, selecting, and promoting qualified candidates. *Retention* comprises the activities of (a) rewarding employees for performing their jobs effectively, (b) ensuring harmonious working relations between employees and managers, and (c) maintaining a safe, healthy work environment. *Development* is a function whose objective is to preserve and enhance employees' competence in their jobs by improving their knowledge, skills, abilities, and other characteristics; HR specialists use the term 'competencies' to refer to these items. *Adjustment* comprises activities intended to maintain compliance with the organization's HR policies (e.g., compensation, discipline), and business strategies (e.g., cost leadership). *Managing change* is an ongoing process whose objective is to enhance the ability of an organization to anticipate and respond to developments in its external and internal environments, and to enable employees at all levels to cope with the changes.

1. Responsibilities and Objectives

These activities can be carried out at the individual, work team, or larger organizational unit (e.g., department) level. Sometimes they are initiated by the organization (e.g., recruitment efforts or management development programs), and sometimes they are initiated by the individual or work team (e.g., voluntary retirement, safety improvements). It might appear that the activities of staffing, retention, development, adjustment, and managing change are the special responsibilities of the HR department. However, these responsibilities also lie within the core of every manager's job throughout any organization—and because line managers have authority (the organizationally granted right to influence the actions and behavior of the workers they manage), they have considerable impact on the ways workers actually behave. This implies two things: (a) a broad objective of HRM is to optimize the performance and prod-

activity of all workers in an organization, and (b) a special objective of the HR department is to help line managers manage those workers more effectively. The HR department accomplishes this special objective through policy initiation and formulation, advice, service, and control in close communication and coordination with line managers.

Generally speaking, HR specialists provide the technical expertise in each area, while line managers (or, in some cases, self-directed work teams) use this expertise in order to manage people effectively. In a small business, however, line managers are responsible for both the technical and managerial aspects of HRM.

For example, in the area of retention, line managers are responsible for treating employees fairly, resolving conflicts, promoting teamwork, and providing pay increases based on merit. To help line managers do these things effectively, the HR department must devise a compensation and benefits system that employees will perceive as attractive and fair, establish merit increase guidelines that will apply across departments, and provide training and consultation to line managers on all employee relations issues, such as conflict resolution and team building.

2. The Evolution of Human Resource Management

To appreciate where the field of HRM is going, it is important to appreciate where it has come from. As it is practiced in most developed countries around the world, modern HRM has emerged from nine inter-related sources.

(a) Rapid technological change that increased the specialization of labor associated with the industrial revolution.

(b) The emergence of free collective bargaining, with constraints established for unions and for employers.

(c) The scientific management movement.

(d) Early industrial psychology.

(e) Governmental personnel practices growing out of the establishment of the Civil Service Commission in the USA.

(f) The emergence of personnel specialists and the grouping of these specialists into personnel departments.

(g) The human relations movement.

(h) The behavioral sciences.

(i) Social legislation and court decisions.

2.1 The Industrial Revolution

Three characteristics of the industrial revolution were the development of machinery, the linking of human power to the machines, and the establishment of

factories in which a large number of people were employed. The result was a tremendous increase in job specialization as well as in the amount of goods that workers could produce. 'Division of labor' became a rallying cry of this revolution.

Clearly, the industrial revolution greatly accelerated the development of business and commerce. Owners and entrepreneurs generally did quite well for themselves, but the average citizen fared poorly in comparison to today's workers in terms of purchasing power and working conditions. Labor was considered a commodity to be bought and sold, and the prevailing political philosophy of *laissez-faire* resulted in little action by governments to protect the lot of workers (French 1994).

2.2 The Emergence of Free Collective Bargaining

Because of the way they were abused, it was inevitable that workers would organize to protect themselves and to improve their lot in life. From the perspective of workers, the industrial revolution fostered specialization, along with the need for workers within each specialization to organize themselves against its abuses. Trade unions, also called 'labor unions,' spread rapidly, and so did the incidence of strikes (see also *Labor Unions*). For example, in 1886 employees at the McCormick Reaper Works in Chicago went on strike for an eight-hour work day (Cohen 1960). In the United States, courts generally adopted an antiunion stance until 1935. In that year the National Labor Relations Act was passed. It focused largely on labor's right to organize. It became an unfair labor practice for an employer to coerce or to restrain employees in the exercise of their rights, to dominate or interfere with a labor organization, or to refuse to bargain collectively with a legal representative of the employees. Subsequent legislation refined, broadened, and set legal limits on the scope of management and union activities. From the perspective of labor, the development of free collective bargaining and the USA labor movement created the need for what is now recognized as effective human resource management.

2.3 Scientific Management

From the perspective of management, the scientific management movement also created the need for effective HRM. Frederick Winslow Taylor was the prophet of scientific management, and the stopwatch was his 'bible' (Bell 1972). Taylor began his experiments in the steel industry in 1885. His objective was the systematic analysis and breakdown of work into its smallest mechanical elements, and then their rearrangement into the most efficient combination. In addition to the scientific study of the task itself ('time and motion' study), Taylor argued that individuals selected to do the work should be as perfectly matched

physically and mentally to the demands of the job as possible, and that overqualified individuals should be excluded.

Employees should be trained carefully by supervisors (whose own work was also divided into specialties) to ensure that they perform the work exactly as specified by prior scientific analysis. In no case, however, should employees ever be called upon to work at a pace that would be detrimental to their health.

Finally, to provide an incentive for the employee to follow the detailed procedures specified (and closely supervised by line supervisors on the shop floor), Taylor felt that employees should receive an addition of between 30 and 100 percent of their ordinary wages when the task was done right and within the time limits specified. The first piece-rate incentive system had arrived.

Taylor also was interested in the social aspects of work, although he saw little good emerging from the social interaction within work groups. He felt that work groups fostered a level of individual efficiency equal to the level of the least productive worker in the group. In other words, he believed that the efficiency of the group would not be any greater than the efficiency of the least productive member. Thus Taylor tried to institute a kind of social physics into the workplace. While many of his ideas are controversial, there is no doubt that application of the principles of scientific management resulted in much higher productivity than would otherwise have been possible.

2.4 Early Industrial Psychology

In 1913, Hugo Munsterberg's book, *Psychology and Industrial Efficiency*, described experiments in selecting streetcar operators, ship's officers, and telephone switchboard operators. His contributions to human resource (or personnel) management are noteworthy for his emphasis on the analysis of jobs in terms of (a) the abilities required to do them, and (b) the development of testing devices—aptitude as well as work sample tests—that were able to forecast subsequent job performance (Munsterberg 1913).

Munsterberg's 1917 book, *Business Psychology*, included the results of questionnaires sent to hundreds of laborers. The questionnaires requested anonymous data on attitudes toward their work, their involvement in the labor movement, and their leisure activities.

Both Munsterberg and Taylor were concerned with how workers were selected for jobs, as well as with the individual worker's feelings and aspirations. Although they differed on several issues (notably, on how social structure affected productivity), Munsterberg's writings clearly suggest that he felt that the two emerging fields of personnel selection and social psychology (the study of how people affect and are affected by one another) were complementary (Landy 1992, Moskowitz 1977).

Other developments at about the same time included the use of rating sheets for interviewers, advances in checking references given by workers, and in statistical methods for estimating validity (the extent to which selection devices accurately forecast job performance). World War I accelerated the development of intelligence tests, such as the Army Alpha and the Army Beta, so that each individual could be matched more effectively with job requirements. Other kinds of psychological measures also appeared during and after World War I, such as measures of aptitude, interest, and personality.

2.5 The US Civil Service Commission

The Pendleton Act of 1883 established the US Civil Service Commission (today known as the US Office of Personnel Management). A forerunner in progressive personnel policies, the act provided that competitive examinations be administered as a basis for employment in the public service. It also provided a measure of employment security for those selected, prohibited discharge for refusing to engage in political activity, encouraged a nonpartisan approach to appointments, and mandated that a commissioner administer the act (Van Riper 1958). Perhaps the major impact of this act was to foster employment and promotion policies in the federal government based on merit. Over the years, these policies have influenced personnel practices in state and local governments as well as in private industry.

2.6 Private Industry's Approach to Personnel Management

Historians consider 1912 the approximate date of the emergence of the modern personnel department (Eilbert 1959). The term 'personnel,' with its connotation of managing people in organizations, began to appear about 1909. Between 1900 and 1920, while advances were being made in scientific management, industrial psychology, and the federal civil service, a number of personnel specialists emerged in companies such as B. F. Goodrich, National Cash Register, and Standard Oil of California. The specialists managed such areas as employment, employee welfare (financial, housing, medical, and educational), wage setting, safety, training, and health. This kind of specialization formed the basis for the organization of the modern human resources department.

2.7 The Human Relations Movement

In Chicago, in 1923, the Hawthorne Works of the Western Electric Company provided the setting for

one of the most famous behavioral research efforts of all time. The purpose of the research was to study the effects of illumination on worker productivity. In one experiment, production went up when the illumination increased. In another experiment, production went up when the illumination decreased. After three years of continually inconsistent results, the researchers concluded that in a situation involving people, it was impossible to change one condition (the lighting) without affecting other variables at the same time. Employee motivation and work group morale seemed to be the really crucial factors.

The results of subsequent experiments at the Hawthorne Works by Professors Elton Mayo, Fritz Roethlisberger, and T. North Whitehead of the Harvard Business School indicated that productivity was directly related to the degree of group teamwork and cooperation. The level of teamwork and cooperation, in turn, seemed to be related to the interest of the supervisor and the researchers in the work group, the lack of coercive approaches to productivity improvement, and the participation afforded the workers in changes affecting them (Pennock 1930, Roethlisberger and Dickson 1939). In short, the researchers came to view the organization of workers as a *social system*, in contrast to Taylor's view of that organization as a *technical-economic system*.

The conviction that group behavior and workers' feelings were associated with morale and productivity characterized much of the research and theorizing in the human relations movement for the next two decades. In practice, unfortunately, many managers seemed to use human relations for the short-term purpose of manipulating workers to increase output, rather than for the long-term goal of satisfying worker needs while meeting organizational needs. Failure to find evidence that these programs made a difference in workers' satisfaction or that happy workers were productive workers helped kill this approach to HRM (Brayfield and Crockett 1955).

2.8 The Behavioral Sciences

The behavioral science approach to managing people is an outgrowth of the human relations studies, although it embraces a wider base of academic and applied disciplines and is concerned with a wider range of problems. The term *behavioral sciences* refers to the social and biological sciences concerned with the study of human behavior. Much of the knowledge of HRM and many of its practical applications have come from such behavioral science disciplines as the following:

(a) *Industrial/organizational psychology*: the study of the behavior of people at work (see *Industrial–Organizational Psychology: Science and Practice*).

(b) *Social psychology*: the study of how people affect and are affected by one another.

(c) *Organization theory*: basic philosophies about why organizations exist, how they function, how they should be designed, and how they can be effective.

(d) *Organizational behavior*: the study of the causes of individual and group behavior, and of how this knowledge can be used to make people more productive and satisfied in organizational settings.

(e) *Sociology*: the study of society, social institutions, and social relationships.

We now know that the ways people behave in organizations cannot be explained simply by human relationships. The organization itself, through its unique 'culture,' molds, constrains, and modifies human performance. The way the organization is structured, the authority attached to different positions, and job and technology requirements clearly affect behavior. Even though the present understanding of the determinants and effects of behavior is incomplete, there is a better sense of the ways in which separate influences interact with each other to affect individuals.

Another area that has exerted a considerable influence on HRM theory and practice is *general systems theory*. Systems theory has developed from such fields as biology, physics, and cybernetics (the study of mechanical-electrical communications systems and devices). It has been applied and elaborated in every behavioral science field.

2.9 Social Legislation and Court Decisions

Governments in most developed countries around the world have passed social legislation and courts have issued decisions on unfair discrimination in employment. While some countries are more progressive on these issues than others, the laws and court decisions frame national policy on equal employment opportunity (EEO). In the USA, discrimination in employment is prohibited on the basis of race, religion, national origin, gender, age, and disability. Aggrieved individuals have the right to pursue their claims in court. At the level of the organization, HRM specialists work with top managers to develop and implement EEO policies to ensure that individuals are treated fairly in all aspects of the employment relationship.

3. Growth Stages of Human Resource Management

The foundation for modern HRM rests on the factors described earlier. Beyond that, HRM as practiced in the USA developed in four stages.

3.1 File Maintenance

The first stage may be called the 'file maintenance' stage, for it typified HRM activities through the mid-

1960s and the degree of emphasis on employee concerns. 'Personnel' was the responsibility of a special department. Its responsibilities included screening applicants, conducting orientation for new employees, collecting and storing personal data on each employee (e.g., date of birth, years of company service, education), planning the company picnic, and circulating memos 'whose impertinence was exceeded only by their irrelevance' (Meyer 1976).

3.2 Government Accountability

The second growth stage of HRM, the 'government accountability' stage, began soon after the Civil Rights Act of 1964 was passed. Laws governing antidiscrimination, pensions, and health and safety were enacted, federal agencies to enforce the laws were created, and court rulings affecting almost every aspect of the employment relationship were issued. All of these events accelerated the rise and importance of the HRM function. Class action lawsuits and the large financial settlements for the winning suits illustrated the costs of mismanaging people. Managers outside the HRM function began to take notice because top management let them know that ineptitude in this area would not be tolerated. Staying out of federal court became a top organizational priority. These trends also signaled the need for specialized competence in each aspect of HRM. Thus specialties began to appear in compensation and benefits, affirmative action (the promotion of minority concerns in all aspects of employment), labor relations, and training and development.

3.3 Organizational Accountability

In the late 1970s and 1980s, when many firms were struggling simply to survive, a combination of economic and political factors (high interest rates, growing international competition, shrinking US productivity growth) led to a demand for greater accountability in dollar terms of all the functional areas of business. HRM activities were no exception. Thus this third stage may be termed 'organizational accountability.' Although methods of assessing the costs and benefits of HR programs are available, they are not widely known (Cascio 2000). In addition, social trends, such as more women in the workforce, more minorities, immigrants, older workers, and poorly educated workers, accelerated the demands for improving the quality of work life, for managing cultural and ethnic diversity, and for continual training and retraining.

3.4 Strategic Partnership

In the 1990s and in the new millennium, HRM has evolved to a fourth growth stage as it assumes a central

role in the struggle of both large and small firms to gain and sustain a competitive advantage in the worldwide marketplace. This stage may be termed 'strategic partnership.' Top management looks to the HR department, as it does to line managers, to control costs, to attract and retain top talent, to enhance competitiveness, and to add value to the firm in everything it does.

4. Learning From the Past, Looking Toward the Future

As noted earlier, the field of human resource management is composed of five broad activities that together constitute the HRM system: staffing, retention, development, adjustment, and managing change. The field as it is known today has emerged from nine interrelated sources: the industrial revolution, the emergence of free collective bargaining, scientific management, early industrial psychology, governmental personnel practices growing out of the establishment of the Civil Service Commission in the USA, the emergence of personnel specialists and the grouping of these specialists into personnel departments, the human relations movement, the behavioral sciences, and social legislation and court decisions.

Since the 1950s, HRM has evolved through four growth stages: file maintenance, government accountability, organizational accountability, and strategic partnership. However, to be business partners who make genuine contributions to the success of an organization, HR professionals need to be proactive, not reactive. They must anticipate changes in the social, legal, political, and economic environments, and then facilitate effective organizational responses to them. Some of these issues include finding and keeping top talent in tight labor markets; capitalizing on the information revolution in ways that will benefit organizations, such as Internet-based recruitment and the development of interactive, company-based intranets to facilitate employee inquiries and inputs; managing the performance of geographically dispersed employees and teams (virtual teams); and providing training and development opportunities on demand. Indeed, this is the new paradigm of work: any time, anywhere, in real space or in cyberspace. HRM will contribute to the bottom-line success of organizations and to the betterment of employee welfare by developing proactive responses to the workplace challenges wrought by this new paradigm.

W. F. Cascio

Human Rights, Anthropology of

Human rights constitute a field of increasing anthropological concern, not only for its substance but also for its inherent tensions. Since 1948, when the Universal Declaration of Human Rights (UDHR) was internationally accepted, anthropology has moved from an explicit opposition to the idea of a universal standard of human rights, over a more routinely skeptical attitude to a growing positive interest of both an empirical and a theoretical nature. This trend is related both to changing notions of anthropology and to the historical process of globalization. (See

Downing and Kushner 1988, and Messer 1993, and Hastrup 2001a, 2001b for overviews of the relationship between anthropology and human rights.)

1. Precursors

Although human rights, in the sense used here, were not on the international agenda before 1948, it was a latent idea for centuries, especially as far as civil rights were concerned. The American 'Bill of Rights' (1776) and the French declaration on '*Les droits de l'homme et de citoyens*' (1789) are often cited as ancestors of the UDHR (along with others), and from there the roots of human rights are traced back to classical Athens or early Christianity. In the nineteenth century, when a wave of humanism swept over Europe, one of the results was a new idea of an essential 'humanity,' deriving from seventeenth- and eighteenth-century treatises in political philosophy as well as from sixteenth-century renaissance humanism. Political philosophy in many respects was a forerunner of anthropology that was to take shape in the late nineteenth century. The idea of a universal humanity was a precondition of the nascent discipline, destined to give the proposition about a shared humanity empirical substance by way of qualifying cultural differences as variations upon the common theme of humanity.

In the early ages of anthropology the conjunction of the two concerns of equal rights and local difference is passionately testified to by Franz Boas, who, in his letter-diary from Baffin Island (1883–4), writes about his sincere wish to live in the USA:

I should much prefer to live in America in order to be able to further those ideas for which I live. ... What I want to live and die for, is equal rights for all, equal possibilities to learn and work for poor and rich alike! Don't you believe that to have done even the smallest bit for this, is more than all of science taken together? (quoted in Cole 1983, p. 37)

We know that later Boas was to fight fervently against racism, and on the whole most anthropologists see their discipline as genuinely respectful of all peoples. This collective sentiment makes no simple entry into the discussion of a universal standard of human rights, however, as this is conceptualized and articulated in those declarations, conventions, charters, and protocols that have been passed in the decades following the UDHR.

2. Anthropological Reactions to the Universal Declaration of Human Rights

Human rights in the modern sense were born in 1948 with the adoption of the UDHR. In the drafting

process, advice and comments were sought from various bodies, including the American Anthropological Association (AAA). A statement was produced by Melville Herskovits (1947) in the name of the AAA which carefully considers the idea of a universal standard and notes its local cultural implications, each of which is firmly anchored in contemporary anthropological knowledge. Noting that human rights appertain to the individual, the argument proceeds through the following successive conclusions:

(a) 'The individual realizes his personality through his culture, hence respect for individual differences entail a respect for cultural differences' (p. 541);

(b) 'Respect for differences between cultures is validated by the scientific fact that no technique of qualitatively evaluating cultures has been discovered' (p. 542);

(c) 'Standards and values are relative to the culture from which they derive so that any attempt to formulate postulates that grow out of the beliefs or moral codes of one culture must to that extent detract from the applicability of any Declaration of Human Rights to mankind as a whole' (p. 542).

This is clearly a stand against what was perceived as a Western bias in the UDHR, and it leads to the final conclusion: 'Only when a statement of the right of men to live in terms of their own traditions is incorporated into the proposed Declaration, then, can the next step of defining the rights and duties of human groups as regards each other be set upon the firm foundation of the present-day scientific knowledge of Man' (p. 543).

What transpires is a profound skepticism, grounded in the state of the anthropological art, including the general professional sentiment that culture is the sole legitimate source of moral values. Herskovits expresses it thus: 'Even where political systems exist that deny citizens the right of participation in their government, or seek to conquer weaker peoples, underlying cultural values may be called on to bring peoples of such states to a realization of the consequences of the acts of their governments, and thus to enforce a brake upon discrimination and conquest' (p. 543).

As pointed out by Richard Wilson (1997, p. 2), this is an attempt to play anthropology's trump card: its unique ability to elicit and assert any culture's underlying values. In addition it could be said that it also features the comparative knowledge inherent in anthropology, a knowledge both of cultural difference and of its translatability into valid, and more or less shared, human standards of good governance and respectable political action. In spite of the disclaimer, which was militantly underscored by Julian Steward (1948, p. 251), when he said 'we are prepared to take a stand against the values in our own culture which underlie ... such imperialism,' the UDHR was passed in 1948.

Together, the two attitudes exemplified by Boas and Herskovits, both of which are understandable and laudable, take us right to the core of anthropology's

comparative consciousness and its ambiguous implications. Since 1948, the discussion of the concept of human rights in anthropology has centered on the unsolved question of universalism or relativism (Dembour 1996). Another target has been the cultural translation of human rights concepts, allegedly deriving from a Western, and Christian, liberal democratic system, into 'like' cultural concepts within other moral and political systems. This is neither an easy task (as shown by e.g., Wilson 1996, and Asad 1997), nor is it an obvious way to go (Hastrup in press).

In actual practice the anthropological concern with human rights has taken various forms since 1948, and has been named accordingly as advocacy, activism, antiracism, and anti-imperialism. It is characteristic, though, that most of these trends have continued the relativistic attitude embedded in the AAA statement (and the implied skepticism toward human rights), while also advocating equal rights on the basis of a vision of a shared humanity. At the beginning of the twenty-first century, when human rights are appealed to by the international community under the banner of a 'culture of human rights' with increasing force, anthropologists have also taken a renewed interest in this culture.

3. The Culture of Human Rights

The intense talk of human rights since the early 1990s is not necessarily a symptom of a high moral profile worldwide, rather it is a symptom of the malaises of the times and of the will to confront them by way of new international laws. The choice of cure reflects a general process of legalization of culture in a post-modern era fraught with ontological insecurity, if we are to believe Anthony Giddens (1991). Where, earlier on, local cultures provided people with a sense of belonging and identity, the present globalization and fragmentation of identities have allegedly left people at a loss. They then look toward the law as the glue of community, whether local or global; the law is the new means of inclusion or exclusion *par excellence*.

Whether it is possible to single out causal links in this complex process or not, we do experience an increasingly strongly articulated 'culture of human rights.' We encounter this notion in most recent statements made by the UN high commissioner for human rights, Mary Robinson, as well as by academics of various kinds (e.g., Rorty 1993). From an anthropological perspective it is a peculiar culture in the sense that it is declared rather than lived, and that it is future-oriented rather than based in tradition. As such it parts company from those cultures that were the traditional object of anthropology, but so does, indeed, anthropology itself, becoming increasingly concerned with connections between the local and the global, and their mutual implications. This provides a

theoretically significant conjuncture between anthropology and the human rights discourse.

The culture of human rights is distinct also in its explicit acknowledgement of multiple sources. Whereas, traditionally, nations and other self-declared ethnic groups have referred to a particular genesis, an ultimate ancestor, or a culture-hero, the human rights culture draws upon all kinds of ancestry. As Mary Robinson (1998) puts it:

Today the Universal Declaration of Human Rights stands as ... one of the great documents in world history. The *travaux préparatoires* are there to remind us that the authors sought to reflect in their work the differing cultural traditions in the world. The result is a distillation of many of the values inherent in the world's major legal systems and religious beliefs including the Buddhist, Christian, Hindu, Islamic, and Jewish traditions.

Not surprisingly, after the demise of colonialism, and with the increasing critique of Eurocentrism and the hegemony of Western values, the search for roots has changed from the attempt at establishing a one-stranded genealogy to suggesting multiple sources. Mary Robinson's statement may be empirically doubtful, but it goes to show that there is a will to shift whatever Western legacy one might like to trace in the human rights instruments to a truly global commitment.

The declaration of a global culture of human rights is thus closely related to the historical process of globalization. In one sense, the notion of globalization simply states the obvious; due to increasingly rapid information and money exchange systems, we experience a time-space compression, that accounts for a new global consciousness. This global consciousness has important implications, one apparently being the appeal to a transcendent 'culture of human rights.'

To invoke a culture is also to invoke a shared language; as far as the human rights culture is concerned, the language is decidedly legal. As 'declarations' the international charters are exemplars both of language and of law. Whether hard or soft law, it is inevitably an expression of particular ideas about society, while not necessarily embracing its total reality. Far from being simply rules for social behavior, law is part of a distinctive manner of imagining the real (Geertz 1983, p. 173).

In the case of the international discourse on human rights, there is a concept of the modern nation-state as the responsible agent vis-à-vis the citizens, and a vision of an international community that transcends the more narrow interests of the states. Clearly, this community is no less 'imagined' than the nation (cf. Anderson 1983). It is imagined in terms of precisely those international charters that are its main expression. As a literally *declared* culture, its language comes to carry a much heavier burden of representation than any 'natural' language, being just one among other media for storing cultural knowledge.

Any culture in some ways rests on representation; for it to be conceivable as a whole, it must be demonstrated as such. In a 'legal culture,' such as the international culture of human rights, the representation becomes of a particularly reductive kind, because the experiences, by being represented as if on permanent trial in a courtroom, become subjected to an unavoidable process of reduction, or as Clifford Geertz has it about law in general, a 'skeletonization of fact, the reduction of it to the genre capacities of the law note' (Geertz 1983, p. 172). Legal thought and vocabularies, then, are constructive of social realities rather than merely reflective of them; this also applies to the legal vocabulary of human rights, and anthropologists naturally take an increasing interest in this particular social construction of a (global) community.

According to some anthropologists, globalization and human rights conjoin in a social transformation of unprecedented magnitude. Ellen Messer, for one, writes like this:

Since the close of World War II, the United Nations has been assembling declarations, legislation, and enforcement mechanisms to promote human rights. Both the ongoing efforts to establish a global community and to base membership on a universal, but evolving standard of values constitute perhaps the greatest social transformation of this century. (Messer 1996, p. 1)

This transformation is part of a larger trend that has often been seen as the end of modernity, implying an end also to ontological security. This could be one of the reasons why human rights have become the new standard of hope to many. The historical changes are matched by new scholarly efforts. We have witnessed important changes in the conception of the anthropological object, that can be summed up under the rubrics of a de-essentialization of the object (culture, society) on the one hand, and a humanization of the subject, seen now to be an active agent of history, on the other. This facilitates a truly anthropological investigation into issues of human rights.

Intellectually, one of the greatest advances of the twentieth century was a willingness to learn from history and anthropology that humans are extremely malleable (e.g., Rorty 1993, p. 115). Thanks to comparative knowledge of humanity in time and space we have realized the flexibility and the self-shaping character of humans, and given up on the idea of a naturally rational animal.

The historical and intellectual climate is thus very much in favor of achieving a 'human rights culture.' While the dominant trends in present day anthropology—the stress upon globalization, on process, and on agency among other things—make a new approach to universal human rights possible, there is no theoretical reason why we should not at the same time maintain a distinct, more or less bounded object

of analysis: the local worlds of people. This has fueled a new interest in what are known as cultural rights.

4. Cultural Rights

In view of the traditional anthropological ambivalence toward human rights, generally based in view of culture as an inviolable and inherently valuable entity, the notion of cultural rights might ease the tension. This is not self-evident, however.

In the early instruments, such as the UDHR and the 1996 International Covenant on Social, Economic, and Cultural Rights (ICESCR), 'cultural rights' are individual rights to 'enjoy culture,' in compliance with the general emphasis on individual rights and the obligation of the state to facilitate them. In addition to this focus on the individual's cultural rights, a more challenging (politically and theoretically) perspective on cultural rights is opening up with increasing force, however. This is a notion of collective cultural rights, in relation to which the individual enjoyment of culture gives way to, or is at least supplemented by, a right of a particular group to protect and develop their culture. It was notable already in the *International Covenant on Civil and Political Rights* (ICCPR 1966, Article 27): 'In those States in which ethnic, religious, or linguistic minorities exist, persons belonging to such minorities shall not be denied the right, in community with the other members of their group, to enjoy their own culture, to profess and practice their own religion, or to use their own language.' It is surprising, perhaps, that the protection of minorities is placed within the civil and political rights, and not the social, economic, and cultural rights; if nothing else, this confirms the lack of clarity with which the concept of culture is hampered in the international instruments.

In spite of the weak beginnings and the unclear focus within the field of cultural rights, there is an increasing interest in them at the beginning of the twenty-first century. It is related to the historical fact that most conflicts today are so-called ethnic conflicts, at closer inspection often rooted in economic discrimination or scarce resources. Ethnic difference often covers other inequalities, at least when they are expressed in conflict. The ethnic conflicts take place within states, that are the traditional duty-holders in the human rights system, and they raise endless new questions of how to define those peoples, minorities, or indigenous populations that are the new beneficiaries of collective rights. In spite of the definitional problems, the UN system proceeds toward an increasing proliferation of instruments dealing with collective rights.

One such instrument is the UN *Declaration on the Rights of Persons Belonging to National or Ethnic, Religious or Linguistic Minorities* (DM) of 1992. As a Declaration it is not legally binding in the strict sense of the term, but state signatories nevertheless commit

themselves to the spirit of the Declaration. In many ways the DM can be seen as an extension of Article 27 of the ICCPR quoted above:

States shall protect the existence and the national or ethnic, cultural, religious and linguistic identity of minorities within their respective territories and shall encourage conditions for the promotion of that identity. (DM, Article 1)

Persons belonging to national or ethnic, religious and linguistic minorities ... have the right to enjoy their own culture, to profess and practice their own religion, and to use their own language, in private and in public, freely and without interference or any form of discrimination. (DM, Article 2)

From an anthropological perspective, what seems problematic is the recurrent emphasis on people's own culture as a natural property. The embedded concept of culture is an (outdated) essentialist one that goes counter to more recent anthropological notions of culture as a more or less temporary framework of understanding.

In the 1993 *Draft Declaration on Indigenous Peoples Rights* (IPR) the notion of culture as essence is further cemented; to give just one example:

Indigenous peoples have the right to practice and revitalize their cultural traditions and customs. This includes the right to maintain, protect, and develop the past, present, and future manifestations of their cultures, such as archeological and historical sites, artifacts, designs, ceremonies, technologies, and visual and performing arts and literature, as well as their right to the restitution of cultural, intellectual, religious, and spiritual property taken without their free and informed consent or in violation of their laws, traditions, and customs. (IPR, Article 12)

While one cannot deny that the indigenous peoples have suffered the more sinister effects of colonialism, it is unlikely that such collective rights that are propounded in the IPR will undo history. It is still only a draft declaration but seen in conjunction with the previously cited instrument there is evidence of a gradual transformation of cultural rights from individual to collective rights, that may potentially threaten the very foundation of human rights: their claim to universality. It seems, then, that at a time when anthropologists have left behind the notion of culture that prompted the AAA to take a stand against the idea of universal human rights, the very same notion hits back from within the system of human rights itself, potentially undermining it.

5. New Anthropological Avenues

The brief discussion of cultural rights shows that there is a need to reconsider the issue of human rights in the light of recent theoretical developments. If the notion of culture as essence is obsolete and cultural relativism generally self-refuting, human rights can no longer be

invalidated as a matter of course. The comparative perspective of anthropology itself is based on an idea of a shared humanity and a cross-cultural comprehensibility that tallies with the idea of equality and dignity in all humans. One of the things that anthropology has helped realize is the imaginability of 'others' as somehow like 'us' in spite of diversity.

Ethnographies of violence and suffering are still needed to add a dimension of experience to the (legal) language of rights, and thus contribute to a shared understanding of those sufferings that a universally accepted standard of human rights may help alleviate. Not only ethnography, but also our regained confidence in anthropological theory will contribute to the achievement of human rights, because anthropology's theoretical language can embrace cultural differences within a single (scholarly) discourse. Theory expresses what is not otherwise said; as such it is a social practice and contributes to the making of the world—not unlike the representation of society in legal terms, as discussed above. This imaginative contribution makes room for the renewed rapprochement between anthropology and human rights that we are witnessing.

Human Rights, History of

The expression 'History of Human Rights' has two different meanings. It can be understood (as it usually is) as the history of the idea and the concept of human rights, or (less frequently) as the historical occurrence and study of human rights and their abuses. Therefore, the basic debates about the idea and concept of human rights are first clarified here from a historical perspective. Then, a range of methodological and ethical problems in the historical study of human rights are presented.

1. History of the Idea and Concept of Human Rights

1.1 Moral vs. Positive Rights

In 1689–90, just after the Glorious Revolution of 1688, the English philosopher John Locke (1632–1704) wrote his *Two Treatises on Government*, which contained the first classical formulation of human rights (then still called 'natural rights'). In retrospect, this work stood at the juncture of a set of amazingly diverse ideas, some of which went back to antiquity and some of which will survive the twenty-first century. Locke's point of departure was the doctrine of natural law as it had developed since antiquity and had been

transformed, in certain respects almost beyond recognition, by medieval Christianity and early-modern philosophers. According to Locke, the doctrine maintained that nature endowed all humans with certain basic moral entitlements (such as the right to life, liberty, and property), to which the man-made laws of society, both positive and customary, had to conform.

These natural rights were thought to possess five distinct characteristics: they were discoverable by reason, itself a faculty of human nature; they existed before humans entered society; they applied to all humans by virtue of their being human; they were inalienable; and they were restricted only by the recognition of the rights of others. As such, these rights limited the power of the society—generally in its predominant historical-political form, the state—and its laws, and respect for them was the first test for the legitimacy of political power. Ancient ideas on rationalism, equality, and the restrained exercise of power formed the substratum for this natural law doctrine, which proved to be very influential. Despite its claim of eternity, however, many of the doctrinal components, such as the exact catalog of moral principles or the source of authority for these principles, turned out to be rather flexible.

Although temporarily in eclipse because of the ascendancy of the sixteenth-century absolutist state, the natural law doctrine would be fostered by three developments initiated in that very period. With the Renaissance came an emphasis on individualism and secularism, the outcome of the religious struggles following the Reformation taught the necessity of tolerance, and the seventeenth-century scientific revolution marked the triumph of rationalism. These developments reversed the philosophical priorities of the hierarchical medieval societies: natural law gradually became associated with rights rather than with duties and with individuals rather than with groups.

The perception of the source of these natural rights also changed. Whereas Christianity had maintained that God was the ultimate source and political absolutism had invested the monarch with divine rights, the consent of the governed came to be seen as the final authority. Individuals gave this consent in a social contract, which presupposed that they possessed rights before entering society. Governments owed their origin to that contract, by which free and equal citizens agreed to entrust to a neutral sovereign body some of their rights, to accept its authority and rules as long as it protected them, and to rebel against it if it did not. This formed the basis for the rule of law and the separation of, and balance between, the legislative, executive, and judicial functions of government.

Although previous theories (such as Hugo Grotius') paved the way and later ones expressed similar ideas, it was Locke's political theory which was to prosper, especially outside England. In the age of Enlightenment it exerted profound influence upon the politicians behind the great revolutions at the end of the

eighteenth century. In the United States and France, natural rights, mainly of a political and civic character, were incorporated into the declarations and constitutions of the revolutionaries. In 1789 natural rights transformed into the 'rights of man' (*droits de l'homme*). This marked the beginning of a process of codification of rights within the constitutions of most states and in international law that still has not ended.

From this brief historical overview, it is clear that, although many aspects of the human rights conception have an ancient pedigree, other crucial ones have not. The concept was the result of a unique historical combination of a series of events and philosophical thought reflecting upon them, and developed relatively late in Western history. The natural law doctrine itself knew a curious fate: with unprovable tenets and with the possibility of abusive claims 'in the name of nature,' it became overshadowed by the powerful state-centered thinking of the nineteenth century (as it had been in the sixteenth), but it survived. It was rehabilitated in a modest form after the two world wars. The twentieth-century approach did not derive human rights from nature any longer, but from (historically determined) rational ideas on human dignity.

1.2 Absolute vs. Relative Rights

The debate on moral vs. positive rights was continued by liberal, conservative, and socialist critics of human rights. Typical of this criticism were the works of Jeremy Bentham (1748–1832), Edmund Burke (1729–97) and Karl Marx (1818–83). These critics argued against the abstract and absolute character of human rights. They maintained that rights had to be related to the society in which they were to be exercised. The liberal utilitarian Bentham believed only in the force of positive legislation. For him, natural rights were imaginary, 'nonsense upon stilts.' He feared that they were powerful rhetoric in the hands of rulers and a substitute for effective legislation.

Unlike Bentham, the conservative Burke did not deny the existence of natural rights. However, he feared them for reasons contrary to Bentham's: in the hands of the common people, natural rights would stimulate revolutionary sentiments and cause social upheaval leading to terror and to the destruction of the social fabric. Rights (and the duties linked with them) ought to be derived from the principles and values emanating from the particular traditions of a society.

For the socialist Marx the human rights doctrine was not radical enough. It left the inequalities generated by capitalism untouched (particularly private property) and therefore served the interests of the ruling bourgeois class. Because of these inequalities, the workers were unable to enjoy their rights fully, which therefore remained largely formal. As a class,

the workers had a duty to create the conditions for social change by claiming collective social and economic rights with which to overturn the economic system. The new, egalitarian society would be one without a state, laws, or rights.

These thinkers did not stand alone in their criticism, but their arguments gained a classic character and inspired powerful currents. Bentham's ideas gave impetus to the tradition of legal positivism. Ideas similar to Burke's would feed the romanticism and historicism of the nineteenth century to the extent that they too emphasized cultural identity and diversity. Marx's concerns heightened awareness of the need for social legislation and influenced the 1917 Russian Revolution.

1.3 Men vs. All Humans and Individuals vs. Groups as Rights-holders

Clearly, until long after the era of revolutions, the concept of 'rights of man' covered only very restricted categories of humans, usually male tax-paying citizens. The large majority of women, slaves, and foreigners were excluded. The struggle to include these categories in the ranks of rights-holders would lead to the final transformation of the concept into 'human rights.' As early as 1791, Olympe de Gouges struggled for women's rights. With the movement against slavery, another group followed. Categories of individuals deemed particularly vulnerable (women, children, aliens, refugees, prisoners, the disabled) were eventually protected by special regulations.

Likewise, the difficult problem of how to realize group rights was introduced at an early stage in the human rights debate. Groups deemed vulnerable (minorities, colonized peoples, indigenous peoples) increasingly received special attention. Specific treaties for national, ethnic, or religious minorities were drafted long before general treaties came into effect. The idea of self-determination appealed to peoples under colonial rule or comparable alien subjugation and proved to be a crucial concept. It was a dangerous concept too, because the narrowing of self-determination to only one of its possible interpretations—secession—was potentially explosive and because consensus was lacking as to whom the rights-bearer ('a people') exactly was. Self-determination was promoted to a group right only in the 1966 covenants (see below).

From an acute attention to making the concept 'human' all-embracing, two further questions on the extension of rights can be derived. First, do past and future generations have human rights? As to past generations, one could think of the right to a decent burial or the right to be treated with respect in historical works. As to future generations, the preservation of the cultural heritage of humanity and of the

natural environment are chief concerns as is the relationship between human rights and the human genome. As to future generations in relation to past generations, the accountability of successor governments for human rights abuses committed by their precursors and the obligation to investigate them are matters of legitimate debate. Second, what consequences does the anthropocentric character of human rights have, as it excludes other sentient beings and is often based on restricted and exploitative conceptions of nature?

1.4 Domestic vs. International Jurisdiction Over Human Rights

Since 1800, two tendencies, one international, the other national, partly opposite, partly complementary, have dominated the debate over who was to control the protection of human rights. A process of internationalization started when human rights were incorporated into the constitutions of growing numbers of countries. At the same time, human rights became part of the agenda of intergovernmental meetings, leading to the humanitarian interventions of the nineteenth century (continuing a tradition dating from the seventeenth century) and the gradual incorporation of human rights into international law. That human rights abuses often created conflicts that threatened international peace was a lesson learned slowly. Treaties were drafted to protect selected vulnerable categories such as slaves, war prisoners, and minorities. The League of Nations, founded in 1919, did not formally recognize human rights but added pioneering treaties for minorities, refugees, and mandate territories.

The decisive historical moment for internationalization, however, came during World War II, when the link between human rights violations and war (hence the link between human rights protection and international peace and security) became clearly visible and, shortly after, when the Nazi and Japanese atrocities led to worldwide condemnation embodied in the international war crimes tribunals of Nuremberg and Tokyo. Although the United Nations only paid secondary attention to human rights in their 1945 Charter, this did not prevent work on an International Bill of Human Rights, consisting of a morally compelling but not legally binding Universal Declaration of Human Rights, adopted in 1948, and two International Covenants, one on economic, social, and cultural rights, and one on civil and political rights, both approved in 1966 and entered into force in 1976.

In the efforts to transform human rights into positive rights by making them enforceable in positive law, usually three stages are distinguished: standard-setting (codification of standards), ratification (making standards binding), and implementation

(enforcing standards via sanctions). Seminal steps for enforcing standards were the elaboration of complaint mechanisms for state and nonstate actors (mainly since the 1970s), the appointment of a High Commissioner for Human Rights (1993), and the adoption of the Statute of an International Criminal Court with universal jurisdiction to prosecute alleged perpetrators (including heads of state and government) of genocide, crimes against humanity, war crimes committed in international and internal conflicts, and crimes of aggression (1998). Important preparatory work for these new devices was done by a coalition of non-governmental organizations, the representatives of civil society. The elaboration of human rights institutions and mechanisms on a world scale was paralleled, and often preceded, by similar developments on a regional scale in Europe, America, Africa, and the Arab world.

In the midst of this evolution, the state was the key player. The cherished principles of the Westphalian world order, established in 1648, were national sovereignty and interstate equality. Their corollary, domestic jurisdiction, excluded interference from abroad in the internal affairs of the state. The vigorous doctrine of nationalism and successive waves of decolonization since the late eighteenth century strengthened these principles. Paradoxically, recognition of national sovereignty made possible progress in international law with its core principle of interference in the internal affairs of states. In the first place, states slowly realized that when they adopted human rights as the basis of the rule of law, they implicitly created a duty to protect them everywhere, including beyond their borders. In the second place, it was painfully obvious that the states themselves were the main perpetrators of human rights abuses. Therefore, states reluctantly but voluntarily began to accept an international monitoring element that restricted their sovereign domestic power. The number of humanitarian interventions increased drastically in the 1990s, but their enabling conditions, forms (diplomatic, political, economic, or military), potential abuses, and effects were hotly disputed.

1.5 First- vs. Second- vs. Third-generation Human Rights

As the success and the criticism of the human rights doctrine expanded the list of human rights, analysts grouped them into generations. The first generation, tied to the idea of liberty, were the traditional or individual rights of a political and civic nature. They were characterized as negative rights ('freedoms from') because they favored governmental abstention. The second generation, tied to the idea of equality, were the modern or collective rights of a social, economic, and cultural nature. They were characterized as

positive rights ('rights to') because they favored governmental intervention. The third generation, tied to the idea of fraternity, were modern or collective rights of a global nature. They were characterized as solidarity rights and usually included the rights to development, human security, peace, and self-determination. The rights of indigenous peoples and the right to a life-sustaining environment are frequently added, but these are also listed as fourth-generation rights by some.

Each generation emerged in a particular historical context. The first generation was the result of the late-eighteenth-century revolutions led by the bourgeoisie that abolished feudalism (and colonialism in the case of the United States). Increasing political emancipation and democratic participation in the next two centuries gave further impetus. The second generation developed in the nineteenth century as the socialist tradition with its reformist and revolutionary strategies, and introduced ideas of welfare and social legislation to counter the exploitation of working classes and colonial peoples and to create the necessary conditions for the full exercise of rights. The third generation is usually associated with the Third World demand for a worldwide redistribution of power and wealth; another factor is the tension generated by the staggering increase of interdependency and global problems on the one hand and the need to safeguard cultural identities and diversity on the other. The three generations of rights can be placed on a continuum with justice at the one end and solidarity at the other.

This bewildering diversity of human rights occasioned controversies on their compatibility, priority, and indivisibility. Because all human rights were conceived as inalienable, they sometimes came into mutual conflict. A classic example of a conflict within the same generation of rights is the tension between expression and religion: what is called 'an opinion' by one person, might be labeled 'blasphemy' by the next. But most conflicts occurred between, rather than within, generations. Whereas first-generation rights assumed the character of universally enforceable standards, second- and third-generation rights were rather aspirations whose fulfilment was utterly dependent on the creation of specific conditions. Faced with all these demands, some states, mainly in the First World, gave priority to first-generation rights, while others, mainly in the Second and Third World, struggled, if not for the primacy, then at least for the equivalence of second- and third-generation rights. Acrimonious debates were held on whether political freedom or economic development was to be accorded priority. Those defending the priority of political freedom ('free minds') were accused of perpetuating inequality, those defending the priority of economic development ('full bellies') of perpetuating dictatorial government. In the Cold War era (and beyond), these arguments were used as political propaganda. The hypothesis that political freedom or democracy should

be suspended until certain levels of economic development are attained is contradicted by the bitter experience that in such cases freedom is usually trampled underfoot, while no economic development is attained after all. Unaccountable governments generally exacerbate economic and environmental crises. Moreover, how can a present suspension of freedom be conceived as preparing for its future protection? The reverse hypothesis seems to have firmer ground: with their political rights respected, citizens will participate more fully in the economic development of their society. The correlation between economic development and political freedom seems to be accepted, but under which conditions, for which precise political and economic areas, and in which causal direction the correlation is valid remains largely unresolved.

At the 1993 World Conference on Human Rights in Vienna, the second such conference ever and the first after the Cold War, the indivisibility of human rights was strongly reaffirmed. Even so, seven rights acquired a special status as they were the only ones stipulated by the 1966 Covenant to be nonderogable, even in times of public emergency. They are the rights to life, to be recognized as a person before the law, and to freedom of thought, conscience, and religion; and the prohibitions against torture, slavery, imprisonment for non-fulfilment of contractual obligations, and retroactive application of criminal laws.

1.6 Universality vs. Relativity of Human Rights

Seen from a historical perspective, most major religions and ethical systems have been concerned with human dignity. Opinions differ, however, on whether they were also concerned with human rights (viewed as one specific way to realize human dignity). Developing the human rights concept took two millennia in Western history and was so full of unforeseen links, ruptures, reversals, and coincidences, that it may convincingly be called a unique product of that history (see above). The quasi-universal emphasis on the community in which individuals had mainly duties switched in Europe and its American colonies to an emphasis on individuals and rights. Elements of the human rights concept, such as some natural law principles, were available outside the West, but the combination of factors that led to its formulation was not. As the West conquered the rest of the world, it introduced its dominance and violence. At the same time, its notions of freedom, nationalism, and cultural diversity, developed initially for home consumption, fell on fertile ground overseas. These notions, including human rights, proved able to transcend their particular roots and context. In the hands of colonized peoples, they echoed similar indigenous values and served to justly criticize Western exploitation in the language of the West itself. Thus, whereas human

dignity is a universal value with venerable traditions everywhere, the claim of the universality of human rights has an anthropological basis, not a historical one, and is rooted in the universal appeal of a specific system of thought.

The anthropological debate was no less vivid than the historical debate. During the preparatory work on the 1948 Universal Declaration, leading American anthropologists emphasized the cultural relativity of values and denounced the universalist pretensions of the intended declaration as cultural imperialism. Moreover, the historical critics of the universality of human rights (presented above) were succeeded by neo-Marxists, communitarians, and postmodernists. But the most influential group of critics were the vociferous ruling elites of some non-Western countries, especially in Asia and Africa. They challenged specific formulations of private rights such as religion or marriage, and advocated, instead of universality, the principle of domestic jurisdiction or the primacy of second- and third-generation rights over first-generation rights. Remarkably, the surviving victims of imprisonment, torture, and other abuses in non-Western countries (among them many future elites of these countries) found such criticism unconvincing. These victims argued that denying universal human rights to citizens outside the West was itself a sign of cultural arrogance. A new consensus seemed to emerge when 171 states unanimously reaffirmed the universality claim at the 1993 Vienna Conference and thereby made the claim far more representative than at the time of the 1948 Universal Declaration which was approved by a vote of 48 to zero with eight abstentions. At the same time, care for second- and third-generation rights is growing. In 1998 a draft of a Universal Declaration of Human Responsibilities was submitted to the United Nations General Assembly, as an attempt to achieve a better balance between freedom and responsibility and between justice and solidarity.

2. History and Historiography of Human Rights and Their Abuses

The second interpretation of the expression 'History of Human Rights' points to historical research on human rights. When looking at this area, we are confronted with a paradox. On the one hand, as human rights encompass so many spheres of life, large parts of the historiographical production inevitably deal with concrete aspects of human rights and their abuses (e.g. the history of education, the history of slavery, the history of censorship). Equally, historians endeavored to write histories of emancipation movements or of freedom. Grand theories of history and world histories sometimes had implicit views on human rights, and the more recent they were, the more they covered the whole of humanity in an equitable manner. Indeed,

with little exaggeration one could say that almost all history touches on some present human rights concern. On the other hand, it is hard to find research explicitly designed to study a particular right in historical perspective. Some of the methodological and ethical problems involved in this type of research are outlined below.

2.1 Methodological Problems

In the following example, a general question is analyzed to demonstrate the methodological complexities of human rights research. That question is: 'Do human rights abuses increase or decrease over time?' A historical question because of its time dimension, it is also an ethical question to the extent that the answer gives clues about the moral progress of humanity (philosophers of all times have been in dire need of such clues). Questions as broad as this one should be rendered operational. This may be done by narrowing the 'human rights' of the question to one of its categories, 'civil and political rights,' by selecting from this category one important right, 'the right to life,' and, finally, by selecting from this right its most serious abuse, 'genocide.' Reformulated in operational terms, the question thus becomes: 'Do genocides increase or decrease over time?' This question can be approached logically and historically.

A priori logical considerations distinguish between absolute and relative levels of abuse. In absolute terms, the case of an overall increase of genocides is defensible. The population growth on earth, the increasing sophistication of repressive bureaucracies and technologies, and the anonymity often physically and morally shielding the perpetrator are all contributing factors in making this statistically probable. Our perception, however, may be deficient in two contradictory directions: we may overestimate the present absolute level of cruelty because of our lack of knowledge of past cases; alternatively, we may underestimate the actual level because we are too impressed by the countervailing forces, especially since the recent expanding human rights awareness has led to a higher state of general alert and perhaps to more deterrence. In relative terms, the question is very different: given that an equal amount of cruelty probably leads to greater destruction in modern times, were societies more repressive or more human towards their citizens in the past than they are today? In tackling this question, one ought to apply criteria for measuring the degrees of cruelty, but which ones? The number of victims in relation to the total population? The presence of especially vulnerable categories of victims? The occurrence of particularly cruel types of repression? In addition to this difficulty, there is the danger of anachronistically projecting back contemporary conceptions and values into the past. In the

face of the pain suffered by each individual victim, however, such considerations on the moral economy of death may sound superficial or scornful. A probable absolute increase of cruelty or repression in history, then, does not imply that humanity is now more barbarous than in the past, nor that it is less.

Does a historical approach shed more light on the problem? The 1948 United Nations Genocide Convention called genocide 'an odious scourge' that 'at all periods of history (...) has inflicted great losses on humanity.' Thus the term 'genocide'—coined in 1944 by Raphael Lemkin—seems to cover phenomena in all historical periods. Which phenomena? The Convention provides a definition (a series of 'acts committed with intent to destroy, in whole or in part, a national, ethnical, racial, or religious group') that genocide scholars reluctantly accept or decline all together. These scholars argue that many more group types than the ones from the definition have been genocide victims (notably political and social groups) and debate the boundaries between genocides and comparable crimes. They also report that many researchers suffer from psychological barriers in studying the almost unbelievable cruelty of genocide. The body of genocide research only began to grow after 1945, and with the exception of the relatively well-studied Holocaust, it is still lacking in many instances.

Not only do definitions and psychological resistance raise problems, so do heuristics and epistemology. It is often excruciatingly difficult to know how many died and what exactly happened during each specific genocide. Drawing statistics on the number of victims that are more than 'guesstimates' is a skill in its own right. Rudolf Rummel's elaborate statistics (1994) show that the democide rate (a concept including genocide, politicide, and mass murder but excluding war dead) was almost certainly higher in the twentieth century than in any previous century: he presents a calculated total of 169,202,000 dead for the period 1900–87 (including 38,566,000 genocide victims) vs. a hypothetical total of 625,716,000 dead for the period from the thirtieth century BCE to 1900. However, these figures do not allow conclusions about a possible increase of democide, and by implication of genocide, because Rummel derived his hypothetical total of pre-twentieth-century democide from the twentieth-century democide rate and the population for each century since the thirtieth century BCE. Linked to the statistical problem is the source problem: few sources normally survive, at least for the earlier genocides, in history. The sources were either not kept, hidden, lost, or destroyed. When they are available, they come from either perpetrators, victims, or bystanders. When there are sources from two or all parties, they frequently conflict with each other. Finally, their authenticity and reliability have to be tested. In short, the usual techniques of historical criticism have to be applied with unusual sharpness. Even when sources allow the historian to distill a picture of the killings, proof of the

intention of the perpetrator to destroy a group as such (an essential component of all genocide definitions) is difficult. Openly stated motives are exceptional and notoriously unreliable and, therefore, intent generally has to be ascribed. This is precarious, especially where the genocide is unanticipated.

Once we have reliable descriptions of the events, the question remains whether they catch the essence of the horror. The limits of representing the unrepresentable have been much debated in recent decades. The analysis and interpretation of the data pose their own problems. First, genocide is a complex interdisciplinary phenomenon with historical, psychological, sociological, political, legal, philosophical, and religious aspects. Second, the systemic and human factors conditioning genocides and the extent to which they are unique and comparable are open to much controversy. Third, it is important to know whether the nature of genocide has changed over time. Among the dozen or so typologies of genocide, some address this problem, however inconclusively. Frank Chalk and Kurt Jonassohn, for example, distinguish between retributive genocide (to eliminate a real or potential threat), despotic genocide (to spread terror among real or potential enemies), developmental genocide (to acquire economic wealth), and ideological genocide (to implement an ideology). They then classify 22 cases from history under the most relevant type. The distribution of cases reveals that the fourth type is a predominantly twentieth-century phenomenon with few historical antecedents. Even if this suggests that the nature of genocide has (partially) changed, the question remains why. With all its methodological difficulties summarily depicted above, the historical approach is obviously far from conclusively answering the initial question either.

2.2 *Ethical Problems*

The historical study of human rights and their abuses also involves ethical problems. Some of these are related to the researching historians, others to the human beings they study. Most are not unique for this type of research, but they present themselves cogently here. Human rights research can be dangerous, especially when the historians are working on contemporary material in their own society or on cases of the past which suggest easy analogies with the present or endanger the legitimacy of present rulers. This may lead to the persecution of the historians and entail reflection on their professional ethics: what are the rights and obligations of historians working under such restrictive conditions and what should their colleagues working under freer conditions do?

What rights do the human beings under scrutiny have, apart from the right to be treated with respect in historical works (see above)? With regard to the perpetrators of crimes, the question is whether moral

judgments of their acts are possible, and if possible, permissible, and if permissible, obligatory. Opinions of historians widely differ on these points. Few believe that they are judges for eternity, but nevertheless most will admit that there is something like a right to historical truth, for which it is never too late. They would probably subscribe to the professional obligation not to deny or forget the fate of the dead and surviving victims. This justified claim, however, can be at odds with impartial research. It is a task with many risks. Without the passion of the survivors, historians may 'normalize' the cruel abuses of the past by inserting them into the stream of history. They may omit crucial findings for fear of breathing new divisive fever into the collective memory. But still, the distinctive professional contribution of historians to the protection of human rights, if any, is to see that the dead do not die twice.

A. De Baets

Human Rights in Intercultural Discourse: Cultural Concerns

Though human rights are generally recommended, there are still some strong criticisms. One criticism refers to human rights, somewhat derogatorily, as the civil religion of modernity and, by this, takes them to be only a historical phenomenon of a particular culture. Other critics fear that the spread of human rights is nothing but a new and subtle version of Western colonialism or imperialism, namely a supremacy of a its legal culture, which forces values on other cultures. But actually, human rights belong to a universal legal morality, which is common to all mankind although it was thought of in the most radical manner by Western modernity.

Within Western legal culture, human rights are taken as a matter of course. But as far as their foundations are concerned, there are difficulties which are partly of a political, partly of an intercultural, and partly of an anthropological nature. A specific philosophical justification, a transcendental foundation of human rights might help to overcome

these difficulties. This foundation, at the same time, might permit one to show the universal validity of human rights beyond liberal legal cultures.

1. Human Rights and Basic Rights

The first, political difficulties arise when one considers the possibility that a declaration of human rights might simply remain a declaration. For instance, the People's Republic of China used tanks against demonstrating students, although it recognizes freedom of procession and demonstration as stated in Article 87 of its constitution. The answer to this may simply be compliance with positive law. In order to give human rights an actual power in the world, instead of remaining just word on the page, they have to become solidly embedded in human practice. To this purpose human rights have to make their way into the sometimes written, sometimes unwritten constitution, thereby doing both: obliging the branches of government to human rights and restricting their power, among others rendering possible proceedings before the court of law against any abuse of governmental power and of the nonrecognition of rights. Wherever this occurs, human rights, which were previously just a component of universal legal morality, become elements of positive law. They are transformed from mere human rights into basic rights of a particular legal community.

Not only does this differentiation of human rights and basic rights direct itself against simple declarations, it also draws attention to those origins of basic rights which lie before and beyond the state. In particular, history's first declarations are aware of this elementary meaning. In this respect, the French *Déclaration* (1789) follows the Virginia Bill of Rights (1776). Their beginning establishes valid rights at a level which lies before the state. Subsequently, the basis for legitimation is laid for the exercise of political power; Virginia's Article 2 and France's Article 3 state that the people is the origin of all government. It is not until the third step that the function of the state is touched upon; here the limitation of the exercise of political power as well as the positive tasks of the state is mentioned. In that sense, from a philosophical point of view, we have to reverse Benjamin Barber's title: not 'Democracy first, then Rights,' but 'Human Rights first, then Democracy.'

This sequence contains my first thesis: human rights are rights of all human beings raised against all other human beings. From the standpoint of legitimation the claims in question are primarily raised by all men against one another and they are at the same time granted to one another. With regards to human rights, people recognize themselves as beings with equal rights. Positive law and the branches of government are legitimized in relation to human rights only at a second and, more specifically, subsidiary level: they are incumbent upon transforming innate rights in the

process of the establishment of a constitution and further legislation into positive law. The scholar of law says, 'rights are guaranteed'; with this he means a secondary accomplishment that is strongly differentiated from a primary accord. In German, we distinguish *gewähren* which is done by men themselves, and *gewährleisten* which is the task of the branches of government: the legislator, the executive power, and the courts.

2. An Intercultural Legal Discourse

The second difficulty with human rights is constituent of the fact that we expect the recognition of human rights from all cultures, but that the discourse on human rights only takes place within one of them, namely the Western culture. For this reason there is a risk that human rights, instead of constituting the core of a universal legal morality, will give away their essence and will thereby decline to the level of an 'export-article of Western culture.' In this sense, the objection of 'ethnocentric thinking' can be raised, for a legal institution like human rights, Western culture claims to be valid for the whole of mankind.

Although itself a product of the West, philosophy lends its voice to non-Western cultures. It does not do so in a now current form of a mutation, an act which turns philosophers into a kind of fundamental anthropologist, into theoreticians of a world society who, like Lyotard (1983), Feyerabend (1987), and Rorty (1989), place themselves in the tradition of American anthropology—one thinks, for example, of Herskovits' 'Statement on Human Rights' (1947)—and who, in their fear of destroying the characteristics of non-Western cultures, support a pure relativism. Instead of getting lost in the byways of fundamental anthropology, and its exaggerated relativism, philosophy engages in an intercultural legal discourse.

This discourse begins, in passing, by invalidating the mentioned fear. What Lyotard describes, somewhat drastically, as the 'tyranny of the universal' is based upon a misunderstanding, namely, the confusion of universality with uniformity as though universal legal principles should be equated with the removal of social and cultural differences. Let us take an example: the equal rights of different religions or that of different languages, from the standpoint of human rights, do not undermine the existence of one of them; by contrast, the principle of equality guarantees coexistence of the different parties.

In the next step, our discourse turns the reproach of ethnocentric thinking into a philosophical challenge, in other words, into a question whose answer is still open: how can a regionally developed institution which is not always taken seriously—we recall that the Virginia Bill of Rights was proclaimed in a slave state—lay claim to an absolute universality? Obviously, such a claim is permitted only on a condition which, from the standpoint of legitimation, is self-

evident but which is all too readily overlooked in the case of human rights. Legitimation must be separated from the historical genesis and evolution. My *second thesis* is this: whoever wants to impute the idea of human rights to other cultures must for once divorce himself from their intellectual history, also from their legal and social history, for instance from the question regarding economic prerequisites. If human rights are truly to exist, then they should do so not for the reason that capitalism, the modern form of the economy, requires a global protection of economic rights. Besides, there are well-known practices which contradict the idea of human rights and are nonetheless compatible with a global protection of economic rights, namely, slavery and human bondage, inequality of man and woman, the lack of rights for children and, last but not least, colonization. Furthermore, the legitimation of human rights also needs to be uncoupled from a certain phase of the modern state's development, namely from Reformation and Absolutism. If innate rights truly exist, then the Western experience can have a thoroughly heuristic significance; but in the end, only culturally invariant arguments have the power of justification.

3. A Copernican Revolution of Anthropology

A third difficulty with human rights is expressed in the question: what remains when one considers the separation of legitimation from the historical genesis and abstracts from the particular context of European modernity? The view that the idea of human rights is connected with a certain image of mankind is widespread. To this there is an annexation which not only profiles the matter as far as its content is concerned, but also limits its validity; namely that an image of mankind presents itself as Jewish, another as Christian, a third as Muslim, a fourth as Buddhist, and finally a fifth—a definitive neither/nor!—as atheist. Moreover, the modern European picture of mankind is individualistic and relatively ahistorical, whereas the African image of mankind is determined by a characteristic solidarity of two dimensions: a solidarity with fellowmen and with the ancestors. We can generalize: all specific images of mankind, all views of human nature are therefore culturally dependent.

The consequence for our justification: we even have to rid ourselves of Western images of mankind and evolve a *logos tou anthropou*. In other words, we have to evolve a concept of mankind which, valid for the whole of humanity, is independent of different histories and cultures.

A concept of mankind which is independent of cultural particularities, and therefore interculturally valid, has for a long time been no stranger to Western thought. Since Greek Antiquity, we know two anthropological definitions: men as *zoon logon echon* and as *physei politikon zoon*. Recently, however, skepticism

is the rule. If one lends an ear to philosophers like Rorty (1989, p. 44), then skepticism towards anthropology becomes such a matter of course that one may content oneself with only a short aside: 'fruitless by way of anthropology.' But scepticism is not new. Since Rousseau's concept of *perfectibilité* (*Discours sur l'inégalité*, part 1) and Nietzsche's dictum that man is 'more indeterminate than any other animal' (*'unfest-gestellter als irgendein Tier sonst'*: *On the Genealogy of Morals*, 3rd essay, section 13), philosophy has doubted whether it is possible to fix an essence of man that is independent of history and culture. In the 1920s it was Georg Lukàcs who supports this skepticism which was reinforced later in the 1930s by Max Horkheimer (1935). Their critique was not directed specifically at human rights, but it was partially to blame for the fact that Western Marxism has had such difficulties with this legal institution up to now. Lukàcs (1923, p. 204) sees it as 'the greater danger of every anthropological standpoint,' that it 'causes man to ossify as fixed objectivity and thus pushes dialectics and history to one side.'

The idea of human rights counters skepticism by weakening its claim. According to Aristotle's classical topos, *physei politikon zoon* (*Politics* I, 2), the specifically Greek form of a community, the *polis*, is the only place where man can lead a really meaningful life. Even if Aristotle is right and human potentialities can be fully realized only in a political community, the form of this community remains open. The above mentioned difference between universality and uniformity first becomes important here: human rights favor neither the Greek city state nor the modern form of territorial state nor any other form of political communities.

Anthropological relativization goes even further. In contrast to Aristotle's *Politics*, human rights allow a largely instrumental understanding of the political community. The state does not have to represent what the great neo-Aristotelian philosopher, Hegel, termed '*die Wirklichkeit der sittlichen Idee*' ('the actuality of the ethical Idea': *Philosophy of Right*, para. 257), at least not its full actuality. What a sociologist, a 'pupil' of Luhmann, Willke (1983) terms a 'demystification of the state' remains possible. The idea of human rights admits that the 'political system' establishes no more than premises and framing conditions, whereas true humanity can be sought elsewhere, and then in different ways. (Contemporary philosophy speaks of the difference between the right and the good.)

Where this openness for different ways is lacking and where what counts is a normative concept of man, a concept of the humane man alone, one runs the risk of denying elementary rights to people who are not so human. According to Aristotle, anyone who suffers a fundamental deficiency in terms of rational endowment—in short, anyone who is mentally handicapped—is *physei doulos* and rightly viewed as having lesser rights, in other words, he is taken as a slave. To

prevent this consequence, the idea of human rights is not allowed to favor particular forms of self-realization; with regard to the humane, we need an intentional nonspecification.

The institution of human rights intentionally contains what I shall call a fragmentary anthropology and for that reason alone can be imputed to other cultures. Although *prima facie* a drawback, nonspecification is in fact an advantage: far from being indifferent to more demanding definitions of man, it is, by contrast, open, ensuring that not only different cultures, but, within those cultures, different subcultures and individuals, enjoy the right to be unique, different, and even eccentric.

Nonetheless, this right is not unlimited. Human rights resist a radical pluralization. They alone make possible the very thing that critical intellectuals such as the 'fundamental anthropologists' mentioned earlier are so keen to achieve but which they are unable to situate adequately within their intellectual framework. The plurality of cultures and subcultures can exist only under conditions which are no longer pluralizable. Thus, in the idea of human rights modesty and immodesty enter into a characteristic union. To limit all plurality and to assume that conditions exist which are equally valid throughout history is an immodest aim. On the other hand these conditions make a modest claim, not demanding to present the form of a human life but to be only a condition of a plurality of forms of life and thus abandoning any normative concept of what is humane.

This connection is possible only if we readjust the anthropological perspective; philosophical anthropology has to undergo a conversion which fully deserves the ambitious title of a Copernican revolution. Instead of defining man from the standpoint that has normally been adopted since classical antiquity, that which allows him *eudaimonia*: happiness, self-realization, or a meaningful existence, we dispense with any teleological or normative concept. My *third thesis* is this: human rights are not concerned with perfecting what is humane but with its initial conditions, with elements which deserve the qualification of the relevant rhetoric: as elements inalienable to each person they are his inherent birthright. Here, we find my initial thesis: since we are dealing with conditions of the possibility to be a man, and not a man in a biological specification but as a responsible agent, we can speak of transcendental elements or o(relatively) transcendental interests, relative to (responsible) agency.

Transcendental interests alone leave the task of legitimation underdefined. This much is clear from even a cursory glance at legal history. Since man was regarded by Judaeo-Christianity as having been made in the image of God or as *zoon logon echon* by the Greeks, the West has been familiar with a universal concept of man. Yet, no legal consequences have been drawn from this; both the Jewish-Christian tradition

and the Greek one allow slavery and the inequality of women. A correlative phenomenon, familiar since the thirteenth century, is the sort of bill of rights typified, for example, by the Magna Charta Liberatum and the Golden Bull of Andrew II of Hungary. Although these charters were drawn up in states in which both ideas—'the image of God' and 'rational endowment'—were taken for granted, freedoms were not given to man as man. This deficiency remained—not, it is true, in the legal text, but in legal reality—until the time of the earliest declarations of human rights (we remember the case of a slave state proclaiming a bill of human rights).

Indirectly we stumble across a further difficulty here, which, from the point of view of legitimation, is even greater. Man should have a subjective claim to certain transcendental or anthropological interests. A claim can be made where another person has to meet that claim; subjective rights are bound by their very concept to correlative obligations, human rights to corresponding human obligations.

Three factors deserve emphasis here. First, the claims do not exist in an absolute sense; the right to exist does not mean, for example, that one does not have to die at all. Second, the right which, although only relative is not conditional, refers to ones fellow men and demands that they refrain from using force.

In an intercultural legal discourse, an objection arises at this point which is familiar from the liberalism/socialism debate: particular attention is given to civil rights and liberties, which, on the African side, are accused of favoring the individualist picture of man familiar to the West. To the extent that our fellow men are required to perform a service, not even civil rights are based on any individualistic anthropology. A social nature is assumed in an entirely traditional way, only its manner is no longer traditional. According to Aristotle, the *polis* is natural because man is invested with certain social impulses which ultimately produce the *polis* through a series of certain intermediary stages. The anthropology of human rights does not question these social impulses; it extends its horizons and discovers a complication which is the third factor deserving emphasis.

The complication has two consequences. In the first place, what has hitherto been called simply the 'social being' is given a qualifying rider: it becomes a *positive* sociality providing mutual help, with a *negative* counterpart in the form of a reciprocal threat. From an extended social anthropology—let us say 'cooperation plus conflict'—our legal institution singles out only one aspect, the conflict, namely, a threat from one of our equals, a threat, moreover, which affects the anthropological interests; these are threats of truly existential weight. Since these threats come from our fellow men, each individual is both a potential agent and, at the same time, a potential victim.

The anthropology bound up with being both victim and agent recalls Hobbes' dictum, *homo homini lupus*,

and, like that dictum, sees itself exposed to the reproach that it presents a pessimistic image of man. But, at least as far as the idea of human rights is concerned, this reproach is unjustified. Being modest once more, negative social anthropology is not claimed to be exclusively valid but, once again, to be fragmentary anthropology—not a basic feature of the individual but a danger which cannot be excluded.

The complication caused by threat has a second consequence, inasmuch as the evolution of the *polis* can no longer be regarded as the mere development of pre-existent social impulses, a far greater contribution of ones own is necessary; although he is a social being, man has to produce himself as a social being. Society arises through mutual recognition, which can assume a variety of forms; human rights emphasize only a small part, and that part concerns the elementary level of anthropological interests.

The anthropology of human rights relates to existential threats but refrains from passing judgement on the nature of the conflict, whether that judgement be positive or negative. Therefore, a *fourth thesis* reads as follows: the danger of conflict is accepted as an anthropological fact which is favored in relation to man's cooperational nature only to the extent that it is his conflictual nature alone which makes human rights necessary. Where social relations consist only of mutual help and where help is not only always spontaneous but can be relied on, in a word, where man's positive social nature exclusively is involved, human rights lose their task.

4. Transcendental Interests and Transcendental Reciprocity

It is the fact that elementary interests are at stake that constitutes the seriousness, even existential seriousness of human rights and explains the feelings and the pathos bound up with this institution. An indispensable element—the character of a claim—is not yet clear, however. In many arguments there is a hiatus at this juncture, a legitimate leap which fails to explain why a subjective claim insists on the recognition of transcendental interests. I do not dare to suggest that I can justify this claim in the face of every doubt, but I am making a proposal based on a generally recognized principle.

A moral claim insists on the recognition of a service where the service is rendered on condition that a corresponding service be rendered in return. This generally recognized principle regards the obligations of legal morality (and not of all morality) as a giving that is made on condition that a countergiving is made; it operates with the reciprocity of giving and countergiving, you could say, with an exchange. Anyone who lays claim to those services which are rendered only under the condition of reciprocity now

stands under an *obligation*. Conversely, a (subjective) *right* is involved as long as one actually renders the service which is performed under the condition of a service in return.

In terms of human rights, this general principle must now be applied to the particular case of anthropological interests. For them, there is a correlation between rights and duties where certain interests not only have an anthropological status but also fulfil the condition that they are realized only in and through reciprocity. Here, and only here, in the case of an 'inherent reciprocity,' or an inherent sociality, is one no longer free to say whether to accept an exchange or not. To the extent that, in keeping with their qualification as anthropological, the interests are indispensable and to the extent that they are also bound up with the idea of reciprocity, the indispensability is transferred to the reciprocity; the corresponding exchange is similarly indispensable.

The proposal obtains a moral, albeit undemanding moral element: at the basis of human rights is a modest morality that is withdrawn from the usual controversies. This morality—fairness in exchange—applies in those cases where it is not a question of one person giving and the other taking, but, rather, where there is a reciprocity of giving and taking and where, moreover, the giving and its recompense are more or less equal in value.

Since a moral element is present, the legitimation of human rights obeys the structure 'anthropology plus morals.' In this legitimation the moral part is as good as uncontroversial, but the same cannot be said of the anthropological part. Human rights represent a problem that is very much bound up with legal *ethics*, and yet it is their other aspect, that of legal *anthropology*, which contains the greater difficulties. At least on *their* account what was formerly a great discipline, philosophical anthropology, merits a minor revival.

It is the both-victim-and-agent anthropology which allows us to describe human rights as an exchange which anyone can enter into with anyone else. Each of us exchanges his own potential for committing an act of violence for the interest of not falling victim to another's violence. Characteristic of this exchange is its inherent reciprocity: one can realize one's own interest only by virtue of a service which the others—all the others—perform. In addition, we rediscover a difference to traditional social philosophy. Mutuality consists not of positive services but of a negative reciprocity, in an all-round rejection of violence. Nonetheless, the exchange has a positive significance as such, and not only as consequence, otherwise there would be no reason to agree to it. When the corresponding human *obligations* are fulfilled, human *rights* should be granted. From the reciprocal refusal to kill one's fellow man, to rob them, or to prevent them from practicing their religion issue the right of life and limb, the right to property, and the right to religious freedom.

The question which now arises is whether, for the sake of the positive purpose, each of us should agree to this negative exchange. Does the condition 'innate interest' apply just as much as the condition 'inherent reciprocity'? The question has the character of a preferential choice which is decided on the question of what people prefer. Do they prefer to have the right to kill, but coupled with the danger of being killed themselves, or do they prefer the integrity of life and limb, but at the price of having to accept the corresponding obligation and no longer kill any person? Or, put another way: does the individual prefer to be both the victim and the perpetrator of violence or does he prefer a neither/nor situation?

According to a first attempt of philosophical legitimation—that of Hobbes—every man has an overriding desire: not to die at the hands of a fellow man. The English Civil Wars of that time make it clear enough that many people see religious freedom as more important, while others prefer political or cultural ideas, and a third group prefers honor.

The counterexamples can be subsumed under the heading of self-preservation. What is preserved, however, is not the physical self but a 'moral self.' Is it here, therefore, that the predominant interest is to be found? In the conflict of 'physical vs. moral self,' one can certainly decide in favor of mere survival. If there is really an innate interest, it must be sought on a logically higher level, beyond the conflict of 'physical or moral self.'

A third attempt remains with the idea of an overriding desire, but takes that desire not as something negative but, rather, positive, something, moreover, which is no longer a dominant but an all inclusive interest. The interest that includes all other interests within it we call happiness. As it fulfils all needs and interests, it forms the natural guiding principle of every individual. With so formal a definition, however, it is not possible to answer the question, whether a person would rather perpetrate a violent act and at the same time be its victim or whether he would prefer neither one nor the other. If we introduce a further definition, therefore, and insist on defining the content, the individual is left with the possibility of sacrificing his happiness to a fellow man or to a religious, cultural, or political ideal. As a formal definition, happiness is unrelinquishable, but it forms too weak a premise; conversely, a definition which takes account of content reflects a predominant desire which can be seen in relative terms and, like this, represents too powerful a premise.

Anyone who concludes from this that there is no interest in the corresponding exchange fails to see that many people want nothing more than their own survival, while others want only religious freedom, others again only political freedom, and so on. On each occasion, the corresponding rights are advantageous, but they are not the same rights for each person. In other words, people are happy to vote for

human rights, but they interpret that vote very differently.

We need to look for a fourth answer which preserves the strengths of the first three attempts while overcoming their weaknesses. On the one hand, we need a stronger premise than a merely formal definition of happiness; on the other, the undue assumption of an absolutely overriding desire must be abandoned; what we are looking for is an interest that is both substantial and nonsubstitutable. My *fifth thesis* is as follows: this double condition is met by interests which one can neither abandon in favor of higher interests nor weigh against interests of equal importance. Truly indispensable—and, therefore, anthropological—interests consist of elements which, logically, are on a higher level and which, *faute de mieux*, are called (relatively) transcendental interests. To the extent that, in our abstaining from the use of force, our interests are realizable only in reciprocity, in other words, in an exchange, one can speak—with the same proviso—of a transcendental exchange or a transcendental reciprocity. Human rights refer to conditions of agency based on reciprocity.

The idea of human rights presupposes that there are indeed interests on this higher level and that there is, therefore, an exchange on a logically higher level. Let us take an intentionally uncontroversial example—the protection of life and limb. Even someone not especially attached to life has an interest—conscious or unconscious—in that life, since he can otherwise neither desire anything nor seek to satisfy his desire. Independently of what one strives to achieve or seeks to avoid in terms of life's content and, therefore, a condition of our ability to act, a condition of agency, life is the precondition of a practical desire. It is at this point that the singular nature of human rights emerges most clearly, without the corresponding acts of renunciation, the very thing that distinguishes man—his agency—is not capable of existing within a social perspective. This is true even of those who are prepared to sacrifice their own lives: the martyr wants to decide in what cause he lays down his life, in other words, he acts out of religious or political conviction and not, say, because of some robber's act of violence.

The natural law of the Enlightenment appealed to the principle of self-preservation. If I consider the principle of agency to be more convincing, it is because it is more formal and, therefore, has fewer preconditions attached to it. When I speak of agency, it is not, of course, an ability to act *sans phrase* but simply that part which involves reciprocity.

5. Against a Liberalist Restriction

Man is not merely a living being. More than life and limb are involved in the indispensable conditions behind his agency; in consequence, there is more than

just this one particular human right. We can argue directly on the basis of our agency. Since the concept of action involves intentionality, the conditions for agency also include the conditions of intentionality, in other words, the ability to speak and think. Furthermore, in accordance with the claim that man cannot become a man but within a society of fellow men, agency is bound up with positive social relations and cooperative conditions, thereby opening up an additional field of transcendental interests. (We find the traditional anthropological definition of man: he is *zoon*: an animal, *logon echon*: endowed with reason and language, and *zoon politikon*, a social being.)

My proposal: the majority of human rights can be reconstructed on the basis of these three aspects, which, taken together, make the ability to act or agency, a real possibility, in other words, the living being, the being who is able to talk and to reason, and the cooperational being. The insight contained herein, namely, that there are further transcendental interests, is not of course sufficient to proclaim corresponding human rights. In order to do that, we also need to prove a transcendental reciprocity.

The politics of recent decades have grown sensitive to other aspects, including questions of personal, social, and cultural identity, of economic and social prerequisites and, not least, ecological conditions. Here, too, there are forms of reciprocal threat for which our legitimation model remains applicable. At all events, we are dealing with new forms, with threats which are both indirect and which involve a collective responsibility, so that the legitimation model needs to be developed further. But even here it can be stressed—and this is my *sixth thesis*—that the last word has not yet been spoken on human rights within the classic, liberalist canon.

According to classical liberalism each should know his interests best; but since Nietzsche and Freud this view has prevailed as naive. The concept of transcendental interests reaches far beyond this controversy. Within elementary interests, transcendental refers to a stratum that we have not only independent of attitude but also independent of being man or woman, Christian, Muslim, or nonbeliever. The singular character is due to the fact that one does not want anything else but the following: to be an entity capable of action.

According to Rorty (1989, p. 28), the thought that the belonging to a biological species implies certain rights is a type of metaphysical consolation, which the pragmatist renounces. The preceding legitimation shows on the one hand that it is not the biological belonging that establishes rights, but rather the interaction of transcendental and moral arguments; and on the other hand, that for a metaphysical consolation not only the pragmatist but also the theoretician of human rights can renounce.

A legal order cannot safeguard human rights without governmental powers. My *seventh thesis*—a thesis

which is itself subdivided—argues against anarchism. According to this thesis, a public power is needed first to provide a more detailed definition of human rights; this is the task of the legislator. But even with more detailed definitions there are controversial interpretations, so that an impartial and authoritative interpretation, i.e. an independent judicial system has to settle the relevant controversies. Finally, there is another complication, and once more a complication in the form of a danger: one can vote for the recognition of rights and still attempt to enjoy the advantage of a mutual renunciation of freedom without paying the price of renouncing of one's freedom. It is above all in those instances where countervailings do not occur at the same time as the giving that one can enter into an exchange of freedoms in the manner of a fare dodger. This possibility reveals a further element of negative social anthropology, namely, the danger of parasitically exploiting a universal advantage. Public powers are demanded a third time, therefore being needed here as an implementational force—a kind of 'sword of justice.'

Even if more detailed considerations are needed for a convincing legitimation (see Höffe 1987, Chaps. 13–14), this hypothesis of differentiation appears nonetheless plausible. Looked at from the standpoint of the institution of human rights, the classical—specifically Aristotelian—idea of a political nature develops as two partial natures, one of which is concerned with the law, the other with the state. Man is a being that needs, on the one hand, elementary rights and, on the other, the public definition and implementation of those rights, and in this context, he needs democracy. By consequence: rights first, but in any case, democracy, too. Against an overrating of the state, this aspect is secondary, however, being subsidiary to the primary task, which is that, in order to be a human being among his fellow men, man needs elementary rights and correlatively elementary obligations.

Human Rights: Political Aspects

Human rights are, literally, the rights that one has simply as a human being. Although the fate of human rights is largely determined by national political struggles and practices, the focus of this article is international, because only in international studies has human rights become a well-established 'mainstream' concern of a social science discipline.

Prior to World War II, human rights was an ignored, even suppressed, issue in international relations. Even the notoriously 'idealistic' Covenant of the League of Nations does not mention human rights. The turning point was the creation of the United Nations, in the shadow of the Holocaust. The UN Charter lists promoting human rights as a principal objective of the Organization. Even more importantly, the Universal Declaration of Human Rights, adopted by the General Assembly on December 10, 1948, established substantive international human-rights norms that have come to be accepted, at least in word, by almost all states and most leading movements of political opposition in all regions of the world.

In the first two decades after the Universal Declaration, however, both superpowers used international human rights largely as an instrument of partisan political abuse. Although decolonization helped to spur relatively nonpartisan international attention to self-determination and racial discrimination, through the early 1970s no prominent state pressed international human-rights concerns except in the presence of strong political interests.

Rights that are given, either by 'benevolent' dictators or foreign powers, usually end up being rescinded. Only when right-holders are able to, and at least periodically do, act to vindicate their rights are they likely to be enjoyed securely. Thus foreign states and international organizations, as well as transnational nongovernmental organizations (NGOs), have increasingly focused their efforts on supporting the development of autonomous, intermediate associations in civil society, in recognition of the fact that international action usually can only be a supplement to national action.

The other major change of the post-Cold War era has been the growing integration of human rights into other areas of the international action. For example,

at the UN during the Cold War, human rights were rigorously segregated from peace and security, and development activities. Today, a human-rights mission is a standard part of peace and security operations. Furthermore, the threats to peace and security to which the UN responds are most likely to arise from systematic human-rights violations.

The penetration of human rights into other domains of international action is far from complete. Most notably, although the United Nations Development Programme stresses the links between human rights and development, human rights have made almost no headway in the work of the International Monetary Fund, which regularly imposes structural adjustment programs that have significant negative impacts on economic and social rights. Nonetheless, at the start of the twenty-first century human rights are increasingly seen as not merely a regular part of international relations but a concern with vital rights enumerated in the Universal Declaration. Thus the Vienna Declaration, adopted by consensus by 171 participating states, in its first operative paragraph 'reaffirms the solemn commitment of all States to fulfill their obligations to promote universal respect for, and observance and protection of, all human rights and fundamental freedoms for all.'

As human-rights values have filtered into the consciousness and practice of states, bureaucrats, citizens, and civil societies across the globe, the bases of national and international political legitimacy have been transformed. The Vienna Declaration, again in its first operative paragraph, proclaims protecting and promoting human rights 'the first responsibility of Governments.' And in sharp contrast to half a century ago, governments today can expect to be reminded, often loudly, of their human-rights responsibilities by foreign states, international and regional organization, the transnational human-rights movement, and, to the extent that they permit it, their own citizens.

The global human rights regime, however, is based on *national* implementation of international human-rights norms. Norm creation has been thoroughly internationalized: the UN Commission on Human Rights drafts treaties and declarations through a process that emphasizes consensus. Implementation, however, lies almost exclusively with sovereign states.

Although the UN Security Council has asserted its enforcement powers in a handful of cases, multilateral human-rights institutions have monitoring rather than enforcement powers. The UN Commission on Human Rights, in addition to its vital work in developing international norms, investigates violations in particular states and substantive issues of broad international concern. The Human Rights Committee (HRC) and the Committee on Economic, Social, and Cultural Rights, which supervise state compliance with the 1966 International Human Rights Covenants, are restricted principally to reviewing periodic reports submitted by states. (The HRC also investigates

individual complaints, but these procedures have been used infrequently—less than 250 decisions in more than 20 years—and its findings have no legal force.) Supervisory committees created under other international human-rights treaties—dealing, most prominently, with racial discrimination, women, torture, and children—are also largely restricted to reviewing and commenting on periodic state reports.

Such reporting schemes have considerable value. In conscientiously preparing a report, states often identify areas where improved performance is possible. At minimum, states know that they are subject to periodic scrutiny by an impartial international body. But these supervisory committees cannot even order, let alone, compel states to alter their practices. Multilateral action thus is most likely to bring change not where violations are most extreme, and thus ‘most needed,’ but in countries where violations are less severe and where governments have a significant internal motivation for change.

The principal exception is genocide, where a system of international enforcement (although not prevention) does seem to be emerging. The Statute of the International Criminal Court, adopted at Rome in 1998, establishes individual criminal responsibility for genocide, crimes against humanity, and war crimes. Furthermore, antigencide norms are increasingly enforced through armed humanitarian intervention (e.g., Bosnia, Rwanda, East Timor). But for all other human-rights violations—that is, all but a tiny (if important) handful of violations—multilateral institutions monitor state practices rather than enforce international norms.

The powers of regional human-rights organizations vary immensely. At one extreme, the European Court of Human Rights provides authoritative judicial enforcement of the 1950 European Convention on Human Rights for the members of the Council of Europe. At the other extreme, there are no regional human-rights institutions for Asia and the Middle East. The Americas lie about halfway in between. Members of the Organization of American States (OAS) are subject to investigation by the Inter-American Commission on Human Rights, but the Inter-American Court of Human Rights has been much less active, and considerably less effective, than its European counterpart. The African (Banjul) Charter of Human and Peoples’ Rights has created only a very weak commission and no court.

In looking at international implementation, we also must recognize that states, for all the talk of globalization, remain the central international human-rights actor, not merely through their control of international and regional organizations but in their bilateral relations. But they still typically apply only the weaker of their available means—praise and protests, symbolic actions, and occasional financial incentives and penalties—in the pursuit of human-rights objectives. No state, weak or strong, ‘nasty’ or ‘nice,’ has been

willing to sacrifice vital national interests, or even very much in the way of economic, security, or political interests, to human rights goals.

But states also lack the authority to use force unilaterally against international human-rights violators. And whether undertaken by states or regional international organizations, sanctions short of direct military intervention, as the embargos against Cuba, Iraq, and Serbia suggest, typically inflict far more harm on innocent victims than the targeted regimes. Furthermore, even where external coercion ends abuses or topples a repressive regime, this usually is only a first step toward establishing a rights-protective regime, as Somalia and Bosnia suggest. Thus even where external actors are willing to use coercive means to pursue their human-rights objectives, it is not clear that they have the capabilities to have a decisive positive impact.

This suggests an unusually important role for transnational human rights NGOs. They have been, and remain, important transmitters of international human-rights norms. They have a single-minded focus on human rights, in sharp contrast to states and international organizations, which must balance a range of often competing interests. And they increasingly understand their role as supporting the local human rights advocates and progressive elements in ‘civil society’ that, along with local governments, hold the key to the future of human rights.

Four events of the mid-1970s signaled the maturing of human rights as an international issue. The 1973 coup in Chile provoked a major and sustained international reaction that for the first time cut across Cold War divisions, with many European states joining the criticism of the US-backed military dictatorship. The Helsinki Final Act of 1975 introduced human rights into the mainstream of East–West relations. The award of the Nobel Peace Prize to Amnesty International in 1977 marked the emergence of transnational NGOs as significant international human rights actors. And when Jimmy Carter became president of the United States in 1977, one of the world’s two leading powers began to raise human rights issues with allies as well as enemies.

Human rights violators continued to meet criticism with vigorous appeals to sovereignty and non-intervention. States rarely went beyond verbal and symbolic action in support of their human rights objectives. The moral power of international and non-governmental organizations to mobilize shame often ran up against shameless governments. Nonetheless, by the early 1990s the international human-rights landscape had been significantly altered.

At the 1993 World Human Rights Conference in Vienna, the Cold War ideological wranglings over the relative priorities of economic, social, civil, and political rights, and parallel North–South debates over the relationship between human rights and development, were largely discredited. Although national

or regional culture continues to be used to justify substantial derivations from international norms, such arguments are generally rejected for the linkages to a wide range of other national and international interests.

We can see a comparable maturing of human rights as an area of scholarly inquiry. Just twenty-five years ago, one could count on one's fingers the number of social scientists who specialized in human rights. Through the end of the Cold war, the scholarly literature on international human rights was largely legal, institutional, and policy oriented, as well as poorly integrated within the leading disciplines. In recent years, human rights has moved into the mainstream of political science and international studies, at least in the English-speaking world. And we are beginning to see a new generation of scholarship that increasingly adopts mainstream disciplinary methods. Thus this encyclopedia appropriately includes an entry on human rights, whereas a comparable project just a quarter century ago almost certainly would not have.

Human Sciences: History and Sociology

Reference to 'the human sciences' is loose and variable. With few exceptions, there is no correspondence between the term and existing disciplines. Indeed, the

term has different connotations for different academics. For some, it refers to what they hope will be a field constituted by debate about what sort of systematic knowledge of human beings is possible, not by a particular body of knowledge. By contrast, others think the field is simply the biology of human beings. Most commonly, the term is one of convenience: 'the human sciences' covers the past and current pursuit of knowledge of human activity, without specifying precisely what is included. The term may cover psychology, linguistics, sociology, anthropology, economics, human geography, and political science, and also parts of the organizational sciences, history, biomedicine, cognitive science, neuroscience, and other areas as well. Nevertheless, it is increasingly common, and significant, for the term to signify a cluster of debates about knowledge and the achievements—or limitations—of existing disciplines.

1. Comparative Meaning and Usage

The difficulty of providing precise definition comes from the subject. 'Man' is not an empirically delimited subject. Theoretical argument about how to characterize the subject, rather than empirical investigation of a given domain, is central. At the same time, empirical research from areas of activity as divided from each other as evolutionary biology and cultural studies have considerable influence. The content of the field is variously said to include the biological human species, the 'Being' of 'Man,' language itself, socially and historically constructed culture, practices of ordering human life, and so on.

When the term refers in an open-ended way to knowledge of humans, usage relates to the '*sciences de l'homme*,' a phrase denoting a conventional division of Francophone academic life covering the psychological and social sciences. There is also overlap between the human sciences and the '*Geisteswissenschaften*,' the sciences concerned with the activity of the human mind or spirit. As German-language usage indicates, the meanings of the word 'science' itself enter argument about the human sciences. In Continental Europe, a disciplined, rational body of knowledge forms a 'science' (theology, for example, may be referred to as a human science), while in the Anglophone world, 'science' is often shorthand for 'natural science.' Except in the usage of some natural scientists, reference to the human sciences follows Continental European usage and includes humanities disciplines as potential 'sciences.' Looked at historically, the human sciences have roots in the eighteenth- and nineteenth-century 'science of man' and 'the moral sciences.' These English-language expressions referred to areas of knowledge thought to be distinctive by virtue of human reason, language, morality, and society.

In the social sciences, it is becoming common for 'the human sciences' to include disciplines that are not subsumed by the natural sciences and that share in

common the goal of understanding human activity and its products. Institutionally, these disciplines often form social science faculties, though they may also spread into natural science faculties (e.g., psychology) or humanities faculties (e.g., history). Reference to the collective term is more than a matter of convenience. Deep and complex issues are at stake. One view holds that debate about the nature of knowledge, or 'science,' of the human subject is intrinsic to being human; 'human science' is therefore an essentially contestable area. The long history of disagreement about the identity, content, and methods of all aspects of the human sciences supports this view. This disagreement continued in the late twentieth century, especially in controversy about the respective contribution of the natural sciences and humanities.

But sometimes scholars have held the view that one particular science provides the foundation for a unified human science. Around 1800, French intellectuals argued on behalf of '*idéologie*,' a science of the origin of action and ideas in sensation and organization. In the USA in the 1950s, there was an attempt to fashion 'behavioral science' as unified human science; more recently, some scientists have promoted evolutionary biology as the basic science of human existence.

2. The Evaluative Connotations of Usage

Earlier encyclopedias of the social sciences contain no reference to the human sciences. Recent usage reflects changing arguments and values in the academic community. First, a number of scholars welcome the interplay of different approaches, and do not think disagreement is a failing of science; according to some, disagreement is intrinsic to knowledge of humans. Second, they argue that the natural sciences do not, and cannot, provide explanations for much of the human sphere. This point is made because natural science knowledge does not address certain topics (e.g., symbolization, and meaning), not because natural science is thought undeveloped.

Third, many scholars hope to establish new relations between the psychological and social sciences and the humanities (that is, disciplines like art history and literary theory). Fourth, an interest in the human sciences often indicates sympathy with the view that history of belief in human realities and their representation is necessary to knowledge. Finally, usage expresses conviction that the existing social science and humanities disciplines are historical, social constructs, which structure knowledge in contingent and possibly restrictive ways. Deeper knowledge may need an overarching conception, signaled by reference to 'the human sciences.'

The spread of the term therefore correlates with the critique of positivist views of the social sciences and of 'behavior' as a unifying concept, and interest in rethinking the relations of history and scientific knowledge and overcoming disciplinary specialization in the

psychological and social sciences. Some observers see correspondence between these values and the spread of a postmodern ethos. The welcome given to open-ended argument, skepticism about the unification of knowledge, and turn to the examination of 'science' using theories and methods developed in other areas of academic culture, does suggest that spreading interest in the category, 'the human sciences,' is part of a wider change.

Yet, there are some scientists for whom the term 'the human sciences' simply describes the extension of the natural sciences to encompass the human sphere. This usage is rejected by most academics. They do not deny that human beings are part of nature (and hence a subject for natural science), but they maintain that human activity is self-created through historical processes of reflection and language (and hence that there are non-natural science forms of objective knowledge). There are major differences of emphasis among those scholars who have no pretension of creating a unified human science. Some, such as the philosopher Charles Taylor, may be called 'humanist.' They have argued for the distinctiveness of the human sciences because of values thought intrinsic to human activity. This orientation has been critically dissected in 'the linguistic turn,' a cluster of arguments about language or representation—rather than 'nature,' 'Being,' or 'Man'—as the subject matter of knowledge. Scholars such as Michel Foucault may be called 'antihumanist,' as their projects deny reference to anything 'essentially human,' and instead consider only the conditions of possibility for knowledge at a particular time. Yet others, such as the philosopher of science, Ian Hacking, find, ways to hold in tension this polarity while opening new views of the human subject.

3. History of the Human Sciences

The modern disciplines of psychology and the social sciences are creations, for the most part, of the late nineteenth and early twentieth centuries. Their establishment is part of the modernizing process, the recreation of human activity as subject to rational discipline, evident at least from the early modern period in Europe. During what historians call 'the Enlightenment,' there was a deeply influential attempt to extend knowledge of laws of nature to include individual and social activity. Scholars worked in a variety of settings, outside as well as within the academy, and according to many intellectual agendas. Giambattista Vico, whose '*scienza nuova*' encompassed myth, poetry, and history as human creations, was a professor of rhetoric at the University of Naples. David Hume wrote 'of human nature' as a literary essayist, while his friend Adam Smith taught about 'the wealth of nations' in courses on moral philosophy at the University of Glasgow. Montesquieu was a French aristocrat whose comparative study of legal systems, government, and custom enhanced notions of

the relativity of social life, while J. G. Herder, a civil servant in Saxe-Weimar, linked the fate of peoples and the fate of culture and language.

There was, however, no reference to 'the human sciences' but rather to 'the science of man.' Historians use the former term to encompass the background for all the intellectual activity divided since the late nineteenth century among the modern disciplines. The philosopher of the social sciences, Peter T. Manicas, for example, claimed that political economy was the first 'scientific' human science. Historians of 'the human sciences' distinguish themselves from historians of psychology, economics, or other disciplines, by stressing the historically relative classification of knowledge and practice.

In the nineteenth century, G. W. F. Hegel, Auguste Comte, Karl Marx, Herbert Spencer, and Charles Darwin each brought human existence within the scope of a unified 'science.' Each attempted to make human existence intelligible through historical forms of explanation. The very generality and scope of their work, however, contributed to the major revisions associated with discipline formation in the social sciences. Speculative historical reconstruction integrated poorly with the disciplined search for precise, empirical knowledge, and with the knowledge generated in the context of social problems.

The outcome was a commitment to differentiating professional and amateur, to institutionalizing research and training within universities as disciplines, and to separating what was held to be science from application. There was debate about the foundations of knowledge and relations between knowledge of nature and knowledge of culture. J. S. Mill, under the heading of 'the moral sciences,' stated the case for explanatory continuity, though he thought that an enormously complex task lay ahead to explain social life by laws of human nature. In the German- and French-language universities, there were arguments, still cited at the end of the twentieth century, about the need for hermeneutic, or interpretative, understanding of human actions; about the distinction between nomothetic (or law-like) and idiographic (or particular) explanations; about structural versus historical explanation (especially in economics and linguistics); and about how values relate to science. The participating scholars—such as Wilhelm Dilthey, Gustav Schmoller, Emile Durkheim, Ferdinand de Saussure, and Max Weber—give the human sciences many of their primary reference points.

In the English-speaking world, especially in the USA, the outcome was the establishment of empirically based disciplines, often accompanied by belief that this followed natural science example. The US model of professional research became dominant almost everywhere after 1945. For many researchers, this carried forward the enlightenment vision of improving human life on the basis of objective knowledge. But only when there were hopes for a more

unified and more effective social science was there discussion of a global project comparable to 'the science of man.' In the interwar years, the Rockefeller Foundation supported a science of personality and society. The Ford Foundation's entry into the social science field in 1952 fostered 'the behavioral sciences.' A commitment to unification was matched at the level of national politics by a perceived 'moral lag,' belief that natural science and technology had outstripped the political and moral capacity to order human affairs.

Reference to 'the human sciences' dates mainly from the 1980s. Weaknesses in both Marxist and empiricist philosophies of social science led to an historical as well as philosophical re-examination of theory. Developments in the humanities and social sciences directed empirical research to the 'representation' of knowledge and power rather than to questions, customary in the empiricist mainstream, about objective truth and material reality. By contrast, some biologists concurrently claimed that their field was uniquely competent to understand human beings. Thus, different groups, with different interests, found it useful to promote the same generic term. The only English-language term available was 'the human sciences,' a term preferred to 'the science of man' in the English-speaking world, as it appeared neutral in relation to gender.

The social circumstances were not propitious for new large-scale institutional arrangements, and the number of scholars who identified themselves as primarily occupied with the human sciences, as opposed to occupied in one of the existing disciplines, remained small. Nevertheless, some organizations, particularly emphasizing history, appeared: a journal, *History of the Human Sciences* (founded 1988); the European Society for the History of the Human Sciences; the *Société Française pour l'Histoire des Sciences de l'Homme*; and a Forum for the History of the Human Sciences within the History of Science Society in North America. When institutions or conferences use the term 'the human sciences,' it tends to be a utilitarian response to local organizational needs, bringing under a common administrative, and sometimes research, umbrella such disciplines as anthropology, applied social science, and social psychology.

4. Theoretical Content

If we take the view that the content of the human sciences is open-ended, the field has the following character. First and foremost, the field does not presuppose what the human subject *is*, but seeks to analyze and understand the historical and epistemic conditions of human activity at any particular time and place. There is therefore a literature about the representation of human action and human nature—

in practice as well as in written, visual, or other sources—and about such basic categories as ‘economy,’ ‘modernity,’ and ‘the self.’ The field, understood in this way, does not presuppose evolutionary biology or, in common language, ‘human nature,’ as the subject of objective knowledge, but rather seeks to understand how what is accepted to be objective knowledge is created through historically or humanly constituted processes. The humanities disciplines have a marked influence, encouraging interest in such topics as symbolic representation, rhetoric, and identity formation, whether of individuals, gender, ethnicity, or culture.

The field overlaps with ‘the history and philosophy of the social sciences.’ But whereas earlier English-language philosophy tended to take for granted the empiricist agenda of social science, and examined, for example, the nature of law-like explanation, realism, and reason and agency, the new field does not. It is more concerned with the constitution of agendas in the first place, and hence examines topics such as the influence of disciplinarity on knowledge, power and representation, and the ‘given’ quality of such basic concepts as ‘society’ and ‘emotion.’ Empirical studies of particulars, rather than abstract theorizing, often suggest the form of analysis.

Recent history and sociology of science (i.e., of natural science) developed independently, for the most part, of questions specific to the psychological and social sciences. But, of course, the sociology of scientific knowledge and technology is itself a major contribution to, and part of the history of, the social sciences. Some scholars, like Kurt Danziger, have extended the sociology of knowledge to the psychological and social sciences. More commonly, however, historians have informally employed the new sociology of science to explain activity in the social sciences in terms of specific factors of time and place—that is, to provide ‘contextual’ explanations.

Much research in the human sciences expresses general shifts, like the increased stress on ‘reflexivity’ and ‘the linguistic turn,’ in intellectual culture. The former term has multiple uses, but in the most general sense it denotes the activity of reflecting—‘reflecting’ in the double sense of making representations of existence and re-creating existence through the process. The most obvious instance is language: language both represents and constitutes the world as it is in human activity. Argument about the impossibility of going ‘beyond’ language to the world, society, or human nature encouraged research focused on language (or other signs, understood as forming a language) as the content of the human sciences. This is ‘the linguistic turn.’ What such claims and shifts imply is subject to intense, and often esoteric, debate. But it is an implication that a field built around such debate is open-ended in its scope and prospects.

Influential discussions derive from Foucault. Foucault, at one stage, claimed that the human

sciences are part of a modern ‘episteme,’ or framework establishing the conditions of truth. This, he held, came into existence around 1800 through practices creating reflection on human beings as subjects, especially in educational and reformatory institutions. He described reflexivity as a special condition of the modern age, and he contrasted this with the manner in which knowledge became possible through language, classification, and political economy in the earlier ‘Classical’ age. While many scholars controvert the specifics of Foucault’s disparate statements, his general exposure of the conditions of knowledge remains significant. His search for the sources of the human sciences in practical arrangements for discipline and government, his exploration of knowledge as power, and his use of discourse bridging the social sciences and humanities, are also conspicuous features of modern research.

Thus, the human sciences exist as an unstable and variable cluster of social science and humanities disciplines and topics, sometimes grouped merely for convenience, but also grouped because shared questions about knowledge and values are at stake. How usage of the term will develop is unclear. But the future will take account of the way the ‘historical turn’ has expanded and rethought historical knowledge about the sources and content of representations of human activity. It will continue to work through the implications of ‘the linguistic turn’ and of representation itself as human activity.

The human sciences add up to a critical reflection on the constitution of disciplines, and indeed of science, in the century and a half since the modern system of legitimating knowledge became established in universities. At the beginning of the twenty-first century, it would be surprising if past prescriptions remained unquestioned. New social forces, such as appear in feminist and postcolonial perspectives, have considerable impact. Different views of how the field is constituted obtain—from an extreme opinion that the human sciences are a branch of biology to the opposite extreme that ignores biology in toto. Within the social sciences, a conception of theory as the unifying and causally explanatory framework for knowledge is diminishing in appeal. Rather, scholars working under the rubric of the human sciences offer empirically researched accounts of matters that, through much of twentieth-century psychology and social science, were taken for granted. If earlier social scientists thought it relatively unproblematic to develop knowledge on the basis of existing categories and concepts, the human sciences open new perspectives by making that unproblematic quality itself the subject of research.

Human-Computer Interaction

The increasing contribution of other disciplines is making human-computer interaction focus less on the individual, with the consequence that a great deal can be gained from other fields within the social sciences, and perhaps, provide more insight into human behavior in return.

Human-computer interaction, more widely known by its acronym HCI, is primarily the study of how people use the complex technological artifacts that now pervade their lives. A secondary, but arguably more important focus, is on how these artifacts can be designed to facilitate this use. As an applied discipline, HCI encompasses theoretical and academic re-

searchers from psychological and computer science backgrounds, who may be interested in the area as a domain within which to apply and evaluate their theories of human or system behavior, as well as designers and engineers from industrial and commercial backgrounds, for whom the pay-off is a saleable product, built faster and more economically than their competitors'. In recent years, with the rapid technological development of computing devices and their increasing ubiquity within telecommunications, the field has expanded to include social and organizational researchers, who examine the impact that the technologies have upon human-human interaction. This itself feeds back to the identification of novel applications and the development of further devices. HCI is now an active, multifaceted, and methodologically diverse component of the domain that it studies, both following and directing technical innovation.

1. Origins in Human Factors and Cognitive Psychology

The roots of HCI predate the invention of computers, and the term itself has only been used since the 1970s. At their simplest, computers are just machines, built to help people carry out tasks, and the dominant paradigm for studying HCI has been that of ergonomics or human factors, with study of the *interaction* between the human and computer subjugated to that of the human's *use* of the computer. An earlier name for the field was man-machine interaction, and within the field, the words person and human are still generally replaced by the term 'user.' In the same way that early time and motion researchers would analyze the tasks that a factory or office worker performed, breaking their job down into its constituent elements, measuring the time each part took and assessing their relationships to each other to identify any 'wasted,' redundant, or unnecessary actions, so too have HCI researchers attempted to decompose the user's task, and to identify task steps that are difficult to perform, hard to learn, or confusing.

This emphasis on task analytic decomposition reflects the early predominance within HCI of cognitive psychologists, who brought with them information processing models of human thought. These models were themselves based on a metaphor of the mind as a computer: one that received sensory input, processed it with access to memory and inferential resources, and produced motor output to act upon the world. By far the most influential of these within HCI has been the GOMS model (Card et al. 1983), which stands for Goals, Operators, Methods, and Selection. Based upon an intentionally simplistic conception of a model human processor (MHP), a GOMS analysis would identify the goals that the user has to reach, and the operators or mental actions available to the user to

carry out the task of reaching the goal. Frequently used series of operators become chunked as easily accessible 'methods' that are linked to a subgoal or specific part of the task, and selection routines enable the user to 'decide' which alternative methods or operators to apply if there is more than one possible route to the goal. The MHP provides estimates of the length of time that executing each basic sensory, cognitive, and motor operator takes (these values being empirically derived from cognitive psychology experiments), and so once an accurate GOMS analysis of the task has been produced, it is possible to sum the durations of each component to produce a prediction of the time taken for the whole task to be performed. Subsequent elaboration of the approach to allow the perceptual, cognitive, and motor parts of the architecture to operate in parallel, and to model the processing of concurrent activities using critical path analysis, has had notable success in modeling the efficiency of telephone toll and assistance workstations (Gray et al. 1993).

Despite successes such as this, a limitation on the application of GOMS in practice is that it is intended to model only the optimal performance of a skilled user in ideal circumstances, and so it is best suited to industrial-style settings where a particular task may be executed hundreds or thousands of times a day. An interface design that is a second or two quicker to use in these situations will thus result in a large saving in time, and presumably money, for the organization that is paying for it. GOMS is unable to say anything about another crucial aspect of interface use, that is, how long it might take someone to become an expert, how many errors a nonexpert might make, or how pleasant or unpleasant the experience of executing the operations might be. Indeed, the critical assumption within GOMS that operators can be chunked as methods is not actually addressed by the model itself. It remains the job of the analyst to recognize which sequences of operators can be represented as methods, and how finely these methods need to be related hierarchically. Recognizing that this development of knowledge about the task is the key to learning about an interface, Newell (1990) proposed what he termed a unified cognitive architecture specifically to allow problem solving and learning to be modeled as a process of goal decomposition, such that goals are iteratively broken down into subgoals. By specifying the operation of this architecture within a 'programming language' called Soar, Newell provided a technique for predicting the way that users would integrate their postulated initial knowledge with information derived from the computer interface through their interaction with it. In effect, a Soar analyst writes a program in the form of 'If, ... Then ...' rules, and this is then 'run' to simulate a user's learning behavior.

The GOMS and Soar research communities have had a great deal of influence within the cognitive psychology side of HCI, but as simulation models,

their attention to detailed aspects of the interface is both their strength and weakness. While it allows them to identify small but critical aspects of a design as crucial problems for a user, they both require complete specifications of an interface, and for Soar, the task context and information available to a user. They therefore come into their own for the contrastive evaluation of extant alternatives, but are hard to apply systematically at earlier stages of design, when the question is 'how?' rather than 'which?' The same is arguably true of newer, more detailed techniques such as LICAI, which is based on Kintch's construction-integration model of goal formation in text comprehension (Kitajima and Polson 1997), and EPIC (Kieras and Meyer 1997). EPIC builds on the model human processor by incorporating many theoretical concepts such as the distinction between declarative and procedural knowledge drawn from Anderson's ACT class of models, and limited capacity visual and auditory working memories coordinated by executive processes. However, as Kieras and Meyer themselves note, 'EPIC was not developed primarily for addressing HCI problems but is a larger scientific endeavor to represent important theoretical concepts of human intelligence or abilities' (Kieras and Meyer 1997, p. 394).

2. *Development of Usability Evaluation Methods*

The apparent concentration of cognitive psychologists on the development of cognitive architectures that would ideally explain all of human behavior, as well as the human use of computers, can justifiably be seen as a problem from the point of view of their colleagues who are involved in the day-to-day design of computer interfaces. It was accepted fairly quickly that full GOMS models were too laborious to be practical, and a simpler (but inevitably less reliable) 'keystroke level model' was developed that avoided the need for a full task analysis. Soar models also require a programming and analysis commitment that can seem disproportionate in the context of design, especially when an apparently small modification in the design requires the whole model to be reprogrammed and rerun. It can also be difficult to identify reasons for the simulated behavior that results from an analysis. These cognitive architectures, then, may prove to be more useful in informing their core disciplines than in practical application.

In reaction to these perceptions of too much cost for too little benefit, a number of 'cut down' usability evaluation methods have been developed. All are to some extent derived from well-founded and principled psychological theories, but by encapsulating key components of the modeling techniques within a process of some form, seek to minimize the overhead costs of learning the theory itself, and to provide a positive cost-benefit trade-off by reducing the need for user

trials to be conducted with early prototypes or mock-ups of interfaces (Nielsen and Mack 1994). Cognitive walkthroughs, for example (Polson et al. 1992), provide a checklist by which aspects of the interface can be compared with the user's notional task, step by step, and screen by screen. The steps of the checklist are in fact derived from cognitive complexity theory, and the method focuses on the semantic appropriateness of the verbal labels or commands used throughout the interface, although the practitioners applying it do not need to know this.

Other approaches seek to avoid any role for theory at all, and base themselves in the codification and reuse of practical experience. From the earliest days of HCI, sets of guidelines have been compiled, both within design teams to provide a 'house style' and in a wider sense as a shared set of 'best practices,' so that designers encountering a problem for the first time have access to the solutions found or attempted by others. Some, such as those presented by Gardiner and Christie (1987), have an empirical basis, and specify specific design features such as acceptable screen color combinations and choices for typefaces. Others are less formal, and direct the designer towards desirable attributes or practices such as aiming for consistency, compatibility and coherence. The rapidly evolving nature of the domain conspires against such stored knowledge, however, for anything designed before the mid-1990s is almost certain to be based on expired technology, whose constraints no longer apply. Concrete prescriptions about design solutions become outdated too quickly for their promulgation, while the more abstract (such as 'be consistent') have proven too abstract to be of much real use.

3. *HCI and the Design Process*

This focus upon evaluation reveals a fundamental problem in early notions of the relationship between design and modeling. An implicit assumption of many HCI approaches was that design could be thought of as a sequential or 'waterfall' process, with discrete stages progressing from a requirements analysis, through specification layers, to implementation, with a final evaluation of the finished product. By locating evaluation at this final stage, HCI staff found themselves limited to what became known as a 'fire-fighting' role, being asked to repair problematic designs at a point when any redesign would result in a product falling behind schedule, further worsening the cost implications of their involvement. Organizationally, it is very difficult to convince people that the design they have been committed to for months has some basic usability flaws.

As Landauer (1995) has pointed out in his economic analysis of the computer industry, design flaws have to be identified much earlier in design if their identification is to be helpful and cost effective to repair. Fortunately, few designs actually proceed in

such a strictly formal manner, with a more serendipitous, parallel, and iterative process being more typical. Such cyclical processes allow HCI contributions to be made at more appropriate junctures, and have led to an emphasis upon user-centered design (e.g., Norman and Draper 1986), in which user testing becomes a central aspect of design throughout the process, design itself is directed towards prototyping, and designers are encouraged to 'plan to throw one away,' following Brooks' seminal advice (Brooks 1975).

A very different approach to providing support to designers in these less structured situations comes in the form of a notational decision support tool called QOC, or questions, options, and criteria (MacLean et al. 1991). Aimed at recording the 'design rationale,' QOC represents the design space through which a product has traveled, listing the questions that the design team were trying to answer at various points, the options that were considered, and the criteria that they used to choose one option over another. By making decisions and trade-offs explicit, and recording the reasons that were cited for making them, QOC provides a mechanism both for managing the decision process and for recording it for later review. It has been found to be particularly helpful in providing background information for people who were not part of the decision at the time, either because they only became involved at a later stage or because they were working on some other part of a large project. QOC is important in that it represents a wider concern with design as a process, rather than simply with evaluating its final products.

Involvement in design at a point before the final product has been created means, inevitably, that HCI methods need to provide advice to designers rather than evaluating finished designs. While 'cut-down' usability inspection methods and heuristic evaluations can be conducted on partial designs and mock-ups, it has been argued that their pragmatic separation from theory weakens their value. While they may well identify problems in a design, the fact that they are not associated with an explanatory theoretical underpinning means that the causes of the problems can remain unexplained. The benefit to the designer of a rapid identification of problems is accompanied by the cost of working out why the problem has occurred and what is to be done about it. May and Barnard (1995) recommended that HCI researchers should work towards providing 'supportive evaluation methods' that assist the designers by accounting for usability problems in terms of some theoretical concepts that are helpful in suggesting redesigns.

They referred to a distinction made by Long (1987) between the 'discovery representation' of a scientific theory and its 'application representations.' The discovery representation allows academics and researchers to explore phenomena, such as typical error patterns in HCI, or the way that users learn about interfaces

and solve problems. The application representations, on the other hand, are encapsulations of the theory specifically targeted towards practical application. These may take several different forms, depending upon the intended practitioners and the expected purpose. Unlike cut-down methods, the application representations retain a direct link to the parent theory and, in order to use them, information has to be expressed in theoretically important ways. The advantage for practitioners is that the results of their use is also couched in theoretically relevant forms, and so is linked to an explanatory body of ideas that can be recruited to assist in redesign.

May and Barnard (1995) present the example of a cognitive architecture called interacting cognitive subsystems, or ICS. As a discovery representation, it is unlike GOMS, Soar or EPIC in that it does not seek to simulate cognitive processing, but provides a framework for identifying bottlenecks in the flow of information through a series of cognitive subsystems, each of which is specialized for processing a different level of mental representation (see *Cognitive Science: Overview*). Like the simulation models, these levels include sensory, cognitive, and motor representations. The modeling process involves describing the likely pattern of exchanges between the various levels, the degree of skill-based behavior of relevant aspects of a task, the involvement of the user's recent and longer-term memories, and, crucially, the structure of the user's conceptual task or of perceptual representations of the interface. In this discovery form, the modeling is too complex to be carried out by anyone other than an expert in the theory itself, and the results are couched in terms of the processes and their configuration, rather than specific design consequences.

To support the use of ICS within design, two alternative application representations have been developed: one is a production rule-based 'expert system,' which partly replicates the role of the ICS theorist in constructing a principled model of an interaction; the other is a pencil-and-paper technique for reasoning about the changes over time in the structure of the mental representations encoded at the various ICS subsystems (Barnard and May 1999). Both of these application representations require some familiarity with the core concepts of ICS, but neither requires practitioners to construct a full ICS model themselves. Their value lies in providing problem-solving tools for designers to apply to partially specified or speculative ideas about interfaces, before any commitment has been made.

4. Influx of Novel Approaches

In moving away from a simulation of a user interacting with a computer, ICS is part of a trend away from the concentration upon a dyadic, turn-taking relationship between a single user and a single computer. Classical HCI models can be caricatured as having a human

issuing commands to a computer, waiting for it to carry them out, and then inspecting the screen while the computer patiently waits for them to form some new goals. While this might have been an appropriate model for HCI in the early 1980s, the advent of distributed computing architectures and the massive interconnection of computing systems over the Internet means that it is inadequate. Even modern personal computers will be carrying out multiple tasks, doing background processing almost in-between each keystroke. The humans are not always isolated users pursuing solitary goals, either, but are using computers as part of their everyday activities, often in social or work settings that involve interacting with other humans with the support of their computers. An analysis of interaction that does not allow for such factors has inevitable flaws.

These developments have led to a new involvement within HCI of social and organizational psychologists, as well as researchers from other social sciences such as ethnomethodology, anthropology, and sociology (Dourish and Button 1998). This has led to an influx of novel theoretical ideas, in particular Vygotsky's activity theory (e.g., Nardi 1995) and Suchman's situated action (Suchman 1987). These ideas re-emphasize the relevance of the context within which human actions are formed, and as Carroll (1997) noted, have brought a continental European perspective into what had previously been a largely North American and British endeavor. Instead of the user and their system, activity theory deals with an 'activity system' composed of social aspects such as attitudes, beliefs, and experiences as well as technological factors.

Another development which moves away from the traditional HCI dyad has come from a computer science perspective, where the idea of a system as a single entity has long been outdated. With the introduction of 'object oriented' ideas, computer scientists have moved towards seeing complex systems as built up from a large number of quasi-independent 'interactors' that exchange information and tasks, with no constraint for these interactors to be part of a single machine. A large body of theory has evolved to model such distributed and concurrent activity, and a logical step has been to see a user's cognitive processes as just another set of interactors. The unit of analysis for such 'syndetic models' (Duke et al. 1999) is the overall system composed of human and computer interactors, and their conjoint activity can be modeled using mathematical formalisms to prove literally that certain interactions can or cannot occur, or that certain assumptions must be met for them to be possible.

5. Prospects for HCI as a Discipline

Both the social and the computational contributions to HCI currently fall into the discovery mode of analysis, in Dowell and Long's terms, rather than the

application mode. It is not yet clear whether these novel directions will crystallize into methods or representations that are directly applicable by design practitioners, or whether they will serve more to direct the commercial development of products away from the classical PC in an office towards other niches. They may also represent the evolution of HCI as a discipline in its own right, with its own methods and theories, rather than as an interdisciplinary area colonized by theories developed in cognitive psychology and artificial intelligence. The tension between academic theorists and practical developers will undoubtedly continue to be a major dynamic upon the field, with its predominance of conference papers enabling non-empirical presentations of novel technologies or design tools to share the limelight with hard-nosed experimental evaluations. In recent years, the increasing theoretical quality of the few specialized HCI journals may provide justification for those who have argued for universities to establish HCI departments in their own right, with their own undergraduate courses. On the other hand, the progressive involvement of computing artifacts within our everyday lives is making their use an ordinary part of human behavior. The increasing contribution of other disciplines is making HCI focus less on the individual, with the consequence that a great deal can be gained from other fields within the social sciences and, perhaps, provide more insight into human behavior in return.

Human-Computer Interface

1. Definitions: The Interface as a Carrier of Epistemologies

The computer/human interface refers to the modalities through which people interact with computational technologies. These include different data input devices: you can give the computer information through punched cards or through typing numbers on to a screen. And these include different ways of manipulating software: one can type symbols at a 'command line' or can 'navigate' a data field that appears as a three dimensional space. Specialized applications—software designed for the physically challenged, software designed to simulate airplane flight—have increased the number of available interface technologies. Computer users may employ joysticks, headsticks, trackballs, voice recognition, and touch sensitive screens to communicate with the software that governs the machine's behavior.

The breadth of the topic of computer/human interfaces and how to improve them for usability and ease is too vast to review comprehensively here (Norman 1998, Raskin 2000). This essay examines the most common shifts in interface use over the last half century up to 2000, and centers on the social and psychological implications of interface experience rather than its technical details. Interface design has not only changed the instrumental computer: what the

computer can do for us; it has changed the subjective computer: what the computer does to us, to our ways of relating to others, thinking about ourselves, seeing the world. As the dominant knowledge technology of our era, computational machines offer us images of what it means to know (Penrose 1989, Dennett 1991, Turkle 1995).

Over the last half century to 2000 the trend in interfaces has been from favoring a style of interaction in which the computer is approached as a mechanism towards interactions in which the computer is approached as a behaving and aware organism. Otherwise put, the trend has been from people acting directly on the machine to interacting indirectly with its increasingly elaborate 'self presentation' in which many layers of programming stand between the underlying mechanism and what is presented to the user. The movement has been from interface as an environment for commands (Weinberg 1971) to interface as environment for conversation or theater (Laurel 1990). Whether the computational object presents an interface that demands small or large bodily gestures or particular words or sounds, this direction (increased layering; increased opacity) has had significant psychological and epistemological implications. The computer has moved from being the primary technological model of a culture of calculation towards modeling a way of knowing in a culture of simulation. In a culture of simulation, users are encouraged to take computers 'at interface value.'

1.1 The Recent History of Personal Computing Interfaces

The first personal computers of the 1970s and early 1980s, like the mainframes and minicomputers, required users to know how to issue exact instructions. Being comfortable with their command-line required users to put themselves into the frame of mind of those who had programmed the computer, who had given it its fundamental rules. Those who were most comfortable with this kind of information interface were those who knew something about programming and its intellectual aesthetic (Schneiderman 1987).

Through the late 1970s, the computer interface presented the machine as a giant calculator. The interface carried the message that no matter how complicated a computer might seem, what happened inside it could be mechanically unpacked. The computer interface was a set of command lines that would get you close to those rules that lay beneath the surface of the machine.

The presentation of the machine through its interface captured the essence of the computer in a culture of calculation. This essence corresponded to a modernist or enlightenment model of what it means to understand: it means to have knowledge of what

makes the 'clockwork' tick, and the programmed computer was conceived of very much as mechanical clockwork. When computer users talked about 'transparency' what they meant is that the interface was a window for looking beyond the 'magic' of the machine's extraordinary powers to the mechanism that made them possible.

What was true of the language that surrounded the large mainframes and mini-computers was even more true of the language that surrounded the first personal computers. These machines, first appearing in the late 1970s and early 1980s, required users to know how to issue exact instructions and they were encouraged to optimize their computers' performance by learning assembly language, by going deeper and deeper into the lower levels of a machine's structural organization. By the mid-1980s, increased processing power made it possible to build graphical user interfaces, commonly known by the acronym GUI, which hid the 'bare machine' from its user. The new opaque interfaces—the first popular one on the mass market was the 1984 Macintosh—represented more than a technical change. The Macintosh 'desktop' introduced a way of thinking about the computer that put a premium on the manipulation of a surface simulation. The desktop's interactive objects, its dialogue boxes in which the computer 'spoke' to its user, pointed toward new kinds of experience in which people did not so much command machines as enter into conversations with them (Apple 1985). In personal relationships, we often interact without understanding what is going on within the other person; similarly, when we take things at (inter)face value in the culture of simulation, if a system performs for us, it has all the reality it needs.

In 1980, most computer users who spoke of transparency were referring to a transparency analogous to that of traditional machines, an ability to 'open the hood' and poke around. But when users of the Macintosh talked about its transparency, they were talking about seeing their documents and programs represented by attractive and easy-to-interpret icons. They were referring to an ability to make things work without needing to go below the screen surface. Today, the word 'transparency' has taken on its Macintosh meaning in both computer talk and colloquial language. In a culture of simulation, resonant with a post-enlightenment or postmodern aesthetic, when people say that something is transparent, they mean that they can see how to make it work, not that they know how it works.

2. Simulation and Its Discontents

Suppose you receive this message on a computer screen when playing a simulation computer game: 'Your orgot is being eaten up.' (Turtle 1995). You do not need to know what an orgot is to play the game

although you can infer from the context of the game that it is a kind of organism. Players interact with the interface of the computer game in the same way they interact with the interface of a video game. In computer games, as in video games, one learns from the process of play. You do not first read a rulebook or get your terms straight. The game allows you to manipulate its variables directly; it enables you to avoid commands, but experiment with trial balloons. You are able to act on an intuitive sense of what will work without understanding the rules that underlie the game's behavior. Your game will teach, for example, that you that you must give your 'trilobytes' algae or they will become extinct. Thus, you can keep playing even without any clear idea of what is driving events. Clarity and a grasp of the rules are not essential to the process.

People use their contact with objects to keep in touch with their times, to discover 'what's important.' They use objects to work through powerful cultural images, to help arrange these images into new and clearer patterns. From this point of view, the opaque interfaces of simulation games and simulation tools help to help us think through current challenges to traditional epistemologies where the manifest refers back to the latent, the signifier to the signified. The personal computer culture began with small machines that captured a utopian modernist vision of transparent understanding, but the scintillating, pulsating surfaces of simulation computer games are dynamic, seductive, and elusive, a world without depth, a world of surface. *Players can stay on the surface, taking things at (inter)face value.* The computer interface serves as a carrier object which, in a significant sense, brings postmodernism down to earth.

The culture of simulation presented by the computational interface is our everyday experience of the postmodernist aesthetic. And since it is common to experience the computer as a 'mind machine' this aesthetic influences computational models of mind. For example, 15 years ago the computational models of mind that dominated academic psychology were modernist in spirit: nearly all tried to describe the mind in terms of centralized structures and programmed rules. In contrast, today's models often embrace a postmodern aesthetic of complexity and decentering. Mainstream computer researchers no longer aspire to program intelligence into computers but expect intelligence to emerge from the interactions of small sub-programs. If these emergent simulations are 'opaque,' that is, too complex to be completely analyzed, this is not necessarily a problem. After all, these theorists say, our brains are opaque to us, but this has never prevented them from functioning perfectly well as minds.

Beyond this, the development of the windows metaphor for computer interfaces was a technical innovation motivated by the desire to get people working more efficiently by 'cycling through' different

applications much as time-sharing computers cycle through the computing needs of different people (Microsoft 1995). In practice, however, windows have also become a potent metaphor for thinking about the self as a multiple, distributed, 'time-sharing' system. The self is no longer simply playing different roles in different settings, something that people experience when, for example, one wakes up as a lover, makes breakfast as a mother, and drives to work as a lawyer. The life practice of windows is of a distributed self that exists in many worlds and plays many roles at the same time.

2.1 Conversation, Cuddles, and Creatures

Computers have been thought of as 'artificial brains' for generations. What is new in the current analogies of computers to the brains of behaving systems is the development of interfaces through which we can interact with computers as though they were creatures, either human or animal. An example is the conversational interface used to communicate with software programs known as 'agents' or 'bots.' The computer users types out their side of a conversation in colloquial language; the software agent responds more or less in kind. Of course, such conversations work best if the domain of discussion is highly proscribed, but the experience of such interfaces is quite dramatically that of interacting with an 'other.' Computer agents that literally present 'faces' as their interfaces dramatically increase the degree of anthropomorphism of the computational object. Voice recognition software enhances the conversational effect and the experience of the machine as a being.

Computational creatures are being designed as toys for children. Today, children are asked to interact with these creatures through gesture and touch; in the near future, the interactions will be through language and tone. In the case of the Furby, a furry, cuddly, robotic toy that seems to learn and love, the computational interface presents a creature successfully 'learning' language and being nourished by food; the child is able to respond with gestures expressing affection. In the case of another computational creature, Sony's pet dog robot, AIBO, the computational interface presents a 'trainable' dog whose personality can be shaped by the quality of the user's ministrations, communicated by speech and sound. In the case of My Real Baby, a robotic doll, the interface enables the doll to speak increasingly complex language and show emotional expression through facial musculature while affording the user the possibility of showing nurturance through feeding, caressing, diaper changing, burping, and similarly anthropomorphic 'creature comforts.' Here, perhaps most dramatically, computational design has created an interface that through its emulation of the human explicitly diverts attention from the underlying mechanism and focuses it ex-

clusively on the meaning of the 'baby's' expressions, sounds, and words. Almost no children express curiosity about how the object 'works' in the traditional sense of understanding anything about its 'innards.' They accept its behavior as that of a creature, a creature that while not human, is frequently categorized as 'sort of alive.'

3. Future Trends

Traditional approaches to studying user interfaces have focused on usability, human factors (including level of stress), and psychological studies that have examined sensorimotor adaptation, problems of information overload, ergonomics, and the resonance of interfaces with varying intellectual styles. The projected future of computation and its interfaces suggest that philosophical and even theological concerns might well be added to this mix since the interface is promised to become not only more transparent but more intimately engaged and ultimately fused with its users.

With the computer/human interfaces that researchers project in the near-future the user will experience the interface as a creature (as in increasingly advanced robots) as prosthetics (a pair of glasses that also serve as a computer screen for mobile net browsing), a piece of clothing (with embedded processors that for example use the temperature of the human body as the input to warm or cool the skin), or as a virtual world that people can fully immerse in and navigate by moving their bodies as one would move in the real physical world. Finally, there are proposals for the interface to become part of the self. In this scenario the interface becomes a digital sensor embedded in human flesh. Creatures, prosthetics, immersive environments, and in the end, the interface disappears and people reappear as cyborg.

Human-Environment Relationship: Carrying Capacity

Carrying capacity is the maximum population that a specified environment can support indefinitely without degradation of that environment (Ellen 1982, p. 41). Ecological carrying capacity links population of biota to a given habitat in which biophysical elements of the habitat determine the maximum population. In human-environment relationships, however, carrying capacity involves the added dimension of technology and management strategies; as these human-based elements change, so does the carrying capacity (Brush 1975 and Street 1969). Thus, humankind maintains the ability to expand and reduce carrying capacity, and vastly different assessments of the actual trends underway follow from the spatial scale of analysis (i.e., landscape, region or biosphere) and perspective (i.e., environment as resource commodities or as environmental services) taken (cf. Ehrlich et al. 1977 and Simon and Kahn 1984).

Contemporary uses of carrying capacity suggest that the concept was borrowed from the ecological sciences by the human sciences. In reality, however, the ecological sciences took a cue from the ideas of Robert Malthus and subsequent developments of Malthusian principles about human population-resource relationships. The carrying capacity idea can be found in various kinds of works, even though that label was or is not applied. For example, the geographer-geomorphologist John Wesley Powell used the concept in his assessment of the Homestead Act of 1862 (USA), which allowed people to claim 160 acres of public land for farming. He warned that 160 acres were insufficient in most cases because the land in question, that west of the 100th meridian, was arid and much of it lacked access to water. He maintained that these lands, absent the potential for irrigation, had value primarily for livestock and thus 'a farm unit should not be less than 2560 acres' in the arid West of the USA (Darrah 1951, p. 233).

Such examples notwithstanding, the nineteenth century development of the carrying capacity concept

in the human science is often credited to geographical and anthropological research among indigenous peoples in the less developed world, who typically maintained a fairly direct relationship between subsistence and the immediate biophysical environment (Brush 1975 and Street 1969). The British geographer William Allan (1965), for example, used the concept of carrying capacity to evaluate the Native Reserve resettlement process in southern Africa. The essential data required for the calculation were: '(a) a soil or land map based on a suitable form of land classification; (b) an estimate, for each of the land classes employed, of the proportion of land which is practicable for cultivation under the prevailing system of agriculture; (c) a survey of the customary land-usage of the people concerned, with particular reference to the duration of cultivation and subsequent rest on the soils of each land class; and (d) an average for the acreage under cultivation per head of population at any one time' (Allan 1965, p. 8). He found that the carrying capacity of the Native Reserves, registered as persons per unit area, was exceeded at their founding, based on the customary land uses of the inhabitants. Other versions of carrying capacity assessments have been called for and employed for planned occupation throughout the tropical world, including the colonization of the Amazon basin (Fearnside 1986).

As noted, technology and land resource–use strategies play an essential role in the use of carrying capacity. As these change, so does the capacity assessment. The 'Green Revolution' is a case in point. This massive change and transfer of technology and land-management strategies greatly expanded the production and hence 'carrying capacity' of many areas throughout the world by making possible the intensification of agriculture through hybrid seeds, fertilizers, pesticides, herbicides and irrigation schemes. Yet, this revolution and its land-use impacts also expanded the reach of environmental drawdown, from increased downstream flooding and sedimentation to large-scale releases of trace gases to the atmosphere, raising serious questions about the spatial and hierarchical scales at which carrying capacity should be addressed. While earlier studies could concentrate on a village or small area as a well-defined population–resource entity, it is now recognized that, particularly in industrialized countries, such entities no longer conform to such well-defined boundaries. Technology permits a place-based population to substitute for its environment by importing resources and exporting waste. Thus, carrying capacity now involves an assessment of the worldwide 'ecological footprint' of a place-based population (Rees 1992), or the full extent of the use and environmental impacts of that population. Through this lens, what may appear to be a sustainable carrying capacity in an area, registered by arrested or slowed environmental degradation, or even its reversal, may be obtained by transferring elsewhere the environmental consequences of the

area's occupation and the population's consumption. This situation necessitates an examination of carrying capacity on a global as well as a local basis, as the recognition of the 'silent' services provided by environment, such as pollinators for crops, necessitates an examination that includes more than immediate population–resource relationships (Vitousek et al. 1997).

Human–Environment Relationship: Comparative Case Studies

A comparative case study is a research approach to formulate or assess generalizations that extend across multiple cases. The fundamental intent of a compara-

tive case study—development of knowledge—applies equally in the natural and social sciences, with the latter incorporating qualitative analysis in a discursive mode as well as the quantitative and positivist modes of the sciences. Comparative case studies are particularly important to questions of human–environment interaction, combining case study and comparative traditions and thus extending the depth of the individual case study across several instances in time and/or space.

1. Case Study and Comparative Method

A case study is a rigorous, detailed, spatially bounded, temporally limited description and analysis of an event, process, place, or community intended by the researcher to exemplify a more general insight, principle, or theory. It ‘is an exploration of a “bounded system” or case (or multiple cases) over time through detailed, in-depth data collection involving multiple sources of information rich in context’ (Creswell 1997, p. 61). Case studies of particular communities or places are a common and classical mode of analysis in anthropology, human geography, and sociology.

Comparative analysis, in contrast, explores similarities revealed in different situations or cases sharing some common element(s) while differing in others. Comparative analyses are also common among social sciences, varying in the depth to which components are explicated, from statistical abstractions through vignettes to a level of detail common in individual case studies. Often, a case study has unique elements whose effects on the validity of generalizations may be ambiguous or uncertain. Thus case studies addressed through a conjunction of insights from alternative perspectives will reveal commonalties of particular interest. Comparison between cases can help to delineate such relationships and potentially to clarify ambiguity in a singular case.

1.1 Qualitative and Quantitative Aspects

Comparative analyses may proceed via quantitative analysis of numerical abstractions from cases, through detailed narrative description and qualitative analysis. There is no necessary relationship between qualitative and quantitative approaches in case studies and comparative analyses. Qualitative case studies are frequent in anthropology, some schools of sociology, and contemporary cultural geography. Case studies can also be internally as well as comparatively quantitative, particularly in human and economic geography. Whereas comparative studies are often qualitative, they may be quantitative when there are a large number of cases with a small number of variables, as in social survey research.

1.2 Explanatory Status of Comparative Case Studies

Both case studies and comparative analyses can be *inductive* or *deductive*. However, case studies and qualitative comparative analyses share a common explanatory limitation with models—they are fundamentally *heuristic* rather than *definitive* in that they cannot prove the validity of generalizations beyond providing persuasive evidence in particular contexts (Oreskes et al. 1994). Conversely, a case study illuminating and supporting a general principle does not preclude another case casting doubt. As Leach (1968, p. 344) stated about the comparative method in anthropology,

...comparison...is not, and cannot be, a disguised form of scientific experiment leading to an explanation.’ Moreover, neither misinterpretation of the case nor failure of the case to illustrate a generalization necessarily means that a hypothesis is not valid. However, a comparative case study approach strengthens the heuristic value of individual cases by bringing in-depth understanding in different circumstances, with greater confidence in the conclusions drawn from them. ‘The generality of the case study...is relative to the methodological value of the test process involved in the experiment itself and “holds until proved otherwise” (Hamel 1993, p. 40).

Multiple cases strengthen the confidence of the researcher that the generality is sound.

2. Comparative Case Study Strategies

Researchers investigating human–environment issues can avail themselves of many alternative strategies for developing comparative case studies. Strategies included here are certainly not exhaustive nor mutually exclusive, but they suggest ways in which comparative case studies can be structured creatively for investigation, presentation, and analysis. Often, the power of the comparative analysis is strongly related to the selected strategy. These strategies include research on the basis of community, place, perspective, structure, system, scale, transects, gradients, time, events, analogs, or theory as organizing principles. In practicality, the major organizing principle of a comparative case study often includes others that are subsidiary, but inherent in the nature of the cases selected. For example, selection of case communities along a transect incorporates both community and place perspectives as well, even though the transect is the organizing theme. Examples of each strategy are included in Table 1.

2.1 Community

Comparative case studies in disciplines such as sociology and anthropology often focus on studying

different social communities to ascertain, for example, generalities surrounding a particular cultural pattern (relations between matrilineal systems and matrilineal residence); social experience (immigrants in the new world city); or community structure (comparative political systems). In human–environment studies,

comparison between communities is also important. Examples of such comparative case studies include investigation of traditional or vernacular architecture; studies of pastoral life-styles and range management strategies; cross-cultural studies of local environmental relations; analysis of ethnic farming populations in

the same locale; and studies of traditional navigation technologies and knowledge systems used by island inhabitants.

2.2 Place

Places which provide examples of a shared geographical setting or similar human–environmental process may be comparatively studied. Examples include studies of human–environment relations in specific kinds of environment, such as mountains, flood plains, and island or coastal areas; research on societal responses to extreme population density; and investigation of places affected by technological transformation, such as impacts of transportation change (super highways, dieselization of railroads), agricultural mechanization leading to rural depopulation, management of water resources, and transitions in household energy use in developing countries.

2.3 Perspective

An alternative to selection of different cases analyzed from a similar perspective is to bring multiple perspectives to a single case. Such an approach explicitly invokes a multioperationism desirable in all case studies—the convergence of different kinds of evidence toward a more complete and rich understanding. One common method for an approach based on perspective is the *emic* vs. *etic* familiar from anthropology—the understanding held by the individuals involved in contrast to the analytical viewpoint of the researcher. This distinction is now an important element of postmodern qualitative inquiry across the social sciences. The use of perspective in comparative study includes landscape analysis, analysis of environmental controversy, and multiperspective community or place studies.

2.4 Structure

Comparative case studies may be developed on the proposition that selected cases reflect the functioning of a common underlying structure, somewhat analogous to comparative linguistics. For cross-cultural translation of color terms, a formal Munsell color chart can provide a common structure on which to map various language terms for color. Less formally, comparative analysis may be based on typologies which provide the framework for comparison. In the human–environment realm, structural frameworks used as the basis for comparative case studies include Linnean plant classification compared to indigenous

ethnobotanical plant classification; fundamental requisites of a society; comparative farming systems; and human response systems in the face of natural hazards.

2.5 System–Subsystem

A comparative case study may be organized to look at various levels of a complex system to establish relationships, mechanisms, and emergent properties that vary by the level under investigation. Examples include studies of the public role in environmental management at local, state, and national levels; studies of agricultural change viewed at the family, village, society, and regional levels; and studies of the driving forces of deforestation, from family- and farm-level decisions, through regional and national forces to the global economy.

2.6 Scale Analysis

Case studies of the occurrence of phenomena at different spatial scales may be undertaken to ascertain variance or invariance of form or process. Scale analysis has become an important element in the study of the natural environment, including hydrological, climatological, and ecological systems. In human–environment investigations, scale analysis is undertaken in studies of the causes and potential impact of climate change to suggest local and larger-scale determinants of greenhouse gas emissions; appropriate levels of generalization of impacts, such as climate change on farming; and initiatives for mitigation.

2.7 Transects

Geographical transects provide one kind of spatial sampling that researchers can use to develop information and insight that can be generalized across a society or region. A transect provides one means of minimizing sample bias in an attempt to develop generalizations and analysis of differences within a society or region that might reasonably be assumed to be homogeneous. Such studies include investigation of market towns along a transect in an agricultural region; research on the dynamics of colonist settlement along new roads in rainforest areas; or exploratory archeological investigation of settlement remains in a region. In transect studies, the area being investigated may be found not to be homogeneous, suggesting comparative study of social differences (such as ethnic enclaves in an agricultural region) or environmental

differences (such as local availability of ground water in the High Plains of the USA). One special kind of transect selected in recognition of difference rather than homogeneity is the gradient.

2.8 Gradients

Cultural ecologists in geography and anthropology often undertake comparative case study analyses using sample cases selected across environmental, spatial, or social gradients rather than in areas representative of a homogeneous area. One principle underlying such studies is that society adapts to environmental differences; thus the purpose of study is to understand the nature of adaptations and how they function in the face of environmental change. Examples include studies of agricultural adaptation along an altitudinal or climatic gradient; investigation of the impact of proximity on market involvement in a developing country; or research on the human–environment interactions in different societies occupying similar environments, either across a social gradient within a similar environmental region, such as farmers in Africa, or living interspersed in the same location, such as pastoralist and agriculturalist land use management.

2.9 Time

A temporal approach to comparative case study examines the same place at different times, different places at the same time which reflect temporal differences, or different places at different times. In the first approach, a single place is examined at different times. Such a study might show the development of successive human–environment relations as population or other variables change through time. When a geographical location was occupied by different societies through time, such studies in geography were offered as evidence of ‘sequent occupance (sic),’ one of the strategies used to refute environmental determinism. Investigation of different places at the same time could be seen as a quasi-temporal process when diffusion of an innovation or process of change is spreading geographically and some areas represent an older core location with earlier adaptation while others represent preadaptation or emerging stages. An example might be the diffusion of a cash-cropping complex in a traditional rural society where various locations along a space–time gradient represent stages of adaptation of a new technology.

2.10 Events

In the evolution of comparative case study in the human–environment realm, one salient mode of analysis focused on human response to natural hazards. Natural hazards research sought common-

alties, first, in human response to floods, followed by attention to other natural hazards, to the hazardousness of places, and eventually to technological hazards. In all of these realms, comparative case studies provided the core strategy for the development of general frameworks for natural hazard analysis. Seen more generally, selection of hazard case studies for comparative research may be organized around extreme geophysical events, such as tornadoes, hurricanes, and floods, or longer term environmental threats such as drought, deforestation, or soil depletion and erosion. Comparison was also based on spatial dimensionality and temporal occurrence of hazards, as well as on hazard geometry. The event-based approach can be extended to other kinds of events: human and ecological impacts of dams; local resistance to imposed political or technological change; or suburban sprawl.

2.11 Analogs

An analog is based on the premise that objects or events having some similarity may also have other similarities. Thinking by analogy in fact underlies the comparative case study approach, in that the similarity among cases makes them in fact analogous in some respect. As a formal organizing principle, analogs inherently involve two or more cases that share sufficient commonality that insight can be gained by comparison. There is no formal procedure for developing analogs; rather, good analogies depend on ‘pragmatic considerations regarding contexts, interests and purposes’ (Jamieson 1988, p. 81) and represent *a priori* insight before the full development of the comparative cases. In comparative case study using analogs, there is no necessary juxtaposition of the cases in time or space; rather, comparison originated in a conceptual linkage that appeared promising to the researcher. Analogous case studies are strengthened when they are selected with explicit similarity criteria.

Comparative case studies developed within an analog framework include studies of the impact of modern technology in developing countries; society’s response to acid rain, ozone depletion, and future greenhouse gas stabilization; responses to past climate change; and adaptation to drought. Often, comparative case studies built upon analogs are future-oriented, asking whether insights gained from the analogs can be applied to future decisions.

2.12 Theory

Comparative case studies can address theory, wherein the cases are selected to test hypotheses from the theory. Examples include comparative case studies of the process of agricultural change with respect to population growth; modeling society’s progress through economic, demographic, disease, or mobility

transitions; testing Wittfogel's concept of the hydraulic civilization; or explicating a framework for understanding the processes of environmental adaptation. In such studies, individual cases are not only compared with other empirical cases, but compared also with the expectations from *a priori* theory.

3. The Comparative Case Study Method

The comparative case study approach draws upon the same kinds of method that are common to the case study and comparative methods. The researcher links a hypothesis to certain cases using one or more of the strategies described previously, gathers information about the cases, develops evidence from the cases, presents the cases, and constructs explanation or generalization from the evidence. Insight, creativity, intuition, and even serendipity cannot be dismissed as important elements that the researcher uses to formulate hypotheses and to develop the strategy of research.

The depth of analysis of the constituent cases in a comparative study selected for *instrumental* purposes may not be equivalent to that of an individual case examined for its *intrinsic* interest (Creswell 1997). Focus on an issue or hypothesis draws attention to specific relevant issues or variables in the cases. Yin (1989) referred to this difference as *holistic* versus *embedded* analysis, the latter connoting the selection of cases within a wider research question.

3.1 Tools for Analysis

Researchers developing new case studies for comparative analysis have a wide variety of available tools and data sources, including interviews, surveys, participant observation, ethnographic research, field observation, officially collected information, archival research, environmental analysis, remote sensing, qualitative analysis, quantitative analysis, systems analysis, structural analysis, and various modes of modeling. In contrast, researchers undertaking meta-analysis of previous studies may be confined to information developed through other researchers' selection of tools and information; the researcher may undertake further study to amplify information on the case. As with individual case studies, the results of comparative analyses are usually narrative, although normative, probabilistic, statistical, simulation, or graphic models are possible modes of conceptualizing and communicating research outcomes.

4. Evaluation of Comparative Case Studies

Although there are no formal rules for evaluating comparative case studies, there exist reasonable criteria against which studies can be assessed. These include establishing the relevance of the cases;

thorough identification and consultation of information sources; the adequacy and accuracy of reflecting information from sources; correct interpretation of sources; objectivity in reporting and interpretation; and internal consistency as evidenced by triangulation or multioperationism. If the cases purport to be a 'natural' experiment, controls provide an important strengthening of the argument. Additional criteria include the possibility of replication; reporting of contrary evidence and/or interpretation; specification of exceptions and special circumstances; recognition of and explanation for contrary cases; rigor versus superficiality; and value-added insight and understanding. Primary case studies must also meet the canons of field or archival work in the relevant discipline; comparative case studies built from meta-analysis of previously published work have potential for review by original researchers.

5. Conclusion

Comparative case studies offer a richness of insight that may be lost in the abstractions of statistical analysis, while maintaining the tradition of the case study as a means to explore generalities in the complexity of the real world. The intriguing variety of strategies for organizing comparison means that this approach to understanding human relationships to the environment will continue to be a vital part of human–environment scholarship.

Human–Environment Relationship: Indicators

In 1987 the World Commission on Environment and Development introduced a resonant idea: ‘Sustainable development,’ the commission wrote (1987, p. 43) ‘is development that meets the needs of the present without compromising the ability of future generations to meet their own needs.’ Sustainable development names a hope—that human prosperity can be reconciled with the natural world upon which all material economies ultimately rely. It is a notion that has exercised a broad influence in public discussions, notably in the United Nations Conference on Environment and Development in 1992 and the document *Agenda 21* (see Sitarz 1993) adopted at that conference in Rio de Janeiro.

Finding an operational definition of sustainable definition has proved difficult, however. In a dynamic global economy where substitutes for a wide range of goods and services are readily available—at a price—it

is difficult to define ‘needs’ in a way that makes clear what must be conserved or preserved so that future generations can meet their needs (as they define them). In addition, we have yet to develop a generally accepted accounting system that can render authoritative judgments when an ecosystem verges on environmental bankruptcy. But there is no question that biodiversity is being lost at a historic pace, that fossil fuels cannot be replaced on the timescales on which they are now being burned, or that soil erosion diminishes the agricultural capability of some desperately poor people.

It is in this context that indicators play a significant role as people and societies search for ways to meet the requirements of nature and humans. Sustainable development is a long-term, large-scale phenomenon, if it is feasible at all, and it is likely to emerge slowly and unevenly in the world economy. Like other historical phenomena, sustainability may be hard or impossible to see at the level of everyday experience until it is well underway. Indicators rooted in scientific measurement provide an alternative way to perceive and to assess progress toward a sustainable future.

Indicators are quantitative measures of human well-being, economic activity, and natural processes and conditions; they are needed to sense the degree to which human activity may be continued or expanded in the future. The most useful indicators are repeated, precise measurements of natural and social phenomena. Such data series illuminate trends and identify changes; accordingly, indicators can sound alarms, define challenges, and measure progress. The measure-

ment and interpretation of indicators requires sustained efforts and resources from governments, firms, nongovernmental organizations, and the scientific community. Indicators communicate, sometimes evocatively and often across cultural and national boundaries. The indicators described below illustrate how both social and natural realms have been affected by human action over the long term and on large scales.

Measurements of carbon dioxide levels in the atmosphere warn of climate change, but the warning is ambiguous in policy terms (see Fig. 1). Like other gases, carbon dioxide mixes and spreads in the atmosphere, so that its impacts are widespread even when its sources are localized. (Note the seasonal oscillations, however: blending within the northern and southern hemispheres takes place faster than global mixing.) Like other changes in climate, responses are delayed in time and reflect multiple perturbations, many not of human origin. Nonetheless, the steady long-term trend reflected in this data series has triggered worldwide scientific attention and international agreements. The attention commanded by this indicator is a measure of the influence of environmental concerns in formal decision-making, the arenas in which quantitative indicators are indispensable for communicating credible information.

Estimates of economic output demonstrate that economic growth has been substantial in all parts of the world over the past two centuries. Although even the poorest have seen their incomes increase, the gap between rich and poor has also widened (see Fig. 2). Over the next several decades, indicators will be needed to monitor and report on human welfare and life support systems, with measurements on different spatial and temporal scales to inform social choice and debate. Some of these indicators may come to define whether human populations are heading toward sustainability, in the way that infant mortality and life expectancy symbolize progress in public health. Some indicators can also aid navigation, helping individuals and societies to steer a course toward sustainability.

This article sketches current work on indicators and outlines an approach grounded on a widely shared set of normative objectives.

1. Indicators of Sustainable Development

Humans have made repeated, precise measurements of some phenomena since ancient times; astronomical and meteorological signs have guided agriculture for millennia. The use of indicators expanded as industrial societies sought to measure and manage a widening variety of environmental and societal parameters (see Porter 1995).

Today, many people routinely scan prices, news and weather reports, and other sources to inform action and expectation in the short run. Indicators can perform similar functions with respect to long-term, large-scale changes. A striking example of the influence of indicators is provided by the adoption of a common European currency at the turn of the century. In preparation for monetary union, the governments of the European Union agreed to harmonize economic policies by meeting and maintaining budget deficit targets, defined as specified fractions of gross domestic product.

For complicated social objectives such as sustainable development, no single indicator provides a definitive benchmark. Instead sets of indicators have been proposed, identifying multiple parameters that together provide assessments of three basic dimensions—prosperity, environmental quality, and human well-being. Indicators have usually been interpreted using the Pressure-State-Response (PSR) framework, which posits linkages between human action and environmental consequences (Adriaanse 1993). Human activities exert *pressures*, such as burning gasoline in cars, that alter the *state* of environmental variables, such as the quality of air in a city. Impaired states, in turn, elicit *responses*, such as regulations governing pollution-control technology. PSR makes use of data that often are already collected for administrative purposes. The approach captures an important element of sustainable development:

humans can impair the life-support systems of the natural world, calling forth responses aimed at protecting environmental quality. It is straightforward to expand PSR to include the impact of economic development on human welfare.

There is widespread agreement on the utility of PSR but no convergence on a single set of indicators for the measurement of sustainability. There have been numerous efforts to assemble indicators of sustainable development, however, ranging in jurisdictional scope from municipal to international and spanning ecological scales from watersheds to the planet as a whole. (For a compilation, see International Institute for Sustainable Development 2001.) Many indicators in these sets do not have long time series, so the ability to discern trends is limited. Coverage is uneven. Although environmental indicators outnumber the rest, there is greater depth in economic and some social dimensions. Many variables are available for nation-states but few at smaller spatial scales. Information on land cover and land use is weak, especially in developing countries, and institutional indicators are sparse. Some proposed indicators reflect considerable imagination, notably those proposed by the international Balaton Group (Meadows 1998) and in many community-scale projects. For instance, gardening activity was used as a measure of community vigor in Seattle, Washington.

Indicator sets assembled by the UN Commission for Sustainable Development (CSD) and the World Bank complement one another in an illuminating fashion. The CSD indicators (1996) were assembled using the PSR framework. Selected through a consensus process without an agreed operational definition of sustainable development, the CSD indicators are numerous, diverse in the methods used to measure development or sustainability, and include a large number of indicators where reliable measurements do not exist.

The World Bank (1997), in contrast, estimated three national capital accounts. Each attempts to capture the value of an aspect of national economies. 'Produced' capital includes physical capital and financial claims, both familiar in standard accounting practice. A second account measures natural capital, the resources and services provided by the natural world. In principle this includes standing timber and soil fertility. Estimates of natural capital are as yet primitive. A third component of wealth, quantitatively the largest, is human resources, the economic value of labor, knowledge, and social institutions.

The Bank's indicators are highly aggregated and have been estimated using drastic assumptions, but they are conceptually clear. The wealth of nations should be considered in three parts. At least at the margins, wealth can be transferred from one account to another in ways advantageous to people—as when productive farmland is fenced off to create a nature reserve. By contrast, the United Nations CSD indicators do not warn unambiguously of imminent

hazards in any ecosystem or society, nor do they provide guidance on how to pursue sustainable development.

The United Nations indicator set does include variables that are not now being measured, however. This is a notable strength of its process, reflecting a realization that much of what needs to be sensed about sustainable development remains unclear. The UN also has sponsored a wide-ranging research effort under the aegis of the International Council of Scientific Unions (Moldan et al. 1997).

In sum, the existing indicators of sustainable development are limited in their effectiveness by the lack of agreement on what to develop, what to sustain, and for how long—that is, a lack of agreement on the meaning of sustainable development. Proposed indicators of this politically popular idea have drawn upon work done in past decades on the measurement of human welfare and the condition of the environment. These efforts bring together many sources of illumination but have yet to produce a set of measurements of social and natural conditions that could plausibly lead to prosperity for all while conserving the life-support systems on which human economies rest.

2. Trends and Transitions

That we do not have a clear path to a sustainable future is hardly surprising: identifying indicators that point to a sustainable future is a normative task, one that is inescapably difficult in a fractious world of multiple cultures. One approach, used recently by the US National Research Council (1999), suggests directions in which indicators of sustainability might evolve over the next several decades. In a report entitled *Our Common Journey*, the Research Council's board on sustainable development (BSD) focused attention on a sustainability *transition*, a decades-long process in which human economies might move toward a durable relationship between meeting needs and conserving nature. Instead of the elusive endpoint of sustainable development, the BSD sought to highlight the scientific, technological, and societal innovations required to 'feed, house, nurture, educate, and employ many more people than are alive today, while preserving the basic life support systems of the planet and reducing hunger and poverty.'

The underlying metaphor is the demographic transition, the long-term slowing of human population growth which is projected to lead to a stable population size in the latter part of the twenty-first century. The transition in population, already underway for more than two centuries, has brought the human species from a situation of relative stability with high birth rates and high death rates to a situation of stability at low birth rates and low death rates. Because death rates were lowered before birth rates, there has

been a large net increase in population size. A sustainability transition would correspondingly carry human economies from an agro-ecological past, through a rapidly growing industrial phase, into a future in which materials would be used far more efficiently, generating less pollution. As population sizes stabilize, moreover, wide disparities in material standards of living may be moderated by addressing hunger and poverty. Like the demographic transition, a sustainability transition would evolve over decades.

The sustainability transition is an optimistic scenario; signs that it may be in progress are mixed. The indicators above show rapid, perhaps exponential growth rather than stabilization. Yet forests have regrown in advanced industrial nations; famine has been significantly reduced in poor countries, even as the number of hungry people in the world continues to expand; and environmental concerns arose, perhaps surprisingly, in societies that suffered from some of the worst pollution. None of these indications points to a turning away from unbounded expansion, and there is nothing so clear as the peak in the rate of growth in human numbers which occurred in the late 1960s.

Calling for research to make a sustainability transition possible is an unsurprising message from groups of natural and social scientists. What is less apparent at first sight is the intellectual strategy and its implications for indicators. The sustainability transition eschews prediction in favor of a *normative* definition of the task ahead, to meet human needs while preserving the life-support systems of the planet. The BSD found a basis for defining human needs in treaties and the declarations of international conferences devoted to nutrition, housing, social welfare, education, and employment. While such statements articulate aspirations with few resources or implementation plans to back them up, on the decades-long timescale of a sustainability transition, one can imagine quantitative changes large enough to make a qualitative difference with respect to both human needs and the conservation of the natural world.

3. Navigating Transitions

Like the carbon dioxide trend above, a sustainability transition may well require quantitative indicators to be seen at all. The BSD proposed two families of indicators, one to perceive transitions and one to guide social choice in pursuit of deliberate transitions.

Seeing a sustainability transition using the BSD definition implies sensing the degree to which human needs are met and the degree to which life-support systems are put under stress. Human welfare has been monitored since the depression of the 1930s drew attention to the role of governments in meeting basic needs. Appropriate quantitative indicators have been developed, but at the turn of the century they were not yet being reported regularly in a forum, such as the

annual report of the United Nations Development Program, where crises could be highlighted and emergent transitions discerned.

Environmental indicators are numerous and need conceptual organization. The BSD's proposal was geographic, focusing attention on four scales of significance to a long-term transition:

(a) *Global circulatory systems* are affected by human activity, including the atmosphere, climate and ocean circulation, trade and travel, and the spread of exotic species and diseases. Trouble in the circulatory systems is important because the scale of circulation can implicate the entire planet more rapidly or persistently than governments can regulate. Although greenhouse gases and ozone-depleting substances were carefully studied by the end of the twentieth century, biological and information-intensive flows were not yet being assessed as components of a global circulatory system.

(b) *Regions vulnerable to critical environmental damage* are being identified (Kasperson et al. 1995). For instance, the Aral Sea and the Valley of Mexico are experiencing severe, possibly irreversible damage. Because the governing factors—including a vulnerable natural setting, lack of feasible alternatives, and governing institutions unable to take effective action—vary among regions, there is not a single set of indicators that can monitor the combination of social and natural factors that lead to irreversible damage.

(c) *Ecosystem services for urban areas* are only beginning to be monitored systematically (e.g., Baltimore Ecosystem Study 2001), even though urbanization is continuing to accelerate in developing countries. Because many ecosystem services are unpriced (e.g., flood control) or allocated by monopolies (e.g., water supply), market signals are absent or misleading. Yet ecosystem services tend to be irreplaceable when damaged and inflexible because they are supplied by costly infrastructure.

(d) *Parks and protected areas*, managed to enable their biota to persist indefinitely, have been identified on a place by place basis, rather than through a consistent set of appraisals of their long-term sustainability. Attempts to conserve biodiversity on larger scales (Olson and Dinerstein 1998) are just getting started.

In each of these settings, indicators form an indispensable but incomplete part of the intelligence needed to discern a sustainability transition in the decades to come.

A complementary function of indicators is to inform public policy and other decisions, large and small. Some navigational aids are available, although it seems likely that others may also come into wide use.

(a) *National capital accounts*, emerging from the World Bank's work, could provide a simple but crude measure of sustainability: each of the three kinds of capital might be transformed by human activity, but so long as a nation's total capital increases over time,

its trajectory may lie in roughly the direction to contribute to a sustainability transition. The word 'roughly' is important: a utilitarian metric is inadequate to assess sustainability. But the capital accounts draw attention to transformations among forms of wealth—transformations that will continue through, and beyond, any long-term search for sustainability.

(b) *Assessing policies* using indicators assembled under the PSR framework can lead to adaptive management. Adaptive management treats policies as experiments, designing them so that lessons may be learned reliably from the implementation of policies, even those that fail (Lee 1993). In the PSR context, this means using pressure and state indicators to test the effectiveness of responses.

(c) *Monitoring ongoing transitions* provides analysis of trends, particularly those that carry large future commitments, such as population growth. Even if the population continues to stabilize, it will be essential to improve technology and energy efficiency so that humans can accomplish more, economically, with less impact on the natural world.

(d) *Surprise diagnosis* will be needed because a sustainability transition is an improbable development. Reflecting on environmental surprises over the past three decades, Kates and Clark (1996) concluded that we can learn from surprises, so that we can better anticipate, avoid, or mitigate their consequences. But knowing how to improve management is also a temptation to operate closer to the edge. Surprises could therefore become *more* frequent as humans gain better knowledge of the world; this possibility qualifies the conventional notion that science is valuable because it improves our ability to control or at least to predict danger. From this perspective, surprises are valuable indicators in themselves. It is well accepted that surprise should produce humility. Surprise should also produce curiosity. On the timescale of the sustainability transition, curiosity and the learning it prompts are likely to be important, whether or not control can be extended in the short term.

4. Indicators and Social Learning

There is no agreement about which indicators to use to measure the movement of economies toward or away from sustainability. One should accordingly expect spirited debates over the value, biases, and meanings of indicators. In the related sphere of economic policy one can observe over the past half-century sharp disputes in the US over economic growth, the incidence of poverty, unemployment, and inflation. All these have been indicators that American politicians think will influence voter behavior (Tufte 1978). Remarkably, the independence of the data-gathering and analytical organizations has survived, despite their location within government agencies (see Duncan and Shelton 1978).

This is an important lesson: the independence of science is central to the social value of scientific information. Another lesson is that surprise is itself a valuable indicator. Governments and societies should anticipate unexpected things to happen. In a policy context, this idea is a kind of precautionary principle: because surprise is likely, action should be undertaken with thought, humility, and caution.

Indicators used to report on a sustainability transition are likely to be biased, incorrect, inadequate, and indispensable. Getting the indicators right is likely to be impossible in the short term. But not trying to get the indicators right will surely compound the difficulty of discovering, inventing, and achieving sustainable development.

K. N. Lee

Human–Environment Relationship: Prehistoric

Human–environmental relationships comprise a web of culturally imposed constraints in a complex environment, within which people adopt a variety of subsistence pursuits. These may or may not have long-term effects on that environment. During the course of Pleistocene prehistory, humans were few in numbers and constrained by their technology and social organization from unlimited spatial expansion or assuming the trophic role of a super predator. But they may have influenced megafaunal extinctions or vegetation change through manipulation of fire. By the beginning of the Holocene, greater subsistence success allowed exponential population growth, coinciding with agricultural origins in several world regions. Domesticated plants and animals became artifacts, allowing humans to achieve ecological dominance and incrementally transform their environments. But the management strategies followed and the landscapes created were constructed culturally.

1. Inter-relationships

Human–environmental inter-relationships are complex and nuanced. On the one hand, resources vary over time and are unevenly distributed in geographical

space, so that strategies for utilization will differ for the short and long term, and at small or large scales (Butzer 1982). On the other, human communities subscribe to a wide array of subsistence and cultural modes, and attempt to reconcile new information with traditional values. Alternative pathways for possible change are evaluated through economic and cultural choices, which presume a major role for cognition, information, and decision-making. Environmental factors set ‘boundary conditions’ to human behavior at a particular technological and organizational level only in so far as they pose socially unacceptable risk. Short- or long-term environmental crises may be met by routine accommodation, active mitigation, or shifts in subsistence pursuits or social organization. Outcomes therefore are unpredictable.

2. A Pleistocene Prelude to Change

The roughly two million years of Pleistocene prehistory—the Paleolithic—were critical for human evolution and presumably influenced the ‘hard-wiring’ of basic human behavior. Emerging human–environmental interrelationships not only suggest a datum to examine such patterns in more recent times, but may have set a trajectory for later environmental behavior. Given the rudimentary archaeological record and in the absence of direct ‘observation,’ it is next to impossible to grasp the cognitive assessment of environmental problems, or even to infer a response or to understand attenuated processes of systemic change. A very real danger in Pleistocene prehistory is to posit a cause and effect relationship, based on little more than coincidence of several categories of proxy data. There are no simple answers to the broad, interdisciplinary questions about Pleistocene human–environmental relationships.

2.1 Human Vulnerability to Pleistocene Environments

The expansion of early human groups to higher latitudes and new continents during the course of the Pleistocene gives the impression that they learned progressively to cope with cold or arid environments, where resources were different than in tropical Africa. But the Paleolithic record is strikingly discontinuous in space and time, raising doubts as to the ability or choice of Paleolithic peoples to colonize ‘marginal’ environments with widely dispersed but clustered resources (Butzer 1982, Chaps. 12–14, 1991).

In what is now the semiarid interior of southern Africa, settlement was limited to periods of substantially moister climate and closely linked to water sources. Even some valleys with dependable rivers were unutilized for repeated spans of many tens of

millennia, and not all periods of moister climate were accompanied by an automatic territorial expansion of settlement. Effective human occupation across the dry interior of southern Africa was delayed until well into Holocene times, after 10,000 before present (BP).

Paleolithic people probably avoided this region because food resources would have been few and thinly spread during the dry seasons of poor years. Plant foods would have had low predictability and low net productivity, while the available game would have been difficult to hunt without bow and arrow, sophisticated traps, or complex game drives. If bands of hunters did penetrate such dry regions, they would have been so widely dispersed as to encounter neighboring bands only sporadically, leaving them with incomplete information as to the status of resources, e.g., animal movements or the condition of plant foods (Butzer 1991). During periods of severe drought stress, starving animals also lack fat while excessively lean meat poses severe metabolic problems for starving people (Speth 1987).

The true capacity of drought-prone, low productivity, and low predictability environments (see Butzer 1982) to sustain human life is a great deal less than its overall resources, averaged over time and space, would suggest. A similar ‘marginality’ model is offered by Bocquet-Appel and Demars (2000) for western Europe between 40,000 and 11,000 BP. In glacial-age France settlement was concentrated in a ‘refuge zone’ located in northern Aquitaine. During less harsh, subarctic conditions prior to 22,000 BP small temporary sites extended northeastward to the Rhine, but then retracted to southwestern France during the glacial maximum, c. 22,000–16,000 BP. Thereafter, as the climate ameliorated, an increasing number of larger sites are found in areas previously not occupied, as far afield as Britain and Germany. Across these 30 millennia, regional population may have increased from 4,000 to as many as 40,000 people, in part facilitated by improved hunting skills.

There was a vast ‘marginal’ environment in western Europe where not drought, but the low productivity and predictability of a subarctic environment, with dangerous turns of weather and hard, snowy winters, made glacial-age occupation hazardous except for summer-season hunting forays. Risk-prone environments such as semiarid thorn bush or arctic tundra seem to have been avoided, in favor of demographic clustering in dependable, productive environments. The persistent and extensive spatial gaps of the Paleolithic archaeological record in better-investigated areas appear to be real, rather than simply a function of site visibility and preservation.

Until the close of the Pleistocene, human groups did not demonstrably ‘push the envelope’ by venturing far or long into marginal environments. Incremental human expansion into higher latitudes, especially during the late Pleistocene, probably targeted environmental mosaics capable of supporting sizeable

population clusters on a long-term basis. That implies a cognitive ability to explore new regions, so as to assess viability and risk, in the context of available technology and subsistence skills.

Changing hunting proficiencies are demonstrated by quantitative differences in the animals slaughtered in South African or western European sites of different periods. Before about 40,000 BP hunting focused on relatively docile animals, whereas in Late Palaeolithic times more dangerous animals or those from difficult montane environments were hunted regularly, and aquatic resources were systematically exploited on defined, seasonal rounds (Klein 1999). In part this reflected the invention of the bow and arrow, more versatile throwing javelins, and a variety of harpooning and fishing gear. But better tactical and collaborative organization of hunting and fishing activities will have been just as important.

The exponential increase in hunting efficiency evident across Eurasia between 25,000 and 10,000 BP implies a revolutionary growth in food-energy exploited, making possible rapid demographic expansion during the closing millennia of the Pleistocene. In both Cantabrian Spain and interior South Africa site sizes or artifact concentrations increase exponentially during the Late Pleistocene, and there were some 30 to 70 times as many sites (per millennium) about 10,000 years ago than there were about 100,000 BP. The ‘take-off’ in site numbers and implicit population growth begins at different times in different regions, namely 22,000 BP in Cantabrian Spain, 16,000 BP in France, 14,000 BP in northwestern Siberia, 10,500 BP in North America, and 8000 BP in temperate Australia (Butzer 1991, Bocquet-Appel and Demars 2000).

This carries implications for the relative proficiency of prehistoric peoples to utilize environmental resources. Paleolithic populations remained very small and vulnerable across nearly two million years, precisely because they lacked the technology and cognitive ability to move higher up the trophic pyramid. They only achieved the role of a major predator during the closing millennia of the Pleistocene.

2.2 Late Pleistocene Megafaunal Extinctions

The disappearance of mammoth, mastodon, woolly rhino, great sloths, or sabre-tooth ‘tigers’ from the Holarctic fauna at the end of the Pleistocene continues to intrigue. Giant kangaroos and cow-sized diprotodons from Australia also belong on this list of ‘megafauna’ (Martin and Klein 1984). But unlike the end-Cretaceous extinction of the dinosaurs, those of the terminal Pleistocene did not eliminate the dominant orders of larger animals, but fell within the scope of evolutionary ‘turnovers’ incompletely documented for earlier phases of the Pleistocene.

Species extinctions are a grim reality of recent centuries, and can be attributed to chemical impacts,

habitat destruction and harassment, predation by overhunting, or deliberate extermination. Some such extinctions or near-extinctions were rapid, others followed many centuries of sustained attrition. But for Late Pleistocene megafaunal extinctions there is neither direct testimony nor a promising analytical method to identify cause and effect, such as for the demise of the carrier pigeon, or the near-extinction of bison, bald eagle, or whooping crane.

The scope of this problem is illustrated by the catastrophic extinctions on New Zealand after its first colonization by the Polynesian ancestors of the Maori, less than a millennium ago (Anderson and McGlone 1992). Two families of large wingless birds (moas) became extinct, as well as an array of songbirds and marine taxa, all prior to European intrusion during the early 1800s. Although moa extinction within 4 centuries is well-enough documented, together with butchery, woodland fragmentation, and introduced dogs and rats, we will never know the human dimensions of this event, on the very threshold of oral history. Yet catastrophic extinctions on isolated islands of the Pacific Ocean during the last 2 millennia involved fewer variables than the response of more complex, continental ecosystems to a familiar human predator before 10,000 BP. These recent examples do not therefore provide a model applicable to the Late Pleistocene.

The case of extinctions in Australia makes the point. Between perhaps 30,000 and 14,000 BP a total of 42 larger vertebrates, mainly marsupials, and several taxa were subject to size reduction. Two of the vertebrate families that disappeared were huge, clumsy and slow-moving browsers, reminiscent of large mammals of the early Tertiary. The kangaroo family (Macropodidae) lost six genera (or 30 species), but it could be argued that the surviving kangaroos and wallaby (10 species) are 'modernized,' efficient, and smaller forms of the same lineages (phyletic replacement). In the big picture, this suggests the consequence of intergeneric and interspecific competition.

There also were several major environmental discontinuities during the same time span, including filling and drying of lakes, expansion and 'downsizing' of river systems, and extensive activation of eolian sands (Ross et al. 1992). Pollen profiles suggest re-expansion of browsing habitats about 10,000 BP (Dodson et al. 1992). In combination with the sudden, drastic climatic perturbations for which Australia is noted today, that implies repeated episodes of fragmentation and reduction of habitats during the Late Pleistocene, rather than a single and unidirectional change at its close. Environmental flux of sufficient amplitude would selectively disadvantage the demographic viability of 'archaic' forms, accelerating competitive exclusion among genera with overlapping niches.

People settled parts of Australia before 40,000 BP, but they were few in number, their distribution limited

to more productive environments, and they introduced no animals other than the dingo, at a much later date (Kohen 1995). Artifacts have been found at a handful of faunal sites that lack patent evidence of butchering activity. How does one link the coexistence of human hunters or scavengers with extinctions over a time range of 25 millennia? Alternatively, how does one distinguish an evolutionary turn over from human predation? Temporal correlations do not provide process-links.

The case of North American extinctions is equally puzzling. Seven common genera disappeared 12,000–10,000 BP, at a time of demonstrated human predation, but of the 31 other extinct genera or species (all poorly dated), at least several phased out while even a human presence on the continent is contested (Grayson 1991). Twenty-seven of the extinct genera and six extinct species were found only in North America. In effect, this great faunal turnover primarily impacted New World forms, many of which were 'archaic,' to select for a smaller group of expansive ruminants (bison, deer, pronghorn), and carnivores (bear, wolf, coyote). But not all niches were refilled, and Spanish equids successfully recolonized grassy shrublands of the American West and Argentina.

Late Pleistocene environments in North America have no modern analogs: both grasslands and woodlands were 'patchy,' with fine-grained mosaics, greater local plant diversity, and unfamiliar seasonal productivity patterns (Graham et al. 1996). Both the extinct grazers and browsers were unspecialized, filling their energy requirements with a broad range of plants, as is typical for monogastric ungulates. At the close of the Pleistocene, such 'patchy' biomes were replaced by monotonous grasslands or closed-canopy forests, more suitable for specialized ruminants (bison, deer, caribou), whose stomachs can degrade plant toxins and more rapidly assimilate energy. All the large, monogastric grazers (mammoth, horse) and mixed browsers (mastodon, ground sloths, camelids), which had long gestation periods, became extinct. Also symptomatic of environmental stress, but inadequately understood, is the progressive reduction of size ('dwarfing') of the disappearing taxa during the Late Pleistocene, as is the 'dwarfing' of phyletic replacements among surviving genera worldwide.

Unlike Australia or North America, the contiguous continents of the Old World were little affected by extinctions (Martin and Klein 1984): a few phyletic replacements here and there, and the more dramatic disappearance of elephant and rhinoceros in Palearctic Eurasia for the first time since the Tertiary. Unimpeded contact and faunal interchange in the Old World implies a steady intergeneric competition for overlapping niches, which may have driven Old World faunas to modernize earlier. As on the other continents, that does not exclude human predation as a triggering mechanism for extinction of some vulnerable taxa. But neither does the present evidence single

out humans as super-predators ten millennia ago, whatever the environmental inputs and biological feedbacks of end-Pleistocene extinctions.

2.3 Fire Ecology and Vegetation Change

The human use of fire is a potent tool of habitat alteration or destruction. That is supported by both ethnohistorical evidence and quantification of charcoal particles from pollen profiles. Fire depends on the availability of fuel, climate, and ignition. ‘Natural’ fires, ignited by lightning strikes, have facilitated expansion of grassland and savanna since mid-Tertiary times (Kershaw et al. 1997). Less clear is the degree to which prehistoric peoples manipulated fire so as to alter vegetation ecology, because it is difficult to separate the evidence for artificial vs. ‘natural’ fires.

In Australia, indigenous people continue to use fire for many purposes: to drive game, to clear undergrowth for visibility and stimulate fresh growth, and to serve a range of defensive, domestic, and social purposes. The popular truism that indigenous fires were ‘controlled’ habitually is not supported by the facts, nor is it consonant with the experience of wildfires on other continents. Fire was an instrument of environmental management in that it once kept most Australian eucalyptus woodlands grassy and free of shrubby undergrowth, although such woodlands had already evolved across five million years in an interactive relationship with fire.

Pollen profiles from south-eastern Australia that cover most of Holocene time show charcoal particles increasing exponentially during the last 2 millennia or so, to culminate shortly before or after AD 1800, even though there is no consistent climatic trend during that period. It is possible that the elaborate burning culture recorded after 1788 only evolved during the late Holocene, after changes in cultural practices. The density of archaeological sites in south-eastern Australia doubled during the last two millennia, compared with the previous three (Dodson et al. 1992), suggesting that increasing use of fire primarily reflected demographic expansion or greater mobility. Given the much smaller and disjunct Australian populations of the Late Pleistocene, it seems improbable that human manipulation of fire could have produced a striking charcoal peak 38,000 BP in northern Queensland (see Kershaw et al. 1997), since the ‘event’ saw rainforest replaced by eucalyptus woodland, which instead implies climatic change. To argue that early use of fire was a co-agency in megafaunal extinctions will require a comprehensive, ecological case and an archaeological context.

Unlike Australia, which has a desertic core, sub-Saharan Africa is dominated by grasslands with scattered trees (savannas), mosaics of savanna and open woodland, or open woodland with patches of grass. Although extensive tracts of such open vegetation reflect either sandy substrates or extensive

seasonal flooding, others have been modified and maintained by recurrent fire. It was once believed that Africa’s savannas were created and expanded progressively by deliberate burning through much of human prehistory, but that is no longer tenable. The great diversity of cursorial ungulates for which Africa is noted began to evolve during the Miocene, while Pliocene deposits reveal abundant pollen of grasses as well as evidence of charred wood. During glacial-age intervals of drying, such as 30,000–10,000 years ago, much of sub-Saharan Africa was an almost treeless grassland, with woodland or forest reconstituted at the beginning of the Holocene.

Pollen profiles from the highlands of Malawi show that a mosaic of grassland and forest remained unchanged from the Pleistocene to the present (Meadows 1984). In interior South Africa, the distribution of grass and semidesert shrub shifted according to climatic trends and was little affected by the first appearance of indigenous herders. Until agricultural activities began to create patches of disturbed vegetation in tropical Africa, mainly after 3000 BP, increases in grass pollen and charcoal currently are attributed to episodes of drier climate, thus the opening of the Cameroon ‘Grass Fields,’ formerly believed to be anthropogenic (Zogning et al. 1997). In Africa and elsewhere it is important to distinguish slash-and-burn agriculture, as a focused form of micromanagement within forest environments, from the modification of savannas or open woodlands to attract game or improve pasture for livestock. Prehistoric fire ecology primarily concerns the latter, and assumes that deliberate burning reinforces natural processes.

3. Changing Holocene Relationships with the Environment

Regional population growth at the end of the Pleistocene sooner or later set in train a variety of adaptive responses to new or changing environmental opportunities. In some areas, increasingly skilful hunter–foragers turned to a more specialized exploitation of coastal resources, while others remained more conservative generalists, despite technological innovation. Elsewhere hunter–foragers chose to diversify their ecological niche by investing more time in the harvesting of large numbers of small mammals, at least on a seasonal basis. Tapping into a more predictable food supply, such strategies repaid the effort by allowing a more sedentary residential pattern, even if small hunting parties fanned out in pursuit of bigger game at opportune times. Longer-term residence at central encampments, in caves or out in the open, in turn allowed a more persistent exploitation and manipulation of diversified plant foods.

In several world regions this strategic shift led to the domestication of plants or animals, or both. This was

not a socioeconomic revolution, but a long trajectory of co-evolution, during which people experimented with and eventually ‘managed’ a selection of plant and animal resources. They favored and tended more desirable strains until new domesticated species emerged, to be maintained through deliberate planting and breeding. This inaugurated a novel set of relationships between people and the environment in that both plants and animals became artifacts with which people fundamentally changed their habitats, involuntarily or deliberately replacing native biota with cultivated plants and domesticated livestock.

3.1 The Impacts of Early Agriculture

Agricultural origins have been amply documented by multidisciplinary archaeological research in the Near East and in southern Mexico; similar processes are apparent, but imperfectly understood in Andean Peru, sub-Saharan Africa, and south-eastern Asia. Morphological (‘hard’) evidence for domesticated grasses and legumes is available for sites along the Near Eastern steppe-woodland ecotone by 10,500 BP, implying that the process of experimentation and manipulation began several millennia earlier. Agricultural origins in the New World may have been even more attenuated, but that database is spotty.

As long as communities practicing complementary agriculture remained few, small, and confined to the natural habitats of their cultivated plants and livestock, environmental impact would be minor. But these new pursuits were contagious across the Near East and much of Europe, introducing new plants or animals to environments where indigenous biota were displaced. Agricultural villages appear on the coasts of Greece, Crete, and Cyprus by 8,000 BP, and a distinctive new agrosystem had emerged around the coastal plains of the western Mediterranean about 7,000 BP. In some areas, resident hunter–foragers domesticated local wild cattle prior to agricultural penetration (Yugoslavia), while elsewhere expanding agriculturalists allowed outbreeding of livestock or cultivars (Hungary), to produce new domesticated variants. Dispersal across western Europe before 5,000 BP proceeded in stages, each with a probable sequence of ecological readjustment in new settings, indigenous innovations, interchange between resident hunter–foragers and intrusive farmers, and eventual indigenization of agricultural traits.

This early, Neolithic agriculture was localized and often ephemeral, and most pollen evidence shows that woodlands soon regenerated. But strong counter-examples verify repetitive fire clearance, cultivation, and stockgrazing that converted extensive areas into grass, weeds, or secondary vegetation 6,000–5,000 BP (Poland) (van Zeist et al. 1991). In parts of the Mediterranean Basin, early Neolithic pastoralists probably used fire clearance to open up pasturage in native woodlands as early as 7,000 BP (Greece,

Dalmatia, eastern Spain), with reforestation delayed up to five centuries. Such impacts were local rather than general, but in some areas they may have initiated or reinforced a trend to more xeric forest types. Yet settlement was spatially discontinuous, even in ‘preferred’ environments, until about 4,000 BP, judging by repeated episodes of woodland recovery and presumed local abandonment (Butzer 1996).

3.2 Plow Agriculture, Pastoralism, and Ecological Change

Towards 3,500 BC (5,400 BP) the invention of the plow (Mesopotamia) marked a significant transformation in the complexity and productivity of agriculture. The plow required a draft animal and opened larger fields to cultivation, while also exposing soil to potential erosion. Animals no longer served only as meat on the hoof. Cows, sheep, and goats were milked, and the milk converted to butter or cheese. Wool was skeined and woven into cloth as new breeds of woolly sheep were selected. The fertilizing properties of animal manure were probably recognized, as animals and their products became interlinked systemically with the range of subsistence activities.

More work was invested in a plot of land, including preparation, planting, weeding, and harvesting, to increase productivity. Plowing along hillsides deliberately or inadvertently created stepped slope profiles that may have suggested the principle of terracing. Swamps were drained and heathlands ameliorated with transported soils. In arid environments, opportunistic local manipulation of runoff developed into more complex methods of water control, including canal irrigation. Orchard crops, olive oil, and wine emerged as commercial products. Exchange networks and growing urban markets further reduced risk and, spurred by metals, metal products, and pottery, began to favor economic integration over wider areas.

Particularly in the Mediterranean Basin, much land was unarable, but animals were mobile and could be moved to rough upland pastures when the snows melted or lowlands became subject to summer drought. Short and long distance mobility patterns (transhumance) emerged that brought stony uplands into productivity. Controlled burning began to be used to manage such pastures on a regular basis, keeping woodlands open (but not deforested) and burning back woody or thorny shrubs. By the end of the Bronze Age (1,200 BC), much of the Mediterranean world was used and modified by farmers and herders, even though vast tracts of montane forest remained. A familiar cultural landscape was in place (Levant, Greece), expanding to the far west by Roman times, and bringing a simplified version to higher latitudes during the Middle Ages (van Zeist et al. 1991).

Intensified agriculture represented a quantum jump in production, demography, and interregional

networking, in managed environments that were increasingly artificial. Native biota were replaced progressively, with cultural controls over natural selection, succession, and diversity. To maintain such managed ecosystems required constant or increasing investment of labor, in order to maintain artificial equilibrium conditions and avoid ecological degradation (simplification). This was the case in the Bronze Age Mediterranean Basin and Near East, as well as China. A millennium later, similar transformations are apparent in parts of Mesoamerica, the Andean world, and several nuclei in southeastern Asia.

Changing human–environmental relations were not limited to agricultural regions. In the central USA sedentary utilization of rich, riparian resources incorporated controlled use of a variety of minor plant foods well before the appearance of standard domestication. In arid lands and the sub-Arctic, or in the high Andes, mobile herding patterns emerged that were based on new domesticated genera such as camel, reindeer, and llama. Even in the Arctic, groups of hunter–foragers devised new collaborative methods to effectively exploit coastal resources, by mobile strategies such as those of the evolving ‘Eskimo’ cultures (Alaska to Greenland). A mastery of the environment is broadly evident that was qualitatively and quantitatively different from that of the Late Pleistocene.

With increasing environmental exploitation by expanding populations, the potential for ecological impairment or degradation was rapidly enhanced. But the fact that discernible damage did not keep pace suggests that farmers built on the cumulative experience of trial and error in familiar environments, to articulate more conservationist strategies (Butzer 1996). Ideally, land use seeks to minimize both long-term environmental damage and short-term subsistence risk. Pollen and geomorphologic records show that for the most part, Mediterranean farmers and herders were successful in doing so during the last four millennia, despite sporadic ‘accidents’ of mismanagement in some areas. Only during Late Medieval times, when population was substantially greater than in Classical times, was supplementary food imported from outside the Mediterranean region. Until the early 1900s, productivity was maintained or enhanced, which implies sustainability across 7000 years of agricultural land use (Butzer 1996).

An anomalous episode of disturbance is dated to the transition of the Bronze and Iron Ages, c. 1,000 BC. It saw intense and often prolonged vegetation disruption (Spain, northern Greece, Northwest Turkey) by pastoralists moving into the Mediterranean environment from temperate Europe or the Balkans. Presumably they misapplied management methods better suited to humid environments. Much the same happened during the Middle Ages, after desert nomads moved into the Levant and North Africa, or Slav herders occupied northern Greece. In other cases initial agricultural occupation led to a flush of soil erosion (Greece), and

soil loss was locally problematic after pastoral expansion or agricultural decline, thus during the later first-millennium BC (Palestine, western Turkey, Greece, Italy, Spain) and again in Byzantine or Medieval times (Palestine, Greece, Italy, North Africa, western and central Europe). Although the cultural landscape and its humanized woodlands were repeatedly rehabilitated, soil thinning had to be compensated for with manure, but cumulatively this does not compare with watershed destruction by mechanized agriculture or industrialization since the 1950s.

In the New World, where the focus of recent discussion has been on the impacts of European-style land use, more pragmatic work shows extensive forest disturbance or removal, and even soil erosion, during indigenous demographic expansion many centuries before 1492 (Central America, Mexico, eastern United States) (Pohl et al. 1996, Butzer and Butzer 1997, Peacock 1998).

The human imprint on the landscape at the threshold of history was profound. In combination with the devastation of island ecosystems, such as New Zealand or Madagascar, it includes episodes of biotic impairment and even extinction, with enduring imprints. Yet most environments today, even ‘wilderness’ areas, are humanized to some extent and many if not most agricultural landscapes provide esthetic comfort and psychological anchoring in their particular cultural contexts. The human ascent to unprecedented demographic success and ecological dominance has impoverished floras and faunas the world over, often replacing them with vast monocultures or a handful of livestock species—even before the side-effects of industrialization could pollute the waters or turn machinery loose on the soil mantle. But until the dawn of a global consciousness, the transformations of the last 10 millennia were guided by community decisions, made through culture-specific lenses, with the goal of subsistence success across the generations, guided by imperfect information, despite conservative and conservationist strategies. That is the *reality* of human–environmental relationships, however they are judged today in the face of global ecological crisis.

K. W. Butzer

Human–Environment Relationships

The relations between human activities and their biophysical milieu have never been a subject of deep and sustained interest to the Western social and behavioral sciences. Such attention as they have been given has been fitful and partial, and it has arguably always been much less than their importance merits. Environment—in the sense of the biophysical world—has not been a topic that the orthodox human sciences have felt comfortable in addressing. This article traces the general scope of human–environment relations and of the past and present study of them in the human sciences.

1. The Term ‘Environment’

‘Environment’ is a troublesome word in that it can mean quite different things in different contexts. In some fields, it has long been used to refer to the social surroundings of human existence and behavior. In that sense, it encompasses much of the standard subject matter of the social and behavioral sciences. Elsewhere, it denotes the biophysical surroundings of human activity. In that sense, it encompasses much of what the social and behavioral sciences have deliberately chosen not to study. An emphasis on ‘environment’ is associated confusingly in the one case with the rejection of ‘nature’ as an important factor (as in the ‘nature–nurture debate’) and in the other with its affirmation (as in ‘nature–society relations’). An ‘environmentalist,’ depending on the context, can be one who believes that social influences outweigh hereditary ones in human development (a frequent meaning of the term today in psychology and sociology); that human beings are molded by climate, terrain, and other elements of their biophysical surroundings (the meaning given the term in the 1968 *Encyclopedia of the Social Sciences*); or that vigorous action should be taken to slow or reverse human-induced change in earth systems (the usual meaning of the term in ordinary parlance today). Only the second and third of these meanings correspond to that of ‘environment’ taken, as here, in the biophysical rather than the social sense. Both of them, moreover, exemplify a second problem: the frequent usurpation of the term by a narrow and particular sense of it that obscures its full scope.

Even if ‘environment’ denotes not the totality of the biophysical universe, but only those portions of it that are relevant in some way to human activity, its boundaries are not easy to fix. They can and often do change as human activities change or as understanding of their relations with their surroundings does. At or near the boundaries, the environment can include the mineral deposits of the deep ocean floor (now that the technology for their exploitation exists), the strato-

spheric ozone layer (now that its role in protecting life on the earth's surface is recognized), the stars when they were used for navigation, and a comet or an asteroid threatening to hit the earth. If the outer limits are always uncertain and always in flux, however, the core elements are easily defined: climate, soil, terrain, bedrock, mineral and fossil fuel deposits, atmosphere, fresh and salt water, and biota. They are the basic elements that compose what the Russian geochemist Vernadsky (1929) called the biosphere: the zone in which life as we know it can exist and which life, in turn, can affect and transform.

To speak of nature or the biophysical world as the environment of human existence is at least to some degree to separate the two realms. Such a separation is often challenged and resisted. The question has long been debated whether humans are fundamentally a part of, or apart from, the natural world. The grounds on which they are asserted to, or not to, belong to nature are of the most varied sorts. Social arrangements can be described as given by nature in order to justify and 'naturalize' them and rebut criticism of their injustices. Nature, as in the concept of natural rights, can at the same time be used as a standard by which existing social arrangements are measured and found wanting. During the nineteenth century, Darwinian and Lamarckian theories of human origins tended to dissolve certain boundaries between humanity and nature by emphasizing the importance of the organism's evolution from its surroundings and its continuous shaping by the demands that these impose. They were and have continued to be adopted and employed for widely varying ends by both conservatives and radicals.

At the same time, the American geographer Marsh (1864), a contemporary of Darwin's, tended rather to emphasize the distinctions between the human and the natural. He insisted forcefully, and with a wealth of evidence, that human actions modifying the earth were distinct in kind rather than merely degree from natural processes of change. They were, Marsh pointed out, far more rapid and abrupt in occurrence and far more radical and destabilizing in their character. But the very scale and scope of human impact, which have both grown enormously even since Marsh's time, tend in another way to blur the boundaries between society and environment: by making the latter less and less of a distinct entity. Undoubtedly human impact has altered and even transformed many aspects of the earth. Human actions, both deliberately and incidentally, have reshaped them into what is sometimes called a second nature that can no longer be regarded as something quite separate from society. Many people now spend their lives in climates that, at the scale of the built environment, are controlled closely and deliberately; that locally and regionally have in many cases been altered by human actions though rarely by conscious human intent; and that globally may or may not

already bear the marks of greenhouse gas emissions from fossil-fuel burning and land-cover change. Little of the environment can be considered wholly 'natural' if that term means pristine and unaltered.

Much of the environment has not been transformed, however, and all of it, however much altered, remains distinct from the human realm in another sense. Human beings possess certain characteristics of reasoning and reflexivity different in kind or at least in very significant degree from the rest of the known world. No other species or biophysical agent has equivalent attributes allowing it to carry out equally elaborate projects affecting the environment, nor have the actions of any changed the globe nearly so drastically in so short a time as have those of the one species possessing them. That humanity and environment are in some important ways separate is implied by the very existence of the social and behavioral sciences (and the humanities) as core fields of study distinct from the natural sciences.

Yet their separation very often is challenged from the margins by two broad programs for reducing one to a branch of the other and asserting their unity in terms of both substance and appropriate methods of study. Extreme forms of biological determinism propose to account for human and social action as the product of heredity and evolutionary imperatives, environmental determinism as the product of the shaping forces of climate and other elements of the human habitat. Both seek to annex the social realm to the natural. Annexation of another kind is envisioned by the more radical approaches found in the social studies of science, which propose to treat the knowledge generated by the natural sciences not as a means of explaining social action and processes but as itself one of their products. Science is seen not as a privileged source of fact but as a social activity like any other and governed by the same rules and to be analyzed in the same terms. These perspectives offer valuable correctives to an unthinking separation between the human and the natural. Weaker forms of them—evolutionary psychology, for example, or the study of the social correlates of environmental attitudes and activism—have been fertile sources of challenging new findings and explanations. Thus far, at any rate, some basic distinction between humanity and the biophysical world has continued to be accepted as unavoidable in practice.

2. Human–Environment Relations

But even if environment and society are distinct realms, not so simply and unproblematically related as reductionists on either side would argue, they are closely interdependent and interacting ones. If the autonomy of the social from the natural sciences (or of the natural from the social) is justifiable, what is less so is the thoroughness with which the social sciences, by

and large, have cleansed themselves of contact with the biophysical world. They have, in general, ignored the fact that all human activities, though not reducible to the biophysical plane alone, nonetheless have a biophysical side to them. All human actions require energy and matter from the environment and release both back into it. All have certain prerequisites in the form of the basic necessities of human existence—air, food, water, a tolerable temperature range, and so on—that the environment must provide; and these only begin the list of significant relations between society and its biophysical milieu.

Broadly speaking, the environment can represent a source of services (a term now coming into use to replace the narrower one of ‘resources’). Such services include background benefits from the environment that are enjoyed even though they are not consciously and deliberately exploited as natural resources. Among these are the key life-support systems of the biosphere. Other environmental services range from the absorption of wastes to the provision of spiritual and esthetic satisfaction and natural amenities such as scenery and agreeable weather. The environment can equally serve as a source of disservices, ranging from the hazards of violent natural events such as storms, earthquakes, and epidemic and endemic diseases to disamenities and constraints on human activity. To the extent that the environment acts as a determinant of human qualities, its effects can again be classified into services (the formation of valuable qualities) and disservices.

But there is no such thing as a service or a disservice without a recipient thereof. If some aspects of the environment are essential to the existence of any kind of human life as we know it—though not necessarily as it might exist in the future—whether and how any other plays either role depends crucially on the variables of what it is that people do and wish to do. Environmental features that help them do what they wish to do represent services, those that interfere represent disservices. Actors differentiated by location, occupation, class, status, gender, and any number of other variables will benefit or suffer differentially. The significance of the environment, then, is never determined solely by the characteristics of the environment; it is determined also by the ways of life that people lead within it.

As a result, a change on either side may be sufficient to change the relationship. It is by now clear that the environment on its own cannot be presumed to be stable or equilibrium seeking. Natural processes of change and fluctuation on many different scales of time and space are ubiquitous. Over time, they have increasingly been supplemented and, in some cases, overshadowed by human-induced changes, both those made consciously and those resulting unintentionally from actions taken. These may enhance or lessen the biophysical services and disservices received by different groups and individuals. Possible environmental

instability must be considered in the study of past environment–society interactions and in planning for future ones.

But environmental change, while it can be sufficient to alter environment–society relations, is not necessary for an alteration to take place. Equally sufficient can be shifts occurring on the social side. Changes in technology may mean that some aspects of the environment will cease to provide services or disservices, while others will begin to do so. Falling water was a vital source of industrial energy through direct-drive waterpower in the era before widespread fossil fuel use, and it became one again with the development of the means of hydroelectric power production. Uranium became an important resource only through the development of nuclear power generation. Some technologies are developed to alleviate existing problems in environment–society relations: those of weather monitoring and forecasting, for example. Others incidentally create new problems: the new role of clouds, fog, and downdrafts as hazards created by the development of aviation. Technological changes themselves are entangled closely with changes in social organization, which themselves may also alter society–environment relations. Such variables as the structure of ownership and exchange, household and gender relations, and political system, for example, all play an important mediating role between natural events and their possible human consequences. Famine, for example, may follow drought that drastically reduces the crop harvest, but a severe drought is neither a necessary nor a sufficient condition for famine. One of the few well-established regularities in the social sciences, documented by the economist Amartya Sen, is that no modern famine has occurred in a country, however poor, with well-functioning democratic institutions. They act, it would seem, to prompt effective government interventions preventing disaster. A certain environment, environmental feature, or environmental event, even if unchanged, will thus bear different relations to society at different times. Changes in the environment itself, of course, whether themselves natural or human-induced, can also alter the role of the environment in the lives of its inhabitants.

But an account of human–environment relations in these largely utilitarian terms remains only a partial one. It excludes, most notably, questions about environmental ethics or the proper relations between humanity and environment. The social sciences have found it difficult enough to address issues of values where only human actions are involved. Their particular focus has almost disabled them from assimilating or even recognizing arguments about the rights of other species and other features of the environment: the American biologist Leopold’s (1949) ‘land ethic,’ to take one example. Their usual tendency is to treat such beliefs—and understanding of the environment more generally—as expressions of social position

rather than to grapple with their possible validity. But the rise of Green parties and ecocentric groups and movements and of expressed support for notions of the rights of nature pose external challenges to the use of purely human-centered criteria, ones that have grown in urgency as human power to alter the environment, with likely effects including the widespread extinction of other species, has also grown.

3. *Human–Environment Relations in the Social Sciences*

These observations suggest the wide range that human–environment interactions cover. The actual range of interactions recognized and studied by the mainstream social sciences at any one time has always been much narrower. The most important early form in which environment impinged on the fledgling social sciences was that of environmental determinism. This doctrine offered one promising and plausible way of solving the formative puzzle of the social sciences: explaining why human behavior and institutions varied so widely from one place and people to another. The French political and social theorist Charles-Louis de Secondat, Baron de Montesquieu, in the eighteenth century treated climate and soil in *L'esprit des lois* as important factors in social life. He asserted, for example, that the people of cold or barren or mountainous areas tended to be vigorous and freedom-loving and those of warm, fertile plains to be more indolent and passive. Political and social institutions suited to one environment, he maintained, would be inappropriate to another. Many thinkers of the French and the Scottish Enlightenment echoed Montesquieu in seeking to explain differences between societies as at least in part growing out of differences in climate or other aspects of the physical environment.

But the concept of environmental influences soon changed from a useful part of the social theorist's conceptual baggage into an irksome burden. The shift proceeded in step with the organization of the social sciences into separate disciplines of sociology, anthropology, history, geography, economics, law, and so on. A few nineteenth-century historians—Henry T. Buckle in England, John W. Draper in the US, and V. O. Klyuchevsky in Russia among them—continued to assert the fundamental importance of environment in human affairs, but the trend of studies ran strongly in the opposite direction. Far more typical was the stance taken by Emile Durkheim in sociology. In his chief empirical work, he rejected meteorological and climatic explanations of patterns of suicide in favor of ones involving the character of social organization. At a more general level, he proposed that social facts be explained solely in terms of social causes. The approach excluded not only psychological or individual-level explanations in sociology, but also biological and physical-environmental ones. Not all of sociology was

Durkheimian, but the rejection of environment as a significant factor in social life was not one of its claims to be contested widely within the discipline. It was paralleled by the work of Franz Boas and others in anthropology who likewise insisted on the liberation of social inquiry from environmentalist as well as biological theories of cultural differentiation. Environmental determinism lasted longest in geography, but even there it faded under strong criticism from within and without the discipline.

Classical political economy from the outset recognized environmental conditions as determinants of scarcity and cost. It attributed the key phenomenon of land rent to differences in the inherent quality of the soil. Malthusian population theory presented the disparity between limited natural resources (the ability of the land to produce food) and potentially unlimited human wants as a basic condition of social life. The classical labor theory of value, however, tended to promote human activity over nature as the key source of wealth. Environment was demoted to a secondary role in another and more decisive way in neoclassical economics. Natural services were absorbed into the wider stock of capital and deprived of any distinctive qualities vis-à-vis human-produced goods. Natural capital and services were presumed to be perfectly replaceable by non-natural and the possibility of absolute scarcity of vital elements of nature neglected. Market mechanisms would ensure that nonrenewable resources would be depleted at the socially optimal rate and would also ensure that substitutes for them would be devised as necessary. These assumptions were questioned only by fringe schools of thought that had the standing of heresies vis-à-vis the orthodox consensus: theorists who proposed energy rather than monetary measures of wealth and efficiency, conservationists who warned of the exhaustion by waste of key resources not readily replaced by others.

In orthodox Marxist thought, not only the labor theory of value, but also the violent rejection of Malthusian notions of absolute scarcity as ideological fictions and the emphasis on class conflict and on a universal sequence of stages of evolution left environment little room to play a serious role. The chief exception was the much debated concept of distinctive 'hydraulic societies' expounded in the mid-twentieth century by Wittfogel (1957). Developing the earlier notion of the 'Asiatic mode of production,' he proposed that the formation of stable centralized despotisms was favored by the demands of large irrigation and water-control systems in dry climates—the characteristics of the environment thus playing an important role in social outcomes. But the idea only represented such a heresy within Marxism as energy economics did within the neoclassical discipline.

Elsewhere in the social sciences, determinism was for a time replaced by the opposed doctrine of possibilism, prefigured in the work of late nineteenth and early twentieth century French regional geo-

graphers led by Paul Vidal de la Blache and influentially expounded in the 1920s by the historian Febvre (1922). Possibilism pointed to the fact that different societies maintained quite different relations with similar environments as proof that the environment itself never determined any particular way of life. It offered, rather, a wide range of possibilities for habitation and use, some of which any particular society would be inclined to exploit and many of which it would not. In the postwar years, a possibilist approach was one of the many novelties informing the work of a school of historical research centered on the journal *Annales: Economies, Sociétés, Civilisations*. Close study of nature-society relations remained an important endeavor not only in *Annales* history, as it came to be known, but also in the subfield of anthropology and geography known as cultural or human ecology. It too was possibilistic in showing how society-environment relations, especially those of subsistence in nonindustrial settings, could be understood only by study of the characteristics of culture and habitat both. The very strength of environmental research in these precincts, however, only tended to reinforce the notion that environmental differences mattered and continue to matter chiefly for less advanced societies employing primitive technology and engaged in primary production.

That was not the only belief that tended to discourage wider attention to the environment. Another was the fear that taking the environment seriously led easily to environmental determinism and in turn to political implications of a necessarily reactionary sort. The fear, though excessive, gained plausibility both from some of environmentalism's earlier associations and from an easy analogy with biological determinism. According to the natural world any significant role in human affairs seemed to some, given the unevenness of natural patterns across the earth's surface, a step toward legitimating inequalities of power and position. Environmental determinism was most reliably expelled by expelling environment altogether.

It is understandable and by no means unfortunate that there should have been a strong reaction against a doctrine that had shown itself so intellectually barren and empirically untenable as environmental determinism. It is more regrettable that environmental relations of nondeterministic sorts should have come under the same ban. But their neglect was also a predictable result of the way in which academic research and training increasingly came to be organized. Environmental studies of any sort suffered from the deepening institutional and intellectual division of territory between the social and the natural sciences. Part of the price at which the hard-won autonomy of the social sciences came was the disenfranchisement or marginalization of subjects located in their new boundary zones. Part of the price of the increasing specialization of work within them was the increasing difficulty of acquiring an adequate training in both the

natural and the social elements of any research problem. The way in which the social sciences tended to be defined in opposition to the natural split even geography into human and physical and anthropology into cultural/social and physical branches. It was thereby made most difficult for any topic relating the two realms to be studied with any degree of sophistication.

The 1968 *Encyclopedia of the Social Sciences* appeared at a particular low point in social science attention to the biophysical environment, and the entries reflected it. The entry on 'Environmentalism' was a short account, largely historical, of environmental determinism, and the entry on 'Pollution' discussed not chemical contamination of air and water but ritual defilement in the purely cultural sense. Also included were a short piece on 'environment,' chiefly an exercise in definition (albeit a very useful one), and essays on 'conservation,' cultural ecology, and land and water resources. Biographical sketches of a few important figures such as Marsh and Malthus rounded out its treatment of the theme. Taken together, the entries conveyed no sense of the biophysical environment as an important topic for the social sciences.

But events were already taking place outside of the academic world that would again force environmental questions, at least in some form, on their attention. The environmental movement beginning in the 1960s and 1970s expressed a widespread public sense of concern over the impact of human activities on the earth. The list of new fears included ones as varied as forest damage from acid rain, desertification in arid and semi-arid lands, water supply shortages and water pollution, air pollution at various scales, the loss of biodiversity, and climate change at local, regional, and global scales. Activists called for intervention to protect the environment and combat the social forces—be they overpopulation, overconsumption, capitalist greed, socialist mismanagement, or any other—that they saw as responsible for the degradation and fraying of the biosphere.

Closely following the rise of public concern, attention to human-environment relations has re-emerged in the social sciences, but only in the narrow form of study of the human dimensions of human-induced environmental change. For some social scientists, it has been a characteristic and congenial task to examine environmental concern itself as a social movement having social causes, without necessary reference to any truth that the claims that it makes might possess. Such can be a fruitful path of analysis, one that asks how environmental problems are selected by certain groups and actors for attention among many others that are ignored. It is not difficult to show that public concern about many environmental issues substantially outruns understanding of the scientific basis for concern. Thus, the roots of concern may lie less in the objective situation (even if the scientific account of it is accepted as objective) than in other

areas that many researchers, particularly in Western Europe, have sought to identify. A second line of work has been much more visible and on the whole more generously supported by governments and other funding agencies. This form of attention to human–environment relations has largely accepted the idea that a global environmental crisis genuinely exists or threatens and has sought to shed light on its human dimensions: its causes, its consequences, and the ways by which it might be managed or mitigated. This approach, perhaps the dominant one in the US, evidently stems less from the traditions of social science research than from the pressures of external concerns.

Unfortunately, such research has still more often than not been conducted with the tools and within the assumptions and frameworks of the existing social science disciplines and subfields whether appropriate to environment or not. Orthodox social theory developed with little or no reference to environment is, thus, brought to environmental questions and used to recommend policy as if it required no modification to meet them. Yet its inadequacy to deal with many questions without being modified is plain. The long-standing neglect of biophysical issues of scale, scarcity, and irreversibility in economics has been challenged by the emergence of ecological economics, but to date with little apparent impact on the larger field. Sociological, anthropological, and political paradigms developed in other contexts tend to be applied indiscriminately to environmental questions without careful consideration of how applicable they are. The anthropocentrism of the social sciences as a whole makes it difficult if not impossible for them to deal with notions of the rights of nature and inherent value seriously. Most recently, many adherents of postmodernism in the social sciences have had to struggle with the labor of trying to reconcile their reluctance to acknowledge anything as objectively true with their belief that a genuine global environmental crisis exists and must be addressed.

The long separation between the study of society and the study of the earth has hindered the growth of theory indigenous to and appropriate to nature–society issues that does not oversimplify either side of the relation. The natural sciences have been no less reluctant than the social sciences to modify their favored theories and approaches in order to address the full range of links between society and environment. Where they have not ignored the human role, many have tended to fall back on a narrow and reductionist set of social theories to make sense of it. A characteristic example is the currency in natural-science discussions of environmental problems of the concept of ‘carrying capacity,’ the supposed maximum population that an area can support. It is a concept largely rejected as too mechanistic by social scientists who emphasize the culture-bound nature of the assumptions that must be made to define capacity in

particular cases. The view that human overpopulation and overconsumption are the key driving forces of environmental degradation is more widely held in the natural than in the social sciences, whose practitioners, for their part, are sometimes prone to suppose that the capacity of the environment to support life and activities is infinitely flexible or that the only serious limits are social. Many natural scientists also show an affinity for technical solutions to environmental problems—such as carbon sequestration, albedo modification, or a shift to nuclear power as a response to the threats of global climatic change—without adequate consideration of the crucial problems tied up with their social feasibility or public acceptance.

Human–environment relations may now be far more urgently important a research topic than ever, given the possible dimensions of rapid global environmental change and the measures that coping with it might demand. Yet a long period of neglect means that the knowledge base in this area is weak. Little is known about what environmental change might mean for society because little is known about what environment means for society. The present atmosphere of crisis does offer some hope that at last a detailed understanding of human–environment relations will begin to be constructed. Yet an adequate assessment of many environmental issues cannot be achieved from a background only in the natural or social sciences, and it remains to be seen whether the organization of education and research will prove capable of providing the necessary conditions to nurture such work.

Humanistic Geography

Humanistic geography studies people's relationships to nature, space and time, their behavior, feelings and perspectives on environment. Sharing enquiry with other branches of the discipline, its domains of interest overlap strongly with the humanities and social sciences. Its scholarly value and main contribution to society consists in its ability to raise people's levels of awareness about taken-for-granted ways of life and thought, inviting critical reflection on humanity's relationships to the earth.

'Diversity is at the heart of geography—from the varieties in continents and climates to the interrelationships between natural resources and how people live. Diversity is also central to human rights.' Thus, Mary Robinson, UN High Commissioner for Human Rights, addressed delegates at the 29th International

Geographical Congress in Seoul, August 14–18, 2000, upon receipt of the *Earth and Humanity Medal 2000* from the International Geographical Union. She was honored for not only her championing of civil liberties and economic opportunity, but also for proclaiming access to intact and healthy environments as basic human rights. A few weeks later, scholars from all over the world assembled in Rome to explore the potential role of universities in the quest for a 'new humanism.' Renaissance humanism, one speaker recalled, 'set up a new idea of truth as a dynamic statement, not previously defined or constructed, but something to be discovered and then applied ... the joint venture of new scientific discovery with the humanistic approach to mankind's problems enabled the university to nourish innovation and offer a rigorous critique of institutions and social relations' (Bricall 2000). Such 'airing' of university life, he noted, was sadly lacking today. 'Humanistic geography' may have been a twentieth-century invention, but many of its central themes at the dawn of the twenty-first century resonate with centuries-old melodies.

1. Geography and Humanism

Humanists down the centuries have explored the nature of humanity, its passions and powers, while geographers have studied the earth where humans, among many other life forms, make a terrestrial home. For each facet of humanness—rationality or irrationality, faith, emotion, artistic genius, or political prowess—there is a geography: for each geographical interpretation of the inhabited earth there are implicit assumptions about the nature of humanness. To slogans such as Protagoras' 'man is the measure of all things' and Alexander Pope's 'the proper study of mankind is man,' geographers would note that *Homo sapiens* is a terrestrial species, with projects and plans played out in particular environments, even if diverse cultures have created and been inspired by myths and symbols. *Humanus*, literally, means 'earth dweller.'

The term humanism evokes at least four distinct connotations. First, it implies questions regarding the nature of humanness (*humanitas*) with concerns about individuality and sociality, freedom and responsibility, rationality and hedonism, conservatism and creativity. Second, it refers to humanist modes of knowing which oppose scientific reductionism, aiming to elucidate rather than to explain, emphasizing the subjectivity of consciousness and the need for intersubjective dialog. Third, it is expressed in the humanities—fields of learning in the arts, classical literature, and the cultivation of civic virtue. Fourth, it is evident in an enduring concern about the human condition, e.g. in humanitarianism, which has sought to encourage social responsibility and liberal politics. Historically, from whatsoever ideological stance it has emerged,

humanism has included a call for critical reflection on conventional ways of interpreting reality and a plea for integrity and authenticity in everyday life (von Wright 1978, Buttimer 1990).

Humanistic geography also reveals these four lines of concern. What is subsumed under this rubric varies from one country or language tradition to another, the terms 'social,' 'radical,' 'critical' and 'humanistic' often being seen as virtually interchangeable (Buttimer 1974, 1976, Tuan 1976, Relph 1981, Rowntree 1988, Pellegrini 1992, Claval 1999). For some the main goal is still to restore human subjectivity to a field where scientific objectivism has been so dominant, some emphasizing human attitudes and values, others cultural patrimony; some focusing on the aesthetics of landscape and architecture, others on the emotional significance of place in human identity (Ley and Samuels 1978, Buttimer and Seamon 1980). Several also advocate humanitarian concern and engagement in the resolution of social or environmental problems. Virtually all would agree with the formulation of Yi-fu Tuan that 'the humanist's competence lies in interpreting human experience in its ambiguity, ambivalence, and complexity' (Tuan 1976, p. 275). For over three decades humanistic geographers have explored the aesthetics of landscape, issues of memory and myth, moralities and imaginations, and the multifaceted textures of place (Adams et al. 2001). This 'humanist turn' has thus evoked sharper sensitivity to the inextricable connections between thought and context, experience and expertise, and the adequacy of geography to elucidate contemporary reality.

Some have looked askance on these developments as a retreat from problems or as simply a critique of the status quo (Entrikin 1976, Relph 1981). Anti-humanist strains have also been heard from doctrinaire structuralists, and staunch advocates of positivist spatial analysis. In the 1980s many, disillusioned about contradictions in Western legacies, condemned humanism as the arch culprit, a source of *hybris* and vaunting ambition, a myth overdue for dismissal. Postmodernist scenarios of texts reproducing texts in a labyrinth of self-reflecting mirrors precluded assumptions about human intentionality or meaning in lived reality. By the late 1980s there was a growing awareness of the extent to which the entire intellectual heritage of the West had shaped, and been shaped by, the peculiar social history of Western humanity. By century's end there was a notably increased interest in critical emancipatory elements which had previously remained marginal within the profession. These diverse currents pointed to weaknesses in the inherited lore and have opened up new worlds of exploration. And linked to this, there has also been a re-affirmation of geography as fundamental education for mature citizenship, for cross-cultural understanding and for environmentally sustainable ways of life. The 'new humanism' promises to be far more 'geographical' than its predecessors.

An enduring concern of humanistic geography has been the increased level of specialization among knowledge fields. While the narrowing of analytical focus has yielded sharper insight into particular processes, the overall fragmentation of research horizons has seriously diminished the geographer's capacity to deliver comprehensive perspectives on humanity and environment. In a so-called *Magna Carta* for the 'Humanities,' William Caxton (1422–91) insisted that attention be confined to mankind as an object of study in itself, not as part of 'nature,' which was the concern of biology, nor as an object of divine grace, which was the concern of theology. Hence emerged a clear separation of scientific and humanist modes of knowing. The former was to provide analytical guidelines for the analysis and representation of research results, while the latter was to invite discovery and understanding, processes which might not only vary from one individual to another, but also imply elements of emotion, aesthetics, and moral judgment which, strictly speaking, were to be eliminated from the scientist's agenda. At the dawn of the twenty-first century, there are resounding cries for liberation from such institutional dogmatism and inherited meta-discourses which obfuscate and distract attention from the far more tyrannizing meta-discourses of commercially-driven globalization.

An essential quality of humanist discourses in Western scholarly traditions, it could be argued, is a plea for freedom: freedom from bonds of ignorance, fear, oppression or oblivion, freedom to create and to explore new horizons in thought and life (Buttimer 1990). The emergence of a 'humanist' turn within geography during the latter half of the twentieth century might be described as a liberation cry for aspects of thought and experience which had been ignored or suppressed within the practices of previous generations. At the heart of humanist concern at the dawn of a new millennium is the patent failure of well-intentioned scientifically-based attempts to alleviate poverty, inequalities and injustices worldwide. Ironical indeed is the apparent paradox that, as volumes of environmental research have grown, so too has the magnitude of environmental problems. Questions now arise as to whether our taken-for-granted sectorally specialized kinds of science are adequate for elucidating these problems, or whether, in fact, taken-for-granted application of scientific results is part of the problem (Escobar 1997).

The twentieth century ended with a litany of 'post-' and 'anti-'movements in the scholarly world—emphasis placed on elements from which many sought to be free; horizons toward which a humanist spirit would aspire remained unclear. And yet there emerged a resounding chorus proclaiming plurality and diversity. Far from one orthodox brand of geographical knowledge, there are varieties of geographical knowledges—those based on everyday lived experiences, those of women, children, minorities, immigrants and

emigrants, professionals and clients, rich and poor. In fact, many of the major challenges facing humanity and environment today could be redefined in terms of competing, contested or conflicting geographical knowledges.

2. Humanistic Geography

Geography today is recognized as not only a professional field of expertise, an academic discipline, but also a reality of everyday lived experience. Humanistic geographers have consistently promoted attention to everyday geographical experience, not only for individual human persons, but also for the diverse cultural worlds whose home territories are increasingly invaded by globally organized technological and commercial systems. They advocate coresponsible engagement in matters of territorial and social discretion in humanity's modes of dwelling. Illustrations of contemporary themes for research and reflection in humanistic geography include (a) Dwelling, (b) Nature and Culture, (c) Mindscape and Landscape, and (d) Text, Image and Construction of Regional Knowledges.

2.1 Dwelling: Essential Quality of Humanness

Geography is the stuff of everyday experience for all forms of terrestrial life. Mountain and plain, river and lake, woodland and wildlife may be 'explainable' in the categories of natural science, but in reality each cultural group understands nature, space, and time through its own special filters. To survive on planet earth, all creatures develop a geographical sense, a sense of place, space, time, and movement. How to negotiate our diverse geographies is surely one of the enduring challenges of existence, from the politics of empire to the arrangement of one's kitchen, office, and garden. A geographer tells stories of dwelling, and the interplay of mindscapes and landscapes, in terrestrial environments.

The progressive 'humanization' of the earth over the past half-million years, offers fascinating ground for study and reflection (Glacken 1967). Humanity has assumed a dominant role in shaping landscapes, harvesting resources, tipping the natural checks and balances among other life forms, in culturally and technologically diverse ways of life. Each cultural group has devised its own variety of ways in which the bio-physical environment was understood and how humans should relate to it. Some, as in the Judaeo-Christian and Hellenic traditions, have placed humanity above all other life forms and have regarded intellect as the highest manifestation of human spirit. In Hindu and Buddhist traditions, humanity has been regarded as an integral part of cosmic order, recycling, like other life forms, in a continuous process

of reincarnation. Symbolic transformations are quintessentially human projects: the representation of reality in art and artifact, monument and metaphor, science, technology, and national flags. The human body itself has been a universal catalyst for symbol making in many civilizations, most common of which has been the organic analogy of the human person as a whole (body, soul, personality) as a microcosm of the universe.

Human modes of dwelling, with central themes of place and space, home and horizon, memory and identity, remain a primary focus of attention for humanistic geographers (Buttimer and Seamon 1980, Seamon and Mugerauer 1985). Emphasis is placed on the aesthetics and appropriateness of human settlements and the dramatic differences in built environments throughout the world. Humanistic geographers are skeptical of universal generalizations such as those which glorify or demonize humanity. Latecomers anyhow to earth history, some have argued, humans may now be en route toward self-destruction. While acknowledging some grounds for such gloomy prognoses, humanistic geographers continue to probe diverse landscapes, documenting evidence of human ingenuity in adapting lifeways to environment throughout history, and reiterating the perennial challenge of environment and ecology for global humanity today.

2.2 Nature and Culture

Throughout human history nature has constituted the source of inspiration and foundation for cosmology and human identity. Australian Aboriginals revere rocks as dreaming centers and song-lines evoke a sense of on-going creation. The *Upanishads* celebrate the eternal Asvatta (fig tree) and banyan tree, while North American Sioux build their entire cosmology around the sacred cottonwood tree. For East Asian societies, life was seen to emerge from the sacred lotus, and devout Hindus bathe in the sacred waters of the Ganges. Artefactual and cartographic evidence suggests that most cultures have imaged their own place as the center of the world, with horizons varying in shape and extent depending on their livelihoods and travel. The cargo cults of Polynesian islanders re-enact the stories of colonial occupation, Obijwe and Cree have detailed mental maps of trapping lines across the North American Plains—territory viewed by Euro-settlers as a vast undifferentiated arena for conquest by railway, lumber company, or settler (Brody 1981).

Humans everywhere have looked to nature for insight into the secrets of creation, birth and death, meaning and purpose in everyday life. Human inventions such as the domestication of animals and plants, technological innovations in agriculture, transport, and commerce have been construed and defended in

terms of cosmology and value system. The enduring salience of symbolism in shaping contemporary landscapes constitutes a central platform for 'new cultural geography' (Cosgrove and Martins 2000).

For the 350 million so-called indigenous peoples of the earth today, nature and human identity are inseparable. Multinational companies, often in league with national governments, find themselves confronted with a resounding *cri du coeur* from autochthonous populations eager to protect the integrity of their home environments and maintain discretion over minerals, forest, fish, and wildlife in their ancestral lands. The dramatic clash of human interests which characterizes the use of earth resources has at last found its way to public consciousness. The languages within which such clashes are overtly negotiated are characteristically those of technical expertise in the service of governments, corporations or transnational lobbies; the voices of *dwelling*, by people in place, are often ignored. Humanist geographers seek alternative bases on which human discourse about earth resources might be negotiated. Acutely aware of the extent to which scientific and popular notions of 'nature' have been socially constructed and applied in sometimes contradictory ways, they provide catalysts for critical reflection on taken-for-granted policy and programmes.

2.3 *Mindscape and Landscape*

The visible forms of landscape are the texts that geographers read and seek to interpret. To understand the humanized landscape one needs to understand cultural diversity among societies: not only their economies and traditional skills, but also the sense of sacred and profane in their perceptions of nature, space, and time. Successive groups have migrated over time from one area to another bringing their talents, images, hopes and prejudices with them. Characteristically, they try to recreate the new landscape in the image of the past, usually an idealized version of it. Contemporary landscapes have all been formed through the sedimentation of many layers of human occupation.

Among the strongest advocates of the 'humanistic' turn in geography were scholars who already acknowledged the hermeneutic value of landscape interpretation (Meinig 1979). 'Our human landscape,' Pierce Lewis remarked, 'is our unwitting autobiography, and all our cultural warts and blemishes, our ordinary day-to-day qualities are there for anybody who knows how to look for them' (Lewis 1985, p. 13). Landscape interpretation, adopting some of the models of literary criticism, 'read' landscape texts and signs as products in their own right, while also inviting enquiry into culturally varying modes of symbolic transformation in history. Debates over agency versus structure

in the social construction of landscape features became the *sine qua non* preamble to many research ventures of the 1980s and 1990s, as reflected in new scholarly journals such as *Ecumene* and *Géographie et Cultures*.

To communicate insight on the interactions of mindscape and landscape naturally poses critical issues of language, a challenge which geographers share with colleagues in literature, philosophy and art (Pocock 1981). It has surely been on questions of language and power, semiotics and symbolism, that humanistic geographers found challenging moments of interaction with structuralists. Slogans of 'death to the human subject,' short-lived but militant, scoffed at notions of potential human creativity to transcend structural imperatives. The deconstruction of inherited meanings, as suggested in the work of Derrida, could reveal the multiple and conflicting readings that could be made on particular texts. In the 1980's, post-structuralist discourses emphasized the multiplicity of potential interpretations and the undecidability of scientific propositions. In sharp contrast with the previous generation's deeply held convictions about epistemological certainty and images of the world as a mechanical system, many voices of the late 1980s were casting doubt on all scientific claims to objectivity.

2.4 *Text, Image and Construction of Regional Knowledge*

Humanistic geography is concerned not only with ways in which humans, in their everyday lifeworlds, have interpreted their surroundings. It is also concerned with images of the earth projected in academic (scientific) products (Dematteis 1985, Buttner et al. 1999). As with the earth's landscapes, the mindscapes of professional geographers have reflected the cultures and world-views of their sponsors and audiences. Geography's status as an academic discipline has mirrored the fluctuating fortunes of nations and empires, flowering at moments of societal self-confidence, altruism, or expansionary challenge; relaxing in routine operational tasks of housekeeping and inventory, text-book writing, and functionally specialized research in times of stability or depression. And as active participants in a global community of scholars, geographers have also negotiated their practices within the reigning scientific paradigms of particular periods.

Once national ministries of education established geography in university departments, the discipline's agenda became harmonized with that of its major sponsor, the state. To this day, with some notable exceptions, the practice of geography has borne a distinctively national character. From its beginnings as an academic discipline, geography has been valued as training ground for the exploration and conquest of space and resources; for the imposition of order

deemed rational by the conqueror; for the delivery of information on areas, distances, flora and fauna, peoples and cultures, in language categories and narrative frames which could be understandable and useable 'back home.' It is indeed ironic that while most places are subject today to influences which transcend territorial boundaries, the practice of geography is so tightly shaped by national and institutional contexts.

Humanistic geography is interested primarily in examining the geographical knowledges which have been promulgated in various settings. Starting from the accounts of geographers themselves, it examines the story of ideas in practice, the interplay of creativity and context in the practices of various periods, seeking to evaluate the implications of such practices for everyday life and landscape. Such approaches have not been popular, as Yi-fu Tuan warned in the mid-1970s: 'self-knowledge, the prime reward of the humanistic enterprise, has always been suspect in Western culture' (Tuan 1976, p. 276). While little evidence of its popularity in other cultures is available in geographical literature, it is certainly laudable that Yi-fu Tuan, indubitably the most influential writer of humanistic geography, has now shared his own autobiographical reflections on a fascinating, and possibly unique career journey (Tuan 1999). This account should prod readers to think critically about their own career journeys and taken-for-granted perspectives on life and world.

3. Conclusions

Each discovery in humanity's geographical understanding of the world has heralded changes in its self-images, hopes, and fears. The dawn of a new millennium reveals radically revised perspectives on mind-scape and landscape. Geographers have dared to look inwards, exploring cultural differences in environmental perceptions and experience, while colleagues in the humanities dare to look outwards, freely exploring themes such as landscape, identity and place, space and time. Today's world map of power and politics has taken on radically new dimensions due to transformations in technology and trade. The explosion of information and the transcontinental circulation of people, commodities, and ideas raise exciting new possibilities for thought and life. The spatial juxtaposition of culturally diverse peoples should become the springboard for new creativity in politics and social life, rather than problems to be solved by social engineering. Humanistic geography has much to offer by way of cross-cultural and historical evidence of creativity in discovering environmentally appropriate solutions. Gaia's human envelope, the anthroposphere, needs to be understood more as a complex drama than simply as battleground of ecological versus economic rationality; more as *oecumene*, pot-

ential home for humanity, a species which urgently needs to rediscover the art of dwelling.

Much rhetoric has been aired on the Western world's anthropocentric perspectives, critics usually implying alternatives such as the deification of nature, of the social collective, or the reification of ideologies playing out their purposes with humanity and nature. Perhaps the West, far from overestimating *humanus*, has grossly underestimated it. Recovery of the human subject, and recognition of human agency as an integral part of the lived world, the creativity again apparent on peripheral and previously marginalized regions, all betoken fresh potential for humanistic geography today. As a stance on life, humanism welcomes the challenge of discerning the creative potential of individuals and groups to deal with the surface of the earth in responsible and co-responsible ways (von Wright 1978). Nor is human creativity confined to the intellectual sphere; it involves emotion, aesthetics, memory, faith and will. The humanist turn in geography has delivered inspiration to practitioners of physical, economic, cultural and social geography. Its aims are not well served by investing energy on staking claims for becoming a special branch of the field. Humanism should thus more appropriately be considered as a leaven in the dough rather than as a separate loaf in the *smörgåsbord* of geographic endeavor. The emancipatory *élan* recuperable even from our Western traditions could enable geography itself to perform as leaven in the mass of contemporary science and humanities. The Renaissance of humanism calls for an ecumenical rather than a separatist spirit; it calls for excellence in special fields as well as a concern for the whole picture. From our Western corner, perhaps the greatest challenge is that of bridging worlds through dialog and mutual understanding.

A. Buttner

Humboldt, Wilhelm von (1767–1835)

1. Politics

When Wilhelm von Humboldt, born June 22, 1767 at Potsdam, resigned from his office as the Prussian Minister of Constitutional Affairs at the end of 1819, this was a major catastrophe for the political future of Germany. For Humboldt himself it was an act of liberation and a step towards what he regarded as his real vocation, the study of languages, to which he dedicated the rest of his life. Chateaubriand, the French poet and politician, considered this strange scientific activity as the spleen of somebody who had to kill his time as a consequence of the loss of political influence. But it was in fact the achievement of a

philosophical and anthropological quest which had started in Humboldt's youth. Studying the languages of the world was not at all something completely extraneous to his political work. The same motivation which would guide his linguistic work had also governed his political activities: it was a quest for the creative center of the human mind and for the achievement of individual felicity and autonomy within the totality of other individualities.

This is exactly what had created his political difficulties. At the end of his political career, Humboldt had elaborated a project for the constitutional transformation of Prussia: a proposal to establish a constitutional monarchy with a gradually developing representational system. The French Revolution, which he had welcomed as a decisive step in the history of humanity, had failed in Humboldt's eyes because of its rationalistic one-sidedness: the transformations of France had been governed too radically by abstract rational principles and had not taken into account historically grown entities. For Humboldt, the creation of the new should always be the result of a 'synthesis,' of a sympathetic union of two entities which, creating a new entity by their union, maintain their identity (the alternative—and lesser—methods of uniting two entities are 'isolation' and 'incorporation,' the former being only the juxtaposition of the two, the latter the brutal destruction of their integrity through their unity). Humboldt proposed a 'synthesis' of the traditional prerogatives of the monarch and the interests of the economically active classes (with a consideration also for the traditional rights of the nobility), a 'marriage' which would have transformed Prussia eventually into something new, a constitutional monarchy—and which would have had a model function for the rest of Germany. Not only for the inner organization of Prussia, but also for the whole of the area called 'Germany,' Humboldt projected a political structure according to the same principle of a 'synthetical' union: a confederation which would have left quite a lot of autonomy to its members but nevertheless have given important political functions to the whole (like warfare, freedom of movement and free trade within the union—very much like the USA).

But, in 1819, the times were not propitious anymore for reforms and for the creation of new political structures as after the defeat of Prussia by Napoleon which was the beginning of so many happy reforms in Prussia, like the reform of the educational system, the renewal of the municipal administration and the emancipation of the Jews. Now Napoleon was defeated and the old classes were striking back and were not willing to make any concessions to the bourgeoisie, to the memory of the 'people's war' or to the experience of freedom and civil rights imported by the Napoleonic armies. Humboldt was the representative of liberal political reforms, and, as such, he had to disappear—in the time of Austria's Metternich, of Hardenberg and a reactionary king in Prussia.

2. University and Bildung

But if Humboldt did not succeed in realizing his constitutional dreams, he seems to have had an overwhelming success with the establishment of the University of Berlin some years earlier. Humboldt is best and generally known for this activity, which in fact occupied him for little more than a year (from February 1809 to June 1810) and which was only a part of the reorganization of the whole Prussian educational system. Humboldt indeed made the decisive administrative step for the establishment of the University of Berlin. But what was established was only partially Humboldt's University. He planned the university as a state-independent, economically autonomous institution, with an independence that would guarantee the freedom of research and instruction. Therefore, Humboldt requested that the university should be given a donation of land as the economic basis of that autonomy. Instead, the Berlin University was from the very beginning a state establishment which—it is true—set unprecedented standards by the quality of its new faculty, by new forms of teaching, by the unity of research and teaching for professors as well as for students. The concept of the research university was successfully realized. As a state-dependent institution it would forge a well-trained loyal elite for the King of Prussia rather than free citizens of the realm of the spirit.

Humboldt's proposals for the establishment of the Berlin University and the other educational institutions became, however, seminal texts for a pedagogical theory whose central concept was that of *Bildung* (educational and cultural development). Following the convictions of German idealistic philosophy and the classical German poets (Schiller and Goethe), Humboldt wanted human individuals to be given every possible means to develop their physical and intellectual capacities. The educational institutions have to grant access to that formation of the human individual. The main aim of *Bildung* is not the acquisition of professional skills but the unfolding of the highest intellectual and artistic aspirations. Ancient Greece as the absolute summit of human development is the cultural reference of that educational program. The concept of *Bildung* certainly gave an ambitious aim to the educational institutions of Prussia and of Germany as a whole. This concept even served as a justification of otherwise unexplainable investments of the state in intellectual enterprises like the humanities, which have no practical ends. *Bildung* was an enormously successful concept as one of the central values of German identity, giving education a very high position in the value system of the nation. But just as Humboldt's University project was only partially realized in the Prussian University, the idea of *Bildung*—a generous and grandiose idea—did not so much create the (also politically) autonomous and free individuals Humboldt was thinking of, but had

more of a compensatory function: consoling the German bourgeoisie for its nonparticipation in political power. Hence, all that wonderful *Bildung* did not prevent the German catastrophe.

3. Anthropology

The establishment of the University of Berlin and *Bildung* secured Humboldt's place in the pantheon of the German nation. But his main activity and—in the long run—also his most successful intellectual achievement, was his linguistic and philosophical work. In this domain, however, Humboldt is not—as some historiographers tend to think—a founding father of the scientific project of historicocomparative linguistics that is linked to the names of Franz Bopp and Jacob Grimm. Bopp and Grimm invented the principles for a historical reconstruction of the unity of Indo-European, Germanic, Romance, Slavic, and other languages and for the comparison of historically related languages. This was to be the successful—romantic—project of the mainstream linguistics of the nineteenth century. Humboldt is, on the contrary, the founder of an alternative linguistic project, which is more the summary of the linguistic ideas of the Enlightenment: the study of the diversity of the languages of the world. *Verschiedenheit*, or diversity, is the key term of Humboldtian linguistics which was to flourish—at least in part—in the twentieth century, when the historicocomparative paradigm was relieved by synchronical descriptive linguistics.

Humboldt's linguistic project was integrated into a larger 'anthropological' project. 'Anthropology' in the eighteenth century was a term which designated the empirical study of human beings, as opposed to philosophy, which investigates the universal nature of the human race. Humboldt sketched a vast research program for the investigation of the cultural manifestations of humankind. Understanding the creativity of the human mind was the philosophical motive that gave Humboldt's anthropological project its special dynamics. Two events which occurred in his lifetime were decisive for this research into creativity: first, as for any young intellectual of his generation, the French Revolution, the creation of a completely new, enlightened, political organization. Hence, one of his first publications was an article on the first French constitution (1791) and for his friends he wrote a booklength political treatise 'On the limits of the activity of the state' (1792), which was printed only after his death and which became a founding document of political liberalism. The other revolutionary event in Humboldt's lifetime was Goethe. Here again, what fascinated the young intellectuals was the 'genius,' the mystery of an unprecedented creativity. Humboldt lived in Jena, as a friend of Schiller's, in close contact with Goethe. He studied Immanuel

Kant, whose philosophy was to become the framework of his own theoretical developments. Humboldt's work is centered around the Kantian concept of imagination, *Einbildungskraft*, the faculty of the human mind that is responsible for the creation of the new.

Since imagination as the mediation between the senses and the intellect had remained rather mysterious in Kant's philosophy, Humboldt set out to find its roots. He discovered them in the difference between the sexes. The opposition of the male and the female in nature is the very basis of every new creation, not only of physical generation (*Erzeugung*) but also of the most 'sublime creature' of the imagination: thought. The loving embrace of the female and the male generates new living beings in the physical as well as in the intellectual world. Kant was shocked by Humboldt's somewhat pre-Freudian interpretation of his philosophy. But despite Kant's criticism, sexual union, 'matrimony' (*Vermählung*), love, would be the structural model for everything Humboldt set out to investigate: art, politics, education, and language. Just as dialectics is the fundamental figure of thought in Hegel, the erotic encounter is the basic structure of Humboldt's thought.

After his reflections on the anthropological roots of creativity, Humboldt wrote a book on Goethe (1798) which contains a very modern theory of aesthetics: art is not only a creation of the artist's imagination but also a (language-like) communicative event between the producer of the work of art and the observers, the readers, the listeners who recreate the work of art in their act of reception and thereby accomplish the creative process.

4. Language

While still in Jena, Humboldt wrote his first reflections on language: 'On thinking and speaking' (1795–6), a short sketch which already contained the main features of his language theory. Humboldt's sojourn in France and in Spain (1797–1801) would be decisive for his making language the very center of his intellectual endeavours. In Paris, he discussed philosophical issues with the *Idéologues*, in whose philosophy language played a crucial role, and here and in his journey to the Basque Country, he encountered the Basque language whose profoundly divergent structural properties intrigued Humboldt. Later, his brother Alexander would bring linguistic material from America, and in Rome Humboldt had access to the linguistic materials of the Jesuits (Lorenzo Hervás). For years, the Amerindian languages were Humboldt's empirical linguistic objects before he turned to the Malayopolynesian languages to which his main—posthumous—work *On the Kavi Language on the Island of Java* (1836–9) is devoted. The introductory volume of that book, *The Diversity of the Human Language-*

Structure, completed before his death on April 8, 1835 in Tegel (near Berlin), is Humboldt's major work. With language, Humboldt arrived at the very heart of his general quest for the creation of the new by that mysterious Kantian faculty of *Einbildungskraft*.

Language is not just a means for the communication of thought, it is the very creation of thought. According to the Kantian system, the senses and the intellect create the concept through their synthesis. But for Humboldt, the concept is not created independently of the word: word and concept form an undissoluble synthetical unity; thought is created as sound. Language is the 'formative organ of thought' (*das bildende Organ des Gedanken*, 1903–36, VII, p. 53), 'labor of the mind' (*Arbeit des Geistes*, 1903–36, VII, p. 46). Like art, language (thought-sound) also needs the dimension of the other: it must be heard and understood. Language as a cognitive activity reckons with the other, language is thought in the dimension of the other: *Mitdenken*, or cocognition. But surpassing art, language is a reciprocal creative activity: the hearer becomes speaker, 'the word formed by me resounds from the mouth of the other' (1903–36, VII, p. 56). This ultimate reciprocity is the completion of the linguistic syntheses. The duality of I and Thou is the 'fundamental type' of language.

Humboldt discovered that language is actually at the center of the Kantian system. Humboldt's language philosophy was a linguistic turn of transcendental philosophy. Since Bacon's discovery of the *idola fori*, European philosophy had become gradually aware of the fact that language is not just a device for the communication of thought but first and foremost a cognitive activity. This insight finds a coherent post-Kantian formulation in Humboldt.

The second important moment of that philosophy of language is the insight that the formation of thought, the linguistic 'transformation of the world into the property of the mind' (1903–36, IV, p. 420), always proceeds according to the special ways of historically particular communities, that is, according to particular languages. There is no such thing as language in general, language comes in languages. Thought generated by language, hence, is not uniform and universal but historically and culturally fragmented in different 'worldviews' (*Weltansichten*). The task of language, the generation of thought, is universal, but that task is realized in thousands of different ways in the different languages of humankind.

Now the new—or Leibnizian—moment of that insight is its positive interpretation: from Bacon onwards, philosophy has lamented over the particularity of worldviews in the different languages and wanted to get rid of those 'prejudices'; the semantics of natural languages is like 'a mist before our eyes' (Locke) which philosophical enlightenment must discard. Only Leibniz gave an optimistic twist to the discovery of the linguistically generated diversity of thought when he envisaged a study of all the languages

of the world in order to know the ‘marvellous variety of the operations of our mind.’ Herder took that idea from Leibniz, and Humboldt not only integrated it into the Kantian framework but also developed a huge program of descriptive linguistics.

5. Comparative Study of Languages

All the languages of the world were to be described according to what Humboldt calls their ‘inner coherence’ (*innerer Zusammenhang*), their particular structure. The languages of the world had mostly been grasped according to the traditional categories of Greek and Latin grammar. But the structural properties of a language can only be captured through its own categories. Humboldt envisaged an encyclopedia of the languages of the world, a new *Mithridates*. He started a whole series of descriptive works on different languages of the world of which only the *Mexican Grammar* (Humboldt 1994) has been published up to now. A second kind of structural studies aimed at a revised form of general grammar (which was also based on the Greco-Latin grammar): comparative investigations of linguistic categories throughout the languages of the world. Humboldt’s article on the dual (1827) is an example of that research. After the completion of these structural descriptions, research into the parental relationships of languages (genealogy) or into structural similarities among languages (typology, classification) can be undertaken.

What is often considered as Humboldt’s main contribution to linguistics, the so-called Humboldtian ‘typology,’ is neither central to his linguistic aims nor did Humboldt propose typology as an alternative to the dominant linguistic school, that is, to the historicocomparative studies of languages. On the contrary, in his last book, his unfinished work on Kavi, Humboldt eventually envisaged a comparative study of the Malayo-Polynesian languages which would follow Grimm’s and Bopp’s work on the Germanic and Indo-European languages. Humboldtian typology is a linguistic myth created by superficial readings of his texts. Humboldt was very sceptical about the classifications of the Schlegels, and eventually he explicitly refuted the legitimization of classifying languages, since languages are individuals and should be described as such.

The summit or keystone of Humboldtian linguistics is therefore the investigation of the ‘character’ of languages. This is just the opposite of classification and typology, of grouping similar entities together. It is a tentative attempt to grasp the very individuality of each individual language. Humboldt was not sure whether ‘characterization’ was still a scientific task. But whatever it is, it has to be tackled since it is the ultimate aim of linguistics to see how the human mind uses the instruments it has created, to investigate the very end of language: speech and discourse. The—necessary—structural description of a language is only

‘comparable to its dead skeleton’ (1903–36, VI, p. 147), the life of a language is discourse (*verbundene Rede*), a life giving ‘character’ to that language. Therefore, only languages that have a multifaceted literature yield the possibility of being described as having characters.

Nearly two centuries after Humboldt’s sketch of a huge linguistic program, it can be said that the structural description of human languages he envisaged was the main task and achievement of linguistics in the twentieth century. It is not by chance that Humboldt is present in the seminal theoreticians of modern linguistics (Saussure (see *Saussure, Ferdinand de (1857–1913)*), Bloomfield (see *Bloomfield, Leonard (1887–1949)*), Hjelmslev). The nineteenth century was not very Humboldtian, with its emphasis on diachronical research as well as in its naturalistic research methods. Humboldt’s ‘keystone’ of linguistics, the ‘characterization’ of languages, was attempted by some literary-minded linguists (e.g., Vossler), but was discredited by nationalistic and ideological interpretations of linguistic structures. Since the structural descriptions of the languages of the world have now virtually been completed, it is not astonishing that in actual linguistics typological attempts are again very important. The so-called Humboldtian typology is often quoted in that context. But it is—even more than the other famous Humboldtian invention, ‘Humboldt’s University’—rather a myth than a creature of the author. Without any foundation in Humboldt’s work is also the widespread conviction that Humboldt discovered fundamental principles of Chomskyan linguistics, like the ‘infinite use of finite means.’ Humboldtian linguistics as a whole is in direct opposition to that kind of linguistic research: it is a hermeneutical research into the cultural diversity of human languages in historical communities, preferentially through (literary) discourse, and not a naturalistic investigation of the structure of the universal human mind considered as a universal grammar.

J. Trabant

Hume, David (1711–76)

David Hume, a leading figure in the Scottish Enlightenment, contributed significantly to the disciplines of psychology, history, political science, and economics—as well as to more theoretical discussions in ethics, aesthetics, epistemology, and philosophy of religion. He was a controversial figure in his own day because of his criticisms of both natural and revealed religion and because of the political opinions he was thought to express in his *History*. His skeptical arguments concerning induction are still discussed by philosophers interested in probability theory, and his account of the foundations of morality enters into current disputes about the source of moral obligation.

1. Life and Writings

Hume was born in Edinburgh on April 26, 1711. The family was of genteel but of modest means: His father, Joseph Home, an advocate and member of the minor

gentry of Scotland, died when he was 2 years old and his mother Katherine, who never remarried, brought up him, his sister, and older brother on their small estate of Ninewells in the Scottish Borders. Hume probably began taking classes at Edinburgh University in 1721 where he studied the Latin classics, moral philosophy, mathematics, natural philosophy, and possibly history. There is no record of his ever having taken a degree (which was not unusual at this period) and, in a short autobiography written just before his death, he notes that, while his family intended that he study law, his own interests were in ‘Philosophy and general Learning.’ He probably began planning his first philosophical work, *A Treatise of Human Nature*, in 1729 when he was about 18 years old.

Suffering from complaints which we would now consider to be largely psychosomatic, Hume decided in 1734 that he needed to pursue a more active life; he left Scotland for Bristol where he worked briefly for a merchant. After a few months he went to France, where he spent the next 3 years writing and studying. He went first to Reims, but soon settled at La Fleche in Anjou, in the vicinity of the Jesuit College where, more than 100 years earlier, René Descartes had been a student. The first two books of his *Treatise of Human Nature* (‘Of the Understanding’ and ‘Of the Passions’) were published in 1739, about a year after he returned to England, and the third (‘Of Morals’) was published in 1740 after he returned to Scotland. The *Treatise*, from which he hoped to gain literary fame, ‘fell dead-born from press,’ though it is taken by modern scholars as an important and seminal work. It was followed in 1741–2 by his very successful *Essays, Moral and Political* which were written to reach a more popular audience.

Hume unsuccessfully applied for university chairs at Edinburgh University in 1744–5 and at the University of Glasgow in 1751–2, where he had strong support from his friends (among them William Cullen) but was opposed by many of the clergy, who accused him of irreligion. While his *Treatise* contained no explicit discussions of religion, this was changed in the rewriting of its first book, which was published in 1748 under the name of *Philosophical Essays Concerning Human Understanding*. It contained his famous argument against rational belief in testimony for miracles, as well as the basis for his later attack on the design argument for the existence of God. Continuing to search for a career, Hume spent some time during the 1740s as secretary to General St. Clair and participated in a rather futile attack in 1746 on the coast of Brittany during the War of Austrian Succession. In 1747 he traveled with the General as his aide-de-camp on a Military embassy to the capitals of Britain’s allies, Austria and Sardinia.

In 1749, Hume returned once more to Scotland and began an immensely productive decade. In 1751 he moved to Edinburgh from Ninewells; he was to live

there much of the rest of his life as a leading figure of the Scottish Enlightenment. Hume was elected secretary of the Philosophical Society of Edinburgh—a group devoted to the study of science and technology. (He was later, in 1762, to present to the Society Benjamin Franklin’s paper describing the use of lightning rods.) In 1751 he also published his *Enquiry Concerning the Principles of Morals*, a reworking of the third book of his *Treatise of Human Nature*. His correspondence at this time also indicates that he had already written substantial portions of his posthumously published *Dialogues Concerning Natural Religion*. In 1752 Hume published his popular *Political Discourses* and began work on what was to become his most successful piece of writing, namely his multivolume *History of England*. He became Keeper of the Advocates’ Library (later incorporated into the National Library of Scotland) in January, which gave him direct access to a large collection of historical sources. The first volume of the *History*, concerned with the reigns of James I and Charles I, was published in 1754 and the remaining volumes between 1756 and 1761. In 1758, Hume published *Four Dissertations*, which included his *Natural History of Religion*, *Of the Passions*, *Of Tragedy*, and *Of the Standard of Taste*.

In 1763, after the end of Seven Years War, Hume was invited to go to France as Secretary to the Ambassador, Lord Hertford. In France, where his writings were admired, he was lionized both by the mighty and intellectuals. He developed close relations with many of the philosophes, especially d’Alembert. Hume was *Charge d’affaires* for about 4 months in 1765 after Hertford left Paris. He returned to England at the beginning of 1766 bringing with him Jean-Jacques Rousseau, on the advice of Parisian friends; Rousseau sought refuge in England from persecution on the Continent. Hume and other British friends procured a pension for Rousseau from the King. However, this whole affair turned into a disaster as a result of Rousseau’s paranoia. Rousseau denounced Hume as his enemy. Hume’s defense of his own conduct was published by d’Alembert and Suard in Paris in October of 1766. Hume’s last public appointment was as an Under Secretary of State from February 1767 to January 1768. He retired to Edinburgh where he continued to publish new editions of his works and died on August 25, 1776 as Britain’s foremost man of letters.

2. General Philosophical and Psychological Principles

Philosophers still disagree about the nature of Hume’s basic philosophical principles. It is agreed that he was a skeptic who argued throughout his writings that our basic commerce with the natural and social worlds is not founded on reason, but on the non-rational

processes of the imagination and passions. What is in dispute is the nature of his scepticism, and the degree to which he sought to radically alter the conceptions of the natural and social worlds as conceived by his contemporaries (Read and Richmond 2000). While early twentieth-century philosophers saw Hume as an early forerunner of positivism, this interpretation has been challenged by recent scholars (Wright 1983). The question concerning Hume’s adoption of conservative or liberal principles has also been a subject of dispute—though he claimed neutrality in discussing the political debates of his own day (Livingston 1998, Stewart 1992).

In his *Treatise of Human Nature* Hume set out to found all the other sciences on the science of human nature, and stressed that this science itself must be based on experiment and observation. Hume’s foundational science of human nature was a science of the human mind. The basic psychological principle that he sought to establish in his *Treatise* was that of the association of ideas and impressions through resemblance, contiguity in space and time, and causality. He followed Locke in rejecting innatism and holding that the elemental building blocks of our ideas must be based on experience—the impressions of external and internal experience; however, he argued against Locke that these sources cannot supply us with our common sense or scientific conceptions of reality. Rather, the latter arise through irrational processes of the imagination and habits, based on the principles of association.

In a famous analysis, Hume argued that the principle of scientific induction by which we infer from past instances to future ones is based on custom and habit, and is not susceptible to rational justification. He denied that we have any understanding of the principles by which the natural world operates; at the same time, he argued that we naturally believe in causation between successive events that we observe to be constantly conjoined.

Hume held that we have as much reason to believe in necessary causes in the human as in the physical world. He argued that ‘the conjunction between motives and voluntary actions is as regular and uniform, as that between the cause and effect in any part of nature’ (1999, p. 154). At the beginning of his *Treatise of Human Nature* he set out to apply the experimental method to man, as it had been applied by Galileo, Newton, and others in the previous century to physics. At the same time, he believed that there is a problem in carrying out controlled experiments in the human sciences, because ‘reflection and premeditation’ would disturb the natural processes of the mind (2000, p. 6). He proposed to base his experiments on an observation of human behavior as it manifests itself ‘in the common course of the world, by men’s behaviour in company, in affairs, and in their pleasures.’ While much of his data throughout his writings is taken from history, in Book 2 of the

Treatise, Hume made a series of observations of contemporary social behavior, testing his hypotheses concerning the causes of the passions of pride, shame, love, and hatred. He asked his reader to do thought experiments in which the antecedent circumstances were varied and the resulting passions were predicted. He regarded the subjects which we today call sociology and psychology as closely intertwined.

3. Historiography, Economics, and Politics

Hume was both a philosopher of history and a philosophical historian. He both articulated and applied principles for the assessment of historical sources. These principles are carefully laid out in his essay *Of Miracles* where he discusses the criteria we ought to use to judge the reliability of witnesses, as well as the need to balance those results against the intrinsic likelihood of the occurrence of an event (1999, p. 169ff). Following discussions of probability in John Locke and other early modern writers (Stewart in Stewart and Wright 1994, p. 171ff), he formulated criteria for the reliability of written or oral testimony: these included considerations such as consistency with other reports of the event, the determination of the character and expertise of the witnesses, the number of witnesses, and the self-interest of the witnesses in convincing others of the truth of their accounts. Hume held that we need to balance these considerations of the reliability of testimony against the absolute likelihood of the occurrence of a miracle. He held that in identifying an event as a miracle (i.e., a violation of a law of nature) we are already committed to the view that it has a 'proof' against its very occurrence. This claim is based on his argument that the only evidence we have for laws of nature is past regularity. He concludes that in the case of miracle reports the witnesses would have to be absolutely unimpeachable—a state of affairs that has never obtained. More generally, Hume argues that we must balance the testimony given by historical witnesses against the probability of the occurrence of any event. Thus, in his essay *Of the Populousness of Ancient Nations*, in *Essays Moral, Political and Literary* (1987, p. 377ff), he denies the claims of his ancient sources concerning enormous populations and armies of the ancient world. He argues, mainly on economic grounds, that the ancient nations, unlike modern ones, could not have supported such high populations as ancient writers claimed (D. Wootten, in Norton 1993, p. 281ff). In his *History of England*, Hume frequently appealed to general principles of human nature—those which he believed to be established by the newly emerging human sciences—to evaluate the credibility of his historical sources.

Hume is an important forerunner of classical economic theory. He argued that economic forces influence political structures, and that the development

of modern liberty and government by law had been due to the development of trade and industry. Indeed, in the *Wealth of Nations*, Adam Smith states that Hume was the first writer to reverse the accepted view that political liberty precedes economic development. Hume saw in the rise of the merchants and tradesmen a check to the despotism that existed in premodern society. He argued that it was in the interest of these classes to live by equal laws and to limit the power of the aristocracy and the monarch. His analysis was based not only on his study of the rise of parliament in the early seventeenth century that led to the English civil war, but also in comparisons of modern European society generally with that of the ancient and medieval worlds. While Hume accepted James Harrington's social determinist view of the development of modern society, his originality lay in his postulation of the commercialism as a key factor in limiting the absolute power of the monarch (D. Wootten, in Norton 1993, p. 281ff).

Hume regarded man's economic behavior as deeply rooted in his psychological makeup. He argued that there are three factors that constitute human happiness—action, pleasure, and indolence (*Of the Refinement of the Arts*, in *Essays Moral, Political and Literary* 1987, p. 268ff). He regarded industry as a key to the leading of a balanced life in which pleasure and indolence follow naturally after a period of engaging activity. But, above all, he claimed that there is no pleasure that feeds on itself so much as the desire of the merchant to see his fortune grow. The habit of industry stimulated by this desire creates a frugality that does not naturally exist in an agrarian society based on inherited wealth. The love of gain which marks the activity of the tradesman and merchant results in large sums of money which can be lent at interest to stimulate further economic growth (*Of Interest*, in *Essays Moral, Political and Literary* 1987, p. 301). Low interest rates will be maintained by continuing increase in wealth.

Hume also argued that 'the encrease and consumption of all the commodities, which serve the ornament and pleasure of life, are advantageous to society' (*Of the Refinement of the Arts*, in *Essays Moral, Political and Literary* 1987, p. 272) and that a consumer society encourages the development of hard-working persons whose labor can be turned to the service of the state in times of national need. Key to his analysis is the idea that habits of hard work motivated by self-interest strengthen the nation-state. Developing the ideas of Bernard Mandeville, Hume argued against those in his day who complained that wealth and self-indulgence of the individual enfeeble both the individual and the society as a whole.

While Hume argued that 'Politics may be reduced to a Science' (1987, p. 14ff), he was skeptical about the ability of theorists in his own day to arrive at more than a few general principles of political behavior that would always apply (*Of Civil Liberty*, in *Essays Moral*,

Political and Literary 1987, p. 87ff). Certainly, he thought that history has taught us some general political principles concerning the different political behaviors of men under the different forms of government such as monarchy, aristocracy, and democracy. For example, from the ancient world we have learned that nonrepresentative democracy results in constant ‘tumult and sedition.’ However, he also argued that, given the relative newness of civilization, and the potential effects of ‘education, customs, or principles’ on human beings, it is impossible to predict how political behavior might evolve under circumstances which have not yet existed. He noted that among a number of other false generalizations, Machiavelli had concluded that if a prince relies on a single advisor that advisor would overthrow his master. Hume acknowledged that the evidence of ancient history, as well as that of ‘the little disorderly principalities of Italy’ of Machiavelli’s own day, encouraged such a generalization; but he pointed out that it had been proved false by the experience of European hereditary monarchies of the seventeenth and eighteenth centuries. In general, while Hume thought that while there were a few generalizations that could be relied on in the science of politics, a cautious scholar needed to put principles forward as mere hypotheses to be modified by future circumstances.

Hume argued that political institutions evolve slowly, and that a necessary condition for civil liberty, namely the balance of power between parliament and the monarch, is the result of complex historical factors; liberty, he believed, is always under the threat of disappearing if one side or the other develops too much power. This caution, and his fear of the mob, made him a profoundly conservative thinker, especially toward the end of his life.

Hunger and Eating, Neural Basis of

Eating is a familiar behavior. In humans, it is strongly influenced by cultural, social, and experiential factors. Consequently, eating has been a subject of considerable interest to social and behavioral scientists. In mammals, including humans, food intake is also a regulatory behavior with the primary function of supporting the continuous energy demands of body tissues. When considered from this perspective, food intake is influenced by hunger, satiety, and the biologic mechanisms that couple eating with internal caloric supplies and a stable body weight. This article discusses the signals that are important in enabling the central nervous system to control food intake, and also describes mechanisms thought to integrate these signals.

1. Historical Perspective

Biologic and behavioral studies on the control of appetite and satiety have shifted their focus markedly during the past three decades. The earlier preoccupation with the ‘dual center’ model, whereby food intake was controlled by a lateral hypothalamic feeding center and a medial hypothalamic satiety center, was based largely on investigations in which the putative centers were destroyed by stereotaxic electrolytic lesions (Stellar 1954). This once-dominant idea has now been discarded by most investigators in light of subsequent observations that have led to reinterpretation of the initial results. Specifically, the prolonged period in which animals do not eat after lateral hypothalamic lesions has been reproduced by destroying the dopaminergic neurons that ascend through the diencephalon; this aphagia and other related behavioral impairments appear to reflect a

decrease in cerebral arousal that precludes all voluntary behaviors, not just feeding (Stricker and Zigmond 1976). Moreover, the syndrome of over-eating and obesity after medial hypothalamic lesions seems to derive primarily from the greatly increased level of insulin in the circulation associated with a decrease in sympathetic neural tone, as a result of which ingested calories are rapidly and preferentially stored via lipogenesis rather than being used gradually for ongoing metabolic demands (Friedman and Stricker 1976, Powley 1977).

More recent studies have emphasized metabolic and humoral factors in peripheral organs, in addition to the brain. An increasing number of investigations have related food intake to the functions of the stomach, liver, and adipose tissue, and have suggested an important role of peptide hormones, especially insulin, cholecystokinin (CCK), and leptin, in the control of food intake. In considering these issues, most contemporary investigators have abandoned the traditional depletion-repletion model, whereby a deficiency of caloric nutrients somehow triggers an appetite for food, the ingestion of which then leads to nutrient repletion and satiation. It is now clear that there are no true shortages of metabolic fuels under normal physiologic conditions. Instead, the key variable in controlling food intake seems to be the alteration in the source of the metabolic fuels used during each of the two phases of caloric homeostasis: during the absorptive phase metabolic fuels are supplied from recently consumed food that still is in the alimentary canal and being assimilated, whereas in the post-absorptive phase metabolic fuels are generated from accumulated triglyceride, glycogen, and protein stores derived from food consumed more remotely in time. Thus, according to this perspective the shift from satiety to hunger is not associated with an absolute metabolic deficit, but instead occurs when animals enter the postabsorptive state and must mobilize calories from tissue stores in order to maintain caloric homeostasis. Moreover, eating does not correct a true deficit or restore some aspect of tissue function to normal; rather, it simply re-establishes the pattern of an ample supply of usable calories from the gastrointestinal tract instead of from stores in adipose tissue, liver, or muscle (Woods and Stricker 1999).

2. Satiety Signals

Because the cells of animals cannot long survive depletion of calories, hunger cannot result from cellular nutrient shortages. Instead, the sensation of hunger apparently does not need to be stimulated but is always present, and animals are constantly stimulated to eat unless they have just eaten, in which case the inhibitory effects of satiety generated from the previous meal are still operative. In support of this

perspective are laboratory findings that (a) experimenters cannot easily precipitate eating in satiated rats but can do many things to stop eating by hungry rats, (b) the size of spontaneous meals eaten by laboratory rats is unpredictable, but however much the animals eat in a given meal, meal size predicts how long they wait until they eat again, and (c) food deprivation does not cause a shortage of caloric nutrients in the circulation. The point here is that food intake appears to be initiated by the gradual disappearance of inhibitory satiety stimuli that were generated by the previous meal, not by the gradual increase in an excitatory hunger stimulus (LeMagnen 1985).

2.1 Gastric Distension

Several signals appear to stimulate satiety after a meal. One results from gastric distension, detected by stretch receptors on the walls of the stomach; the greater the distension, the greater the inhibition of eating (McHugh and Moran 1985). This afferent signal projects to the caudal brainstem via the gastric branch of the vagus nerve; as expected, animals eat unusually large meals when the gastric vagus is cut or its projection sites in the brain are destroyed. Experiments in rats have revealed that an intestinal hormone secreted during the meal, CCK, potentiates the gastric vagal signal and produces a heightened sensation of satiety related to gastric distension. This signal is related to the volume of the gastric contents, not its nutrient contents, because there are no known detectors of calories in the stomach. Drugs that acutely block CCK receptors increase food intake during a meal, as if the animal were less aware of gastric distension signals (Smith and Gibbs 1992).

2.2 Ingestion of Calories

The ingestion of calories, detected in the liver and possibly in the intestines, provides a second satiety signal, which is sent to the brainstem by another branch of the vagus nerve. This stimulus appears to develop only in the presence of insulin, a pancreatic hormone secreted when food is consumed. Thus, satiety normally is not lost as the stomach empties because the gastric signal related to distension is replaced by the postgastric signal related to caloric delivery (except in animals with insulin-deficient diabetes mellitus).

2.3 Thirst and Nausea

Two other meal-related signals also are known to be potent inhibitors of food intake. One is thirst,

resulting, for example, from the presence of relatively large amounts of salt in the food. The other is nausea, which might result from the inadvertent intake of toxins in food. However, these two variables are not relevant to most meals. Receptors that detect dietary salt have been located in the hepatic portal vein, which receives ingested food soon after it has been absorbed from the intestines. Receptors for circulating toxins are located in the area postrema in the brainstem. These two signals, together with gastric distension, provide three noncaloric stimuli that have marked inhibitory effects on food intake (Stricker and Verbalis 1991).

2.4 Body Weight

The influence of body weight on food intake must also be included in any consideration of satiety signals because food intake and body weight have been shown to be closely related. Thus, following a period of food deprivation, food intake is increased until the lost body weight is restored. Similarly, following a period in which food has been consumed in excess, food intake is diminished until the body weight that has been gained is lost.

Changes in body weight largely reflect changes in the storage of calories in adipose tissue. These stores are diminished during food deprivation to provide the calories needed for cellular function, and they are replenished when food intake resumes. Thus, as ingested calories are siphoned off to the adipose tissue, their effects on the liver are diminished, thereby reducing the duration of this postgastric satiety signal. In addition, food empties from the stomach more rapidly, thereby reducing the duration of gastric satiety. The opposite effects occur when calorie stores in adipose tissue have been augmented during a period of excessive food intake; both gastric and postgastric satiety signals are prolonged because the rate at which calories are stored in the swollen adipocytes is decreased (Stricker 1984).

2.5 Leptin

Aside from this indirect influence of body weight on food intake, in recent years a direct inhibitory signal to the brain from adipose tissue has been discovered. This satiety stimulus is a blood-borne protein, leptin, that is secreted from adipose tissue in proportion to adipocyte size; the fatter the animal, the more leptin is secreted and the less inclination the animal has to eat. Leptin receptors have been found in the basal hypothalamus, and when they are stimulated food intake is reduced (Woods et al. 1998).

The discovery of leptin illuminates genetic obesity in two strains of mice. Mice of one strain are born with

leptin receptors in their brain but without the capacity to synthesize leptin; mice of the other strain are born without leptin receptors in their brain but with the capacity to synthesize leptin. As might be expected, an intravenous infusion of leptin reduces food intake in the first strain but not in the second.

3. Central Neural Systems

Food intake is a simple behavior influenced by a very complex array of stimuli and situational variables, the details of which remain to be fully illuminated. However, it is already clear that there are many levels at which the central nervous system exerts control over eating. For example, the spinal cord and brainstem influence all aspects of caloric homeostasis via the autonomic nervous system. The hypothalamus and limbic forebrain receive diverse signals related to the food being eaten and the degree of body adiposity, and integrate them with information about the taste of the food, the memory of that food and previous eating opportunities, competing motivations, and other aspects of the environment. Among the numerous neural controls of food intake, those located in the brainstem and hypothalamus are perhaps the best known, so this section will focus on these two brain areas.

3.1 Brainstem

Considerable evidence has accumulated that some control of food intake can be exerted by the brainstem. For example, it is well established that the nucleus of the solitary tract and the adjacent area postrema in the brainstem receive sensory fibers from gustatory receptors in the mouth and throat as well as afferent information from the stomach, intestines, and liver. Thus, these linked brainstem sites likely are the first locus at which relevant sensory input from the viscera is integrated with taste sensations in the central control of food intake. Other evidence derives from investigations of the decerebrate rat, in which all axonal connections between the caudal brainstem and the forebrain are severed at the midcollicular level in the midbrain (Grill and Kaplan 1990). The animal cannot seek food or initiate spontaneous meals but, like intact animals, it will reflexively swallow liquid food put directly into its mouth. Thus, when investigators deliver sucrose solution through an oral fistula, the decerebrate rat will swallow the sweet fluid, provided its stomach is empty, as after a period of food deprivation. However, it will not swallow water or saline when deprived of food and it will no longer swallow sucrose solution (but instead lets the administered fluid passively drip from its mouth) when its stomach is full, or after having received a systemic injection of CCK. Hence, sufficient control of food

intake for such appropriate responses exists entirely within the caudal brainstem, although decerebrate animals clearly are incapable of receiving input from forebrain sites that could modify their intake based upon learning or other experience.

Recent experimental observations provide additional support for an important role of the brainstem in the control of meal size. When the area postrema is ablated, rats eat much larger meals than normal, although total daily food intake is normal; that is, they compensate for their large meals by eating less frequently, indicating that long-term controls of food intake are not impaired. Similar effects are obtained in rats pretreated with capsaicin, a neurotoxin that destroys (among other things) most gastric afferent vagal axons and thereby eliminates the food intake-reducing effects of CCK, and therefore is assumed to damage the signal of gastric distension.

The food-related sensory information that enters the brainstem is relayed along prominent neural projections to the hypothalamus, amygdala, and other portions of the limbic system, as well as to the thalamus and gustatory cortex. Reciprocal neural connections to the brainstem from these rostral sites allow cognitive functions and emotions to influence the control of eating. Linked elements participate in the central control of the gastrointestinal tract, the liver, and autonomic function generally.

3.2 Hypothalamus

Complementing these controls of meal size are the influence on meal frequency exerted by body weight. As mentioned, changes in body fat stores are reflected in the levels of leptin in the circulation. Receptors for leptin are concentrated in the *arcuate nucleus*, which is located in the ventrobasal portion of the hypothalamus. Receptors actually have been associated with two different types of neurons in the arcuate nucleus. One, located in the medial arcuate nucleus, uses *neuropeptide Y* (NPY) as a neurotransmitter. These cells are of interest because it is well-established that injection of NPY into the brain of rats evokes eating, and that chronic infusion of NPY into the brain leads to obesity. Furthermore, axons of NPY-synthesizing neurons project from the hypothalamic arcuate nucleus to the same focal site in the lateral hypothalamus at which eating is elicited by direct administration of NPY. Food deprivation stimulates activity in these NPY-containing neurons, whereas obesity or systemic administration of leptin depress their activity (Woods et al. 1998).

The other group of cells, located in the lateral arcuate nucleus, contain pro-opiomelanocortin (POMC). Those cells also have leptin receptors but, unlike the NPY-containing cells, the POMC-containing cells increase their activity when stimulated by leptin. The POMC-containing neurons use α -melan-

ocyte stimulating hormone (α -MSH) as a neurotransmitter, and activate melanocortin receptors on lateral hypothalamic cells to decrease their activity and thereby inhibit eating. As might be expected, food deprivation decreases activity in the POMC-containing neurons, whereas their activity is elevated when rats are obese and circulating leptin levels are high. In short, there is a dual control by the arcuate nucleus over lateral hypothalamic activity and its control of food intake, one neural input (NPY) stimulating feeding and the other (α -MSH) inhibiting it; this influence is normally stimulated by alterations in blood-borne leptin reflecting changes in body adiposity (Elmqvist et al. 1999).

The noncaloric signals (i.e., gastric distension, thirst, nausea) all have been shown to stimulate oxytocinergic neurons in the paraventricular nucleus of the hypothalamus (Stricker and Verbalis 1991). Projections from NPY- and POMC-containing cells in the arcuate nucleus also terminate in the paraventricular nucleus, allowing the integration of these various stimuli so as to influence output systems that control autonomic function and, indirectly, food intake. The central neural circuits that integrate the peripheral signals that control meal size (i.e., signals associated with the gastric, intestinal, and hepatic stimuli generated by a meal) with those that control meal frequency (i.e., signals associated with blood-borne leptin and perhaps other signals reflecting adiposity) are also currently under investigation.

E. M. Stricker

Hunter–Gatherer Societies, Archaeology of

Hunter–gatherer societies traditionally have been regarded as representing the ‘original’ human society—that is, preagricultural peoples reliant upon ‘wild’ foods and interacting with ‘natural’ landscapes. In this way, they have been differentiated from other, agricultural, societies. From a sociological perspective, hunter–gatherers emerged as the ‘precapitalist’ baseline in Marx’s evolutionary framework—functioning as the original ‘communal’ society, practicing an economy different from those of others (Lee 1988). From a biological perspective, Darwin, among others, envisaged them as the human prototype, a position they still hold in more recent biological–ecological frameworks (Bettinger 1991). Anthropology and archaeology have absorbed these viewpoints, but more recently there has developed a significant change in emphasis—a redefinition of hunter–gatherers incorporating a much wider range in societal variation (Ingold et al. 1988).

Narrower, more traditional definitions had emphasized the following features. Hunter–gatherers had been perceived as small-scale, essentially egalitarian societies, of low population size and density and generally rather mobile. These societies were seen largely as *avoiding* accruing an economic surplus, practicing storage and impacting significantly upon

land and resources. In contrast, recent revisions consider that hunter–gatherers also incorporated more complex societal formations within their ranks. These included extensive social networks and signs of social hierarchy—as well as chiefdoms based on hereditary ranked lineages. Demographics included relatively high population sizes and densities, heightened territorial behaviour, and levels of sedentism. Hunter–gatherer economies can be composed of significantly high levels of intensification achieved through economic surpluses and storage. It is envisaged that they had considerable impact upon land and resources via firing and other practices now recognized by recent ecological impact assessments (Williams and Hunn 1982).

Ethnographic studies of the northwest coast peoples of North America (from northern California to British Columbia) included many of the characteristics described above, some living in permanent wooden-housed villages of up to 1,000 people. These hunter–gatherer peoples placed a strong emphasis upon fishing and practiced no agriculture (Suttles 1968, Ames 1985). The Calusa of Florida, another North American ethnographic example, reflect all these features and more—including a centralized state formation which extracted tribute from subservient villages, a royal family, and a standing army. The Calusa also were without agriculture (Marquardt 1988). Recently the ethnographies of more classic hunter–gatherers have also been considerably revised (Schrire 1984, Lourandos 1997). In all, this evidence points to the possibility of a similarly broad range of pre- and nonagricultural peoples having existed in the past, when most of the habitable environments of the world were occupied by hunter–gatherers. Archaeology can provide answers to these questions, as recent investigations have unearthed.

1. Archaeological Examples

Archaeological examples of the historical evolution of these more varied features of hunter–gatherer society have been studied recently in a number of time periods and regions of the world. We now discuss five of these case studies in turn.

1.1 European Upper Palaeolithic

The Upper Palaeolithic in Europe took place during the final stages of the last ice age, from about 35,000 to 10,000 years ago. Modern people, *Homo sapiens*, had colonized the continent by this time. While the cultures of this lengthy period have much in common, clear trends towards more complex hunter–gatherer patterns are discernible in the last half of this period. For

example, after the coldest, driest phase which occurred around 20,000–18,000 years ago (the glacial maximum), climates were milder, especially in well-located southern latitudes such as southwestern France. At this time, known as the Magdalenian period, spectacular painted rock art, including images of extinct herd animals such as mammoth and bison, appear in limestone caves across the region. Occupation sites at this time are more numerous and much larger than previously. The suggestion is of increased numbers and densities of people living a more sedentary lifestyle. Hunting strategies were to target large numbers of herd animals that migrated seasonally to the highlands and back again, following the bloom of pasture grasses. The cave art which occurs in varied, regionalized styles, suggests the development of more territorial social units, each with their own set of artistic repertoires. Cave art, site numbers, and the economy, therefore, among other things, reflect a more populous, sedentary hunter-gatherer society. Burials, which are more common during this period, indicate that certain individuals were afforded more attention in death, suggesting the appearance of aspects of social differentiation (Conkey 1985, Gamble 1986, Jochim 1983, Mellars 1985).

At this time, out on the frigid and largely treeless southern Russian Plain, hunters resided in permanent hamlets of well-constructed mammoth bone dwellings. These bases were located in the lengthy riverine corridors, such as the Don and Dnepr, through which myriads of large herd animals migrated annually. Meat was stored in frozen subterranean pits. Hamlets were part of an intricate network of long-distance exchange—in exotic stone, shell, and ‘Venus’ figurines—which united peoples resident in a harsh, vast arctic desert. Social inequality is suggested by unequal numbers of storage pits around individual dwellings, and perhaps ‘status’ burials, in a prior phase (Soffer 1985). More intensive economic strategies are evident during this period, as was the case also in southwestern France.

1.2 Eurasian Mesolithic

Traditionally, the Mesolithic of Eurasia was considered a depauperate period when contrasted with the more spectacular Upper Palaeolithic. Recent re-evaluations, however, point to complex trends, culminating in patterns of land and resource management, and ultimately, in some areas, to agriculture. This was a time of major climatic change, as warmer, moister conditions, similar to those of today, followed upon the colder glacial Pleistocene period around 10,000 years ago. The Mesolithic, therefore, is a time of adaptation by hunter-gatherers to changing environments both natural and cultural. The temperate zones of central and northern Eurasia were transformed from arctic deserts to mosaics of deciduous forests, lakes, and marshes. Following upon melting glaciers,

the seas rose, creating, for example, the vast Baltic Sea and its resource-rich coastline in northwestern Europe. Populous, semi-sedentary hunter-gatherer societies appeared on these coastlines, of for example present-day Scandinavia, as sea levels stabilized about 6,000–5,000 years ago. They established large shell middens and practiced a wide range of fishing, hunting, and gathering (including storage of nuts). Comparable societies appeared in estuaries and river valleys throughout Europe (Price 1987, Zvelebil 1986).

At the same time in Japan, beginning around 12,500 years ago, the Jomon hunter-gatherers on the rich environments of the main island of Honshu lived in semi-sedentary subterranean pit houses along the coast and inland. They fished intensively and stored quantities of nuts, acorns, and seeds in underground storage pits. It has been suggested that nut groves may have been an economically managed resource as perhaps also were seeds, including grass seeds. These populous, territorially based and ritually complex hunter-gatherers intensified still further their fishing/storage economies through time. In the final stages of their history they resisted for some time the introduction of agriculture (from the Asian mainland) (Akazawa 1986, Crawford 1992), as did also the Scandinavian hunter-gatherers.

It was in drier regions of the Middle East (southwest Asia), however, that Mesolithic hunter-gatherers developed complex societies and economies that also gave rise to agriculture. The Natufian hunter-gatherers of present-day Israel and Palestine between 12,500 and 10,500 years ago practiced intensive collection and storage of wild grass seeds and nuts. They resided in hamlets of small, round huts, and practiced the long-distance exchange of obsidian and shells. Shrines are found within their hamlets where they also buried their dead. Around 10,000 years ago, the domestication of wild grasses—including wheat and barley—took place, signaling the shift to agriculture. However, all other cultural features were essentially similar to those existing before. Agriculture, therefore, was but an extension of the complex hunting-gathering out of which it had sprung. And later agricultural villages, including the walled town of Jericho, were centered upon previously existing Natufian hamlets (Bar-Yosef 1987, Henry 1985). The dynamics of complex hunting-gathering, therefore, gave rise to agriculture as we know it today.

1.3 Archaic North America

The Archaic period of North America, like the Mesolithic, takes place as climate shifted from glacial to modern after about 8,000 years ago. Long-term trends, taking thousands of years, can be recognized in the rich riverine regions of the American mid-continent, where the densest hunter-gatherer populations resided. In riverine corridors such as those of the Mississippi and Ohio, population grew slowly over

thousands of years, while in the Illinois valley, semi-sedentism in the form of cold-weather bases appeared in time. Intensification of the hunter-gatherer-fisher economy accompanied these developments. It took some 4,000 years for long-term trends towards more complex social formations to develop in these regions during the Middle Woodland period. By about 2,100 years ago complex ceremonialism in the form of extensive mounded burial precincts and exchange and trade in a wide range of exotic material (copper, obsidian, pottery) united most of the regions of mid and eastern North America. The richness of the natural environment cannot be the only factor controlling the development of these complex hunter-gatherer societies, as prime environmental conditions had been established as far back as 6,000–5,000 years ago, long before the above cultural features appeared and flowered. Some of the most complex societies—such as those of the Ohio Hopewell—were located outside the riverine corridor itself, on the more arid plains and were relatively mobile rather than semi-sedentary. Their most common unifying feature lay in the ceremonial realm (Bender 1985, Brown 1985). Although agriculture was known to these peoples, it was not adopted by them until more recent times—held at bay, as we have already observed, for some Mesolithic hunter-gatherer societies.

1.4 Preagricultural Mesoamerica

Less archaeological evidence is available for observing trends towards hunter-gatherer cultural complexity in preagricultural Mesoamerica, the region which lies between the two continents of North and South America. Hunter-gatherers of this region also developed agriculture independently. Very long-term trends, however, spanning some 4,000 years, suggest a gradual shift towards higher levels of 'domesticated' produce since about 7,000 years ago. Even by about 4,000 years ago less than one third of the diet was agricultural. By this time some of the main domesticated plants included the staples of later times, maize and beans. Sedentism, in the form of villages, occurred *after* this time, when agriculture had been more firmly established. Aspects of complex exchange and trade had accompanied these trends, and agricultural villages (and later cities) were constructed around ritual precincts, which strongly suggests that one of the key driving forces behind communal aggregations (that is, sedentism) was inter-group ritual itself (Flannery 1968, 1976, MacNeish 1970).

1.5 Holocene Australia

Recent evidence from the continent of Australia suggests that comparable trends towards more com-

plex hunter-gatherer societies, similar to those of the Mesolithic and Archaic periods discussed above, are evident in Australia, especially from about 4,000–3,000 years ago. Aspects of these trends are also evident long before, for example after the glacial maximum or from about 16,000 years ago. In more recent times, however, long-term trends towards greater numbers of archaeological sites and use of sites occurs in many regions of the continent, including most major environmental zones—arid, tropical, and temperate. Demographic changes, including increasing populations and greater levels of sedentism, or reduced mobility, are suggested here, and are accompanied by other sociocultural changes (Lourandos 1997). In the tropical Cape York peninsula located in the northeast, shifts to more regionalized patterns of painted rock art occur during the last 2,000 years or so, suggesting more territorially based societies (David and Lourandos 1998, 1999). In arid Australia during the same period, a shift occurs towards more intensive seed-based (including grass seed) economies. The ethnographic descriptions of seed use (including grass seeds) by Australian Aborigines indicated they were managed via a wide range of practices including firing, irrigation, and the planting and broadcasting of seeds (Smith 1989, Veth 1989). As in all world regions studied, climatic change—in this case towards drier climates—accompanies many of these trends, but cannot on its own explain them.

2. Discussion

Trends can be observed, therefore, in many areas of the world which incorporate features of broader societal variation among nonagricultural peoples. These have included: increased population sizes and densities; sedentism storage and surplus; intensified and specialized economic practices; the suggestion of land and resource management; and broader social, including more hierarchical, formations. To what extent these prehistoric societies reflect ranking, including chiefdoms and the like, is more difficult to discern clearly. However, aspects of this, and the social context in which these systems are embedded, has been established in a number of case studies. The trends themselves took place over huge spans of time covering, in some cases, thousands of years.

Explanations of the trends in the development of hunter-gatherer society are many but tend to be somewhat polarized. As seen in the above case studies, climate, among other things, strongly influenced many of the general patterns and trends. But the dynamics within hunter-gatherer society itself also need to be considered. For example, incentives to intensify production (economy) may be embedded within the competitive social arena itself. In all, however, such

large-scale processes must have involved a complex set of factors—among them, ecological, demographic, and sociocultural.

Methodological problems also limit our investigations. Difficulties lie in gaining access to finer-grained, middle-range archaeological details. Issues of scale, for example, tend to blur distinctions between macro and micro issues in both time and space. Enormous spans of time and vast regions have been investigated in the general models offered. Access to archaeological data is a slow, meticulous process and answers to many of the questions raised here will take time to resolve.

In all, future directions lie with a much wider range of questions and approaches than were posed in more traditional times. The history of our hunter-gatherer past, quite clearly, has begun to be written anew.

Hunting and Gathering Societies in Anthropology

'Hunting and gathering' is a conventional term for subsisting on the 'natural produce' of the earth by hunting and trapping wild animals, gathering wild roots, fruits, and berries, fishing, and collecting honey of wild bees, as opposed to producing food by agriculture and herding. By hunting and gathering societies (HGS) ethnographers mean contemporary indigenous people who fully or partly engage in these activities, now or formerly, or who see themselves as hunters. (For brevity, the terms 'hunter-gatherers,' 'hunters,' and 'foragers' are sometimes used synonymously.) The term is also used in general reference to prehistoric populations, living before the agricultural revolution (around 10,000 years BC). In common usage, it also stands for an alien 'Other,' diversely constructed by modernity in order to define itself. In this article, the primary focus is placed on the first meaning, while note is taken of its brush with the other two. The term is first examined historically, with an outline of its origins and changes of usage over time. Next, several clusters of features that are partially shared by these societies are presented in model terms, after which the diverse populations concerned are described by region, with the focus on their historical circumstances.

1. Contested Meanings

An understanding of the expanding meanings of HGS necessitates a return to the origin of the field and perusal of its historical development. In the seventeenth century, writers invoked 'primitive peoples,' who hunt and gather for their subsistence, in discussing the 'natural state' of humankind. By the eighteenth century these were typed 'hunter-gatherers,' in distinction from 'herders,' within a broad 'savage' class, in writings on the origins of property relations. In the nineteenth century evolutionist work continued to draw on these specific peoples, often without referring to the class as a whole, in studies of the origins of a variety of other social institutions, from kinship through politics to religion.

The notion consolidated as a central term in early twentieth-century cultural-ecology theory, most influentially in Julian Steward's work (1936). Concerned with the relation between society and environment, Steward argued that for any given mode of subsistence, successful adaptation determines a certain level of

socio-cultural integration. In the case of hunting-gathering, he argued, this is a 'band,' which is universally patrilineal, exogamous, and territorial. HGS was associated with bands, and hunting peoples were comparatively studied as band-societies (see, for example, Damas 1969), until the 1966 symposium 'Man the Hunter' (Lee and DeVore 1968). This interdisciplinary symposium is commonly considered the beginning of modern hunter-gatherer studies.

The symposium was inspired by the assertion that human beings had subsisted by hunting for over 99 percent of the time of human life on earth. Linking cultural-ecological and (neo)behavioral-evolutionary perspectives, its major objective was to learn about human origins and nature by comparing 'living hunters.' Uniform patterns found among them, it was posited, can be regarded as hunter-gatherers' successful adaptations, present and past.

Serious reservations were raised about its agenda. One objection, for example, was that no contemporary group could be seen as 'living relics,' or as direct descendants, of the Pleistocene. Even if a group had been found to subsist purely on hunting, its people would have had a history as long as any other, and they would not have lived any longer in a world populated by hunters as in the Pleistocene. Another objection was that over the span of 2,000,000 years humans had changed considerably, biologically, and psychologically, enough to render homogenizing them inappropriate.

The ethnographic comparison, at the same time, shook accepted wisdom to the core. Contrary to Steward's persistent thesis, research revealed that most bands are actually socially fluid and nomadic. In many cases, gathering makes no less important a contribution to subsistence than hunting. In contrast to contemporary stereotypes and bourgeois intuition, the comparison showed that these peoples meet their needs with surprisingly little labor. (Marshall Sahlins provocatively dubbed them 'the original affluent society'.)

Outweighing the reservations, this successful outcome entangled HGS with the 'Man the Hunter' project. HGS came to mean a type of people, rather than diverse peoples engaged in a type of action, encompassing populations over a vast evolutionary span of time. The term now embodied the hypothesis that, at their core, these populations have similar socio-cultural forms, determined by adaptation to the environment. From a vague term of reference to 'very simple' peoples, and then to 'band societies,' it connoted a firm, homogeneous, and exclusive social category, a category of humanity defined technoeconomically.

Subsequent ethnography research, which burgeoned in the wake of 'Man the Hunter,' grew diverse in focus and approach, as seen for example in the series of International Conferences on Hunting and Gathering Societies (1978 to the present, e.g., Ingold et al.

1988, Vols. 1–2, Burch and Ellana 1994). Issues arising from late twentieth-century indigenous circumstances and cultures were addressed, including political struggles and self-administration in modern states, and indigenous peoples' own perceptions of their environment, economy, and self. Historical, interpretative, regional, and applied perspectives commanded attention; evolutionary-ecological studies of foraging behavior increasingly took a separate course. Indigenous people started contributing to academic research, as anthropologists and interested parties. This growing ethnography showed a diversity of social forms among hunting-gathering peoples, from egalitarian to hierarchical, and even slave-owning societies. The 1970s meaning of HGS, as a firm, homogeneous, and exclusive social category, was increasingly challenged. In an attempt to save it, the category was diversely divided into subtypes (e.g., see Woodburn 1982); or it was recharacterized, for example, by a collective appropriation of nature (see Ingold 1987) or by a distinct cultural perception of the environment (see Bird-David 1990).

The 1980s and early 1990s saw many controversies (see review by Myers 1988), sparked partially by inflexible readings of the term HGS. Scholars disputed the category as pertaining to a class of societies that are both singularized by hunting-gathering and distinguished from agricultural and pastoral peoples, because the ethnography revealed continuities between hunter-gatherers and other societies, as well as great diversity among the hunter-gatherers themselves. Other scholars questioned the categorization of societies by mode of subsistence, as research showed heterogeneous and changing economies. Hunting-gathering was found to be articulated with other pursuits, going back in some cases centuries and even millennia, and, at any rate, undergoing rapid changes since the mid-twentieth century. Students debated whether any living group sufficiently complies with the subsistence criterion and whether this criterion generates a meaningful category, one whose members share more than the selecting mode of subsistence. Even the field at large was critiqued as spurious, by researchers seeing it in terms of the 1960s objective to learn about prehistory and evolution. Their criticism drew on ethno-historical and archaeological work suggesting arguably that these societies have not escaped world and regional forces. HGS is sometimes used nowadays simply to denote the assemblage of indigenous peoples discussed by practitioners within the field of hunter-gatherer studies (see Kelly 1995).

HGS has acquired multiple layers of meanings. It is a circumlocution for a historically-situated field of research that provides a stimulating comparative context and a scholarly communal framework within which to explore a broad array of distinctive issues. Ethnographers construct 'partial connections' (in Strathern's (1991) sense) between these societies by studying their respective groups while keeping the

others 'in mind.' They call to attention partially shared features, which determine common issues in the field, and contribute distinctive perspectives to anthropology generally. Hunting and gathering activities are a focus of attention, rather than a criterion of demarcation, for scholars as for the indigenous peoples themselves.

2. Issues

This section presents in model terms some of the partially shared features that came to light in the course of ethnographers' comparative discussion of their field experiences and material.

2.1 Hunting and Gathering

In many of these societies, people combine these activities with other economic pursuits (e.g., trade in minor forest produce, horticulture, work for neighbors, wage-labor, social benefits, etc.). However, hunting and gathering themselves carry special significance; they are a total phenomenon encompassing economic, social, and symbolic aspects. Hunting-gathering, moreover, often influences the way in which people carry out such other activities. They often return to hunt and gather at least periodically, when not prevented from doing so. They regard what they collect as 'real food,' and while they do pursue other activities, in some cases hunting-gathering still provides a major part of their diet.

2.2 Band Society

In many of these societies people live in small groups (bands) consisting of several families; the groups are flexible. Making visits, and even shifting residence, from place to place, are common. The total population numbers a few thousand, and may be as low as several hundred. Men and women often know each other personally: they all are (or at least are classified as) family and relatives. Their sense of themselves as family often survives growing integration into nation-states.

2.3 Sharing

The land and its resources in many of these societies are often collectively appropriated (see Ingold 1987). Game is publicly shared; other resources, whether procured from the environment or purchased, are shared in response to requests directed by those who lack something to those whom they perceive have it ('demand-sharing': Peterson 1993). Sharing and the expectation of it is part of broader nonaggrandizing

economic reasoning and conduct. While hard to express in modern urbanite language, sharing extends not only to distributive but also to social experience. People in the group share 'each other' (Ingold 1987): company, dwelling spaces and work, stories, memories, and personal histories. They experience their selves as coalescent, rather than as a group of separate individuals. Relationships between people, rather than being regenerated by coercing external structures, spring from the vivid experience of sharing. Sharing, which is normatively promoted, fosters an egalitarian society in many cases (see Woodburn 1982). While closely connected, people usually enjoy considerable personal autonomy.

2.4 *Giving Environment*

Nature is locally experienced neither as a mechanical system nor as objects for human use and ownership, but as an assembly of sentient beings related to and shared with (Bird-David 1990). These beings (animals, forest, winds, hills, etc.) frequently are approached as relatives, often as grandparents. People care for them, and this helps sustain their collective identity. People engage with these beings through Shamanistic practices and by pursuing hunting-gathering. To hunt and to gather are perceived not just as subsistence pursuits but also as means of communication with the 'natural' relatives. Even when forced to reside away, and to adopt modern life-styles, people commonly practice their rituals, and return to their places to hunt-gather and 'keep in touch' with these relatives. This animistic perception is integrated with deep ecological understanding of their neighborhood. It often propagates responsiveness to and sometimes responsibility for the environment, along with its utilization.

3. *Populations*

The indigenous populations considered as hunter-gatherers are described in this section, by geographical cluster, in keeping with the *Cambridge Encyclopaedia of Hunters and Gatherers* (Lee and Daly 1999). The figures provided should be regarded as suggestive, as politics of identity, especially in First World situations, and dispersal and inaccessibility, especially in Third World countries, severely limit enumeration.

3.1 *Australia*

About 266,000 people identify themselves as of Aboriginal or Torres Strait Islander descent, constituting 1.6 percent of the national population (1991 census). This is the case on a continent inhabited solely by hunter-gatherers until the arrival of Europeans in 1788. Compared with an estimated 200 languages and 600 dialects in that year, they now divide into groups speaking about 50 languages. Among the best known

are Aranda, the nineteenth-century study of whom was pivotal in anthropology, and Walipi- and Pintupi-speakers, desert-dwellers and the last to make contact with Europeans. A disproportionate number of Aboriginal people are now largely dependent on social security payments, and do poorly by any standard social indicator. At the same time, a revival of tradition is on the increase, in part due to the growing national and international markets for Aboriginal art (especially the desert 'dot-painting'). Politically, significant advances have been recently made. First was the establishment in 1990 of the Aboriginal and Torres Strait Islander Commission (an indigenous body formed to make policy and distribute federal funding for Aboriginal people). This was followed by the High Court recognition in 1992 of native land title (the 'Mabo case').

3.2 *North America*

Commonly called American Indian Nations in the US, and First Nations in Canada, there are about 500 indigenous groups in this subcontinent. The stratified Tlingit and Haida of the northwest coast, and the egalitarian Arctic Eskimo-Aleut speakers, are renowned for their role in early anthropology. The sub-Arctic Innu, Cree, and Dene are known for their opposition to contemporary environment-threatening development schemes. Prior to European colonization, two-thirds of the subcontinent had been occupied by hunting and gathering people. Devastated by the colonization, some groups perished, and some survived in fragmented forms in reservations. To date, a disproportionate number experience severe social problems. However, recent decades have seen expansions of indigenous organizations, rapid growth of arts, and revival of traditional spirituality (attracting New Age followers). Hunting and gathering economies are being renewed, especially on the north and the northwest coast, as a result of some judicial breakthroughs that brought a degree of recognition of aboriginal and treaty rights. A major landmark was the 1999 establishment of Nunavut, an Inuit majority territory within Canada's federal structure.

3.3 *South America*

Foraging people in the subcontinent's southern cone were almost extinct by the 1920s, and only a handful of each group remains today, assimilated into other communities. A wide spectrum of forest communities, cultivators and hunters by trade, live scattered in the Amazonian hinterlands. In the 1960s they were viewed predominantly as devolved agriculturists, and only later did their egalitarian and nomadic life-styles earn them the attention of the discipline. The Paraguayan Ache is one of the best known groups. Most of these indigenous people have been converted and restricted to reservations; since the 1960s large-scale economic

development has threatened their environment and life-ways even more. As a result of joint campaigns by indigenous activists and international conservation and human rights movements, a slow but significant movement towards recognition of indigenous territories has been taking place since the 1980s.

3.4 North Eurasia

Latecomers into the hunter-gatherer discourse, there are 26 Arctic and sub-Arctic groups in the Russian north. They are divided into at least six language families, and number approximately 184,500, constituting 0.06 percent of the entire Russian Federation population (in 1990). In the seventeenth and eighteenth centuries the majority moved to reindeer pastoralism as their main subsistence occupation, supplementing it by hunting and fishing. Autonomous districts were established for some of them in the 1930s, although political and economic decisions were still made in Moscow. A substantial majority is now modernized, urbanized, and Russified, but activists (mainly writers) campaign for cultural renewal. Under the mounting economic difficulties in Russia, many are attempting to restore some traditional practices.

3.5 Africa

Bushmen (San) and Pygmy groups caught the 1960s' imagination, not least as their habitat was regarded the 'cradle of humankind.' They number 100,000 and 285,000 respectively; each comprises diverse linguistic groups spread across more than half a dozen countries. A further 55,000 people, largely in East Africa, bring the total number of African foragers, part-foragers, and former-foragers to 440,000. Only a tiny fraction of them subsist intensively on foraging. Most keep close ties with cultivators and pastoralists; the Pygmy groups are known for what is described as symbiotic relationships with their neighbors. With worsening circumstances, some groups sought help from development agencies and church groups and some joined environmental activists in protest against ill-advised large development schemes. The Ju/'hoansi (alias !Kung), the best known hunter-gatherer group owing to Lee's extensive work (e.g., 1979), have initiated self-help schemes intended to develop awareness of nation-politics, and leadership and management styles adapted to it.

3.6 South Asia

Less than two dozen indigenous groups live in the South Asian subcontinent. These total less than 20,000 out of over 1,000,000,000 people (wider estimates, including former foragers, put their number at 1,300,000). They include the exceptional Jarwas and Sentinelese of the Andaman Islands, who by hostile behavior have warded off outside contact up to the

present, and South Indian forest-groups who, going back 2,000 years, have played an important part in the economies of the subcontinent's ancient civilizations. The latter groups have provided the main society with exotic spices, medicinal herbs, honey, and meat, occasionally guiding Hindu pilgrims and officiating in their forest temples. Some groups are being pressed to 'develop' into settled agriculturalists by a national modernist policy that sees them as 'backward people' whose existence shames the country; some combine hunting-gathering with trade in minor forest produce and wage-work. Sri Lanka's Wanniyala-aetto (formerly Veddahs) raised strong opposition to their forced relocation, going as far as the United Nations.

3.7 Southeast Asia

Foraging and swidden farming are closely linked in this region, with historical shifts back and forth between them, frequent combinations, and close trade-links between foragers and farmers. In the Philippines there are about 25 distinct linguistic groups, totaling 15,000; in Malaysia, eight linguistic groups total 2,500 people; in Indonesia the total is 15,000, in Borneo it is 12,000, in China it is 4,500, and in Sumatra and Thailand it is 800 and a few hundred, respectively. Governments in this region encourage commercial exploitation of these people's forest habitat, and they rapidly become poor farmers and laborers.

4. Conclusions

Stimulated by the hope to learn about human evolution and prehistory, the study of 'living hunters' has developed into a fruitful area of study in and for itself. These living peoples still afford a study of behavioral-ecological parameters of hunting-gathering, which are important for them, and which they pursue when they can. Over and above this, however, they open a window to socioenvironmental ethics and praxis, conceptions of society and nature, human relationships and economy, which are markedly different from familiar models. In broadening scholars' imagination, that cannot but be biased by urban life-experiences and intuitions, hunting and gathering peoples can help scholars think about other forms of life: human life in the past as well as possible futures. Indigenous peoples for their part increasingly explore new modernities that integrate their traditional practices with life in twenty-first-century nation-states.

Hurst, James Willard (1910–97)

It is hardly controversial that J. Willard Hurst of the University of Wisconsin was the most influential scholar ever within the realm of US legal history. By emphasizing factors beyond legal doctrine and by altering the way people think about time, place, and change itself, Hurst enlivened and transformed an entire academic field. As leading legal historian Lawrence Friedman said: ‘Willard Hurst, as a scholar, did what few scholars have ever succeeded in doing: he created a whole new field of study, and virtually out of nothing.’

1. Biographical Background

James Willard Hurst was born on October 6, 1910 in Rockford, Illinois, where his father ran a movie theater and had other business interests. When Hurst attended Williams College from 1928 to 1932, he majored in economics, became editor in chief of the student newspaper, and president of the International Affairs

Club. He also wrote a prize-winning student essay on international implications of the English Gold Clause crisis of 1931, published in the *Journal of Political Economy* the year he graduated. Hurst then attended Harvard Law School, and reported that he was disgruntled about the emphasis on abstractions and the failure to pay attention to the Depression and to the ideas of the legal realists. A note editor of the *Harvard Law Review*, Hurst graduated in 1934 and spent the 1935 to 1936 academic year as a research fellow for Felix Frankfurter, working primarily on a lecture series which Frankfurter published as *The Commerce Clause under Marshall, Taney, and Waite* (1937).

Hurst next served as law clerk for 80-year-old US Supreme Court Justice Louis D. Brandeis during the 1936 term, one of the court’s most contentious ever. Frankfurter reported that Brandeis said that Hurst ranked as his best clerk ever, ‘professionally speaking.’ Brandeis thought the states to be invaluable laboratories for progressive regulation and lawmaking, and he urged young men who worked for him to return to their home regions. Hurst became one of the very few to heed Brandeis’s advice. He began his lifetime association with the University of Wisconsin in 1937, when he joined the law faculty in Madison, only a short drive north of Hurst’s hometown.

By 1941, Hurst had compiled several books of teaching materials and had coauthored *Law in Society* with his dean, Lloyd Garrison. This pioneering case-book focused on the myriad ways that the plight of a widow—whose husband, a carnival worker, was crushed under a company tractor—intersected with legal institutions beyond the courts. After Pearl Harbor, Hurst and his wife, Frances Wilson, moved to Washington, DC. Hurst first worked for the general counsel of the Board of Economic Warfare and then joined the navy, where his assignments included work on a highly publicized treason case, leading eventually to his *The Law of Treason in the United States* (1971).

Even before returning to the Wisconsin law faculty after World War II, Hurst began to articulate in print the crucial link he perceived between legal history, done in a new way, and ‘opportunities to apply informed, humane reason to influence the course of events.’ The ‘Wisconsin idea’ of enlightened political leadership had lasting appeal for Hurst—and he repeatedly rejected job offers to teach at other prestigious institutions. In the course of rejecting an offer from Yale Law School in 1938, for example, Hurst wrote to his mentor Felix Frankfurter that Wisconsin afforded ‘just about an ideal “laboratory” situation.’ Despite Yale’s offer of higher rank and twice the salary, Hurst advised Frankfurter that he preferred Madison ‘particularly because of this extraordinarily interesting state government machinery here on the doorstep.’ Although Hurst was extremely reluctant to travel from his Wisconsin base throughout his life, he nonetheless was directly involved in launching the

international Law and Society movement, as well as in pioneering a new approach to legal history that has had worldwide impact. He taught full time at Wisconsin until 1980 and continued to publish after retiring from teaching. Hurst died in Madison on June 18, 1997.

2. Hurst's Scholarship

Hurst's scholarly career repeatedly underscored a core idea. In 1971, he summarized the enormous project he had undertaken: 'A realistic history of law in the United States will be a social history of law, taking law as man-made, and as the product of both deliberation and drift, but not of any immanent superior order of reality.' Doing legal history from the outside—from the perspective of sociological jurisprudence—led Hurst to turn his back on the 'great man' tradition and to reject the previously dominant focus on formal judicial opinions. He firmly opposed teleological accounts that tended to celebrate the gradual improvement of law over time. Instead, Hurst focused on economic matters—as shaped by the general culture—and on the ordinary processes of statutes, administrators, low-level cases, and the everyday work of lawyers.

In particular, Hurst concentrated on analyzing what he termed 'our prime inheritance,' which he defined as 'middle-class ways of thinking.' With exceptional tenacity, he set about tracking 'the expansion of middle-class energy.' He sought to describe and to analyze how most people in the USA responded to a central problem. That basic issue, according to Hurst, confronts 'whether men will be able to use the power of the politically organized community to secure the basic conditions of a decent life for the individual, without thereby destroying the very values they are trying to realize.'

Throughout his decades of scholarship and teaching, Hurst combined unrelenting and careful attention to massive low-level details with sweeping descriptions of general patterns. He sought to develop a new integration of the social-science ideas of his era with careful historical consideration of the largely unexamined mass of law as it functioned on the ground, far removed from the doctrines promulgated by selected appellate judges that dominated—and still dominate—US legal education.

Robert Gordon described the great reach of Hurst's innovative academic project as follows:

After expanding the relevant record beyond prior appellate cases and their facts to all prior legal acts and the social influences on them, and the pending proceedings to the overall task of designing workable legal-regulatory arrangements for the present age, Hurst wrote his books as background briefs for present-day lawmakers.

To Hurst, social patterns mattered greatly. But he perceived that generalized thoughtlessness and a

strong tendency to accept inertia and drift often served to counterbalance, or even to disable, other strong, competing US commitments.

Through his prodigious output of scholarship on markets, legislation, monetary policy, and administrative actions large and small, Hurst pointedly emphasized the frequent unthinking clash between core US values. He seemed to delight in clearly describing basic and sobering paradoxes. Thus, for example, Hurst observed: 'Individuals realize their humanity only in society, but they realize their individuality only in self-awareness, which consists in some sense of separateness.' Moreover, he noted that such tensions afford protective coloration for 'shrewd men' who 'warp individualistic symbols of the constitutional ideal to sanction unchecked organized power.'

As Hurst challenged traditional legal distinctions between public and private activity, he pushed himself and those who followed him to develop both extensive local data and expansive theories to capture and explain overarching patterns. In *The Growth of American Law* (1950), Hurst argued that 'law has been more the creature than the creator of events.' This famous book emphasized the impact of physical, technological, and social facts on nineteenth-century law and paid particular attention to the often inglorious role of the legal profession. Some have criticized Hurst for being too much a functionalist, and for inadequately attending to issues of power. Yet Hurst's 946-page *Law and Economic Growth: The Legal History of the Lumber Industry in Wisconsin, 1836–1915* (1964), for example, highlighted the failures of laissez-faire. It also extensively documented Wisconsin's broad and detailed state regulation of a single industry—during a period generally thought to have been at or near the apex of free-market ideology.

3. Hurst's Impact

William Novak asserted in 2000 that Hurst surely ranks as 'a broad-gauged socio-legal thinker of the first order, writing in the tradition of Tocqueville, Weber, Holmes, and Pound.' Hurst was original in his particular emphasis on place and time, particularly through his focus on his native Midwest. He also innovated through his unusual illustration of the difficulty in discerning any clear patterns of progress in US legal developments. Indeed, Hurst concentrated on exploring the intricate network of constraints—some perceived, some never understood, some formally legal, some not legal at all—that repeatedly confined and constrained the freedom of everyone.

In Hurst's view, Americans competed fervently, if often blindly, to manipulate whatever system they found in place in their particular context. He generally found it necessary to bemoan the power of deep habits that often produced irrational development and sub-

stantial depredations over time. Yet Hurst also provided crisp accounts of the constitutional impulse among Pike Creek squatters, for example, as well as broad studies of such issues as the fierce, largely irrational conflict over gold and silver currency in the late nineteenth century.

Hurst sometimes has been inaccurately caricatured as part of the celebratory framework of some forms of ‘consensus history.’ Yet the very broad-gauged quality of his work (an ongoing quest, in Novak’s words, ‘to try to twist the tail of the cosmos’) emphasized the mainstream at the cost of excluding, or at least understating, the importance of minorities and of dissenting viewpoints throughout US legal history. Hurst’s faith in fact-gathering led him to produce not merely a new way of looking at law, but also an extended historical critique of what he called ‘bastard pragmatism’—the propensity of people throughout US history to allow themselves to be dominated by the short term and the bottom line.

Through his entire career, Hurst emphasized the difficult, if not impossible, goal of increasing both public and private accountability. In *Law and the Conditions of Freedom* (1956) he noted a clear historic preference among Americans for ‘the promise of the future over commitments to the past, but also for the ambitions of the present over the claims of the future.’ Somewhat ironically, Hurst nevertheless remained deeply committed to the progressive ‘Wisconsin idea.’ To Hurst facts were crucial. Only through facts could a doubting optimist, such as Hurst himself, imagine enlightened leaders actually enhancing the general pursuit of ‘lives of good conscience and fulfillment.’ If Hurst sometimes seemed unabashed in adopting what Daniel Ernst called ‘a presentist approach to the past,’ he remained first and foremost an innovative, exceptionally influential historian.

The unusual number and breadth of symposia about Hurst’s work only begin to suggest how significantly his emphasis on the impact of markets, legislation, monetary policy, social habits, and administrative actions transcended earlier boundaries. Through his enormous output of scholarship, his legendary generosity in giving scholarly assistance to others, and his decades of noteworthy teaching, Willard Hurst changed the way US legal history is written and taught. By now, as Lawrence Friedman put it, ‘You’re either a Hurstian or a reviser of Hurst.’ Hurst not only redefined an entire academic field, but he did much to open the borders of legal history to other disciplines. Hurst’s career challenges his successors to consider carefully the intricate, crucial, often paradoxical intertwining of legal ideas and social realities within the many realms in which people actually live.

A. Soifer

Husserl, Edmund (1859–1938)

Edmund Husserl was one of the most influential philosophers of the twentieth century. Inventor of the ‘phenomenological method’ for the analysis of physical and mental phenomena, initiator of the ‘phenomenological movement’ of contemporary human sciences, he became the great critic of naive naturalism in philosophy and psychology (‘psychologism’), and of what he regarded as the loss of orientation, certainty, and thereby of credibility, of modern science. His appeal for ‘going back to the things themselves,’ and for a foundation of all science and philosophy in a clearly understood ‘life-world’ (*Lebenswelt*), inspired the work of a great number of philosophers (e.g., Gadamer, Heidegger, Ingarden, Levinas, Merleau-Ponty, Ricoeur, Sartre) and social scientists (e.g., Buytendijk, Lewin, Schütz).

1. Life and Academic Career

Edmund Gustav Albrecht Husserl was born in Prossnitz, Moravia, on April 8, 1859. He studied mathematics, physics, astronomy and philosophy at the universities of Leipzig (1876–1878), Berlin (1878–1881), and Vienna (1881–1882), where he obtained his Dr.Phil degree in mathematics with Leo Königsberger in 1883. After a short period as assistant

to the mathematician Karl Weierstrass in Berlin, and a year of military service, Husserl continued his philosophical studies with Franz Brentano in Vienna from 1884 to 1886, and with Carl Stumpf in Halle between 1886 and 1887, where he qualified as lecturer in 1887 with a postdoctoral thesis entitled 'Ueber den Begriff der Zahl. Psychologische Analysen' ('On the Concept of Number. Psychological Analyses').

Husserl became a professor in 1894, and moved to Göttingen in 1901. In 1916, he accepted a call to Freiburg to succeed Heinrich Rickert in the chair of philosophy there. Husserl retired in 1929. After the seizure of power in Germany by the National Socialists in 1933, his status of emeritus professor was suspended because of his Jewish descent, and, after a short reinstatement, definitively revoked in 1936 after the Nuremberg race laws. Husserl died in Freiburg on April 27, 1938.

2. Writings, Subjects, Approaches, and Contexts

Husserl's significance for philosophy, which is certainly greater than that for the social and behavioral sciences, rests on his establishment of a new way of dealing with philosophical problems, which he called 'phenomenology,' turning this expression into a 'technical' term by giving it a clearer delimitation and a weightier role than it had enjoyed with earlier philosophers such as Lambert or Hegel. The methods and content of Husserl's phenomenology, however, changed considerably during their development, which may be summarized in terms of three 'turns' of direction and aims: (a) the turn from early foundational work to anti-psychologism, (b) the shift from descriptive to 'constitutive' phenomenology, and (c) coping with the 'crisis' of modern science by a new focus on the life-world.

2.1 From Early Foundational Work to Anti-psychologism

In *Philosophie der Arithmetik* (*Philosophy of Arithmetic*, 1891, Husserl 1950, Vol. XII, pp. 1–283), Husserl made an attempt at a descriptive—psychological foundation of arithmetic, presumably having in mind an extension of Weierstrass's program of basing the vast number of mathematical concepts on a small number of fundamental ones, by providing an even deeper foundation for the latter by grounding them in the psychical acts underlying the mathematician's work. In the course of these investigations, Husserl introduced (independently of C. von Ehrenfels, who is normally credited with this discovery) 'gestalt qualities,' which he treated under the name *figurale Momente*.

Less successful (with hindsight) was Husserl's criticism of G. Frege's definition of number. It invoked an

objective but sharp counter-critique by Frege, which seems to have persuaded Husserl of the impossibility of taking the special science of psychology (which proceeds inductively, falling short of universally valid statements), as a foundation for mathematics or even for all special sciences ('psychologism'). Therefore, in *Logische Untersuchungen* (1901), aiming at a foundation of logic which at that time was usually set up on a psychological basis, Husserl advocated a consequent anti-psychologism which influenced contemporary philosophy profoundly. This concept was extended in his work 'Philosophie als strenge Wissenschaft' ('Philosophy as a Rigorous Science') (Husserl 1950, Vol. XXV, pp. 3–62) to a critique of historicism and (under the label of 'naturalism') scientism (1910–1911).

The positive foundation of logic was to be laid by a new foundational discipline to which Husserl, oddly enough, gave the name 'descriptive psychology,' despite his claim that it differed from empirical psychology as well as from Brentano's descriptive classification of psychical (mental) phenomena; it was to be 'descriptive' in the sense of presenting the immediately given mental facts without presuppositions (*voraussetzungslos*). According to this earliest form of phenomenology, that which is intended in a mental act (perception, judgment, idea, etc.) is transcendent to the act itself and given only in 'adumbrated' (*abgeschattet*) manner, through changing phenomena, and therefore inadequately. By contrast, everything immanent to the act is free of adumbration and can therefore be regarded as given in an absolutely adequate manner. Moreover, intuition of what is immanently given appears as free of structural complications like those attributed to judgment in contradistinction to sensation. The contents of the sphere of immediate experience (*Erlebnisse*) are beyond every doubt; with 'intentionality' at its center, it is the secure ground of a foundational discipline which is capable of justifying statements about essences (*Wesen*) and their relations, by a method which Husserl first called 'eidetics,' but later called 'intuition of essences' (*Wesensschau*).

Particular relevance to a philosophy of the sciences may be claimed for Husserl's remarks on 'pure logic.' Pure logic is an *a priori* theory of science dealing with two kinds of fundamental categories: categories of meaning (concept, proposition, truth, inference, etc.) on the one hand, and categories of objects (object, state of affairs, connection, number, etc.) on the other. Husserl takes the unity of the propositions of a science (or a discipline) to consist in the unity of its explanatory principles, and finds his next task in the uncovering of the conditions of the very possibility of theories. The route is to proceed from preliminary studies, e.g., a 'purely logical grammar' investigating the components and connections of propositions, via the statement of laws obtaining between such categories, to an *a priori* 'theory of possible theory forms.'

These investigations, continued only in *Formale und transzendente Logik* (*Formal and Transcendental Logic*, 1929) and in *Erfahrung und Urteil* (Husserl 1939), share a methodical aim: the ‘fixation of unambiguous, sharply distinct verbal meanings’ (Husserl 1901, Vol. I, p. 244; Husserl 1973 (English translation 1973), Vol. I, p. 238).

This search for ‘verbal meanings’ is also one of the foremost goals of contemporary methodical philosophy and philosophy of science. Husserl, however, did not approach the joint methodical aim by actually constructing a language of science, but recommended an ‘intuitive presentation (*Vergegenwärtigung*) of essence in adequate ideation,’ obviously conceived as independent of and antecedent to any linguistic construction. The ideation to be performed is not an idealization (as in geometry), but pure description, aiming at the elevation of that which is inexact and essentially vague to something typical, a ‘type.’ By setting out in this way, phenomenology increasingly moved away from the other methodical currents of modern philosophy and came closer to the philosophy of life (*Lebensphilosophie*), from which, however, Husserl differs sharply methodically by ascribing a foundational value to experience, after its precise rendering as ‘pure experience’ (*reines Erleben*) in which meaning, anterior to everything real, is believed to constitute itself (philosophical intuitionism).

2.2 The Step from Descriptive to ‘Constitutive’ Phenomenology

Object and method of phenomenology were extended and partly revised in *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* Husserl (1913), and pure logic was also characterized in a new way. In Husserl 1901, the predicate ‘ontological’ had been restricted (diverging from tradition) to sciences such as geography, astronomy, and anatomy, which deal with concrete objects, and not with abstract objects (like the theoretical or nomological sciences). Now, the old term ‘ontology’ is taken up again in a new sense. Husserl takes being to be subdivided into highest kinds or ‘regions,’ so the sciences which deal with them yield ‘regional ontologies.’ Above these (material) ontologies we find the formal sciences, mathematics and logic, which are aimed at ‘form essences’ (*Formwesen*) and give rise to a *mathesis universalis*. Treating the ‘empty forms of region’ as such, they comprise the forms of all possible material ontologies, and are nothing else but a ‘formal ontology.’

In *Formale und transzendente Logik*, formal logic was subdivided into (a) a pure doctrine of forms of meaning, or logical grammar, (b) the logic of consequence, or logic of non-contradiction, and (c) the logic of truth. The purely formal ontology was characterized

more clearly as the logic of objects by severing it from the ‘apophantic’ logic of judgment, while the nomological sciences are deductive, formal–analytic sciences describing ‘definite manifolds.’ Fundamentally new is Husserl’s assessment of ontology as a naïve–dogmatic discipline that is turned into a science only by its founding on a ‘transcendental logic.’ The term ‘transcendental,’ as explained in 1936, refers to ‘the motif of inquiring back into the ultimate source of all the formations of knowledge, the motif of the knower’s reflecting upon himself and his knowing life’ (Husserl 1954, p. 100). Husserl’s reflective ‘pure consciousness’ of 1913 is now determined further by its function as the ‘transcendental ego,’ having everything as its object, while never becoming an object itself, and granting access only through ‘eidetic intuition.’

The absolute sphere, which is the foundation of ontology and may be distinguished from the ontological sphere as ‘semasiological’ (R. Zocher), is the object of a ‘critical’ transcendental philosophy, which Husserl can only conceive of as a fully developed phenomenology. It makes use of the grasping of essences as a tool for analyses which approach the problem of foundation not as a methodological task, but as a problem of constitution in the classical sense: in this sphere, according to Husserl, valid statements may be obtained only by a sequence of increasingly radical reduction steps, each of which is to consist in a certain ‘abstention’ (*epoché*). The first two steps, i.e., ‘phenomenological reduction,’ leading to the phenomena, and ‘eidetic reduction,’ leading to the essential structure of consciousness, carry us on to the transcendental sphere. Access to it, however, is only given by ‘transcendental reduction,’ which is the ‘absolutely universal reduction,’ opening up the transcendental subjectivity which constitutes the meaning of the world and its contents, and thereby all objecthood.

2.3 The Crisis of European Science and the Life-world

The period between World War I and the seizure of power by National Socialism in Germany abounds with diagnoses of crises, from the foundational crises in most sciences (claimed for psychology, sociology, economics, etc., following the foundational crisis of classical mathematics so dramatically exposed by H. Weyl in the 1920s) to a general crisis of the times, of intellectual and moral orientation, and of European (‘rational’) culture generally.

Husserl gave much thought to this phenomenon and made out a growing loss of confidence in the sciences hitherto regarded as the firm foundation of Europe’s rational culture. He analyzed this situation comprehensively in an article ‘Die Krisis der europäischen Wissenschaften und die transzendente Phänomenologie’ published in 1936 in a new and little-

known Serbian journal and later forming the first two parts of the monograph bearing the same title (Husserl 1954). The sciences, it seemed to him, while ‘functioning’ as well as ever technically, had lost sight of their origin as well as of their aims, and thereby lost their former role and status as a guide and a standard of reliable knowledge and moral responsibility. Husserl hoped for a renewal by recognition of the fact that all scientific knowledge and activity is grounded in and grows out of everyday life. This is a realm usually not reflected upon but capable of thorough analysis as our ‘life-world,’ the domain not only of the physically ‘given,’ but primarily of our social life. Our immediate experience is not that of objects given to our consciousness, but that of situations in which we find ourselves with other people, in social groups and institutions, participating in common meaningful action, handling (linguistic and other) symbols, and approaching with understanding even ‘the great symbolic systems such as language, myth, religion, art, etc.; all of which are essential elements of the *Lebenswelt* and therewith of highest interest to the social sciences’ (Schütz 1959, p. 96). The phenomenological analysis of these largely ‘pre-predicative’ constituents of the life-world was envisaged by Husserl in the *Crisis* treatise and begun in his late and posthumously published work *Erfahrung und Urteil* (1939), where he has recourse to the life-world and to the primacy of praxis over mere contemplation. But in front of them, he places the ‘pre-predicative’ evidence of perception and of judgment based on perception, and thereby once more a prelinguistic foundational domain. The new approach remained to be developed by others.

3. Contexts of Discussion and of Influence

Notwithstanding the fact that ‘Husserl literally “thought through his pen”’ (Embree et al. 1997, p. 327), entrusting an incredibly large part of his ideas to shorthand memos that remained unpublished during his lifetime (and part of them until now), his thinking did not develop monologically, without context. During Husserl’s student years, the careful study of Descartes, Leibniz, the British empiricists and Brentano was recommended to him by T. Masaryk (today less famous for his *Versuch einer konkreten Logik* of 1887 than for his later career as the first president of Czechoslovakia), and Husserl himself testifies to the influence of William James’s *Principles of Psychology* of 1890 on the shaping of his phenomenological thought. Having acquired some fame as a creative philosopher, Husserl corresponded with many experts in science and philosophy, and discussed his ideas at invited lectures at other German universities, and abroad in Vienna, Prague, Paris, Amsterdam, London and elsewhere—events certainly prepared by the translation of the *Logische Unter-*

suchungen and the *Ideen* into several foreign languages.

The beginning of the ‘phenomenological movement’ may be seen in the exchange of ideas with students and collaborators of T. Lipps in Munich, who learned about Husserl’s investigations through their fellow student J. Daubert after he met Husserl in Göttingen in 1902. In spite of having nothing in print, Daubert had considerable influence on the ‘Munich phenomenologists’ (among them M. Geiger, A. Pfänder, and A. Reinach), some of whom (like H. Conrad-Martius, A. Koyré, and E. Stein, later one of Husserl’s private assistants) came to Göttingen to work with Husserl. They became the leading members of the ‘Göttinger philosophische Gesellschaft’ and main authors of the *Jahrbuch für Philosophie und phänomenologische Forschung*, founded in 1913, which published some of the great contributions (phenomenological and other) to contemporary philosophy, such as Husserl’s *Ideen* in 1913, M. Scheler’s *Der Formalismus in der Ethik und die materiale Wertethik* (*Formalism in Ethics and the Material Ethics of Value*) in 1913–16, and M. Heidegger’s *Sein und Zeit* and O. Becker’s *Mathematische Existenz* (*Mathematical Existence*), both in 1927. After its discontinuation in 1930, the publications’ goals and role were taken up by the American journal *Philosophy and Phenomenological Research*, founded in 1940.

In Husserl’s most active period, private assistants helped organize his literary production, defended his positions (e.g. E. Fink against neo-Kantian critics), and prepared lectures and notes for publication (e.g., the *Zur Phänomenologie des inneren Zeitbewußtseins*, prepared by E. Stein and edited by M. Heidegger in 1928, and, posthumously in 1939, *Erfahrung und Urteil* by L. Landgrebe). In 1940, H. L. Van Breda saved most of Husserl’s *Nachlass* (including 40,000 pages of manuscripts, Husserl’s private library and much of his correspondence), which today forms the core of the Husserl Archives at the Catholic University at Louvain, Belgium. Philosophical and related work in the phenomenological spirit is, beyond this, upheld by ‘Phenomenological Societies’ in several countries.

4. Impact on the Social and Behavioral Sciences

Husserl’s own writings did not take up any topics directly relevant to the social and behavioral sciences and therefore had little influence on them during his lifetime. Yet, they greatly stimulated interest in the phenomenological method in other authors, who explored its applicability and fruitfulness within the social sciences, broadening and strengthening the phenomenological movement. Whereas the investigations of A. Reinach into the *a priori* foundations of civil law, and of M. Scheler into the origins of cultural development, are contributions to the philosophy of

the social sciences rather than to social sciences proper, the potentiality of a phenomenological approach was recognized early in the psychology of personality (especially in the psychology of the subconscious and in psychiatry), and in experimental psychology, where it opened up new vistas for social psychology and the psychology of perception (D. Katz, A. Metzger, M. Wertheimer); the development of gestalt psychology (K. Köhler, K. Koffka) and of K. Lewin's field theory are unthinkable without the impact of Husserl's phenomenology (see also MacLeod 1947). In the field of sociology, the *formal sociology* (or sociological formalism) of A. Vierkandt and G. Gurwitsch have drawn explicitly on phenomenological ideas, and more recently, sociological systems theory, social constructionism and ethnomethodology have been clearly influenced by phenomenological thought (P. Berger, H. Garfinkel, E. Goffman, T. Luckmann, Niklas Luhmann, I. Srubar).

According to A. Schütz, 'Husserl's signal contribution to the social sciences consists ... in the wealth of his analyses pertinent to problems of the *Lebenswelt* and designed to be developed into a philosophical anthropology' (Schütz 1959, p. 97). This development was brought about by Schütz himself, who met Husserl personally only in 1932, after publication of his own pioneering work *Der sinnhafte Aufbau der sozialen Welt* (*The Phenomenology of the Social World*, 1972), but established close intellectual contacts for the six remaining years of Husserl's life. Schütz became the towering figure of phenomenological sociology, and it is due to the considerable impact of his work that Husserl's phenomenology, beyond its historical merit of exhibiting the limits of naturalistic and atomistic thinking, has gained a lasting influence on the social and behavioral sciences of today.

Hutterite Demography

The unique demography of the Hutterites—a contemporary Mennonite sect of Germanic origin who live in the Great Plains of the USA and Canada—has played an important role in the development of demographic theory and methods. They practice no birth control for religious reasons and their high fertility levels give reason to believe they do not intentionally control their fertility (Eaton and Mayer 1953). Their communally shared life-style, including the sharing of material resources, is also presumed to limit social or cultural variations in Hutterite fertility (Larsen and Vaupel 1993). Because of their uniformly high and apparently uncontrolled fertility, studies of the patterns and determinants of fertility among the Hutterites have helped to shape our theoretical expectations for populations that do not make any conscious efforts to limit childbearing. And, as a result,

the Hutterites have also been widely used in demographic methods as a fertility standard to which other populations are compared.

1. Hutterite Fertility

Many different estimates of fertility and fertility determinants among the Hutterites have been published in different studies (see Larsen and Vaupel 1993). All of these studies agree, however, that Hutterite fertility is exceptionally high. Eaton and Mayer (1953) reported a median completed family size of 10.4 children among married women over the age of 45 in 1950. Recalculations using the data published by Eaton and Mayer report a lower completed family size with a median of 9.4 children, and a mean of 8.97 among the same women (Lang and Göhlen 1985). These estimates are consistent with the modal completed family size of 10 children, and the maximum of 15 children, reported for the Hutterite sample analyzed by Larsen and Vaupel (1993). Even in this very high fertility population, however, fecundability and the probability of conception decline substantially with age. The monthly probability of conception is estimated to decline by about two-thirds between ages 20 and 35 (Larsen and Vaupel 1993), likely reflecting age-related influences such as higher probabilities of fetal loss, lower coital frequency, longer postpartum amenorrhea, etc., among older age women. Nonetheless, the age-specific influences on Hutterite fertility resulting in a decline of fecundability across ages appear to be largely biological in nature. Compared with other populations, the Hutterite population has exceptionally high fertility levels and the age-related decline in fecundability offers no apparent evidence of intentional fertility limitation.

2. The Hutterites as a Natural Fertility Standard

Because of their doctrines and behavior, the Hutterites are presumed to represent a *natural fertility* population. That is, as Henri (1961) argued, their child-bearing patterns reflect no efforts to limit fertility bound to the number of children already born, i.e., parity-specific fertility limitation. In fact, the Hutterites were one of the populations Henri (1961) used to define and illustrate the concept of natural fertility. He also ensured a special standing for the Hutterites as a high fertility standard when he found that they had the highest age-specific fertility levels of 13 historical populations he studied, all of which appeared to be natural fertility populations.

2.1 The Hutterites as a 'Standard Natural Fertility Population'—Coale's 'I' Indices

Hutterite fertility levels and age-specific fertility patterns have been used as standards in some of the most

widely used fertility measures of recent years. The Princeton European Fertility Project (Coale and Watkins 1986) popularized the use of Coale's (1969) 'I' indices which compare fertility in a population with that of the Hutterites through indirect standardization. Coale's index of overall fertility (I_o) compares the number of births to women in a population with the number of births these women would have had if they had experienced the same high age-specific fertility rates as married Hutterite women (i.e., 0.550 births per year among women aged 20–24, 0.502 to those aged 25–39, 0.447 to those aged 30–34, 0.406 to those aged 35–39, 0.222 to those aged 40–44 and 0.061 to those aged 45–59, see Henri 1961). Coale's index of marital fertility (I_g) similarly compares births to married women with the fertility they would have had if they had experienced the Hutterite age-specific marital fertility rates. And, Coale's index of illegitimate fertility (I_h) draws the same comparison for nonmarried women, again using Hutterite age-specific marital fertility rates as a standard. A final fourth index is intended to capture effects of the proportion married upon fertility (I_m) through comparing the fertility married women would have with that which all women would have, if both experienced Hutterite age-specific marital fertility rates.

2.2 Age Patterns of Hutterite Fertility as a Standard—Coale and Trussell's 'M' and 'm' Indices

Coale and Trussell's (1978) more formal mathematical modeling of age-specific marital fertility control also incorporates the fertility pattern of the Hutterites and Henri's (1961) other natural fertility populations as a standard for comparison. Coale and Trussell used 10 of Henri's natural fertility populations, including the Hutterites, to specify a standard age-specific pattern for natural fertility (see *Demographic Models*). The Coale–Trussell model attempts to parameterize the differences in overall levels and age patterns of fertility from these natural fertility expectations in populations with varying levels of fertility control. The level of fertility is then captured by two parameters of the model, Coale and Trussell's 'M' index of fertility levels and their 'm' index indicating departures from a natural fertility age pattern (1978).

2.3 Hutterite Fertility Determinants in Micro- and Macrosimulations

Not surprisingly, demographic simulation models have also made use of Hutterite fertility standards. Ridley and Sheps' (1966) initial (i.e., Cohort A) microsimulation of fertility, for example, used values of fecundability and postpartum nonsusceptibility which were derived from the Hutterite population. Bongaarts' more recent (1976) macrosimulation of fertility also incorporated Henri's (1961) natural fertility estimates as standards for age-specific patterns of

fecundity and for infecundity associated with sterility. In these simulations the Hutterite fertility standards are used to represent biological fertility parameters in the absence of fertility control.

3. Limitations of the Hutterite Fertility Standard

As the theoretical definition of natural fertility has been challenged, so have the measures of fertility control which have utilized the Hutterite fertility standard. Comparisons with a Hutterite standard population, such as Coale's I_0 index, may reflect differences in fertility which do not arise from parity specific control (Santow 1995). And, as in the case of Coale's ' M ' and ' m ' indices, such comparisons may also fail to capture the heterogeneity of fertility behavior in populations being compared with the natural fertility standards (Okun 1994), including the possibility of fertility control which is not closely tied to parity such as birth spacing. Although comparative indices and methods face many of the same limitations as any indirect standardization, incorporating the Hutterites as a constant standard population for empirically-based comparisons has nonetheless been of considerable advantage to demographers. Use of the Hutterite standard has allowed meaningful comparisons of fertility levels and patterns across widely different historical populations. The Hutterite standard has also provided indices with a clearly interpretable and unambiguous reference to an empirically observed high fertility standard. And most criticisms of the measures incorporating the Hutterite standard concern their interpretation in terms of underlying fertility behavior (e.g., diffuse birth spacing or parity-specific stopping) rather than their ability to index the levels and patterns of age-specific fertility across populations.

4. The Hutterites and Bio-demography

Underlying their use as a high-fertility standard in many different methods, the Hutterites in and of themselves offer a unique opportunity for demographers to explore biological aspects of fertility and fecundity. An absence of any evident parity-specific fertility control, along with very high fertility levels, makes the Hutterite population one which may be used to study biological determinants of fertility without the confounding influence of fertility limiting behaviors. However, a troubling concern in the study of historical populations that lack widespread evidence of fertility control is the extent to which there may be many subgroups within the population with different fertility levels and patterns arising from different behavior and sociocultural circumstances. The Hutterites' communal lifestyle and uniformly high fertility give no reason to suspect wide differences

in fecundability and fertility from social or cultural forces. And the uniformity of the population in many demographic behaviors (e.g., universal marriage and early ages at marriage, short durations of breast-feeding and early weaning, short birth intervals, absence of induced abortion, and low levels of premarital conception, etc.) is likely to minimize many sources of variation in fertility compared with other populations. This relative homogeneity, or absence of subgroup variation, is especially important to the recent use (and assumptions) of event history methods to estimate the underlying biological patterns of fecundability among the Hutterites. This allows researchers estimating fecundability with Hutterite data to assume the underlying patterns and variations they discover arise from biological variation (see Larsen and Vaupel 1993 for a review and example of such studies).

As further studies provide more refined estimates of Hutterite fertility and fecundity, these will likely continue to serve as empirically grounded standards for our demographic expectations in the absence of intentional fertility limitation. The theoretical importance of these expectations to demography is evident in the significant role which studies of the Hutterites have had in shaping the concept of natural fertility and debates over the nature of fertility limitation. Their methodological import is clear in the wide variety of methods already grounded in the Hutterite fertility standard.

D. L. Anderton

Hybridity

'Hybridity,' originally a biological term, has been used by authors in the social sciences, literary, artistic, and cultural studies to designate processes in which discrete social practices or structures, that existed in separate ways, combine to generate new structures, objects, and practices in which the preceding elements mix. During the 1980s and 1990s its use has increased, particularly in English and Spanish, whereas in other languages, such as French, the term coexists with adjacent concepts like *mestizaje* and syncretism, favored in French literature. Some authors include these classic terms in 'hybridization,' conveying greater flexibility to the term to include processes of intercultural confluence.

1. The Term Hybridity in Biology and in Social Sciences

The use of hybridity in humanistic and social science studies has been questioned due to the biological origin of the concept. The risk of transferring the sterility commonly associated with the term to society and culture is put forth. Even though this criticism can still be found in recent writings, it is the extension of a nineteenth-century belief, when hybridization was looked upon with suspicion because it was believed to harm social development. However, this opinion has changed since 1870 with Mendel's theory of the enhancement produced by genetic mixing and its twentieth-century examination (Olby 1984). Strictly considered, biology, particularly botany, teems with fertile hybridizations which take advantage of characteristics of cells from different plants to enrich the growth, resistance, quality, and economic and nutritional worth of food stuffs made from these combinations (Callender 1988). Hybridization of human DNA with bacteria to produce protein is also common; this is, in fact, the main means to generate insulin.

Adoption of the term by the social sciences is not legitimized by its biological background. Similarly to

other concepts taken from biology, for example, *reproduction*, for which a new elaboration had to take place in order to talk about social, economic, and cultural reproduction, the theoretical solidity and explanatory power of hybridity in social sciences depends upon the manner in which the term is relocated within networks of specific concepts referring to society and culture.

On the one hand, hybridity is linked with more or less classical notions of social thought that allude to the separation and mix among cultures and strata: race, ethnicity, *mestizaje*, miscegenation, syncretism, identity, multiculturalism, heterogeneity, creolization, transculturation, bricolage. On the other, its treatment and epistemological consistency depends upon the manner in which different authors link the concept with terms and theories, such as tradition, modernity, postmodernity, border, contradiction, globalization, that condition the understanding of hybridity.

The sociocultural construction of hybridity has taken place in several disciplines. As a linguistic process it was elaborated, among others, by Mikhail Bakhtin, who used the term to characterize the co-existence of learned and popular speech in the same group, or even in a single speaker, and by Homi Bhabha, who defines hybridity as a metonymy of presence and places it amidst power relations, noting differences between colonial and resistance hybridization, depending on whether the linguistic and literary mixes serve domination or subversion (Bhabha 1994). Some historians of the Americas speak of hybridity to explain the interweaving of pre-Columbian imagery with the colonizers' Spanish one and with the culture developed later, during modernity (Gruzinski 1999).

2. Mestizaje, Syncretism, Transculturation, Creolization, and Hybridization

Mestizaje and hybridization are as old as exchanges among peoples, migrations, and wars of conquest wars. The Tower of Babel is a story of *mestizaje*. Pliny the Elder spoke of hybridization when referring to the migrants that arrived in Rome in his day. Several historians and anthropologists have illustrated the decisive role of *mestizaje* in certain areas, such as the Mediterranean, since the days of Classical Greece (Laplantine and Nouss 1997). But the more intense—or researched—periods of interethnic and intercultural mixing happened with Europe's expansion into America.

The mix of Spanish and Portuguese colonizers first, then of English and French, with American Indians, to which the African slaves were added, made *mestizaje* the prevailing process within the societies of the so-called New World. Nowadays, less than 10 per cent of the population of Latin America is descended from

indigenous peoples alone (this percentage decreases in the US and Canada). Communities of European descent that have not mixed with native peoples are also a minority. Thus, the makeup of all of the Americas requires the notion of *mestizaje*, both biologically—production of phenotypes from genetic crossbreeding—and culturally: blending of European and native American habits, beliefs, and ways of thinking.

For a very long time, studies on physiognomic and chromatic aspects of *mestizaje* were privileged. Skin color and physical features are still critical in the ideological construction of subordination and discrimination; however, in the social sciences and in more democratic political thought, *mestizaje* presently centers on the cultural dimension of the combination of identities. In anthropology, cultural studies, and cultural policy making, the issue is presented as devising ways to share multicultural life styles (Kymlicka 1995).

Of the diverse crossings that take place among cultures, the religious ones have received the most attention. They are usually referred to by a specialized term: syncretism. European expansion in Africa, Latin America, and Asia gave way to multiple mixed forms where heterogeneous beliefs fused and new divinities emerged (the Virgin of Guadalupe in Mexico; the combination of African ancestors, indigenous figures, and Catholic saints in Brazilian Umbanda). Practically every religion has fundamentalist currents that seek to defend pure forms, but the magnitude of migration and the transcontinental spread of rituals and beliefs during the eighteenth and nineteenth centuries stressed these hybridizations and increased tolerance towards them to such a point that in countries such as Brazil, Cuba, Haiti, and the US, it was frequent to find a double or triple religious affiliation. An example may be a Catholic person participating in an Afro-American ritual or in a New Age ceremony. If we consider syncretism in a wider sense, such as the simultaneous adhesion to several belief systems, not only religious ones, the phenomenon grows remarkably, particularly among the many people who resort to indigenous or Asian medicine for certain ailments, to allopathic medicine for others, and even to Catholic or Pentecostal rituals. The syncretistic use of these health resources usually is combined with musical fusion and multicultural social organization systems, as is the case in Cuban *Santería*, Haitian Voodoo, and Brazilian *Candomblé* (Rowe and Schelling 1991).

Some of these phenomena were what Fernando Ortiz, Cuban historian and anthropologist, thought about when he proposed the term *transculturation* (Ortiz 1995/1947) to designate 'processes in which features are not mechanically aggregated, but give way to a new phenomenon, independent and original.' Bronislaw Malinowski's endorsement of that utterance in an introduction to Ortiz's book, and its future development by literary critics Angel Rama and

Mary Pratt in their study of travel writing, are still appealing; particularly in literature and in Anglo-Saxon and Latin-American cultural studies.

The word creolization has also been used to refer to intercultural combinations, especially in anthropology and linguistics. Rigorously, it designates the language and culture created by variations of the basic tongue with other languages in the context of the slave trade. It includes the mixtures French has undergone in America and the Caribbean (Louisiana, Haiti, Guadeloupe, Martinique) and in the Indian Ocean (Reunion, Mauritius), or Portuguese in Africa (Guinea, Cape Verde), in the Caribbean (Curaçao) and Asia (India, Sri Lanka). But whereas it presents paradigmatic tensions between orality and writing, learned and popular sectors, center and periphery, in a diversity *continuum*, Hannerz suggests its usage could be extended to the transnational field to name 'processes of cultural confluence' characterized 'by power, prestige, and material resources inequality' (Hannerz 1997). Even though he is not the only author to stress the inequality and discontinuity present in hybridizations, the emphasis he places on examining increasing flows between center and periphery, together with the asymmetries among markets, states, and educational levels, helps avoid considering *mestizaje* as simple intercultural homogenization and reconciliation (Hannerz 1996).

3. Hybridization, Modernity, and Globalization

3.1 Hybridization

Whereas the terms mentioned above are nearly used as synonyms by several authors, *mestizaje* takes precedence in studies devoted to the mix of races or ethnic groups, and syncretism to refer to religious fusion or traditional symbolic movements. Besides the fact that *mestizo* has no English equivalent (some authors include the Spanish word in their English writing), research carried out during the 1980s in Spanish, English, and occasionally in French and Portuguese adopted 'hybridity' to include diverse intercultural mixes: ethnic *mestizaje*, syncretism regarding beliefs, and other modern fusion in which arts and crafts integrate with industry, the cultured with the popular and traditional and with mass media messages (Bhabha 1994, García-Canclini 1995, Bernd and de Grandis 1995, Papastergiadis 1997, Webner and Modood 1997).

3.2 Modernity

Modernity, an expression of which are nation states, has coherently organized—sometimes in reality, others in appearance—the diversity of cultures. There

are fewer than 200 nation states which comprise more than 600 languages and some 5,000 ethnic groups. These states have had to organize multiculturalism through diverse policies, at the same time that they facilitated communication among ethnic groups and the different languages included in their territory. Even in the cases in which a single language was imposed over the 20, 50, or 100 groups that formed the nation, that common language adopts diverse modulations in the same English- or Spanish-speaking country when they combine or hybridize with the words, syntactic structures, and semantic references of the speakers of other tongues.

In the meantime, two other characteristics of modern development, transnational expansion of capitalism and of mass communication technologies, advance relationships and exchanges between local traditions and cultures of modernity. The crafts and celebrations of peasant groups travel, together with their producers, to cities and often to other countries, or they enter into contact with foreign tourists. Ethnic music, linked to specific rituals of a certain group, is not only taped in CDs, movies, and videos to be distributed worldwide; it is also mixed with classical and contemporary music, with jazz, rock, salsa, and other local and regional kinds of music. This is how the *chicha*, a mix of Andean and Caribbean rhythms was produced. Other examples include the jazzy reinterpretation of Mozart by the Afro-Cuban group Irakere, the re-creation of English, Indian, and other music by the Beatles, Peter Gabriel, and many other musicians.

The rigid borders established by nation states became porous. Few cultures can be defined today as stable units, with precise boundaries based on the occupation of a confined territory. But the multiple opportunities to hybridize neither imply indeterminism nor unrestricted freedom. Hybridization happens under specific historical and social conditions, in the midst of production and consumption systems that sometimes operate as constraints, as can be witnessed by the lives of many migrants. One of the social entities that support but also condition hybridization are the cities. The multilingual, multicultural megalopolis, for example, Paris in the nineteenth and twentieth centuries, Vienna at the beginning of the twentieth century, London, Berlin, New York, Los Angeles, Buenos Aires, Sao Paulo, Mexico, and Hong Kong are studied as centers where hybridization fosters greater conflict as well as greater cultural creativity (Appadurai 1996, Hannerz 1996).

3.3 Globalization

Globalization stresses these trends of modernity by creating world markets of material goods and money, messages, and migrants (workers, tourists, exiles).

These constant streams and interactions have weakened borders and frontier posts; also the autonomy of local traditions. At the same time, they foster many more forms of hybridization than they ever did in the past: productive, commercial, communicational, and in consumption habits. To the characteristic modalities of hybridization, which came into existence due to migrations and trips, as well as to the educational integration policies by nation states, the mixtures generated by cultural industries have to be added. Industrialization encompasses not only the mass media (radio, movies, television, video), but also industrial production for massive audiences in international exhibitions, folkloric groups' tours, and globalized theme parks such as Disney's (Harvey 1996).

However, the main globalization analysts note that it not only integrates and generates *mestizajes*; it also segregates, produces new inequalities, and stimulates differentialist reactions. Identity alliances emerge (Latins or Arabs in the US or in Europe) as do organizations of regional integration (European Union, NAFTA, Mercosur), which in part aim at strengthening partial groupings to counteract the indiscriminate interaction of globalism (Beck 2000). Some of the actors find resources to resist both globalization and hybridization at once in these alliances.

3.4 The Future

Several anthropologists and cultural studies specialists maintain that the generalized relevance of hybridization requires changes in the ways social sciences are formulated. It is impossible to analyze large units, that is, nations, states, transnational enterprises, without noticing their internal diversities and modulations, as often happens in disciplines devoted to analyzing at the macro level, such as sociology and economics. It is not acceptable either that anthropology, traditionally dedicated to small communities, continues to see solely their homogeneity, and overlooks the heterogeneity and hybridization caused by the transnational goods and messages that intersect these communities. To be able to politically negotiate diversity and hybridizations, we need a '*mestizo* way of thinking' (Laplantine and Nouss 1997, Gruzinski 1999).

Fundamentalisms are not the only opposition to religious syncretism and intercultural *mestizaje*. There is an extended resistance to accepting hybridization because it generates insecurities within cultures and conspires against their ethnocentric self-esteem. It also presents a challenge for modern analytical thought, used to the binary separation: civilized, wild; national, foreign. This schematism leaves aside frequent ways in which culture is shared nowadays, for example, take

someone who is Brazilian by nationality, Portuguese by tongue, Russian or Japanese by origin, and Catholic or related to Afro-American religions.

Hybrid thought will not look forward to working with radically different, homogenous, compact units as much as with intersections, transitions, and transactions; less with identity than with heterogeneity and multiple senses of belonging. To understand the contemporary world it is indispensable to study how cultures mix, to what rhythms and modalities, what they lose and gain in the process, how they agree to cohabit, and how they negotiate to keep the difference alive. To comprehend hybridity and to learn to be cosmopolitan, 'multicultural gourmets', capable of traveling in diverse cultures and savoring the differences, has become necessary to fathom globalization and the ethnic and national societies' crisis. In brief, to understand society.

Hypertension: Psychosocial Aspects

Hypertension is a complex disorder of physiological regulation involving many interacting biological and environmental factors. Although the prevalence of hypertension has decreased over recent years, the latest US survey placed the age-adjusted prevalence (> 140/90 mmHg) at 20.4 percent. Interest in the role of psychosocial factors in hypertension has a long history beginning with theories about social stress, affective processes, and individual behavioral dispositions in its etiology. Noteworthy are the early psychosomatic writings about the significance of anger expression and suppression for high blood pressure.

1. Direct and Indirect Evidence

Numerous studies provide evidence of a definite role for psychosocial factors in hypertension. Direct evidence is derived from cross-sectional studies of individuals with hypertension compared to control samples and longitudinal studies to determine what factors are associated with the development of hypertension. Indirect evidence comes primarily from studies of psychosocial factors affecting blood pressure in healthy individuals with or without various predisposing characteristics. Psychosocial factors are also relevant to the degree of adherence to medications, engagement in health-related behaviors affecting risk for hypertension, effectiveness of antihypertensive medications, and nondrug methods of managing hypertension based on psychosocial concepts and methods.

2. Blood Pressure Reactivity and the Sympathetic Nervous System

Elevations in blood pressure can be elicited by many different stimuli and circumstances involving psychological and social factors. Examples are exposure to noxious, painful, threatening, or otherwise stressful

stimuli and events, participation in demanding tasks requiring repeated behavioral and/or mental adjustments, continuous striving and active coping, frustration in achieving goals, mental effort especially in solving difficult problems, momentary moods and behaviors involving fear, anger, and other emotional states, inhibition or suppression of emotional states and reactions, conflicts about the expression of angry feelings or other emotions, and interpersonal and group conflict. Socialcultural norms define what are appropriate and desired reactions and behaviors. The extent to which blood pressure is affected is determined by the balance between demands placed and the individual's resources and ability to cope with the demands.

A common theme in the literature is that individual differences in cardiovascular reactivity to various stimuli and events serve as a risk factor for hypertension and cardiovascular disorders in general. Increased sympathetic nervous system activity and associated hormonal changes is considered the neural source of excessive cardiovascular reactivity (Folkow 1989). In established hypertension, sympathetic activity is increased, particularly in individuals in whom the elevated blood pressure appears to have a basis in the nervous system ('neurogenic' hypertension) (Esler et al. 1977). Moreover, most antihypertensive medications appear to regulate blood pressure by interfering with mechanisms of sympathetic activation. Low parasympathetic activity (vagal tone) may also be a factor in hypertension and may contribute by slowing cardiovascular recovery from stress.

The large body of experimental evidence linking excessive cardiovascular reactivity in humans to established hypertension is compelling on empirical as well as theoretical grounds (Light 1987). Moreover, psychosocial factors are also associated with higher casual or ambulatory levels of blood pressure, suggesting that the transformation from excessive reactivity to a chronic elevation may take place with repeated instances of blood pressure increases. Thus, in some samples of subjects, during waking hours and even during sleep, average levels of blood pressure have been found positively associated with such personality traits as hostility and defensiveness (Shapiro et al. 1993). Physiological models have been developed to describe the cardiovascular dynamics underlying the transformation from early heightened reactivity to later established higher levels of blood pressure.

3. Methodological Complications in Human Studies

Despite the vast literature, debates continue about the conclusiveness of the evidence supporting the cardiovascular reactivity hypothesis based on responses to laboratory stressors. The findings are not always consistent or easily integrated. Individuals vary widely

in their blood pressure responses to various circumstances. Variations in the kinds of individuals and methods chosen for study may result in different findings and conclusions. Laboratory settings may impose constraints on the participants so that they may not respond to challenges and threats with their preferred method of coping. Individuals also vary in the degree to which their responses persist over time for any one provocation or generalize across provocations. The association between perceptions of stress and the blood pressure response to such stress is not consistent because some individuals tend to report not feeling stressed, anxious, or angry while at the same time showing increased physiological reactivity to provocations or elevated blood pressure levels in general. These individuals either generally do not feel negative emotions or wish to make a good impression on other people. This characteristic has been labeled 'defensiveness.' Finally, many individuals learn to cope effectively with stress or to keep their emotional responses under control. For example, experienced air traffic controllers or other professionals dealing with emergencies do not necessarily show elevated levels of blood pressure (Sega et al. 1998). By taking these various factors into account, further sense may be made out of some of the apparently inconsistent findings, thus adding to confidence in the soundness of the reactivity model.

Thus, the ability to predict individual differences in reactivity and in the development of sustained high levels of blood pressure and established hypertension has been improved by considering other psychological factors such as various personality traits and coping styles (anger/hostility, defensiveness and emotional suppression, denial and repression, anxiety, lack of control and helplessness, Type A behavior pattern, depression, pessimism) (Johnson et al. 1992, Jorgensen et al. 1996, Suls et al. 1995). In the social domain, contributing factors are low socioeconomic status, social disintegration and family disruption (poverty, high crime rates, high divorce rates), occupational stress (job strain, job dissatisfaction, high job demands, little independence in one's work duties or latitude in the ability to make decisions), low levels of family and social support, social isolation, taxing responsibilities such as providing care to disabled family members, marital conflict, minority social status, certain ethnicities, and certain gender roles (Colhoun et al. 1998, Pickering et al. 1998). For example, anger and hostility do not necessarily have the same implications for men and women.

4. Psychobiological Models

The ability to predict whether repeated elicitations of increases in blood pressure will lead eventually to chronically elevated blood pressure and to cardiovascular disease is probably best improved when

certain biological factors are included in the test models, such as obesity, physical inactivity, poor physical conditioning, salt sensitivity, excitable autonomic nervous system, deficiencies in certain vitamins and minerals, intake of sodium and potassium, presence of other disorders such as diabetes, high glucose, insulin, or lipid levels, certain racial characteristics, and other genetic or constitutional predispositions such as family history of hypertension and cardiovascular disease. For example, in a study of occupational stress in nurses, those nurses for whom both parents had hypertension and who were hostile, defensive, or anxious had elevated ambulatory blood pressure, which was highest during work days (Goldstein and Shapiro 2000). Other psychosocial, life style, and habitual behavior patterns need to be considered as they are relevant to one's diet, activity level, and intake of caffeine, alcohol, and other substances. For example, high levels of social stress or certain personality traits like a high level of trait hostility may be associated with unhealthy health habits such as smoking, low levels of exercise, poor physical conditioning, and poor nutrition.

5. Diagnostic Issues

Psychological factors are relevant to the diagnosis of hypertension. Some patients may show elevations in blood pressure during a doctor's visit and evaluation but not at other times ('white coat effect'). This effect has been related to an alerting response to the examination or anxiety about one's health. In one study, trait hostility was found relevant to this effect. Those individuals who were highly hostile were consistently high in blood pressure during the examination and over the course of the day, whereas low hostile individuals were more likely to show elevated pressure only during the evaluation and not during the day (Jamner et al. 1993). By having the patient record blood pressure at home, useful information is obtained on blood pressure variability at different times and occasions that may guide decisions about treatment and increase the patient's adherence to medications or otherwise facilitate pressure reduction. Reliable devices are now available for this purpose.

6. The Problem of Blood Pressure Variability

Blood pressure can be quite variable both in the short term with a range of 5 mmHg or more over the course of a min and 30–40 mmHg or more over the course of waking hours during the day. These facts provided the impetus for the development of portable automatic 24-hour blood pressure recorders, initially used in the diagnosis of hypertension and the evaluation of drug effects and more recently in the investigation of blood pressure in different settings (Shapiro et al. 1993). Ambulatory blood pressure recording methods but-

tressed by information obtained from diaries of self reports of moods and the situations encountered in everyday life offer many advantages, including a large number of blood pressure measurements under different conditions (work vs. nonwork or off days, sleep vs. waking periods) and in a variety of repeatedly occurring situations, locations, and activities. Valuable data have been obtained from studies of special populations: paramedics, traffic control agents, secretaries, laboratory technicians, emergency dispatchers, nurses, bus drivers, college students. The research is challenging because of the complexities and uncontrolled nature of the observations, but novel analytical tools show great promise.

7. Psychosocial Factors Affecting Treatment

Psychosocial factors play a role in the treatment and management of hypertension. The response to anti-hypertensive drugs may partly depend on psychosocial factors, although research is sparse on this topic and these factors are not usually considered in the choice of medications used to treat patients. In one example, individuals with high levels of hostility were found less responsive to diuretics than nonhostile individuals, suggesting that the former might be more responsive to agents directly affecting the sympathetic nervous system. Ethnicity can affect the response to drug and non-pharmacologic treatments of hypertension (Brownley et al. 1999). Psychological factors influence degree of adherence to medications and may affect the degree to which side effects of medications occur and affect quality of life.

A great deal of research has been devoted to the evaluation of nondrug treatments of hypertension derived from psychological principles (Silverberg 1990). These procedures seem most suitable as alternatives in patients with mild hypertension, especially those who are free of significant cardiovascular disease risk factors (family history, high cholesterol level, smoking) and in other patients as a means of reducing the amount of medication needed for blood pressure control or completely eliminating the need for such medication. Reducing drug requirements may be of special value in dealing with undesired side effects of medications in some patients. The methods include progressive relaxation, simple relaxation, biofeedback-guided relaxation, biofeedback training involving blood pressure, heart rate, and other cardiovascular measures, biofeedback training using measures associated with sympathetic nervous system functioning, cognitive behavioral methods of facilitating coping with stress and dealing with anger ('stress management training'), hypnosis, and autogenic training. As yet there is no consensus about the effectiveness of these procedures, and major trials remain to be done. Other traditional methods such as yoga and meditation may be useful as a means of increasing awareness and control of mental and bodily functioning. Regular physical exercise can

facilitate blood pressure reduction and improve the coronary circulation. Whether or not people exercise, avoid or take medications, or use herbal, homeopathic, or various nondrug methods is determined by many different psychological, social, and cultural factors.

8. Summary and Conclusions

From the standpoint of the social and behavioral sciences, hypertension has attracted a great deal of attention. It forms the backbone of the growing fields of health psychology and behavioral medicine, and benefits greatly from the integration of methods, concepts, and findings of psychology, psychophysiology, social psychology, physiology, and biological and medical sciences. The evidence is supportive of the role and significance of psychosocial factors in the etiology, course, and treatment of hypertension. These factors include personality and coping styles, social and occupational stress, social status, family and social support, ethnicity, and gender roles. This knowledge has the potential for deepening our understanding of the mechanisms involved in hypertension, improving the effectiveness of both drug and non-drug approaches to treatment, and facilitating efforts to prevent the disorder. There is great need for further systematic research and especially for theoretical and empirical integration of psychosocial and biological knowledge of the disorder.

Hypnosis, Neural Basis of

Modern conceptions of hypnosis can be traced directly to the work of Franz Anton Mesmer, a Viennese physician working in Paris just prior to the French Revolution. Within 30 years of Mesmer's work, most of the basic hypnotic phenomena from amnesia to pain control to hallucinations had been reported (see Ellenberger 1970). James Braid, a Scottish surgeon, coined the term hypnosis in the 1840s. Nowadays, hypnosis refers to the acceptance of a social role, usually involving deep relaxation, and engagement in fantasy. During hypnosis a lowering of critical judgment permits a wide range of behavioral, cognitive, and affective responses to suggestion (see, for example, Orne 1970). This article addresses the question of whether response to hypnosis can be related to specific neural mechanisms or events.

During the last two hundred years, a variety of exaggerated and mistaken claims have been made for hypnosis. Claims have ranged from enhanced psychic abilities to past life regression, to revived memories of alien abduction. In the past, such claims have resulted in periods of scientific disrepute for hypnosis. Nevertheless, during the last century fine scientists (e.g., Hull, Hilgard, Orne, Barber, Sarbin and their students) have been drawn to study hypnosis (see Sheehan and Perry 1976). As well as elucidating the domain of hypnosis, their careful investigations have increased understanding of the potential pitfalls that appear in

experimentation with human research participants (see Orne 1959, 1970).

An observer, watching a demonstration of hypnosis with a highly hypnotizable research participant, sees a series of simple verbal suggestions that result in relatively spectacular alterations of behavior, thought, emotion, and perception. For example, the hypnotized burn patient lies quietly and reports no pain, seemingly relaxing while his dressings are changed: a highly painful procedure (Hilgard and Hilgard 1975). The laboratory research participant asked to re-experience the distant past seems to become childlike, entirely captured by the delusion that he or she is many years earlier. Asked to hallucinate the absence of an obstacle between where the participant sits and some other place, the participant claims to see nothing in the intervening space. But when asked to walk to that place (and thus, through the obstacle whose absence is being hallucinated), the participant walks around the obstacle without seeming to notice doing so. Asked to look back and see that there is nothing there, there is easy agreement with no seeming sense that walking around the obstacle has just contradicted this statement. Asked to forget all that has happened until a pencil is tapped twice, the participant will later 'awaken' with amnesia that is (almost always) temporary and reversible.

Thus, in response to brief verbal suggestions, the hypnotized individual seems to see, hear, feel, smell, and taste in apparent contradiction to the stimuli actually present (see Orne and Hammer 1974). Memory, the sense of volition, mood, and even awareness of self may be altered. With appropriate suggestions, such effects may be extended into the posthypnotic period.

Hypnotic phenomena are easy to elicit and robust. A graduate student, given two or three hours training and a standardized script, such as one of the *Stanford Hypnotic Susceptibility Scales*, can elicit all the major hypnotic phenomena in a psychology laboratory (Weitzenhoffer 1959, 1963; see also Shor and Orne 1962). There they can be studied under controlled conditions. Note that for all practical purposes, hypnotic suggestions are likely to be carried out only in settings seen as culturally appropriate. These include therapeutic, classroom, entertainment, research, and forensic settings (Orne 1970).

1. Problems with Seeking Psychophysiological Concomitants of Hypnosis

People commonly speak of being 'hypnotized' or in a hypnotic 'trance.' The underlying assumption is that hypnosis is a distinct, altered state of consciousness. Most early theorizing (and much current clinical thought) about the hypnotic state employed circular reasoning that goes something like this: Q: Why do you say that person is hypnotized? A: Because she is

responding to hypnotic suggestions. Q: Why does she respond to hypnotic suggestions? A: Because she is hypnotized.

As Orne (1959) showed us, the hypnotized participant acts as shared cultural expectations suggest. In fact, the deeply relaxed hypnotic participant lying or sitting quietly while listening attentively to the hypnotist's voice manifests only one of many forms hypnosis has assumed. For example, in the late eighteenth century, Mesmer's Parisian patients sometimes had pseudo-epileptic seizures during hypnosis. In the late nineteenth century, Charcot's Parisian patients demonstrated first catalepsy, then lethargy, and finally somnambulism (but generally did not have seizures) when deeply hypnotized. At the same time in the south of France, Bernheim's hypnotized patients simply restfully reclined (see Ellenberger 1970). Most modern research participants and patients sit quietly and look very relaxed during hypnosis, although they may also be hypnotized with an 'active-alert' induction, involving, for example, pedaling a stationary bicycle vigorously (see Banyai and Hilgard 1976).

Obviously, peripheral neural activity during these varying hypnotic activities differs widely, reflecting the activity, not hypnosis. Nor has there been any evidence of brain activity unique to hypnosis *per se*. Nor is there evidence of specific brain activity that accompanies the entire hypnotic experience. After 50 years of modern research, the lack of evidence for any unique psychophysiological marker of a hypnotic trance state is one of the factors that have led researchers largely to abandon the concept of a hypnotic trance as a causal explanation for response to hypnotic suggestions (see Kirsch and Lynn 1995).

Concepts such as response expectancies, role involvement, self-delusion, and cognitive abilities are currently used to explain hypnotic responses. This does not mean that hypnotizing people does not have specifiable effects or that the experiences of highly hypnotizable subjects are consciously faked or otherwise theoretically unimportant. Rather, hypnotic effects result from making suggestions to willing participants of differing abilities and from the expectations and cognitive models that a hypnotic induction engenders both for the hypnotist and the participant (see Sheehan and Perry 1976).

At present, it is clear that the ability to respond to hypnotic suggestions lies largely in the subject (and not in the skill of the hypnotist as was previously held). Reports of being hypnotized or in a trance are seen as reflecting a subjective experience that is one of the many effects of cognitive and emotional set, social and historical setting, and suggestion (see Kirsch and Lynn 1995). And while all subjective experiences must have some neurophysiological substrate, psychology as a field of study has not reached the point where many can be pinpointed. Nonetheless, if phrased properly, reasonable questions about the psychophysiological concomitants of hypnosis can be asked.

2. Psychophysiological Differences in Response to Hypnotic Induction

A discussion of the neural basis of hypnosis may be phrased in terms of answers to three questions. First, are there measurable differences in brain activity in response to hypnotic induction among those who subsequently respond strongly to hypnosis in comparison to those who do not? Second, when measured outside hypnosis, are there overall psychophysiological differences between participants who usually respond to hypnotic suggestions for major changes in perception, memory, and/or cognition and those who do not? Third, are there patterns of brain activity associated with response (vs. lack of response) to specific hypnotic suggestions? While there are interrelated issues among these three questions, it is probably least confusing to look at these questions sequentially.

First, does hypnotic induction result in measurably different neural patterns among those who subsequently respond to the more spectacular hypnotic suggestions (those calling for hallucinatory or major cognitive changes) and those who do not? The evidence, while mixed, favors a tentative 'Yes, but for reasons that render the difference unimportant.' Brain function studies are divided between those that find highly hypnotizable, well lateralized, right-handed research participants shifting to greater relative right-hemisphere activation after hypnotic induction and studies that find no differences. The lack of consistent findings may be methodological: studies finding differences tend to use ratio measures that are meant to be sensitive to small differences (see, for example, LaBriola et al. 1987). Studies that do not find differences after induction tend to look at absolute values of measures of brain activation, a less sensitive measure (Graffin 1995). So there is some evidence that successful induction of hypnosis often involves a 'shift to the right' a finding in line with task performance measures of the effects of induction.

Why is this unimportant? Activation changes in response to induction are relatively small and disappear once other suggestions are made or tasks required. Relative hemispheric activation, with or without hypnosis, depends on the mental task participants are asked to perform. So the 'shift to the right' seemingly reflects a response specific to the 'task' of induction. And that response might well change were a different type of induction used (see Crawford and Gruzelić 1992).

3. Psychophysiological Differences between Highly Hypnotizable Participants and their Less Hypnotizable Counterparts?

Many studies distinguish between highly hypnotizable subjects and their less hypnotizable peers. Most modern scales of hypnotic responsiveness comprise

standardized, relaxation oriented inductions followed by 5 to 12 hypnotic suggestions that are each scored pass/fail based on an objective criterion. Entire hypnotic scales are often administered by tape recorder and both experimenter-scored individual formats and self-scored group formats are available. Total score, the measure of each participant's hypnotizability, is simply number of suggestions passed (see Kihlstrom 1985).

All social scientists use Pearson's reliability coefficient, a coefficient that varies from +1.00 (relative scores on two measures are identical) to 0.00 (no linear relationship between two sets of scores) to -1.00 (relative scores are identical in size but opposite in sign). Hilgard and his colleagues have found that test-retest reliability of hypnotizability scales usually averages about +.90 over periods of one week and about +.70 over periods from 10 to 25 years (Piccione et al. 1989). These data indicate that hypnotizability is a highly stable difference among individuals. Among personality traits, the reliability of hypnotizability measurement is equaled or exceeded only by multi-task measures of intelligence.

Hypnotizability is not easily modifiable and governs the large majority of the variance in most experimental studies of hypnotic phenomena. Moreover, what has come to be called 'hypnotizability' is observable in response to suggested alterations in perception, memory, and/or cognition with or without formal hypnosis (see Kihlstrom 1985).

There are two fairly well established psychophysiological correlates of hypnotizability. First, highly hypnotizable research participants (highs) show higher levels of resting theta activity than their less hypnotizable counterparts. Spontaneous EEG activity may be viewed as constituted of waveforms of different frequencies (delta -0 to 3 Hz, theta -4 to 7 Hz, alpha -8 to 13 Hz, beta -14 to 30 Hz). Waking EEG records are largely made up of alpha and beta activity, with a small percentage of theta activity. When measured during rest, this small proportion of theta activity is slightly higher among the more highly hypnotizable participants, especially in recordings from the more anterior brain regions. While no convincing explanations for this phenomenon have yet been advanced, the notion that the theta differences between highly hypnotizable participants and their less hypnotizable counterparts are related to attentional abilities is the most popular hypothesis (see Graffin et al. 1995, Sabourin et al. 1990).

Second, if a variety of other factors are controlled (e.g., task difficulty, familial history of right handedness), well lateralized, right-handed research participants will show greater relative left cerebral hemispheric activation during verbal and mathematical tasks and greater right hemisphere activation during mental imagery. This pattern of task specific hemispheric asymmetry is seen more clearly among highly hypnotizable participants than among their less

hypnotizable counterparts. Highs show greater relative left cerebral hemisphere activation during verbal and mathematical tasks than do less hypnotizable participants. Similarly, highs show greater relative right hemisphere activation during imagery than do low or moderately hypnotizable participants. (The inclusion of moderately hypnotizable subjects provides some control for compliance. Moderates show the same level of compliance to behavioral suggestions as the highs, but are largely unresponsive to hallucinatory suggestions.) These findings have been interpreted as showing greater cognitive flexibility for highs and are in line with some findings in studies using task performance measures (see Crawford and Gruzelić 1992).

4. Psychophysiological Correlates of Response to Specific Hypnotic Suggestions

The third question is whether psychophysiological differences can be found between those responding to specific hypnotic suggestions and those who fail to respond. This question can be asked in respect to hypnotic phenomena of central interest to experimental psychologists (e.g., hypnotic hallucinations), clinicians (e.g., healing of skin and immune system related disorders), or both (e.g., hypnotic analgesia).

Until the recent advent of functional magnetic resonance imaging (fMRI), activity in the normal waking human brain has been studied, for the most part, using measures of spontaneous and evoked electrical activity in the brain. Researchers usually utilize one of three electroencephalographic (EEG) technologies in which brain activity is recorded from the surface of the skull using standardized electrode placements. Obtaining EEG signals is similar to making an electrocardiogram except that EEG signals are measured in microvolts rather than millivolts signals studied with an EKG. (Since much greater amplification is required, EEG recording requires great care in avoiding electrical, movement, and other artifacts.)

Once having obtained an artifact free EEG signal, researchers digitize and transform it. Most frequently they use signal processing, mathematical (Fourier) transformations to determine the proportion of time in which alpha, beta, and theta activity occur. Alternatively, one may integrate the total area under the curve of an EEG record and compare total area at various sites in the brain during different tasks. In both methods one examines the signals from many recording periods (usually of 1 second to 10 minute duration) over minutes or hours of total recording time (see Karlin et al. 1980, Perlini and Spanos 1991, Sabourin et al. 1990). Almost all the research underlying the conclusions in the earlier sections of this essay has used one of these two techniques.

A third EEG procedure involves the presentation of brief, repeated auditory, visual, or tactile stimuli to elicit acute changes in electrical brain activity called event-related evoked potentials. Evoked potentials can be seen when the spontaneous EEG, used as data in the first two methods, is mathematically removed and only short-term changes in EEG signals remain. The precise shape of evoked potentials differs in relationship to a variety of factors including the duration, intensity, predictability, meaning, and sensory modality of the stimulus. However, when such factors are controlled, one expects a sequence of alternating positive and negative potentials during the second or so after stimulus presentation.

Several studies seemingly indicate that hypnotic suggestions to hallucinate alter evoked potentials among highly hypnotizable participants in ways consistent with their reported hallucinatory experiences. In these studies, highly hypnotizable participants who claim to experience either a particular hallucination or amnesia are compared to less hypnotizable counterparts who do not report similar experiences. Across visual and auditory stimuli and across experiments, highly hypnotizable participants seem to show augmented or faster positive evoked potentials and/or decreased or delayed negative potentials when asked to hallucinate the presence of stimuli that are not there. Again consistent with suggested hallucinations, when asked to hallucinate the absence of stimuli that are present, highly hypnotizable subjects show decreased or delayed positive evoked potentials, and/or augmented or faster negative evoked potentials compared to their less hypnotizable counterparts. Parallel findings to those found in negative hallucinations have emerged after amnesia instructions. In sum, highly hypnotizable participants show brain activity consistent with their reports of hypnotic hallucinations (see Crawford 2001).

Perhaps because it is the most clinically relevant negative hallucination, the effects of hypnotic analgesia instructions, instructions not to experience pain when exposed to a painful stimulus, have been studied with a variety of measures of brain activity. These have included fMRI, cerebral blood flow using 133-xenon, SPECT, and integrated EEG. Such studies confirm the pattern seen in the evoked potential studies: instructions to experience analgesia leads to measurable changes in brain function indicating central amelioration of the painful stimuli among highly hypnotizable participants, but not in lows or moderates (see Crawford 2001, Karlin et al. 1980). It is also noteworthy that other studies indicate that hypnotic analgesia is not mediated by endogenous opiate systems (Hilgard and Hilgard 1975).

As to immune system and skin disorders, the positive data remain largely anecdotal. There is a long history of treating skin disorders with hypnosis. (For example, hypnosis is still treatment of choice for warts that do not respond to conventional treatment.)

Similarly, asthma may be treated with hypnosis (although there is some evidence that hypnotic effects are limited to relaxation of the upper airways, rather than changes at the level of the lung where oxygen exchange occurs). Finally, there have been a number of studies on the ability of suggestion and imagery to alter immune responding directly. However, findings have been mixed and no clear conclusions can yet be drawn other than that large, robust effects seem unlikely (see Rhue et al. 1993).

5. Conclusions

Hypnotic responses remain intriguing, somewhat spectacular effects produced by simple verbal suggestion. Since the 1950s, careful rigorous work has been done to elucidate underlying mechanisms and any psychophysiologic concomitants of these phenomena. Inducing hypnosis *per se* has no clear physiologic effects. However, when compared to their less hypnotizable counterparts, highly hypnotizable subjects show slightly higher levels of theta activity during rest and greater task consistent asymmetry on strongly lateralized cognitive tasks. This is consistent with the notion that highs are capable of more flexible attention than are their less hypnotizable counterparts. Moreover, when successfully engaged in positive and negative hallucinations, including hypnotic analgesia and amnesia, highly hypnotizable subjects show cortical activity consistent with their reported subjective experiences across a number of measures of brain function.

Hypnosis, Psychiatry of

1. Definition

This treatment technique is thought to have received its name from the English surgeon James Braid (1795–1860) whose clinical observations likened the physiological condition of those who were responsive to the intervention to the state of sleep. It is the direct descendent of the seventeenth and eighteenth century

practices then called 'Magnetism,' 'Somnambulism' and 'Mesmerism,' although its roots can be traced to the religious and healing arts of antiquity. Today practitioners of hypnosis would subscribe to the American Psychological Association's (1993) definition of hypnosis as a 'procedure wherein changes in sensations, perceptions, thoughts, feelings or behaviors are suggested.'

2. Relevant History

Chroniclers of hypnosis (see Ellenberger 1970, Gauld 1992) point to the work of Franz Anton Mesmer (1734–1815) as the cornerstone for the establishment of this technique in modern medicine. Mesmer's belief that an imbalance in magnetic fluid led to disease states in humans gave rise to the ritualized application of magnets to individuals with a variety of medical and psychological problems. Not only the metal apparatus, but also certain people were thought to possess the 'animal magnetism' to restore the magnetic equilibrium and health. French government and scientific investigators who tested his work were able to dispute Mesmer's disease theory, but not the results. People continued to recover from a variety of ailments by means of suggestions (i.e., ideas) provided by charismatic individuals, and the technique soon spread throughout Europe and the USA.

Sigmund Freud (1856–1939) made his living as a young psychiatrist by treating patients, almost exclusively, with hypnosis. As a student of the famous neurologist Jean Martin Charcot (1825–1893) and the physician Hippolyte Bernheim (1840–1919), he learned about the efficacy of an idea to facilitate an action or symptom relief. His early technique employed suggestions to deny his patients' complaints energetically and to provide assurance and motivation for the performance of more adaptive behaviors. Freud also observed hypnotized subjects seeming to possess knowledge without realization, carrying out post-hypnotic suggestions without awareness of the source, and blindly following the commands of the hypnotist. From this clinical data and as a translator of Charcot's and Bernheim's writings on suggestion, hysteria and hypnosis, he became convinced that there were powerful, unconscious mental forces extant in humans that influenced behavior.

In Charcot's Salpêtrière, Freud learned that traumatic events create trance states in hysterics, similar to hypnosis, wherein individuals are vulnerable to auto-suggestion, and painful emotions become pathologically trapped in the nervous system. Hysterics, then, suffered painful reminiscences of these traumata that became expressed cognitively, affectively, somatically and/or behaviorally. Since they possessed similar characteristics, hypnotic trance was employed to assist the individual to revisit the scene of the original trauma, re-experience the original affects for cathartic discharge and recover from their symptoms through

catharsis and insight. This technique was the basis for Freud's uncovering treatment in the *Studies on Hysteria* (Breuer and Freud 1893–1895) and hypnosis became one of the underpinnings of psychoanalytic theory and technique.

The power of suggestion, the influence of unconscious mental processes in humans and the use of hypnosis to access memories were not the only contributions of hypnosis to psychoanalysis. Freud was fascinated by the question of 'influence' and what led people to follow the directions of others. He reasoned that group activity and hypnotic treatments encourage people to minimize individual interests, personal control, discernment, personality style, etc., and to develop intense emotional relationships with people for reasons that are difficult to account for objectively. Freud saw the rapport created between doctor and patient in hypnosis to be comparable to that of tribal members for the chief and used it as a paradigm for his understanding of therapeutic influence and transference.

Where Mesmer might be credited with taking hypnosis away from the exorcists and placing it at least on the fringe of traditional medicine, Freud clearly explored hypnosis for what it could offer as a psychotherapeutic technique, and for what it might contribute to his model of the mind. It is clear from a close reading of his work that Freud continued throughout his career to use hypnosis as an archetype with which to compare and study his incipient psychoanalytic theory. However, his report that psychoanalysis began with his rejection of hypnosis relegated this technique to an inferior place among methods for mental health treatment. Very few of his followers would risk alloying the 'copper of suggestion' with the 'pure gold of psychoanalysis.' Freud's efforts to distance himself and psychoanalysis from hypnosis had something of the same dampening effect as Mesmer's failure to validate magnetic theory scientifically.

The birth of psychology and social science research techniques during the twentieth century brought new methods of inquiry into the essence and effects of hypnosis. The rise of interest in mind–body medicine also fueled clinical interest and investment in this area. Both of these developments, along with the creation of several professional journals and international societies for the study and practice of hypnosis, contributed to the continued development of this field.

3. Therapeutic Applications

3.1 Medicine

A technique that can alter sensations, perceptions, thoughts, feelings and/or behavior can be especially helpful in today's medical setting (Covino and Frankel 1999). Patients and practitioners have long experi-

enced anecdotal reports of symptom relief from something that a physician said, did or provided. Researchers in the laboratory and clinical setting have been laboring to establish empirical support for the use of hypnosis with a variety of symptomatic complaints and to manage common emotions in the medical setting to facilitate treatment.

Most clinicians have witnessed the influence of a patient's perception on the subjective experience of pain. Where an objective physiological event almost always serves as the cause of an injury, the meaning that the person makes of the event determines the amount of suffering. In experimental laboratories, hypnotized subjects have demonstrated an ability to tolerate electric shock, ischemic and cold pressor pain better than their nonhypnotized peers or when they employed other pain management strategies. Hypnotic suggestions for analgesia, distraction, and dissociation have been found to be superior to placebo, relaxation, and cognitive interventions in the management of a variety of painful conditions. Clinical research finds success for hypnosis in the management of pain associated with surgery, cancer, reflex sympathetic dystrophy, burns, interventional radiology, angioplasty, bone marrow transplant, and colonoscopy.

A number of experimenters have been successful at producing raucous breathing and decreased pulmonary function among a subset of asthma patients by means of suggestion alone. Whether these patients were invited to believe erroneously that they were encountering an allergen or breathing a bronchoconstricting drug, the idea alone was enough to affect their breathing adversely. Several well-designed studies have found that hypnosis training has a better impact on asthma symptoms, 'as needed' (p.r.n.) medication use, and pulmonary function tests than education, relaxation, guided imagery, and placebo inhalers. Furthermore, asthma patients who were trained to use hypnosis to manage their breathing have demonstrated a superior ability to tolerate methacholine challenge testing.

Allergists, dermatologists, and others have reported successful treatment of warts, eczema, psoriasis and other skin conditions with hypnosis. In clinical studies, suggestions to imagine bathing in salty water, increasing warm and tingling feelings on the skin, reducing blood flow to infected areas and general healing have assisted patients to relieve itchiness, reduce inflammation and decrease the number and size of warts. Likewise, patients with severe burns have been able to refrain from scratching, tolerate dressing changes and reduce their use of pain medications with the help of hypnosis.

Many patients with irritable bowel syndrome experience emotional distress in the form of anxiety and anger that adversely impacts gastric secretion, motility, and pain. A considerable number of these patients find relief from placebo interventions and

several studies report alterations in gut physiology with hypnosis. Gastric acid secretion, gut motility, bowel habits, abdominal distention and abdominal pain have been reported to improve with very brief hypnotic interventions aimed at increasing relaxation, controlling smooth muscle and gut activity and bowel function.

Hypnotic training has been found to diminish the severity and frequency of bleeding episodes among patients with hemophilia. Training a small sample of patients to use hypnosis for relaxation and anxiety reduction has controlled factor usage, spontaneous bleeding and the need for transfusion. In addition, preoperative training in self-hypnosis for the control of anxiety and bleeding has been found to reduce the number of blood transfusions required by surgical patients.

One of the most common causes of noncompliance with chemotherapy among cancer patients is the significant distress that they experience from the associated nausea and vomiting. Anti-emetic drugs often have their own side effects and are typically ineffective with the anticipatory emesis that is often a conditioned response. General anesthesia, also, commonly causes postoperative nausea and vomiting among surgical patients. Well-designed clinical interventions have found support for hypnosis training over relaxation techniques, distraction or individual counseling in the management of nausea and the frequency and intensity of emesis. This has been the case for pediatric as well as adult cancer patients.

Although a number of factors including maternal age, number of previous deliveries and medication use can influence the duration of labor, women trained in hypnosis have experienced speedier and more satisfactory deliveries. Suggestions for relaxation, analgesia and comfort have been successful in influencing analgesic medication use and pain ratings as well as the length of time spent in the first and second stages of labor. Hypnosis trained primigravid women performed more like parous mothers than first time mothers without hypnosis on the above variables.

Numerous methodological difficulties limit confidence and widespread application of hypnotic techniques in medicine. As with most clinical research, the heterogeneity of the patients in terms of illness onset, type, course, previous treatments, co-morbidity etc., limits what can be said with confidence regarding the use of hypnosis in medicine. Also, many experimenters fail to include an adequate description of hypnosis, or might include hypnotic interventions as a component of a more complex psychosocial interventions, or fail to ascertain whether the subject was indeed hypnotized during the test. Nonetheless, qualified empirical evidence exists to support the efficacy of hypnotic techniques in the treatment of pain, asthma, dermatological disorders, irritable bowel syndrome, hemophilia, hyperemesis and obstetrics (Pinnell and Covino 2000).

3.2 Psychotherapy

The addition of hypnosis to cognitive-behavioral treatments for anxiety and habit disorders (smoking, weight control) improves the effect of traditional psychotherapeutic interventions. The ability to alter perception, adjust expectations, increase motivation and imagine more adaptive behaviors facilitates change, especially among those suffering from anxiety disorders.

Where it was once thought that autonomic nervous system hyperarousal was the result of so called stressful life events, recent research highlights the importance of cognitive processes such as perception. One person's strain might well be another's relief, depending upon the meaning that is made of the situation. An invitation from the hypnotist to perceive an event in a more benign fashion creates the opportunity for emotional relief and more adaptive behavior. Imaginative individuals can, also, use their capacity to picture frightening situations vividly to expose themselves to feared stimuli successfully. These patients are able to achieve some of the same mastery as '*in vivo* exposure' without the time and travel. Behaviors can be mentally rehearsed, problems anticipated and resolved with the help of suggestion, focused concentration and imagery. Likewise, unique motivational ideas can be the object of attention without distraction or criticism, and used to provide significant force for behavioral change.

Most efforts to use hypnosis for smoking cessation and weight control have seen modest results. Patients often report achieving relaxation and satisfaction with the technique, but pounds lost have been few and smoking abstinence is rarely achieved by more than 20 percent of program participants. This might well be due to the manner in which suggestions are employed to motivate patients and reduce appetite and desire. Anxiety symptoms related to surgeries and phobias have been especially responsive to hypnotic training, especially when combined with other psychological techniques. Much more is known these days about the complex manner in which patients cycle through processes of habit change as well as the benefits of medication support. Further work in this area would do well to integrate differing hypnotic approaches into the diverse phases and processes that people use in making habit change happen.

A number of clinicians have advocated the use of hypnosis for patients in psychotherapy. The hope in this area is to assist people to recover memories of difficult experiences as well as to teach a coping mechanism for managing extreme anxiety and dissociative symptoms. These therapists propose that the absorption, dissociation and intensity of emotions that often accompanies hypnotic trance are similar to the experiences of many victims of trauma. In a manner similar to state-dependent learning, and in much the same way that Charcot and Freud employed

this technique, patients are invited to experience hypnosis, revisit the initial trauma and have an opportunity to express, integrate and control their associated emotions. In addition, those who spontaneously experience dissociative states are taught to enter into a hypnotic trance to reduce anxiety and to achieve some ability to terminate or control hyperarousal.

In a fashion that mirrors Freud's later work, the use of hypnosis as a psychotherapeutic technique is the focus of considerable controversy at the moment. In general, as was the case with Freud, the main idea of memory recovery sits in the context of credibility and veridicality. For some patients and practitioners it is painful and angering to raise the issue of truth in memory, since so many of those who were physically and sexually abused in their youth were frightened into secrecy. Yet, Freud seemed to see the inevitable intertwining of suggestion with dissociation in hypnosis as limiting the utility of this technique in psychotherapy.

Laboratory research finds that some modest gains in memory can be achieved from efforts to recall, especially when these are made proximate to the experience. Cues, reviews, relaxation, and other motivational techniques also seem to aid the recovery of memory. Nonetheless, hypnotic techniques have generally failed to improve recall of word lists and eyewitness reports. On the other hand, considerable evidence is mounting to suggest that people in clinical and experimental situations can be lead to the erroneous belief that an event or experience did indeed occur. The fact that these circumstances are more likely to take place in situations of heightened emotionality, uncertainty and unfamiliarity makes many clinicians cautious about using hypnosis as an 'uncovering' technique.

4. Essential Elements and Putative Mechanisms

At the end of such a review, it would be nice to be able to say clearly how and why hypnosis is and has been so helpful to patients in a variety of circumstances. Despite its age as a psychological intervention, this is not yet possible. A good deal of research has, thus far, failed to identify a specific neurological marker or neurophysiological substrate for hypnosis. There are, however, several ways that the beneficial effects of hypnosis have been understood.

Suggestions are ideas presented to a subject for uncritical acceptance. In hypnosis, the subject is asked to concentrate on these ideas in a manner that diminishes distraction, lessens logical analysis and maximizes acceptance and acquiesce. Suggestions are not commands, but invitations that can be rejected or accepted. However, like the response of patients to placebo medications, there is often a sense of

involuntariness to hypnotic responses and an attribution of causation to the hypnotist. The physical context, psychological expectations or the pressure to fit in well with a group can also provide direction for a person's thoughts, feelings or behaviors. Some theorists maintain that these psychosocial factors alone or in combination result in successful hypnotic response.

The ability to become absorbed in an idea as if it is real and to use fantasy and imagery to alter cognition and/or behavior is also seen as a determinant of successful hypnotic response. Such special concentration is thought to invite a state of dissociation where consciousness is divided. The ability to separate awareness of sensation, memory, time, behavior etc., is not only part of daily experience (e.g., shifting the gears of a car without awareness, daydreaming), but it can be created by hypnotists and imaginative patients. Such an ability is thought to facilitate the use of hypnosis in management of painful conditions and anxiety. Since the higher cognitive faculties are blocked from elaborating pain or anxiety signals, emotional or behavioral responses are muted or stopped.

There are a number of clinical, and perhaps non-specific, factors that facilitate or hinder the response of patients to hypnosis. Patients must be motivated to follow the suggestions of the hypnotist. A fearful, overly defensive, unwilling person will rarely succeed with hypnosis and one who feels safe, valued, and cared for by an 'expert' most likely will. Research indicates that hypnotizability appears to be a rather normally distributed, stable, trait. Although there are some that claim that anyone can achieve some benefit from hypnotic interventions, many hypnosis experts find that those with heightened ability are the most helped. Certain conditions favor suggestion such as ambiguity, uncertainty, novelty and hyperemotionality. Good hypnotic technique endeavors to recruit or develop some of these elements.

Hypothalamic–Pituitary–Adrenal Axis, Psychobiology of

This article will examine the role of psychological factors on the regulation of the hypothalamic–pituitary–adrenal (HPA) axis. The HPA axis regulates the primary endocrine responses to stress, which in turn regulate major metabolic and neural processes. The major principle that will be elaborated is that both activation and inhibition of the HPA axis are in part modulated by psychological factors. We will examine first specific interventions that occur during development that permanently alters the responses to stress. Second, we will discuss some of the mechanisms whereby responses to stress can be modulated behaviorally.

1. The HPA Axis

The secretion of glucocorticoids (GC) by the adrenal cortex under conditions of stress is an important mammalian mechanism of adaptation. The response to stress involves complex interactions between the neurosecretory hypothalamic neurons, the corticotrophs of the anterior pituitary, and the adrenal glands. Various neural afferents mediating the stress response converge at the parvocellular neurons of the hypothalamic parvocellular nucleus (PVN). The cell bodies of the PVN neurons are one of the primary sites of the synthesis of corticotropin-releasing factor (CRF) and project to the median eminence. Activation of the PVN neurons by a variety of different stimuli induces release of CRF into the portal capillaries through which CRF is transported to the anterior pituitary.

The binding of CRF to receptors in the anterior pituitary in turn induces the release of adrenocorticotropin (ACTH). Subsequently, ACTH in the general circulation stimulates the secretion of GC, primarily corticosterone in the rodent and cortisol in primates and humans. GC secreted by the adrenal serve a variety of regulatory and permissive functions which recruit the organism's endocrine, metabolic, immune, and behavioral responses to stress (Munck et al. 1984). Further circulating GCs participate in their own regulation by exerting a negative feedback on stress-induced activity. There are numerous negative feedback sites, which include the PVN, anterior pituitary, and possibly the hippocampus.

The HPA axis is highly responsive to changes in both the interior and exterior environment. One of the more interesting developments in this field is that there appear to be different neural pathways that respond to different stimuli that activate the PVN neurons. Currently, five different pathways have been described (Sawchenko 1991). Certain pathways are activated when visceral and interoceptive signals are involved in the activation of the HPA axis. One of the major pathways involves the structures of the principle components of the limbic region of the telencephalon, which includes the hippocampal formation, the septal, and the amygdaloid nuclear complexes.

Not only have the limbic structure been implicated as possible sites for GC feedback but they are also implicated in the processing of emotional responses (LeDoux et al. 1988). The amygdala plays a pivotal role in the 'fear circuit' described by Davis (1992). The hippocampus also appears to play an important role in the processing of affective information. Given the importance of affective stimuli in the activation of the HPA axis it is not surprising that there should exist neural pathways responsible for processing this class of stimuli.

2. Early Experience

After more than four decades of research using a variety of animal species it has been well established that the effects of early experience are diverse and pervasive. One early experience manipulation, early handling, modifies the HPA axis so as to permanently alter the endocrine (ACTH and GC) response to stress and to modify the neural components of the HPA axis that are involved in regulating the stress response. The early handling paradigm involves an apparently innocuous manipulation in which the experimenter removes the rat pup from its mother once daily, placing it either alone or as a group in a novel container for a few minutes and then reuniting it with the dam in the home cage. Early handling is most effective if initiated between birth and 14 days postnatally.

The early studies demonstrated that early handling profoundly altered the GC response to several different challenges. In general, as adults, the magnitude of the GC response was reduced and further, the GC response in the early handled rats returned to basal levels more rapidly indicating a more efficient negative feedback mechanism (Batnagar et al. 1996). The initial studies were limited by the technologies available at that time. With technological advances it became possible to study other components of the HPA axis. Thus, early handled animals showed a reduction in ACTH secretion following stress when compared to non-handled rats. Early handled rats also have significantly lower basal levels of CRH gene expression (Plotsky and Meaney 1993).

Another well-documented effect of early handling is to permanently modify the GC receptors in the hippocampus. In the central nervous system (CNS), two types of GC receptors are found and each functions to regulate different aspects of HPA activity (DeKloet 1991). The mineralocorticoids (MR) are involved in the tonic regulation of the HPA axis, that is, circadian rhythms. In contrast, the glucocorticoid receptor (GR) appears to be an important extrahypothalamic site of an inhibitory feedback effect on HPA activity although it is not clear that the hippocampus is a negative feedback site for GC. Occupancy of available GRs seems to be required to restrain stress induced ACTH secretion.

In an extensive series of studies Meaney and co-workers (see Batnagar et al. 1996) have established that early handled animals have an increase in hippocampal GR sites as well as increased GR mRNA. Early handling has little effect on the MRs. It has been postulated that the increase in GR density increases the sensitivity of the hippocampus to circulating GCs, enhancing the efficiency of the negative feedback inhibition of HPA activity, thus permitting early handled animals to reduce the poststress levels of ACTH and GC.

All the current information on the effects of early handling on the HPA axis indicates that manipulation permanently modifies several of the important components of neural circuitry that regulate the HPA axis. Thus, the effects of early handling can be attributed largely to alterations in the CNS mechanisms that regulate ACTH and GC secretion.

One hypothesis proposed to account for the effects of early handling is that handling affects the pup indirectly by producing changes in the behavior of the dam (the maternal mediation hypothesis). Maternal behavior parallels and compliments the need of the developing organism and the parent–offspring relationship is most intense during the preweaning period when the dam's role in regulating vital neonatal functions is fundamental. Disturbances of mother–infant relationships by brief periods of maternal separation alters the pup's behavior in a manner that would elicit increased pup-directed behavior by the dam, such as licking, grooming, retrieving, etc. This increase in pup-directed behavior could bring about pervasive changes in regulation of the HPA axis. Using a more naturalistic approach (Caldji et al. 1998) demonstrated that pups who received high levels of licking and arched-back nursing from their dams showed the characteristic pattern of HPA activity that closely resembled the early handled pups.

Plotsky and Meaney (1993) have used relatively long postnatal maternal separations as a model of adverse early experience. Thus, pups were separated from the dams for 3 hours daily beginning on day 2 and continuing through day 14. When compared to pups that had experienced short periods on maternal separation GC levels were significantly higher fol-

lowing restraint and further, basal levels of CRH gene expression in the PVN were elevated. Other investigators have used more extended periods of separation, that is, 8 hours every other day, and have also found that HPA activity is altered in the direction of a more exaggerated response.

Thus, it appears as though the HPA axis can be modified bidirectionally depending upon the length of the separation. It is possible that the signals emitted by the pup are different following brief vs. a more prolonged separation and that the effects on maternal behavior are manifested in very different ways resulting in seemingly paradoxical outcomes. The data do clearly indicate that early experiences do result in a permanent and apparently irreversible influence on the adult HPA axis regardless of the direction of these changes.

3. Coping

Based primarily on the initial observations of Selye (1956), it became clear that the endocrine system and more specifically increased secretion of the so-called stress hormones ACTH and GC was a critical component of the response to stress. Selye also described these responses as nonspecific. Thus, regardless of the stimulus that provoked these responses they were general and occurred nonspecifically to any or all challenges.

Mason (1968) presented a point of view which differed radically from the widely-held beliefs of the time. Mason emphasized a crucial role for 'the psychological approaches involved in the emotional or arousal reactions to threatening or unpleasant factors in the life situation as a whole.' He argued that the nonspecific response to stress is primarily behavioral or psychological in nature. However, although Mason recognized the importance of psychological factors associated with the endocrine activation following stress he did not elaborate on what some of these dimensions could be.

In an attempt to further specify the psychological aspects of the endocrine stress response Levine and Ursin (1990) invoked a cognitive approach in which the lack of information (uncertainty) resulted in the activation of the HPA axis. Uncertainty could be a function of the absence of information and/or the failure to fulfill an expected outcome or to avoid a negative one. The absence or loss of control and the lack of predictability also creates uncertainty which when processed by the brain activates the neurobiological events that result in increased HPA activation.

3.1 Control

One of the most critical psychological dimensions that contribute to the regulation of the HPA axis is control. In a remarkable series of experiments Weiss (1972)

convincingly demonstrated the importance of control in reducing the physiological consequences of exposure to stress. Using gastric ulceration as the measure of stress it was shown that rats that could make a response that terminated an electric shock showed a marked reduction in the number of gastric ulcers when compared to a 'yoked' group that received identical shocks but were not permitted to respond. This initial experiment clearly demonstrated the importance of control. In further studies two other psychological operations also ameliorated the extent of gastric ulceration. These were predictability and feedback. These three elements, control, predictability, and feedback, all serve to reduce arousal and thus HPA activity and are postulated to contribute to the process of coping.

There are many examples of the importance of control in modifying the response of the HPA axis. Rats permitted to escape from shock showed a reduction in GC levels although they received shock on every trial (Davis 1977). In contrast repeated exposure to inescapable shock resulted in increased secretion of GC (sensitization). Hanson et al. (1976) exposed Rhesus monkeys to a loud noxious noise. One group of monkeys was allowed to control the duration of the noxious stimulus by making a lever press response to terminate the noise. A comparable group of monkeys were exposed to the identical duration of the noise, but were not permitted to regulate the duration. The monkeys that exercised control showed levels of GC that were similar to nonnoise exposed monkeys. In contrast, the 'yoked' control animals exhibited extremely high levels of GC. In this experiment the monkeys that could control the duration of the noise were re-exposed to the noise on a subsequent day but on this occasion they were not permitted to exercise control. Their GC levels were now elevated and exceeded those of the noise alone group. This finding represents an example of yet another psychological dimension involved in the regulation of HPA activity, the failure of expectancies.

3.2 Expectancies

Physiological activation in response to uncertainty is a central component of the model presented by Sokolov (1963). Although this model was an attempt to account for the neural mechanisms involved in the process of habituation, a broader interpretation of this model could also account for why uncertainty would result in the activation of the HPA axis. When a subject is presented with a stimulus that not been previously experienced or is unexpected an orienting response occurs. Both behavior and physiological responses are elicited by the stimulus. Amongst the number of physiological components of the orienting response is HPA activation (Hennessy and Levine 1979).

If the stimulus is repeated frequently the response tends to diminish and eventually disappears. Sokolov's

model is based on a matching system in which new stimuli or situations are compared with a representation in the CNS of prior events. This matching process results in the development of expectancies. Uncertainty can, therefore, be viewed as a violation of expectancies. From this perspective it is the evaluation of the event or events by the individual that is crucial in determining whether that event will elicit a stress response resulting in HPA activation.

(Bolles 1972) identified two distinct types of expectancies, stimulus and response outcome expectancies. Stimulus expectancies refers to the storage of information that one stimulus precedes another (classical conditioning). Response outcome expectancies results from the learning that a particular response results in a positive outcome, that is, obtaining reinforcement or avoiding a negative outcome. The development of positive outcome responses is dependent on some of the coping mechanisms previously described. Thus, if an organism can exercise control by making an active response that leads to a predictable outcome this information will be stored in the CNS as a positive outcome expectancy.

Thus, when rats can obtain reinforcement on a highly predictable schedule removal of the reinforcement (extinction) produces a marked elevation in GC. Further when rats are shifted from a highly predictable schedule to an unpredictable schedule of reinforcement GC are again elevated. In contrast when the shift in reinforcement schedules is from low predictability to high predictability GC levels significantly decrease. More recently a similar outcome has been reported in primates. Squirrel monkeys were required to obtain food in a laboratory model of foraging. When the foraging demand was high and food was available unpredictably cortisol levels were persistently elevated. When these monkeys were shifted to a low demand foraging schedule cortisol levels decreased rapidly. The effects of violations of expectancies are also observed in aversive situations. Rats that successfully learned to avoid shock show a progressive decrease in GC as their performance reached asymptote. However, if the animals are prevented from making the avoidance response, although shock is not administered, GC levels are once again elevated.

3.3 Social Factors

There is a large literature that has documented the importance of social behavior and social relationships on the HPA axis. At first glance these may appear to be a separate class of events. They can be, however, subsumed within the more general theories of stress and coping. An extensive series of studies using nonhuman primates (Levine and Coe 1988) demonstrated that at almost every point in development social variables can modulate the HPA axis, both in terms of increased activity and the inhibition of the response to environmental perturbations. Disruptions

of social relationships invariably result in increased HPA activity. Conversely, the presence of familiar social partners can reduce, and at times eliminate, the normal increase in HPA activity in squirrel monkeys. One of the most robust increases in GC levels is observed when infant squirrel monkey are separated from their mothers and other members of their natal social groups. These responses occur even when the infants are separated repeatedly and show no signs of habituation. If the infant is separated from the mother and permitted to remain with their familiar social partners the response is markedly reduced. This occurs only when mother infant dyads are group housed. When the dyad is housed individually the magnitude of the GC response is similar regardless of whether the infant or the mother was removed from the home cage. This phenomenon is often called social buffering, and has been demonstrated in the adult monkeys. Thus, when adult squirrel monkeys were exposed to a natural predator (a live Boa Constrictor) placed in a wire mesh enclosure above their cage, individually housed animals show a striking elevation of plasma cortisol, whereas if the monkeys are exposed to the snake when group housed cortisol levels do not differ from basal levels. Other experiments using different paradigms have demonstrated that the presence of social partners ameliorates the HPA response to stress.

These findings are consistent with the proposed effects of control and feedback on the HPA axis. For the infant, the mother is the primary source of emotional security and serves to reduce the infant's arousal levels. Thus, the infant's capacity to achieve contact and maintain proximity to the mother is perhaps the infant's earliest experience with the use of control. For the adult, the availability of stable and familiar social relationships provides a set of predictable outcomes due, in part, to a prior history of social interactions. Therefore, the predictability of these social interactions would serve to reduce uncertainty.

4. Summary

The contemporary view of stress largely is characterized as an imposition model. The voluminous number of studies in which severely traumatic stimuli were used to elicit HPA activation supports this view. However, there are numerous examples of HPA activation being elicited by the omission of a predictable outcome (frustration) or the absence of a salient feature in the environment such as maternal loss. In both classes of events the common element appears to be the lack of information (uncertainty) related to obtaining positive outcomes or the avoidance of negative outcomes.

The view presented in this article focuses on the capacity of the brain to process information pertaining to obtaining of positive outcomes and/or the avoidance

of negative outcomes. Stimuli that induce HPA activation do so as a consequence of the lack of information (uncertainty) concerning the obtaining of positive outcomes or the avoidance of negative outcomes.

Hypothalamus

1. Introduction

The hypothalamus is a small brain structure (0.4 percent of total brain volume) primarily of gray matter providing important functions which can be summarized to maintain homeostasis. From an evolutionary perspective, the hypothalamus can be considered a very old component of the central nervous system.

Historically, the first observations concerning hypothalamic functions were described for the control of the pituitary gland since endocrinological abnormalities (e.g., due to tumors) were more obvious than disturbances of autonomic functions, which are also under hypothalamic control. In 1930 Ernst and Berta Scharrer developed the concept of 'neurosecretory' hypothalamic cells derived from their morphological structure, and this dramatically stimulated subsequent research. It became obvious that the hypothalamus combines characteristics of glands and neuronal tissue. However, the focus of interest remains in investigations of hypothalamic control via the pituitary gland, which led to the discovery and chemical characterization of vasopressin and oxytocin in the early 1950s. The finding by Schally and Guillemin that the hypothalamus controls the secretion of other fundamentally important hormones such as TSH, FSH, ACTH, and LH was honored by the Nobel prize in 1977.

2. Neuroanatomical Localization and Structure

The hypothalamus is located in the diencephalon. It is laterally bounded by the subthalamus, medially by the third ventricle, rostrally by the lamina terminalis, caudally by the mesencephalon, and dorsally by the thalamus.

Although these boundaries are well defined, the anatomical structure of the hypothalamus is much more complex. From stimulation and lesion studies it is known that the hypothalamus consists of several

Figure 1

neuronal clusters referred to as nuclei (see Fig. 1). Previous attempts at describing the anatomical relationships between these nuclei made use of a hexagon (see Fig. 2).

Based on the systematic topography of the hypothalamus given in Fig. 1, several areas can be distinguished. Most of the nuclei are located in the midline, medial, and lateral areas, which are themselves divided into supraoptic, tuberal, and mammillary sections. The preoptic nuclei are located in the preoptic region of the medial zone. The preoptic region is bounded by the septum in both directions. The anterior (supraoptic) region contains the anterior nucleus, the supraoptic nucleus, and the paraventricular nucleus. The intermediate (tuberal) region consists of the dorsomedial nucleus, the ventromedial nucleus, and the infundibular or arcuate nucleus. In the posterior region of the medial zone, the posterior nucleus and the mammillary nucleus can be identified. Finally, the lateral zone consists of the lateral hypothalamic nucleus. In the area of the periventricular zone many neurons have been identified as having

Figure 2

fundamental importance for the secretion of releasing or inhibiting neurohormones. However, a clear distinction of the different nuclei has not been given for this area.

3. Functions

Although the hypothalamus can be considered a small brain structure, its functions are widespread and of fundamental importance. It is known that the hypothalamus is responsible for at least seven categories of functions. These are: the regulation of the anterior pituitary; the control of water balance; the regulation of autonomic responses; the regulation of feeding; the regulation of drinking; the regulation of reproductive functions; and the reinforcement and control of circadian functions. For an understanding of these functions, the characterization of hypothalamic inputs from other systems is essential (for a review, see Risold et al. 1997).

Retinal ganglion cell axons project through the retinohypothalamic tracts to the ventral regions of the suprachiasmatic nuclei (SCN). It is known that these nuclei couple the *biological rhythms* to the light/dark cycle. These rhythms can be divided into several categories depending on their frequency. Events repeated nearly every 24 hours are defined as circadian rhythms (e.g., changes in concentration of ACTH and cortisol). Periods with lower frequencies are considered circa-annual or infradian (e.g., season-dependent behavioral or metabolic changes or the menstrual cycle). Those with shorter frequencies (faster occurrence of periods) are defined as ultradian rhythms (e.g., respiration). The hypothalamus controls infradian and circadian rhythms. The important role of the SCN can be demonstrated by lesion studies in

which animals lost rhythmicity. The SCN projects to the paraventricular nucleus, which is connected to the spinal cord by efferent fibers. Noradrenergic fibers project to the pineal gland and affect the production and release of melatonin, concentrations of which markedly depend on the light/dark cycle. Moreover, recent studies have demonstrated that the SCN is involved in the regulation of autonomic responses (changes in heart rate) after brief stimulation by a flash of light.

Interestingly, the lateral hypothalamus seems to be a target for pheromonal stimuli derived from the main olfactory inputs. Moreover, projections from the medial amygdalar nucleus, as well as from the bed nuclei of the stria terminalis, provide accessory olfactory signals to some regions of the medial zone of the hypothalamus. This close connection to the vomeronasal organ is not fully understood with respect to its physiological function. However, two different pathways including amygdalar projections seem to be involved in the modulation of sexual and/or aggressive-defensive behavior.

Another source of 'information' is derived from viscerosensory and somatosensory signals. Most of these projections into the lateral hypothalamus are derived from the solitary tract and the parabrachial nuclei, which both receive visceral information from cranial nerves. However, there is evidence that the periventricular zone is an important target for projections providing 'visceral' signals derived from the brain stem involving catecholaminergic fibers. It is a likely assumption that these projections may provide information inducing the regulation of complex processes such as ingestive behavior. The lateral hypothalamus has been identified as a main target for spinal cord fibers which send information concerning sensations of touch or pain. The presence of fibers presenting auditory information has been demonstrated for the ventromedial nucleus of the hypothalamus. It has been suggested that these projections are important for regulation of lordosis and milk-ejection in lactating females. Somatosensory signals including nociceptive stimuli seem to reach the hypothalamus by activating neurons of the spinohypothalamic tract or involving the catecholamine system located in the brain stem. As a consequence, norepinephrine is released from the paraventricular nucleus (PVN) of the hypothalamus. In general, catecholaminergic projections to the PVN may play a pivotal role in stress responses by activating neurosecretory functions of the hypothalamus, as indicated by a reduced or blocked activation of the hypothalamus-pituitary-adrenal (HPA) axis after lesions of catecholaminergic fibers of the brain stem. There is agreement that the hypothalamus is one of the most important brain structures preparing the individual for appropriate reactions when faced with threat or other types of stress. One set of reactions concerns the cardiovascular system, which is controlled by the hypothalamus via the autonomic

nervous system, especially the vagus nerve and/or the initiation of hormone secretion. The fundamental role of the hypothalamus in orchestrating multiple influences on the pituitary will be discussed later.

Hypothalamic control of thermoregulation can be considered an excellent example for maintaining homeostasis. A center responsible for heat dissipation has been identified in the preoptic area and the anterior hypothalamus. The main physiological consequences of an activation of these neurons is suppression of shivering, panting, and vasodilation of cutaneous vessels with the common goal of reducing temperature. On the other hand, conservation of temperature seems to be mediated by the posterior hypothalamic region. Reactions to maintaining or increasing temperature are shivering, vasoconstriction, and suppression of panting. In his early work Bligh (1966) suggested the presence of two regulatory systems. One is mainly responsible for maintaining the normal variation of body temperature, whereas the other becomes activated as a consequence of more serious increases or decreases in body temperature. It is known that the neurons involved are sensitive to higher (37°C–40°C) and lower (32°C–36°C) than normal temperatures. Afferent pathways transport peripheral information (e.g., cooling or heating of the skin) to these neurons, initiating the regulatory responses. However, one has to realize that the hypothalamus is not the only structure involved in thermoregulatory responses. It is known that in 'spinal' animals (brain disconnected from spinal cord) some basic thermoregulatory responses are still intact, indicating the presence of lower centers for regulation. There is agreement that thermoregulation involves several regulatory circuits acting on different levels, with the hypothalamus the most sensitive one (Satinoff 1978).

Early lesion studies had revealed that the hypothalamus mediates ingestive behavior. Distinct areas responsible for feeding have been identified in the ventromedial nucleus as a kind of satiety center, and in the lateral hypothalamus as a feeding center. Lesion of the ventromedial nucleus results in hyperphagia and polydipsia, whereas stimulation leads to the opposite behavior. There is some evidence that the paraventricular nucleus affects the vagus nerve via its projections to the brain stem, and that the lesions result in a disturbed parasympathetic control of the liver and the pancreas. A closer look reveals that after lesion of the ventromedial nucleus, hyperphagia occurs with temporary dramatic weight gain. However, after a state of obesity has been reached, ingestive behavior becomes normalized and no further weight gain can be observed, although the hypothalamic function is still disturbed. This clearly demonstrates that further brain structures are involved in the regulation of ingestive behavior.

For the lateral hypothalamus, stimulation leads to hyperphagia, and lesions lead to aphagia. However, the mechanisms involved are much more complex

since animals with lesions of the lateral hypothalamus start to eat after an appropriate period of time. Again, other brain areas such as the amygdaloid nuclei, the frontal cortex, and the substantia nigra are involved in regulation of feeding. More recently it became clear that leptin produced by fat cells is important for the regulation of ingestive behavior. Leptin receptors have been identified in the lateral hypothalamus (Hakansson et al. 1998), the supraoptic arcuate, and the paraventricular nuclei. A low quantity of leptin can be considered a signal for increased fat intake. Peripheral (derived from the gut in response to food intake), as well as central (probably produced within the hypothalamus), cholecystokinin seems to play an important role as a satiety hormone. However, neuropeptide Y, known to stimulate appetite, is found in the arcuate nucleus, the medial preoptic area, and the paraventricular nuclei of the hypothalamus. Application of neurotransmitters or neuropeptides into the paraventricular nucleus leads to preferences for different food components. While norepinephrine is accompanied by intake of fat and carbohydrates, galanin stimulates the intake of fat. Leptin suppresses both stimulations of ingestive behavior induced by NPY and by galanin. Orexin has been discovered as a protein that is exclusively produced in the lateral hypothalamus. This neuropeptide markedly increases eating behavior after injection into the hypothalamus.

The most common reason for the induction of thirst is loss of water due to sweating, urination, or respiration. This osmotic thirst, rather than the thirst caused by hypovolemia, is regulated by the hypothalamus. The basis for this is the presence of osmoreceptors in hypothalamic cells. In fact, injection of salty fluid into the hypothalamus induces drinking. Neurons responding to changes in osmotic pressure have been identified in the preoptic area, the anterior hypothalamus, the supraoptic nucleus, and the circumventricular organ. As a consequence of stimulation, AVP (vasopressin, antidiuretic hormone) is released to stop further loss of water. Moreover, increased concentrations of angiotensin II and stimulation of baroreceptors are sensitive signals to the preoptic area resulting in drinking behavior.

Another important function of the hypothalamus is coordination and control of sexual behavior. For female behavior, it is known that estradiol, a sex steroid produced during the ovulatory cycle, specifically stimulates neurons of the ventromedial hypothalamus. These neurons exhibit receptors for estrogen and progesterone, and they are mainly responsible for inducing so-called lordosis behavior. This signals the receptivity of the female to the male population by several postural and physiological signs. It can be concluded that the ventromedial hypothalamus is important for controlling changes in steroid hormone concentrations and, furthermore, that it activates several pathways at the appropriate time during the ovulatory cycle to induce the lordosis response. It is

believed that estrogens can activate the hypothalamic receptors for progesterone. During pregnancy, when progesterone levels are very high, a down-regulation of these receptors appears with a decrease in sexual receptivity. The medial preoptic area of the hypothalamus is enriched with steroid-sensitive neurons, and evidence has been published that lesions in this area completely abolish male copulatory behavior in many species. The medial preoptic area is a target for pheromonal stimulation as well. Vomeronasal information reaches the amygdala, which sends signals to the medial preoptic area, indicating that this specific hypothalamic area plays a salient role in coordinating sensory and motor responses important for copulation. Both aspects are initiated by levels of testosterone which, interestingly, affect neuronal targets after aromatization into estrogen. The preoptic area of the hypothalamus is characterized by a sexual dimorphism, which may explain the differences in male vs. female sexual behavior. Taken together, the preoptic area of the hypothalamus is of fundamental importance for controlling sexual behavior, moreover, for sexual orientation as well. Interestingly, a clear-cut sexual dimorphic nucleus of the preoptic area could be identified as being larger in males than in females (Gorski et al. 1978). The reason for this dimorphism is brought about by testicular androgens (testosterone), which obviously influence the development of this specific nucleus within the preoptic area of the hypothalamus.

From animal studies, it is known that the medial preoptic area plays a key role in mediating maternal behavior (Numan 1978). Lesions in that area abolished nest-building and pup care in animals. Important pathways mediating these effects are the connections between the medial preoptic area and the ventral tegmental area. Disruptions of these connections lead to the same effects as described for lesions of the medial preoptic area. Estrogen receptors in this hypothalamic area are of major importance for regulating maternal behavior, as demonstrated by direct injections of estrogen or by suppression of this behavior after treatment with specific antagonists. Moreover, the stimulation of maternal behavior has been demonstrated for other hormones such as progesterone, oxytocin, and prolactin as well. However, more recent reports suggest the involvement of additional hypothalamic areas such as the ventromedial part for mediating maternal behavior.

A last behavioral component mediated in part by the hypothalamus is aggressive behavior. The first reports demonstrating that stimulation of the hypothalamus induces aggressive behavior were published about 70 years ago (Hess 1928). However, the precise mechanisms of these responses are still unknown. There is evidence that the lateral and frontal area of the ventromedial nucleus is of major importance. Hypothalamic aggression can be facilitated by testosterone, which indicates the initiation of offensive

Table 1
Hypothalamic-releasing hormones stimulating tropic hormones of the pituitary

Hypothalamus	Pituitary
Gonadotropin-releasing hormone (GnRH)	Follicle-stimulating hormone Luteinizing hormone
Thyrotropin-releasing hormone (TRH)	Thyroid-stimulating hormone (TSH)
Corticotropin-releasing hormone (CRH)	Adrenocorticotrophic hormone (ACTH)
Somatocrinin Somatostatin	Growth hormone (GH)
Prolactin-releasing peptide Prolactin-inhibiting factor	Prolactin

rather than defensive behavioral patterns, since androgens are ineffective in defensive behavior. Other data from the literature support the view that the hypothalamic type of aggression is offensive because behavior is not suppressed by benzodiazepines or alcohol (which is not true for defensive aggression) but by serotonin agonists, which are more potent in reducing offensive behavior. Interestingly, many peripheral hormones seem to stimulate offensive aggression by affecting hypothalamic neurons. Of special interest is the finding that injections of cortisol into the hypothalamus of golden hamsters induce aggressive behavior. This may explain why stress, which activates the HPA-axis, resulting in increased levels of glucocorticoids, is frequently associated with aggression.

One of the most important functions of the hypothalamus is the orchestration of hormone regulation. Nuclei from the hypothalamus, such as the supraoptic nucleus and the paraventricular nucleus, are sources for the two hormones oxytocin and arginine-vasopressin (often called antidiuretic hormone, ADH). These hypothalamic areas elicit neural impulses to the posterior pituitary in order to release the hormones into the circulation. The important function of vasopressin for water balance has already been discussed. Oxytocin has several functions concerning reproductive and parental behavior (see above). Furthermore, oxytocin stimulates contractions of the uterus and is involved in the milk ejection reflex. However, this hormone is present in males as well, and it has been suggested that oxytocin is of importance for social contacts and attachment.

Another fundamental influence on hormone secretion can be seen in the hypothalamic control of the anterior pituitary. The mechanism of regulating anterior pituitary hormone release is quite different from the hypothalamic influence on the posterior pituitary. While neurons from various hypothalamic nuclei transport the hormones along the axons into the posterior pituitary and release them after specific stimulation, neuroendocrine or neurosecretory cells of the hypothalamus influence the anterior pituitary. They release hormones and transport them into the

medium eminence; after stimulation by action potentials, these hormones are transported into the hypothalamic pituitary portal system. These releasing hormones reach the anterior pituitary and stimulate other cells to release tropic hormones into the blood stream; these are different from the releasing hormones provided by the hypothalamus. Table 1 shows the releasing hormones from the hypothalamus, and corresponding tropic hormones derived from the pituitary.

The stimulating effects of releasing hormones derived from the hypothalamus on secretory cells of the pituitary are of fundamental importance since they regulate energy metabolism (e.g., TRH), sexual and reproductive functions (e.g., GnRH), and growth, as well as behaviors related to adaptation (e.g., CRH) and homeostasis. The precise functions of these tropic hormones secreted in the pituitary, as well as their endocrine effects at the levels of target organs, are not within the scope of this entry. However, it should be noted, as described above, that the hypothalamus is the target for many of these peripheral hormones, leading to the modulation of behavior on the one hand and providing complex negative feedback loops for controlling further secretion of hormones on the other.

4. Summary

The hypothalamus can be considered to be a brain structure which integrates the complex interactions between hormonal and behavioral processes with the purpose of maintaining homeostasis and survival of the individual and the species (Freeman 1995). It is involved in many different fundamental processes—not only in the regulation of metabolism and hormones, but also in feeding, drinking, reproductive, maternal, and aggressive behavior. It has therefore been suggested that one of its major functions is organization of behavior.

Hypothesis Testing in Statistics

A *statistical hypothesis* is a statement about a population parameter, and the two complementary hypotheses in a hypothesis testing problem are called the *null hypothesis* and the *alternative hypothesis*. They are denoted by H_0 and H_1 , respectively.

If θ denotes a population parameter, the general format of the null and alternative hypotheses is $H_0: \theta \in \Theta_0$ and $H_1: \theta \in \Theta_0^c$ where Θ_0 is some subset of the parameter space and Θ_0^c is its complement. Typically, a hypothesis test is specified in terms of a test statistic $W(X_1, \dots, X_n) = W(\mathbf{X})$, a function of the sample. The sample space for W is partitioned into the *rejection region*, R , and its complement, the *acceptance region*. If $W \in R$ is observed, the null hypothesis H_0 is rejected and the decision is made that H_1 is true. If $W \notin R$, H_0 is accepted as true.

For example, in a study to examine the factors that influence a student's success at completing a four-year

college, one factor of interest might be socioeconomic status (SES). If, for simplicity, we just have two groups (high SES and low SES), and the success probabilities of the respective groups are p_h and p_l , then a hypothesis test of interest may be $H_0: p_h = p_l$ vs. $H_1: p_h > p_l$.

This is an example of a one-sided test, in which the alternative hypothesis specifies a direction. In contrast, we may consider the two-sided test $H_0: p_h = p_l$ vs. $H_1: p_h \neq p_l$ in which no direction is specified in the alternative. If we let $\hat{p}_h$ and $\hat{p}_l$ denote the observed success rates in the two SES classes, the one-sided test would reject the null hypothesis if $\hat{p}_h - \hat{p}_l$ is big, while the two-sided test would reject the null hypothesis if $\hat{p}_h - \hat{p}_l$ is either big or small.

A hypothesis test of $H_0: \theta \in \Theta_0$ versus $H_1: \theta \in \Theta_0^c$ might make one of two types of errors. If $\theta \in \Theta_0$ but the hypothesis test incorrectly decides to reject H_0 , then the test has made a *Type I error*. If, on the other hand, $\theta \in \Theta_0^c$ but the test decides to accept H_0 , a *Type II error* has been made. In our example, in testing $H_0: p_h = p_l$ versus $H_1: p_h > p_l$, if we conclude that $p_h > p_l$ but, in fact, $p_h \leq p_l$ we have made a Type I error.

1. Constructing Tests

There are many methods of deriving test statistics for a hypothesis test, a few of which follow.

1.1 Likelihood Ratio Tests

The likelihood ratio method of hypothesis testing is related to maximum likelihood estimators (MLE) (discussed in *Estimation: Point and Interval*). Suppose that we have a sample $X_1, \dots, X_n$, where the X_i are independent, each with distribution $f(x|\theta)$. The observed values of these random variables are denoted by $\mathbf{x} = (x_1, \dots, x_n)$, with likelihood function $L(\theta|\mathbf{x})$ given by

$$L(\theta|\mathbf{x}) = \prod_{i=1}^n f(x_i|\theta) \quad (1)$$

The *likelihood ratio test statistic* for testing $H_0: \theta \in \Theta_0$ vs. $H_1: \theta \in \Theta_0^c$ is

$$\lambda(\mathbf{x}) = \frac{\sup_{\Theta_0^c} L(\theta|\mathbf{x})}{\sup_{\Theta_0} L(\theta|\mathbf{x})} \quad (2)$$

A likelihood ratio test (LRT) is any test that has a rejection region of the form $\{\mathbf{x}: \lambda(\mathbf{x}) \leq k\}$, where k is any number satisfying $0 \leq k \leq 1$.

If we interpret the likelihood function as measuring how likely the values of θ are, then we see that the LRT

is comparing the plausibility of the θ values in the null hypothesis with those in the alternative. Small values of the LRT statistic are then interpreted as being evidence against H_0 , and lead to rejection.

If the null hypothesis consists of a single value θ_0 , and the alternative is everything else, then the LRT statistic is simply $\lambda = L(\theta_0 | \mathbf{x}) / L(\hat{\theta} | \mathbf{x})$, where $\hat{\theta}$ is the MLE of θ .

Example. Let $X_1, \dots, X_n$ be a random sample from a $n(\theta, 1)$ population. The LRT statistic for testing $H_0: \theta = \theta_0$ versus $H_1: \theta \neq \theta_0$ is

$$\lambda(\mathbf{x}) = \frac{L(\theta_0 | \mathbf{x})}{L(\bar{x} | \mathbf{x})} = \frac{(2\pi)^{-n/2} \exp[-\sum_{i=1}^n (x_i - \theta_0)^2 / 2]}{(2\pi)^{-n/2} \exp[-\sum_{i=1}^n (x_i - \bar{x})^2 / 2]} \quad (3)$$

If $T(\mathbf{X})$ is a sufficient statistic for θ then, as with maximum likelihood estimators, the LRT statistic is a function of T . That is, $\lambda(\mathbf{x})$ depends on $\mathbf{x}$ only through $T(\mathbf{x})$.

1.2 Bayesian Tests

The Bayesian paradigm prescribes that the sample information be combined with the prior information using Bayes' Theorem to obtain the posterior distribution $\pi(\theta | \mathbf{x})$. All inferences about θ are now based on the posterior distribution. In a hypothesis-testing problem, the posterior distribution may be used to calculate the probabilities that H_0 and H_1 are true.

One way a Bayesian hypothesis tester may choose to use the posterior distribution is to decide to accept H_0 as true if

$$\frac{P(\theta \in \Theta_0 | \mathbf{X})}{P(\theta \in \Theta_0^c | \mathbf{X})} \geq k \quad (4)$$

for some constant k , and to reject H_0 otherwise. Equivalently, we can reject H_0 if $P(\theta \in \Theta_0^c | \mathbf{X})$ is greater than a specified number.

Example. Let $X_1, \dots, X_n$ be independent identically distributed (i.i.d.) $n(\theta, \sigma^2)$ and let the prior distribution on θ be $n(\mu, \tau^2)$ where σ^2 , μ , and τ^2 are known. Consider testing $H_0: \theta \leq \theta_0$ vs. $H_1: \theta > \theta_0$ where we decide to accept H_0 if $P(\theta \in \Theta_0 | \mathbf{X}) \geq P(\theta \in \Theta_0^c | \mathbf{X})$. After some calculation, we find that H_0 will be accepted as true if

$$\bar{X} \leq \theta_0 + \frac{\sigma^2(\theta_0 - \mu)}{n\tau^2} \quad (5)$$

1.3 Union–Intersection and Intersection–Union Tests

In some situations, tests for complicated null hypotheses can be developed from tests for simpler null hypotheses. The union–intersection method of test construction might be useful when the null hypothesis is conveniently expressed as an intersection, say $H_0: \theta \in \bigcap_{\gamma \in \Gamma} \Theta_\gamma$, where Γ is an arbitrary index set. If tests are available for each of the problems of testing $H_{0\gamma}: \theta \in \Theta_\gamma$ vs. $H_{1\gamma}: \theta \in \Theta_\gamma^c$ where the rejection region for the test of $H_{0\gamma}$ is $\{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\}$, then the rejection region for the union–intersection test is

$$\bigcup_{\gamma \in \Gamma} \{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\} \quad (6)$$

The rationale is that if any one of the hypotheses $H_{0\gamma}$ is rejected, then H_0 must also be rejected.

A complementary method, the intersection–union method, may be useful if the null hypothesis is conveniently expressed as a union. Suppose we wish to test the null hypothesis $H_0: \theta \in \bigcup_{\gamma \in \Gamma} \Theta_\gamma$, and $\{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\}$ is the rejection region for a test of $H_{0\gamma}: \theta \in \Theta_\gamma$ vs. $H_{1\gamma}: \theta \in \Theta_\gamma^c$. Then the rejection region for the intersection–union test of H_0 versus H_1 is

$$\bigcap_{\gamma \in \Gamma} \{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\} \quad (7)$$

and H_0 is false if and only if all of the $H_{0\gamma}$ are false, so H_0 can be rejected if and only if each of the individual hypotheses $H_{0\gamma}$ can be rejected.

Example. Returning to our example about success in four-year schools, we might argue that there are measures of success other than finishing. For example, yearly income could be used to measure success, and denoting mean incomes in the high and low SES groups by θ_h and θ_l respectively results in the hypothesis test

$$H_0: \theta_h \leq \theta_l \text{ or } p_h \leq p_l \quad \text{vs.} \quad H_1: \theta_h > \theta_l \text{ and } p_h > p_l \quad (8)$$

where the groups are considered different only if H_1 is accepted.

If we have estimators $\hat{\theta}_h$, $\hat{\theta}_l$, $\hat{p}_h$ and $\hat{p}_l$, a rejection region for the intersection–union test could be given by

$$\{(\hat{\theta}_h, \hat{\theta}_l, \hat{p}_h, \hat{p}_l): \hat{\theta}_h - \hat{\theta}_l > k_1 \text{ and } \hat{p}_h - \hat{p}_l > k_2\} \quad (9)$$

Thus the intersection–union test decides that the high and low SES groups have different levels of success, that is, H_1 is true, if and only if it decides that each of the individual parameters are different.

The topic of acceptance sampling, in which one tests whether to accept a product based on a collection of

measurements, provides an extremely useful application of an intersection–union test (see Berger 1982).

There are many other methods available for constructing hypothesis tests, methods based on invariance, pivots, robust, or large sample arguments, to name a few. For more on hypothesis testing see Lehmann (1986).

2. Evaluating Tests

As mentioned previously, a hypothesis test might make one of two different kinds of errors. The probabilities of making these errors can be calculated using the power function. If R denotes the rejection region for a test, the power function is

$$P_{\theta}(\mathbf{X} \in R) = \begin{cases} \text{probability of a Type I error} & \text{if } \theta \in \Theta_0 \\ 1 - \text{the probability of a Type II error} & \text{if } \theta \in \Theta_0^c \end{cases} \quad (10)$$

A good test has power function near one for most $\theta \in \Theta_0^c$ and near zero for most $\theta \in \Theta_0$.

Example. Let $X_1, \dots, X_n$ be a random sample from a $n(\theta, \sigma^2)$ population, σ^2 known. The likelihood ratio test of $H_0: \theta \leq \theta_0$ vs. $H_1: \theta > \theta_0$ rejects H_0 if $(\bar{X} - \theta_0)/(\sigma/\sqrt{n}) > k$ and has power function

$$P_{\theta}(\mathbf{X} \in R) = P \left(Z > k + \frac{\theta_0 - \theta}{\sigma/\sqrt{n}} \right) \quad (11)$$

where Z is a standard normal random variable.

After a hypothesis test is done, the conclusions must be reported in some statistically meaningful way. One method of reporting the results of a hypothesis test is to report the size ($\sup_{\theta \in \Theta_0} P_{\theta}(\mathbf{X} \in R)$), α , of the test used and the decision to reject H_0 or accept H_0 . The size of the test carries important information. If α is small, the decision to reject H_0 is fairly convincing, but if α is large, the decision to reject H_0 is not very convincing because the test has a large probability of incorrectly making that decision.

Another way of reporting the results of a hypothesis test, one that is data dependent, is to report the p -value. Typically, not one but an entire class of tests are constructed, a different test being defined for each value of α . The p -value for the sample point $\mathbf{x}$ is the smallest value of α for which this sample point will lead to rejection of H_0 (see *Significance, Tests of*).

Because rejection of H_0 using a test with small size is more convincing evidence that H_1 is true than rejection

of H_0 with a test with large size, the interpretation of p -values goes in the same way. The smaller the p -value the stronger the sample evidence that H_1 is true.

Many other types of evaluations of test can be done. The theory of most powerful tests shows how to construct best tests under a variety of conditions (see Lehmann 1986 or Casella and Berger 2001, Chap. 8). Hypothesis tests can also be evaluated using risk functions (see *Decision Theory: Classical*), as in Hwang et al. (1992).

3. Asymptotics

For the likelihood ratio test statistic (2), the following general theorem allow us to construct a large sample test.

Theorem 1. Let $X_1, \dots, X_n$ be a random sample from a probability distribution function or probability mean function $f(x|\theta)$. Under some regularity conditions on the model $f(x|\theta)$, if $\theta \in \Theta_0$ then the distribution of the statistic $-2 \log \lambda(\mathbf{X})$ converges to a chi-squared distribution as the sample size $n \rightarrow \infty$. The degrees of freedom of the limiting distribution is the difference between the number of free parameters specified by $\theta \in \Theta_0$ and the number of free parameters specified by $\theta \in \Theta$.

(The ‘regularity conditions’ are concerned mainly with the existence and behavior of the derivatives (with respect to the parameter) of the likelihood function, and the support of the distribution (it cannot depend on the parameter). See Casella and Berger (2001, Sect. 10.6) or Lehmann (1986, Sect. 8.8) for precise conditions.)

Rejection of $H_0: \theta \in \Theta_0$ for small values of $\lambda(\mathbf{X})$ is equivalent to rejection for large values of $-2 \log \lambda(\mathbf{X})$. Thus,

$$H_0 \text{ is rejected if and only if } -2 \log \lambda(\mathbf{X}) \geq \chi_{v, \alpha}^2$$

where v is the degrees of freedom specified in Theorem 1.

As might be expected, Theorem 1 has wide applicability. In particular, it is extremely useful in categorical data analysis (see *Multivariate Analysis: Discrete Variables (Loglinear Models)*).

Other large-sample test constructions are based on asymptotic normality of a point estimator (see *Estimation: Point and Interval*). Suppose we wish to test a hypothesis about a real-valued parameter θ , and $W_n = W(X_1, \dots, X_n)$ is a point estimator of θ , based on a sample of size n , that satisfies

$$\frac{W_n - \theta}{\sqrt{\text{Var } W_n}} \rightarrow Z$$

where $\text{Var } W_n$ is the variance of W_n and Z is a standard normal random variable. We now have the basis for an approximate test, for example, we would reject $H_0: \theta \leq \theta_0$ at level 0.05 if $(W_n - \theta_0)/\sqrt{\text{Var } W_n} > 1.645$. Note that $\text{Var } W_n$ could depend on θ_0 and we can still use it in the test statistic. This type of test, where we use the actual variance of W_n , is called a *score test*.

If $\text{Var } W_n$ also depends on unknown parameters we could look for an estimate S_n^2 of $\text{Var } W_n$ with the property that $(\text{Var } W_n)/S_n^2$ converges in probability to one. Then, using Slutsky's Theorem (see Casella and Berger 2001, Sect. 5.5), we can deduce that $(W_n - \theta)/S_n$ also converges in distribution to a standard normal distribution. The large-sample test based on this statistic is called a *Wald test*.

4. Conclusions

Hypothesis testing is one of the most widely used, and some may say abused, methodologies in statistics. Formally, the hypotheses are specified, an α -level is chosen, a test statistic is calculated, and it is reported whether H_0 or H_1 is accepted. In practice, it may happen that hypotheses are suggested by the data, the choice of α -level may be ignored, more than one test statistic is calculated, and many modifications to the formal procedure may be made. Most of these modifications cause bias and can invalidate the method. For example, a hypothesis suggested by the data is likely to be one that has 'stood out' for some reason, and hence H_1 is likely to be accepted unless the bias is corrected for (using something like Scheffé's method—see Hsu 1996).

Perhaps the most serious criticism of hypothesis testing is the fact that, formally, it can only be reported that either H_0 or H_1 is accepted at the prechosen α -level. Thus, the same conclusion is reached if the test statistic only barely rejects H_0 and if it rejects H_0 resoundingly. Many feel that this is important information that should be reported, and thus it is almost required to also report the p -value of the hypothesis test.

For further details on hypothesis testing see the classic book by Lehmann (1986). Introductions are also provided by Casella and Berger (2001) or Schervish (1995), and a good introduction to multiple comparisons is Hsu (1996); see also *Hypothesis Tests, Multiplicity of*.

Hypothesis Testing: Methodology and Limitations

Hypothesis tests are part of the basic methodological toolkit of social and behavioral scientists. The philosophical and practical debates underlying their application are, however, often neglected. The fruitful application of hypothesis testing can benefit from a clear insight into, the underlying concepts and their limitations.

1. The Idea of Hypothesis Testing

A test is a statistical procedure to obtain a statement on the truth or falsity of a proposition, on the basis of empirical evidence. This is done within the context of a model, in which the fallibility or variability of this empirical evidence is represented by probability. In this model, the evidence is summarized in observed data, which is assumed to be the outcome of a stochastic, i.e., probabilistic, process; the tested proposition is represented as a property of the probability distribution of the observed data.

1.1 Some History

The first published statistical test was by John Arbuthnot in 1710, who wondered about the fact that in human births, the fraction of boys born year after year appears to be slightly larger than the fraction of girls (cf. Hacking 1965). He calculated that this empirical fact would be exceedingly unlikely (he obtained a probability of $1/483\,600\,000\,000\,000\,000\,000\,000$) if the probability of a male birth were exactly 0.5, and argued that this was a proof of divine providence, since boys—some of whom will be soldiers—have a higher risk of an early death, so that a higher ratio of male births is needed to obtain an equal ratio of males among young adults. We see here the basic elements of a test: the proposition

that the male birth ratio is 0.5, related to data by regarding these as outcomes of stochastic variables, the calculation that the data would be unlikely if the proposition were true, and a further conclusion interpreting the falsity of the proposition.

One of the first statistical procedures that comes close to a test in the modern sense was proposed by Karl Pearson in 1900. This was the famous chi-squared test for comparing an observed frequency distribution to a theoretically assumed distribution. Pearson derived the now well-known statistic to test the proposition, or *hypothesis*, that the probabilities of the various possible (finitely many) outcomes of some random variable are given by certain preassigned numbers. Pearson proved that this statistic has (in a large-sample approximation) the chi-squared distribution; this distribution can therefore be used to calculate the probability that, if the hypothesis holds, the test statistic will assume a value equal to or larger than the value actually observed.

The idea of testing was further codified and elaborated in the first decades of the twentieth century, mainly by R. A. Fisher (e.g., 1925). In his significance tests the data are regarded as the outcome of a random variable X (usually a vector or matrix), which has a probability distribution which is a member of some family of distributions; the tested hypothesis, also called the null hypothesis, is an assertion which defines a subset of this family; a test statistic $T = t(X)$, which is a function of X , is used to indicate the degree to which the data deviate from the null hypothesis; and the significance of the given outcome of the test statistic is calculated as the probability, if the null hypothesis is true, to obtain a value of T which is at least as high as the given outcome. If the probability distribution of T is not uniquely determined by the null hypothesis, then the significance is the maximal value of this probability, for all distributions of T compatible with the null hypothesis. The significance probability is now often called the p -value (the letter p referring to probability). With Fisher originates the convention to consider a statistical testing result as 'significant' if the significance probability is 0.05 or less—but Fisher was the first to recognize the arbitrary nature of this threshold.

A competing approach was proposed in 1928 by J. Neyman and Egon Pearson (the son of Karl). They criticized the arbitrariness in Fisher's choice of the test statistic and asserted that for a rational choice of test statistic one needs not only a null hypothesis but also an alternative hypothesis, which embodies a proposition that competes with the proposition represented by the null hypothesis. They formalized the testing problem as a two decision problem. Denoting the null hypothesis by H_0 and the alternative H_1 , the two decisions were represented as 'reject H_0 ' and 'do not reject H_0 .' (The second decision was also called 'accept H_0 ,' but it will be discussed below that this is an unfortunate term.) Two errors are possible: rejecting a

true H_0 , and failing to reject a false H_0 . Neyman and Pearson conceived of the null hypothesis as a standard situation, the burden of proof residing with the researcher to demonstrate (if possible) the untenability of this proposition.

Correspondingly, they called the error of rejecting a true H_0 an error of the first kind and the error of failing to reject a false H_0 an error of the second kind. Errors of the first kind are considered more serious than errors of the second kind. The probability of—correctly—rejecting H_0 if H_1 is true, which is 1 minus the probability of an error of the second kind, given that the alternative hypothesis is true, they called the power of the test. Neyman and Pearson proposed the requirement that the probability of an error of the first kind, given that the null hypothesis is indeed true, do not exceed some threshold value called the significance level usually denoted by α . Further they proposed to determine the test so that, under this essential condition, the power will be maximal.

In the Neyman–Pearson formulation, we obtain richer results (namely, specific precepts for constructing good tests) at the cost of a more demanding model. In addition to Fisher's null hypothesis, we also need to specify an alternative hypothesis; and we must conceive the testing problem as a two-decision situation. This led to vehement debate between Fisher on the one hand, and Neyman and E. Pearson on the other. This debate and the different philosophical positions are summarized by Hacking (1965) and Gigerenzer et al. (1989), who also give a further historical account. The latter study also discusses how this controversy was resolved in the teaching and practice of statistics in the social sciences by a hybrid theory which combines elements of both approaches to testing, and which has been treated often as an objective precept for the scientific method, glossing over the philosophical controversies.

Examples of this hybrid character are that, in accordance with the Neyman–Pearson approach, the theory is explained by making references to both the null and the alternative hypotheses, and to errors of the first and second kind (although power tends to be treated in a limited and often merely theoretical way), whereas—in the spirit of Fisher—statistical tests are regarded as procedures to give evidence about the particular hypothesis tested and not merely as rules of behavior that will in the long run have certain (perhaps optimal) error rates when applied to large numbers of hypotheses and data sets. Lehmann (1993) argues that indeed a unified formulation is possible, combining the best features of both approaches.

Instead of implementing the hypothesis test as a 'reject/don't reject' decision with a predetermined significance level, another approach often is followed: to report the p -value or significance probability, defined as the smallest value of the significance level at which the observed outcome would lead to rejection of the null hypothesis. Equivalently, this can be defined

as the probability, calculated under the null hypothesis, of observing a result deviating from the null hypothesis at least as much as the actually observed result. This deviation is measured by the test statistic, and the p -value is just the tail probability of the test statistic. For a given significance level α , the null hypothesis is rejected if and only if $p \leq \alpha$.

2. Hypothesis Tests in Empirical Research

2.1 The Role of the Null Hypothesis

In the social and behavioral sciences, the standard use of hypothesis testing is directed at single research questions, practically always fragments of larger investigations, about the existence of some or other effect. This effect could be a difference between two group means, the effect of some explanatory variable on some dependent variable as expressed by a regression coefficient in multiple linear regression analysis, etc. Expressed schematically, the researcher would like to demonstrate a research hypothesis which states that the effect in question, indeed, exists. The negation of this hypothesis, then, is understood as the proposition that the effect is absent, and this proposition is put up as the null hypothesis. The research hypothesis, stating that the effect exists, is the alternative hypothesis. Rejecting the null hypothesis is interpreted as support for the existence of the hypothesized effect. In this way, the burden of proof rests with the researcher in the sense that an error of the first kind is to state that there is evidence supporting the existence of the effect if, in reality, the effect is absent. The usual welcoming phrase for the rejection of the null hypothesis is the statement that a significant result has been obtained.

2.2 Example: The t -test

Consider, as a major example, the proposition that two groups, arbitrarily labeled A and B , are different with respect to some numerical characteristic X . Available data are measurements X_{Ai} of this characteristic for some individuals i in group A and measurements X_{Bi} of the characteristics for other individuals i in group B . The first step in modeling this is to consider the observed values X as outcomes of random variables, usually with the assumption that they are stochastically independent and have a probability distribution not depending on the individual i . The next step is, usually, to focus on the expected values, i.e., population means in the two groups, denoted here by μ_A and μ_B . The tested proposition is formalized as the statement that μ_A and μ_B are different (two-sided alternative hypothesis) or as the statement that one (e.g., μ_A) is bigger than the other (e.g., μ_B) (one-sided alternative hypothesis). The null hypothesis H_0 is defined as the statement that μ_A and μ_B are equal.

The most commonly used test for this testing problem is *Student's t -test*, called after the pseudonym of W. Gosset, who laid the mathematical basis for this test in 1908. The test statistic is

$$T = \frac{M_A - M_B}{\sqrt{\left(\frac{1}{n_A} + \frac{1}{n_B}\right) S^2}}$$

where M_A and M_B are the two sample means, S^2 is the pooled within-group variance, and n_A and n_B are the two sample sizes. (Definitions of these quantities can be found in any statistics textbook.) This formula illustrates the property of many test statistics that an observed effect (here the difference between the two sample means) is compared to a measure of variability (based here on the within-group variance). Student/Gosset showed that, if the variable X has a normal distribution with the same variance in the two groups, then T has, if the null hypothesis is true, the so-called t distribution on $df = n_A + n_B - 2$ degrees of freedom. For the two-sided alternative hypothesis, H_0 is rejected for large values of the absolute value of T , for the one-sided hypothesis H_0 is rejected for large values of T itself. The threshold beyond which H_0 is rejected is called critical value, and is determined from the t -distribution in such a way that the significance level has the pre-assigned value. The one-sided threshold at significance level α is denoted $t_{df, \alpha}$, so that the 'rejection region' for the one-sided t -test is given by $\{T > t_{df, \alpha}\}$. The power of the one-sided test is larger than that of the two-sided test for $\mu_A > \mu_B$ (corresponding to the one-sided alternative hypothesis) and smaller for $\mu_A < \mu_B$. This is, in the Neyman-Pearson formulation, the reason for using the one-sided test if the alternative hypothesis is one-sided (in which case parameter values $\mu_A < \mu_B$ are not taken into consideration).

The conventional value of the significance level in the social and behavioral sciences is 0.05. For large values of the combined sample size $n_A + n_B$, the critical value of the t -test approximates the critical value that can be computed from the standard normal distribution. This is because the fact that the variance is estimated and not known beforehand becomes less and less important as the combined sample size gets larger; if the population variance was known beforehand and substituted for S^2 , the test statistic would have the standard normal distribution, and the test would be the so-called z -test. For this test, the critical value is 1.645 for the one-sided test and 1.960 for the two-sided test. The power depends on many quantities: the sample sizes, the population means and variances, and the significance level. As examples, the power of the one-sided z -test for $\alpha = 0.05$ is equal to 0.50 for

$$\frac{\mu_A - \mu_B}{\sigma} = 1.645 \sqrt{\left(\frac{1}{n_A} + \frac{1}{n_B}\right)}$$

where σ is the within-group standard deviation. The power is equal to 0.95 if $(\mu_A - \mu_B)/\sigma$ is equal to twice this value.

2.3 The Role of Assumptions

The probability statements that are required for statistical tests do not come for free, but are based on certain assumptions about the observations used for the test. In the two-sample *t*-test, the assumptions are that the observations of different individuals are outcomes of statistically independent, normally distributed, random variables, with the same expected value for all individuals within the same group, and the same variance for all individuals in both groups. Such assumptions are not automatically satisfied, and for some assumptions it may be doubted whether they are ever satisfied exactly. The null hypothesis H_0 and alternative hypothesis H_1 are statements which, strictly speaking, imply these assumptions, and which therefore are not each other's complement. There is a third possibility: the assumptions are invalid, and neither H_0 nor H_1 is true. The sensitivity of the probabilistic properties of a test to these assumptions is referred to as the lack of robustness of the test. The focus of robustness studies has been on the assumptions of the null hypothesis and the sensitivity of the probability of an error of the first kind to these assumptions, but studies on robustness for deviations from assumptions of the alternative hypothesis have also been done, cf. Wilcox (1998).

One general conclusion from robustness studies is that tests are extremely sensitive to the independence assumptions made. Fortunately, those assumptions are often under control of the researcher through the choice of the experimental or observational design. Traditional departures from independent observations are multivariate observations and within-subject repeated measures designs, and the statistical literature abounds with methods for such kinds of dependent observations. More recently, methods have been developed for clustered observations (e.g., individual respondents clustered within groups) under the names of multilevel analysis and hierarchical linear modeling.

Another general conclusion is that properties of tests derived under the assumption of normal distributions, such as the *t*-test, can be quite sensitive to outliers, i.e., single, or a few, observations that deviate strongly from the bulk of the observations. Since the occurrence of outliers has a very low probability under normal distributions, they are 'assumed away' by the normality assumption. The lack of robustness and sensitivity to outliers have led to three main developments.

First, there are non-parametric tests, which do not assume parametric families of distributions (such as the normal). Most of these are based on the ranks of

the observations rather than their numerical values. They are standard fare in statistical textbooks. Second, robust tests have been developed, based on numerical values of the observations, which are less sensitive to outliers or heavy-tailed distributions, e.g., by some kind of automatic downweighting of outlying observations (e.g., Wilcox, 1998). The purpose of such tests is to retain a high power as much as possible while decreasing the sensitivity to deviations from the normal distribution or to departures from other assumptions.

Third, diagnostic means have been developed to spot single observations, or groups of observations, with an undue influence on the result of the statistical procedure (e.g., Cook and Weisberg 1999, Fox 1991). The idea behind most of these diagnostics is that most of the observations come from a distribution which corresponds well enough to the assumptions of the statistical model, but that the observations could be contaminated by a small number of poorly fitting observations. Ideally, these observations should also be recognizable by close inspection of the data or data collection process. After deleting such poorly fitting observations one can proceed with the more traditional statistical procedures, assuming that the remaining data do conform to the model assumptions.

3. Confidence Intervals

Confidence intervals are closely related to hypothesis tests. They focus on a parameter in the statistical model. Examples of such parameters are, in the two-sample situation described above, the difference of the two population means, $\mu_A - \mu_B$, or the within-group standard deviation, σ . To frame this in general terms, consider a one-dimensional statistical parameter denoted by θ . A null hypothesis test is about the question whether the data is compatible with the hypothesis that the parameter θ (in this case $\mu_A - \mu_B$) has the particular value 0. Instead, one could put forward the question: what are the values of θ with which the data is compatible? This question can be related to hypothesis testing by considering the auxiliary problem of testing the null hypothesis $H_1: \theta = \theta_0$ against the alternative hypothesis $H_1: \theta \neq \theta_0$, for an arbitrary but fixed value θ_0 . The data may be said to be compatible with any value of θ_0 for which this null hypothesis would not be rejected at the given level of significance. Thus, the confidence interval is the interval of non-rejected null hypotheses.

Another way of viewing the confidence interval is as follows. A confidence coefficient $1 - \alpha$ is determined by the researcher (a conventional value is 0.95). The confidence interval is an interval with lower boundary L and upper boundary U , calculated from the data and therefore being random variables, with the property that the probability that $L \leq \theta \leq U$, i.e., the

interval contains the true parameter value, is at least $1 - \alpha$. It can be proved mathematically that the interval of non-rejected null hypotheses has precisely this property.

The confidence interval can be inverted to yield a hypothesis test for any null hypothesis of the form $H_0: \theta = \theta_0$ in the following way. For the most usual null hypothesis that $\theta = 0$, the hypothesis is rejected if the value 0 is not included in the confidence interval. More generally, the null hypothesis $H_0: \theta = \theta_0$ is rejected whenever θ_0 is outside the confidence interval. This shows that a confidence interval is strictly more informative than a single hypothesis test.

4. Problems in the Interpretation and Use of Hypothesis Tests

While hypothesis tests have been applied routinely by hosts of social and behavioral scientists, there have been continuing debates, sometimes vehement and polemic, about their use, among those inclined to philosophical or foundational discussion. Many contentious issues can be found in Harlow et al. (1997), Nickerson (2000), and Wilkinson and TFSI (1999). Within the context of the present contribution I can only give a personally colored discussion of some main points which might contribute to a better understanding and a more judicious application of hypothesis tests.

The reason that there has been so much criticism of the nature and use of hypothesis tests, is in my view the difficulty of reasoning with uncertain evidence and the natural human tendency to take recourse to behavioral rules instead of cogitate afresh, again and again, about how to proceed. The empirical researcher would like to conclude unequivocally whether a theory is true or false, whether an effect is present or absent. However, experimental and observational data on human behavior are bound to be so variable that the evidence produced by these data is uncertain. Our human tendency is to reason—if only provisionally—as if our conclusions are certain rather than tentative; to be concise rather than accurate in reporting our arguments and findings; and to use simple rules for steering how we make inference from data to theories. We are tempted to reason as if ' $p > \alpha$ ' implies that the investigated effect is nil, and the presumed theory is false, while ' $p \leq \alpha$ ' proves that the effect indeed exists and the theory is true.

However, such cognitive shortcuts amount to serious misuse of hypothesis testing. Much of the criticism of the use of hypothesis testing therefore is well-founded. In my view this implies that better interpretations of hypothesis testing should be promoted, and that tests should be used less mechanically and combined with other argumentations and other statistical procedures. In any case, the user of tests (or

other statistical procedures) should realize that these procedures are based on the assumption that there is random variability in the data which cannot be completely filtered out of the results. Whether a test result is significant or not depends partly on chance, and each researcher obtaining a significant result should be aware that this could be an error of the first kind, just as a non-significant result could be an error of the second kind.

4.1 Some Misinterpretations

The following list tries to correct misinterpretations that have haunted applications of statistical tests. A more extensive discussion can be found, e.g., in Nickerson (2000).

(a) A common misinterpretation is that non-rejection implies support for the null hypothesis. Nonrejection should be interpreted, however, as an undecided outcome: there is not enough evidence against the null hypothesis, but this does not imply that there is evidence for the null hypothesis. Maybe the sample size is small, or error variability is large, so that the data does not contain much information anyway. Usually the alternative hypothesis contains probability distributions that approximate the null distribution; e.g. when testing $\mu_A - \mu_B = 0$ against $\mu_A - \mu_B \neq 0$, the difference between the two population means can be tiny, while the alternative hypothesis is still true. In other words, the power of practically all tests is quite low in a sizeable part of the alternative hypothesis, so if one of the distributions in this part would prevail, chances would be low of rejecting the null hypothesis. Therefore, nonrejection provides support for those parts of the alternative practically as strongly as for the null hypothesis itself, and non-rejection may not be interpreted as support for the null hypothesis and against the alternative hypothesis.

(b) If one wishes to get more information about whether a nonsignificant result provides support for the null hypothesis, a power study is not the answer. Statistical power is the probability to reject the null hypothesis, if a given effect size obtains. Its interpretation cannot be inverted as being the degree of support of the null hypothesis in the case of nonsignificance. Power studies are important in the stage of planning a study. Once the study has been conducted, and one wishes to see in more detail to what extent the null and alternative hypotheses are supported, a confidence interval is the appropriate procedure (also see Wilkinson and TFSI, 1999, p. 596).

(c) Test results tell us nothing about the probabilities of null or alternative hypotheses. The probabilities known as the significance level or the power of the test are probabilities of certain sets of outcomes given the condition that the null or, respectively, the alternative hypothesis is true.

(d) A significant result is not necessarily important. Very low p -values do not in themselves imply large effect sizes. A small estimated effect size still can yield a low p -value, e.g., if the corresponding standard error is very small, which can be caused by a large sample or by good experimental control. Investigation of effect sizes is important, and is a different thing than hypothesis testing. The importance of reporting effect sizes is stressed in Schmidt (1996) and Wilkinson and TFSI (1999).

(e) The alternative hypothesis is not the same as a scientific theory. If a researcher is investigating some theory empirically, this can be based on tests of which the alternative hypotheses are deduced from the theory, but always under the assumption that the study was well designed and usually under additional technical assumptions such as, e.g., normality of the distributions. Since the alternative hypothesis is only a consequence and not a sufficient condition for the theory, it is possible that the alternative hypothesis is true but the theory is not. To find support for theories, one has to find corroborations of many consequences of the theory under various circumstances, not just of one of its implications. On the other hand, it is possible that the theory is true but the alternative hypothesis deduced from it is not, e.g., because the experiment or observation was ill-designed or because the auxiliary technical assumptions are not satisfied.

(f) The null hypothesis is just what it says: a hypothesis. The test is not invalidated by the mere fact that there are other reasons for thinking, or knowing, that the null hypothesis is wrong. Even if there may be other reasons for which the null hypothesis is wrong, still it can be sensible to check whether the data at hand are, or are not, compatible with it.

4.2 Limitations of the Neyman–Pearson Approach to Hypothesis Testing

The Neyman–Pearson (1928) formulation changed the concept of hypothesis testing because it provided a rational basis for the choice of a test statistic. This was obtained at the cost of a quite narrow frame for the notion of a hypothesis test: a two-decision problem in which one error ('type I') is considered much more serious than the other error ('type II'). This model for decision-making is often inappropriate and, when it is useful, it is more commonly a useful approximation than a faithful representation of the actual decision situation. Some of its limitations are discussed briefly in this section.

(a) Even when a dichotomous decision must be taken as a result of a scientific investigation, it is possible that both types of error should be considered equally serious. This is the case, e.g., when two therapies are compared and the most promising one must be chosen for further study or for practical application. If the costs of both kinds of error (choose

therapy B , while A is better; or choose therapy A , while B is better) are about the same, then there is no asymmetry between the two competing hypotheses, and a significance test is not in order.

(b) Often there are more than two outcomes of the decision situation. For example, in the two-sample situation discussed above, where the population means are μ_A and μ_B , and where the researcher entertains a theory implying that $\mu_A > \mu_B$, it is natural to define three decision outcomes defined as ' $\mu_A > \mu_B$ (support for the theory),' 'undecided,' and ' $\mu_A < \mu_B$ (evidence against the theory).' Usually, however, such a situation is represented by a Neyman–Pearson testing problem with null hypothesis H_0 : ' $\mu_A = \mu_B$ ' and alternative H_1 : ' $\mu_A > \mu_B$.' If the t -statistic for $\mu_A - \mu_B$ yields a strongly negative outcome ('significance in the wrong direction') then the researcher only concludes that the null hypothesis is not rejected, whereas the data conveys the message that the alternative hypothesis should be rejected. The data then have to be considered as evidence against the theory embodied in H_1 . Such a three-decision formulation is closer to the actual purpose of hypothesis tests in many situations where a one-dimensional parameter is being tested, cf. Leventhal (1999).

(c) The Neyman–Pearson approach is formulated as if the data at hand is the only evidence available about the null and alternative hypotheses: it is an *in vacuo* formulation. This is almost never realistic. Often the propositions under study are theoretically plausible or implausible, there is earlier empirical evidence, there may be converging evidence (as in the case of triangulation studies) in the same investigation, and other evidence may become available in the future. In the light of this surrounding evidence, it is unrealistic—perhaps arrogant—to presume that the researcher has to take either of two decisions: 'reject H_0 ' or 'do not reject H_0 .' It is more realistic to see the data at hand as part of the evidence that was and will be accumulated about these hypotheses. This is a major reason why presenting the result of the test as a p -value is more helpful to other researchers than presenting only the 'significant–nonsignificant' dichotomy (also see Wilkinson and TFSI 1999).

There are several ways in which the results obtained from the data at hand, perhaps summarized in the p -value, can be combined with other evidence. In the first place, an informal combination can be and often will be made by a sensible, nonformalized weighing of the various available pieces of evidence. One formal way of combining evidence is provided by the Bayesian paradigm (e.g., Gelman et al. 1995). This paradigm presupposes, however, that the prior and current ideas of the researcher about the plausibility of all possible values of the statistical parameter under study be represented in a probability distribution for this parameter, a very strong requirement indeed. Other formal ways of combining evidence have been developed and are known collectively by the name of

meta-analysis (e.g., Cook et al. 1992, Schmidt 1996). These methods require that the several to-be-combined hypothesis tests address the same substantive hypothesis, or that they can be regarded as tests of the same substantive parameter.

5. Conclusion

The statistical hypothesis test is one of the basic elements of the toolbox of the empirical researcher in the social and behavioral sciences. The difficulty of reasoning on the basis of uncertain data has led, however, to many misunderstandings and unfortunate applications of this tool. The Neyman–Pearson approach is a mathematically elegant formulation of what a hypothesis test could be. Its precise formulation rarely applies literally to the daily work of social and behavioral scientists, very often it is a useful approximation to a part of the research question, sometimes it is inappropriate—but sacrosanct it is not. A hypothesis test evaluates the data using a test statistic set up to contrast the null hypothesis with the alternative hypothesis, and the p -value is the probability to obtain, *if* the null hypothesis is true, outcomes of the test statistic that are at least as high as the outcome actually observed. Low values therefore are evidence against the null hypothesis, contrasted with the alternative hypothesis. It is more conducive to the advance of science to report p -values than merely whether the hypothesis was rejected at the conventional 0.05 level of significance.

In the interpretation of test outcomes one should be aware that these are subject to random variability; and that the probability calculations are based on assumptions which may be in error. Incorrect assumptions can invalidate the conclusions seriously. Nonparametric and robust statistical procedures have been developed which depend less on these kinds of assumption, and diagnostics have been developed for checking some of the assumptions. When reporting empirical results, it is usually helpful to report not only tests but also estimated effect sizes and/or confidence intervals for important parameters. To sum up: ‘It seems there is no escaping the use of judgment in the use and interpretation of statistical significance tests’ (Nickerson 2000, p. 256).

Hypothesis Tests, Multiplicity of

Standard procedures for controlling the probability of erroneous statistical inferences apply only for a single comparison or determination from a given set of data. Multiplicity is encountered whenever a data analyst draws more than one inference from a data set. With multiplicity, standard procedures must be adjusted for the number of comparisons or determinations that actually or potentially are performed. If some adjustment is not made, the probability of erroneous inferences can be expected to increase with the degree of multiplicity. In other words, the data analyst loses control of a critical feature of the analysis.

Questions arising from problems of multiplicity raise a diversity of issues, issues that are important, difficult, and not fully resolved. This account empha-

sizes the issues, tries to avoid being trapped in undue detail, and provides examples of the application of a recommended procedure.

It is helpful to recognize several general guidelines:

(a) Two approaches to the same data, with different purposes or with different questions being posed, need not yield compatible results.

(b) Exact equality of long-run values is very rare and should not play an appreciable role either in one's thinking or one's practice.

(c) When posing questions about data, greater realism will be very valuable.

(d) The situations faced must not be characterized either as completely 'fixed' or completely 'random.'

(e) In selecting a bouquet of techniques for the next decade or the next millennium, the selection must not be cast in stone; further evolution is to be expected (in later months, years, or centuries).

Issues of multiplicity appear in a wide variety of settings, including

(a) outcomes, each measured with variability, in several situations:

(i) comparison of all pairs of situations ('multiple comparisons'); and

(ii) comparison between each situation and a standard ('multiple determination');

(b) selection of one or more elements from a set of alternatives:

(i) selection of how variables are to be expressed for analysis (i.e., what re-expression, if any, should be used?);

(ii) selection of which of the available variables are to participate in an analysis (subset selection); and

(iii) reduction in size of a set of alternatives in an attempt to reduce their number without losing the best.

1. Illustrative Settings, Error Rates, and Procedures

Some important issues arise for all of these alternatives. These issues are considered and illustrated for one example of multiple determination and one example of multiple comparisons.

Consider k independent estimates $\bar{y}_1, \bar{y}_2, \dots, \bar{y}_k$ of, respectively, $\mu_1, \mu_2, \dots, \mu_k$ and an estimate of variability applicable to all these estimates. This is typical enough of multiplicity problems to render conclusions that are broadly helpful.

1.1 Multiple Determination

Defining a standard, λ , and for each μ_i , drawing conclusions about $\mu_i - \lambda$ based on $\bar{y}_i - \lambda$ is, by definition, making a multiple determination. (In some applications, μ_i is a mean change from one time to another.

Often in that case, $\lambda = 0$.) Experience and common sense suggest strongly that μ_i and λ are certain to differ in some decimal place, so that a focus on a null hypothesis that $\mu_i = \lambda$ is quite unrealistic and misleading.

With an interest in $\mu_i - \lambda$ for each value of i , it is reasonable to ask for one of these conclusions: (1) to act as if $\mu_i < \lambda$; (2) to act as if the sign of $\mu_i - \lambda$ is not (yet) determined; or (3) to act as if $\mu_i > \lambda$. Here (1) or (3) is a 'definite' result, while (2) is 'indefinite.'

1.2 Multiple Comparisons

Consider the $k(k-1)/2$ individual pair-wise comparisons $y_i - y_j$. Using these to draw conclusions about the set of $\mu_i - \mu_j$ is, by definition, making multiple comparisons, although the definition is more general, and applies to any set of linear contrasts among the μ_i . Because μ_i and μ_j are certain to differ in some decimal place, there is no good reason to focus on the null hypothesis that $\mu_i = \mu_j$. Instead, it should be asked, for each (i, j) pair, whether one should (1) act as if $\mu_i < \mu_j$; (2) act as if the sign of $\mu_i - \mu_j$ were not (yet) determined; or (3) act as if $\mu_i > \mu_j$.

1.3 In General

Notice the use of ' $>$ ' or ' $<$ ' and the avoidance of ' $=$ ' and ' $\neq$.' 'Accepting the null hypothesis' is usually at best misleading. Confounding ' $>$ ' and ' $<$ ' as ' $\neq$ ' is unresponsive and confusing. Thus, focusing on direction is important when dealing with only one comparison (or determination), and becomes vital when dealing with several or many comparisons.

In these formulations, an 'error' is asserting one direction when the (unknown) truth is the other direction. (One should forget about the 'null case' of equality.) Asserting that the direction is not yet established may be a wasted opportunity, but is not an 'error.' The task is to control error while minimizing wasted opportunity, i.e., minimizing indefinite results.

Two classical choices for controlling errors consider expected error rates over replications of the study. (See, for example, Hochberg and Tamane 1987, p. 7.) They are:

$$E \left\{ \frac{\text{number of errors}}{\text{number of comparisons}} \right\} \leq .025$$

('individual,' 'unadjusted,' or 'per comparison')

and

$$E \left\{ \frac{\text{number of errors}}{\text{number of families}} \right\} \leq .025$$

('simultaneous,' 'Bonferroni,' or 'per family').

Here, 0.025 could easily be replaced by another choice. (For consistency with commonly used notation, the chosen value will be denoted by $\alpha/2$.) ‘Family’ refers to an identified set of comparisons whose simultaneous error rate is to be controlled. Normally, ‘number of families’ would be taken equal to unity. These two choices for controlling errors differ by a factor of k for multiple determinations and of $k(k-1)/2$ for multiple comparisons, so the difference between the two can be quite large.

There has been a feeling for decades (e.g., Tukey 1994/1953) that ‘individual’ or ‘unadjusted’ is too soft while ‘simultaneous’ is too severe. More recently, Benjamini and Hochberg (1995) introduced a compromise that is receiving increasing acceptance.

The two parts of their innovation are a definition of an alternative error rate, the false discovery rate (*FDR*), and a moderately simple procedure that, under the simplest circumstances, controls the *FDR*. The definition is the expectation of the ratio of the number of erroneous assertions of direction to the total number of assertions of direction, i.e.,

false discovery rate =

$FDR =$

$$E \left\{ \frac{\text{number of errors}}{\max\{1, \text{number of definite results}\}} \right\}$$

Let p_{crit} be the tail area (usually for each of two tails) of the null sampling distribution of the test statistic for any single comparison being judged by a multiplicity-respecting procedure. Each such procedure will stipulate a probability of error or average fraction of error that is bounded by $\alpha/2$ when judging confidence of direction. The value of p_{crit} will depend on the sort of confidence to be attained. Let K be the number of determinations or comparisons in the family under consideration, where $K = k$ for multiple determinations and $K = k(k-1)/2$ for all pair-wise multiple comparisons. Let $h = 1, \dots, K$ be the rank of the p -value associated with the test statistic for the comparison concerned when ordered from smallest to largest, so that the observed p -values— $p_{(h)}$ for the h th comparison—are weakly increasing from $h = 1$ to $h = K$. Three distinct procedures, two classical choices and one that controls the *FDR*, are defined as follows:

Unadjusted: be confident of the observed direction for comparison h if

$$p_{(h)} \leq p_{\text{crit}} = p_{\text{UNA}} = \alpha/2$$

FDR (Benjamini and Hochberg 1995): be confident of the observed direction of the h th comparison when $p_{(h)}$ is the largest p -value such that

$$p_{(h)} \leq p_{\text{crit}} = p_{B-H}(h) = (h/K)\alpha/2.$$

Moreover, be confident of the observed direction for all comparisons g with

$$p_{(g)} \leq p_{(h)}, \text{ i.e., } g = 1, \dots, h.$$

Bonferroni (per family): be confident of the observed direction for comparison h if

$$p_{(h)} \leq p_{\text{crit}} = p_{\text{BON}} = (1/K)\alpha/2.$$

Because

$$(1/K) \leq (h/K) \leq 1$$

it must be true that

$$p_{\text{BON}} \leq p_{B-H}(h) \leq p_{\text{UNA}}$$

Specifically, $p_{B-H}(h) = (h)p_{\text{BON}}$ and $p_{\text{UNA}} = (K)p_{\text{BON}}$. The three collections of confident directions corresponding to these three approaches are nested, with the collection for the unadjusted procedure the largest and that for the Bonferroni the smallest.

2. Examples: The NAEP Trial State Assessment

Data from the National Assessment of Educational Progress (NAEP) Trial State Assessment were subjected to two separate analyses by Williams et al. (1999). The data for the first analysis consist of average eighth-grade mathematics proficiency scores for the 34 states that participated in both the 1990 and 1992 NAEP assessments; data for the second analysis consist of average eighth-grade mathematics proficiency scores for the 41 states that participated in 1992 (Johnson et al. 1993).

2.1 Multiple Determination

One way of assessing year-to-year change in state mathematics achievement involves directly testing the significance of change in each of the 34 states. An ordinary Bonferroni adjustment for control of Type I error per family, as was used by NAEP (Johnson et al. 1993), results in an effective critical p -value of $p_{\text{BON}} = 0.000735$ for $\alpha/2 = 0.025$. Table 1 contains the computed difference between 1990 and 1992 mathematics achievement means for each state and the computed pooled standard error. It also includes the statistical decision about confidence in direction (with confident direction indicated by ‘ b ’ in each column) for each state under the three multiplicity treatments. For this example, critical p values are used as a basis for comparison of the adjustment procedures. The cutoff

critical t value for each procedure is also displayed in the bottom line of Table 1.

The unadjusted per comparison approach is confident about the direction of 15 differences, whereas the Benjamini–Hochberg (B–H) FDR procedure is confident about 11 of these, and the Bonferroni technique is confident about the direction of only four of the differences.

2.2 Multiple Comparisons

All pair-wise mean differences between the states' 1992 eighth-grade mathematics achievement scores were considered. Because 41 states participated in the 1992

assessment, the family size is $K = 41 \times 40/2 = 820$ comparisons. Using the Bonferroni adjustment, there are 480 confident directions between states, and the use of the B–H technique results in an additional 159. The unadjusted analysis increases the number of confident directions beyond the B–H technique by only six.

2.3 For Both Examples

For each example above, the B–H FDR procedure has led to a greater number of confident directions than the Bonferroni procedure. For the examples, we may expect that no more than 0.025 of the confident

directions identified by the B–H procedure are in error. (This is what it means to control the *FDR*.) As is generally the case, the relative advantage of the *FDR* procedure becomes greater with increasing numbers of comparisons (Kesselman et al. 1999).

3. General Considerations

3.1 Qualitative Status

In a situation where only a very few of the results are definite, the B–H false discovery procedure performs much like the Bonferroni simultaneous approach. Because these situations include those where ‘definite’ is purely accidental, as in extreme instances of ‘data mining,’ it is important that the approach selected resembles a severe procedure, and the *FDR* approach does so.

In a situation where the total number of definite results is a large fraction of the total number of comparisons an algorithm that controls the *FDR* behaves like the unadjusted procedure. If many comparisons deserve a definite result, it is reasonable that the selected approach should not lead to excessively many errors, and again, the *FDR* approach satisfies the criterion.

3.2 Family Size

One of the many problems associated with multiplicity is a frequent strong dependence of result on the number of comparisons in the family. Applying ‘simultaneous’ to Vermont vs. Maine as New England states can give results fairly different from applying it to Vermont vs. Maine as two of the ‘lower 48,’ with a family more than 75 times as large in the latter case. Controlling *FDR* turns out to be much less dependent on family size than the use of simultaneous control.

If the individual elements, e.g., the individual determinations, are stochastically independent, then it is known (Benjamini and Hochberg 1995) that using the *FDR* algorithm does control the rate of false discoveries, and may be unnecessarily conservative. It is reasonable to believe that the result of applying the *FDR* algorithm to elements lightly correlated in the sort of way arising from multiple comparisons will be even more conservative.

For making multiple comparisons in the special case where the true values follow an idealized Gaussian distribution, simulations have shown (Lewis and Tukey 2000) that the algorithm can be made less conservative while still protecting the rate of false discoveries, at least when the number of values being compared is no greater than 25. The modified algorithm follows the B–H approach, but uses $(h/K)\sqrt{(h+1)/2}$ in place of (h/K) in the formula for $p_{\text{B-H}}(h)$, with a caveat that enlargement should stop when the raw modification would otherwise be more liberal than the unadjusted analysis. This modifi-

cation, here denoted by ‘TSR,’ results in the following expression for the series of critical values:

$$p_{\text{TSR}}(h) = \min\{1, (h/K)\sqrt{(h+1)/2}\}(\alpha/2)$$

Simulations indicate that a substantial improvement in power may be attained with this modification to the B–H procedure in the situations for which it is appropriate.

For additional recent work on procedures that control the *FDR*, see Shaffer (1999) and Benjamini and Hochberg (2000).

3.3 ‘Fixed’ and ‘Variable’

A major source of debate associated with multiplicity and factorial design has to do with ‘fixed’ vs. ‘variable,’ i.e., fixed versus random. A significant part of the confusion and conflict can be traced to an unwarranted belief, in tests of hypotheses, that mean squares themselves (or what mean squares estimate) are important. With interest just in directionality, each of the individual questions and answers in multiple comparisons involve $\bar{y}_i - \bar{y}_j$, where i and j are specified, and there is *no sense in asking* whether i and j are fixed or variable. (It may make sense, as shown below, to ask if something else is fixed or variable.)

3.4 A Prototype

The simplest multiple-comparison situation that illustrates the issues is a two-way table of responses with some replication in the cells and questions directed to differences between rows. Starting with k rows and m columns, each comparison involves only two rows. Replacing two rows of measurements by one row of estimated differences yields a 1-by- m table with some replication. (Readers may choose their favorite identities for rows and for columns; in particular, columns = blocks and rows = varieties or treatments gives appropriate realizations.)

If the columns and calculations are fixed, then the uncertainty about the answer is a consequence of whatever makes replicates within a cell different. An estimate of the corresponding variance is, say, an f -error term.

If the columns or calculations would be different were the data to be collected again, in particular, if different applications would require different weights, then the uncertainty about the overall results would reflect two sources of variability: whatever makes replicates differ, and the long-run differences (for a selected comparison) between one column and another.

(The second would not appear if the columns, etc., would be the same.) The resulting error term will be larger than the f -error term; just how much larger will depend on the extent to which differences in columns and calculations are reflected in the overall comparison.

In one crisply specified case where the columns are a random sample from a specifiable infinite population of columns, (and the calculations are fixed), there is a well-determined error term, say, the *r*-error term. Clearly

$$r\text{-error term} > f\text{-error term}$$

In practice, it is not likely to have exactly either columns and calculations fixed, or columns that constitute a simple random sample from a population.

Two alternatives, ‘fixed’ and ‘variable,’ are not enough.

A good way to provide a reasonable amount of realism is to define ‘*c*’ by

appropriate error term

$$= (c)[r\text{-error term}] \\ + (1 - C)[f\text{-error term}]$$

so that ‘everything fixed’ corresponds to $c = 0$ and ‘random’ is a particular case of $c = 1$. It pays then to learn as much as possible about values of ‘*c*’ in the real world.

3.5 *Mathematization vs. Realism*

Those who believe that data analysis can and should be mathematized are likely to be neither happy about the introduction of ‘*c*’ nor highly tolerant of a major role for such a quantity that is not estimable from data. When they recognize, however, that ‘*c*’ is about the data analyst or the data analyst’s client—about just what question is being asked or about what is the most realistic question that can reasonably be asked—then they may be more willing to think about ‘*c*’ and even to work with its default values. Those who recognize the need for more realism today (and even more tomorrow), however, must be prepared for a growing seriousness about ‘*c*’ and a growing impact of nonzero values of ‘*c*’ on the conclusions to be drawn from the analysis of data. Some may find it useful to give ‘*c*’ a Bayesian interpretation, but this is not a necessity.

The only context in which something like being serious about ‘*c*’ has passed into a subject-matter field seems to be climatology. The usefulness of a climatological result is clearly measured by its performance over the set of years from its publication until the publication of its next revision. It will be based on what happened, quantitatively, in a set of years before its construction. Weather is a nontrivial time series (surely not a white noise), so neither $c = 0$ nor $c = 1$ can be expected to do well. Empirical study has led to using a base period for climatology of roughly the last 25 years. This is not directly related to a ‘*c*’ but is of a similar flavor.

Most data analysis intended to illuminate the real world is rather like climatology. The data, whether experimental or historical, has been collected under some circumstances and in the past, while its analysis has been carried out to estimate what will or what would happen in the future. The strength of the link from past to future is important; judging it effectively is not likely to be easy. Difficult issues need to be faced. If analyses are to be increasingly realistic, decisions about those issues will be required.

3.6 *Plausible Defaults for ‘c’*

To begin to face the tasks, some values of ‘*c*’ can be set forth for some crudely described situations. Using such a list as a basis for choosing a ‘*c*’ in real data analyses is likely to be better than doing what has become customary, i.e., to assume either that $c = 0$ or $c = 1$. Values on this list will be likely to change over time as more is learned. (Here ‘columns’ refers to whatever versions are involved.)

- $c = 0.0$ fixed columns and calculation
- $c = 0.1$ fixed columns and somewhat variable calculation
- $c = 0.5$ fixed columns and illustrative weights
- $c = 1.0$ random columns and fixed weights
- $c = 1.4$ somewhat illustrative columns
- $c = 1.6$ illustrative columns
- $c = 2.0$ very illustrative columns

For simple random sampling without replacement from a finite population, the value of ‘*c*’ is $1 - (\text{sample size})/(\text{population size})$.

3.7 *More Quantitative Conclusions*

The focus so far has been on directionality, an appropriate focus when not dealing with crisp measurements, when the hope is to be convinced by the analysis about the definiteness of at least some directions. Especially in some branches of physical science and engineering, the appropriate interest is in the sizes of differences, sizes that may be measured to a small fraction of their nominal value. Instead of directions, the focus will then be upon confidence intervals.

If the concern really is with all the pair-wise differences among k varieties, treatments, or circumstances, or if the pair-wise differences we are concerned about are selected independently of the numbers to be differenced, the Benjamini and Hochberg approach has to regard the results for all differences as definite so that the *FDR* approach could be taken to coincide with the individual unadjusted approach.

If it really is desired to make a simultaneous statement about ‘all differences’ or to validate a process of focusing on the single difference or the few differences that appear to be most different from a reasonable anticipation, the only viable alternative is

to take a simultaneous approach, presumably using percentage points for a Studentized-range distribution.

These two procedures need not yield compatible results. A difference may have a definite direction by *FDR* but a simultaneous confidence interval that includes long-run differences of both signs. Such incompatibility should be regarded only as evidence that the analyst needs to be clear which question is being asked. Is the analyst looking for a few definite directions (or for all the directions that can reasonably be believed to be definite) or is the interest in providing intervals covering the worst that is likely to have happened for any difference?

3.8 Other Kinds of Multiplicity

The broad issues presented here in discussing multiple determination and multiple comparisons appear in most of the other situations where multiplicity matters. Details may vary, but the broad issues are parallel. For more comprehensive treatments of multiplicity, see, for example, Miller (1981), Hochberg and Tamane (1987), and Hsu (1996).

Hysteria

The concept of hysteria is almost as old as medicine itself. Explanations of the complaints and behavior of the predominantly female patients suffering from this enigmatic condition have changed many times in response to changing ideas about the causes of disease, but none of these explanations has ever been entirely convincing. For at least the last 100 years physicians have been puzzled by the varied manifestations of the condition, dismayed by its ambiguities, and often exasperated by the behavior associated with it. As a result the term is now fading into history, though the various syndromes it embraced still exist and still await a satisfactory explanation.

1. The History of Hysteria

The concept of hysteria (from the Greek word *hystera* for womb) originated in the second millennium BC. Egyptian priest physicians attributed the paroxysmal symptoms of their female patients to wandering of the womb, and treated them either by the local application of fragrant potions to entice the uterus back to its proper station, or by the oral administration of nauseous draughts to drive it back. These assumptions were inherited by Hippocrates and Galen, and so was born the tenacious idea of a disease of women manifested by recurrent fits and other dramatic symptoms of sudden onset.

The European literature of the last 400 years is summarized by Merskey (1979). Thomas Sydenham was probably the first to recognize explicitly the role of emotion in the genesis of hysteria, for in 1697 he said in his *Discourse* that 'The *External Causes* of this Disease are either violent motion of the Body, or more frequently vehement Agitations of the Mind by the Assaults of Grief, Anger, Fear and such like Passions.' Sydenham was, of course, allowing for 'internal causes' as well, but the identification of these remained elusive. Sir Benjamin Brodie established in the 1830s that the muscles and peripheral nerves of patients with hysterical paralyses or anaesthesias appeared quite normal when examined postmortem, and by the 1870s Sir James Paget was convinced that the problem was one of volition rather than of neurological pathology. As he observed succinctly, 'They say "I cannot"; it looks like "I will not"; but it is "I cannot will."' Even

so, the great French neurologists Charcot and Janet still assumed at the end of that century that the fundamental cause of the suggestibility and hypnotizability of hysterics was a hereditary nervous degeneration. The assumption that hysteria occurred only in women also persisted well into that era. Landouzy stated firmly in 1846 that it was '*exclusive au sexe féminin*' and Charcot regarded ovarian tenderness as one of the stigmata of the condition and attached great significance to the precipitation of hysterical symptoms by pressure on the ovary. Only in World War I, when large numbers of soldiers in all the combatant armies developed florid hysterical symptoms in response to the appalling stresses of trench warfare, was the assumption of an exclusively female illness finally abandoned.

The idea that hysteria was a purely psychological disorder was introduced by Breuer and Freud (1896) in their famous *Studies on Hysteria* and contemporary opposition to their views owed almost as much to the abandonment of neurological pathology as it did to their novel and disturbing ideas about infantile sexuality. According to the corpus of psychoanalytic theory that developed from this revolutionary treatise, hysteria was a specific clinical entity arising from sexual conflicts originating in the oedipal phase of psychosexual development. Failure to relinquish the incestuous tie to the opposite sexed parent that develops during infancy leads to sexual conflicts in adult life because the sexual drive, or libido, retains its forbidden incestuous quality. The drive is, therefore, repressed and its energy converted into a hysterical symptom, which not only protects the patient from conscious awareness of the incestuous wishes, and hence from the anxiety that would otherwise result (primary gain), but simultaneously provides a symbolic expression of it (the rhythmic movements of a hysterical convulsion, for example, expressing the patient's coital fears or phantasies). In addition, the symptom itself often provided other benefits (secondary gain) by rendering the subject visibly ill, or making crucial activities impossible.

Despite the lack of supporting empirical evidence, and the wartime evidence that widespread and florid hysterical symptoms were precipitated by overwhelming stress rather than by infantile sexual experiences or phantasies, this psychoanalytic concept of hysteria remained dominant until the 1960s.

2. Criticisms of the Concept and its Multiple Meanings

The English physician Skey commented as long ago as 1867 that 'One good reason that may be assigned to the persistent employment of the term Hysteria—a term we all know to be objectionable—is the difficulty of finding a substitute for it.' Those objections and that difficulty have persisted ever since. Indeed, the

objections have been expressed forcefully almost continuously from the early years of the twentieth century by German, English, and even French psychiatrists. The most consistent criticisms of hysteria have centered on the multiple meanings of the term and the wide variety of symptoms and behaviors to which it has been applied. At least seven different meanings can be distinguished.

2.1 Neurological Conversion Symptoms

Muscular weakness or paralysis, affecting one, two, or all four limbs, or resulting in loss of speech; convulsions simulating epilepsy; or a loss of sensation (commonly blindness or tunnel vision, deafness, or a circumscribed loss of cutaneous sensation) assumed to depend on the psychoanalytic mechanism of conversion. As the extent of the paralysis or sensory loss reflects the patient's ideas rather than anatomical facts, and as it can often be demonstrated neurologically that the relevant motor or sensory pathways are undamaged, the diagnosis of hysteria can usually be made with some confidence.

2.2 Hysterical Pain and other Psychophysiological Reactions

Visceral symptoms like vomiting or otherwise unexplained pain assumed to be produced by the same conversion mechanism. Unlike neurological conversion symptoms, there is usually no easy way of demonstrating that such symptoms must be psychogenic and as a result the diagnosis of hysteria remains uncertain.

2.3 Dissociative Reactions

Episodes of amnesia, fugue states, and rare cases of multiple personality assumed, after Janet, to be based on a restriction or dissociation of consciousness. Like conversion symptoms, hysterical amnesias and fugues usually develop in highly stressful situations and have the effect of providing at least a temporary respite from that stress.

2.4 Anxiety Hysteria

An obsolete psychoanalytic term for phobic anxiety, implying that repressed anxiety is displaced onto a neutral object or situation instead of being converted into a bodily symptom.

2.5 Epidemic or Mass Hysteria

Since the 'dancing manias' of fourteenth-century Europe, over 100 outbreaks of mass hysteria have been recorded, usually in schools, convents, or other communities of girls or young women, and usually at times of obvious stress (Sirois 1974). Shared appre-

hensions and suggestion are clearly important as those affected are always in close contact with one another and develop almost identical symptoms. Influential members of the community are generally also the first to be affected.

2.6 Briquet's Syndrome

A well-defined pattern of behavior, first described by the French physician Briquet in 1859 and seen almost exclusively in young women. They repeatedly consult doctors with multiple and constantly changing somatic symptoms for which no adequate cause can be found. They also have unsatisfactory sexual lives and are prone to develop mood disturbances and conversion symptoms. This behavior persists into middle age or beyond, and as a result such women acquire voluminous medical files, have multiple abdominal and pelvic operations, and often become dependent on analgesics or tranquillisers (Guze and Perley 1963).

2.7 The Hysterical Personality

A personality type, first clearly described by Janet at a time when hysteria was still regarded as an almost exclusively feminine condition, which is assumed to be particularly susceptible to develop conversion and other hysterical symptoms. As described, the characteristic features are attention-seeking behavior, shallow, labile emotions, and self-centered, demanding, interpersonal behavior. A variety of tactics are used to attract and retain the attention of others, including striking or sexually provocative clothing, flirtatious behavior, flattery, dramatized accounts of their past lives or current circumstances, and extravagant gestures.

Despite the linkages between these seven meanings the inevitable consequence of this diversity of usage was confusion and serious ambiguity. The situation was summarized trenchantly by the American psychiatrist Chodoff (1974): 'Entities that are clinically quite different are being held together artificially by little more than the authority of an ancient name' he asserted; 'the diagnosis (of hysteria) has become a balloon filled with air rather than substance ... it is a fossil encrusted with and obscured by successive layers of meaning.' For good measure he reminded his audience that the term 'hysteric' was used widely by young male psychiatrists to describe almost any attractive female patient.

3. Hysteria Discarded

Although similar criticisms had been voiced many times before, Chodoff's strictures struck home, and when the American Psychiatric Association produced the revolutionary 3rd edition of its *Diagnostic and Statistical Manual* in 1980 the term hysteria had been

discarded (see *Nosology in Psychiatry*). Most of its constituent syndromes survived, however, though with revised titles. Conversion symptoms became conversion disorder and anxiety hysteria became phobic disorder, and both were shorn of their original psychodynamic explanations. Dissociative reactions likewise became dissociative disorders. Briquet's syndrome was renamed somatization disorder, and the hysterical personality was renamed histrionic personality disorder. Mass or epidemic hysteria was not mentioned, presumably because it was assumed that each individual would be categorized separately under the appropriate syndrome. When the World Health Organization produced the next (10th) revision of the International Classification in 1992 its treatment of hysteria was almost identical. The only significant difference was that dissociative and conversion disorders were combined in a single category. Quite suddenly, therefore, one of the oldest, most evocative, and most reviled diagnoses in medicine's nomenclature had been expunged, at least for all official purposes.

4. The Limitations of the 'Medical Model'

Discarding the term hysteria has not, of course, solved the underlying problem of why the patients previously so labeled behaved in the way they did. A large part of that problem is that physicians have traditionally been conditioned by a set of mainly unwritten assumptions—what social scientists call the 'medical model'—to assume that every *bona fide* patient must have a disease of some kind. If the patient's complaints can be related to a pathology of some sort no problem arises. But if they cannot, most doctors tend to oscillate uneasily between two alternative attitudes: either there is nothing wrong with them or they are psychiatrically ill; and both alternatives are often unsatisfactory. The former may be true in organic disease model terms, but it provides no explanation for the patient's behavior and no relief of their suffering. The latter is easily taken to imply that the patient must have some kind of mental illness with a discrete cause of its own. Traditionally, hysteria has been one of these mental illnesses, but only one of them. For physicians have also invoked the concepts of hypochondriasis, neurasthenia, psychophysiological reaction, psychosomatic reaction, 'functional overlay,' and malingering in an attempt to explain their patients' behavior, and all these concepts, except possibly the last, are inadequately defined and overlap with one another.

5. The Sick Role and Illness Behavior

It is increasingly well recognized that the question to be asked when patients consult doctors with complaints that appear to be symptoms of bodily illness but in whom no evidence of illness can be found is often not 'What is the matter with them?' but 'Why are

Figure 1

A tentative classification of illness behavior (reproduced by permission of Cambridge University Press from Kendell R E 1983 *Hysteria and the hysterical (histrionic) personality*. In: Russell G F M, Hersov L A (eds.) *The Neuroses and Personality Disorders*. Cambridge University Press, Cambridge, UK)

they behaving in this way?' If the issue is formulated in this way the concepts of the 'sick role' and 'illness behavior' originally formulated by Parsons (1951) and Mechanic (1962) provide the starting point for a better understanding of the problem (Pilowsky 1969). As such writers have emphasized, the sick role in contemporary society involves many privileges. Invalids are exempted from many normal social obligations; children don't have to go to school and adults don't have to go to work, and often continue to be paid nonetheless. They are also exempted from responsibility for their incapacity, and so cannot simply be told to pull themselves together. Indeed, others are under an obligation to be kind and sympathetic, and sometimes to take over their responsibilities as well. The only reciprocal obligation on the patient is to seek and accept appropriate treatment, so that they utilize the privileges of the sick role for as briefly as possible.

Patterns of behavior that are rewarded tend to increase in frequency at the expense of those that are not, and the rewards of the sick role are so substantial, and are often experienced so frequently in childhood, that it is hardly surprising that not all those who consult doctors with bodily symptoms have objective evidence of disease. Against this conceptual background, Kendell (1983) proposed a tentative classification of invalid behavior in the form of a Venn diagram (Fig. 1). Although reality is undoubtedly

more complex, the relationships between the three overlapping populations in this diagram illustrate some basic principles. Most illness behavior is generated by recognized disease (including well-defined psychiatric syndromes like schizophrenia and phobic anxiety). But substantial parts of the whole are generated either by fear of disease or by the 'positive reinforcement' provided by the rewards of the invalid role. There are large and important overlaps between these three populations, and the main recognized disease population is surrounded by a penumbra of unrecognized but genuine disease (mainly people with accepted but so far undiagnosed illnesses, like occult cancers, but perhaps also including subpopulations with as yet unrecognized syndromes, like people with narcolepsy 100 years ago). The management of individual patients depends on which of the 11 populations formed by the intersections of these four circles they come from, rather than on which of a few mutually exclusive diagnostic categories they belong to. Broadly speaking, illness behavior generated by fear of disease corresponds to hypochondriasis and illness behavior motivated by the attractions of the invalid role to what used to be called hysteria.

Essentially, the sick role is attractive, and so liable to be adopted, whenever the balance of its advantages and disadvantages outweighs those of health. To some people the demands of everyday life are so onerous—either because they lack the energy or ability to cope successfully, or because only when ill do they receive sufficient affection, sympathy or attention from other people—that the sick role is preferable most of the time. To many more, the sick role becomes attractive only in situations in which their responsibilities are abnormally heavy (soldiers in battle, for example), or when they are in trouble (impending exams, debt, the threat of blackmail or prosecution, and so on), or when the prospect of financial gain increases the attractions of illness still further (so-called compensation neurosis). The very high incidence of hysterical phenomena in exhausted combat troops suggests that everyone is potentially capable of developing hysterical symptoms, just as they are capable of developing epilepsy, but vary in their liability to do so. This variation presumably depends partly on constitutional variables like suggestibility and capacity to dissociate, partly on past experience, and partly on the subject's current social situation.

6. Contemporary Understanding of Hysterical Behaviors

The social and behavioral perspective described above is now accepted widely and implies that hysteria should be regarded not as an illness, or even as a group of related illnesses, but as a set of ways of reacting to stressful situations. It also provides a plausible ex-

planation of what is known of the epidemiology of hysterical symptoms and of the choice and outcome of individual symptoms, and has important implications for diagnosis and treatment.

6.1 Implications for the Epidemiology of Hysteria

Few community surveys of the incidence or prevalence of psychiatric syndromes have generated satisfactory measures of hysteria, because the range of phenomena embraced by the term is so vague and variable, and because most hysterical phenomena are short-lived. Consequently, most of the epidemiological 'facts' referred to below are derived, *faute de mieux*, from the opinions and experience of clinicians. Subject to this proviso, the reason the incidence of conversion hysteria is falling both in the industrial and the developing world (in India there is epidemiological evidence of this) is probably that in both settings levels of education and sophistication are rising and life becoming less stressful. The reason hysterical symptoms are seen mainly in adolescents and young adults is probably because the adoption of a dependent role comes most readily to those who have only recently forgone the privileges of childhood and are least experienced at coping with the demands of the adult world. The predominance of conversion symptoms in women almost certainly has a similar explanation. In most cultures women have always been dependent on their husbands or fathers. As a result, they have been forced to utilize the few opportunities provided by that dependent role to get their own way in a male dominated world. Only in the last two or three generations, and only in industrial countries, has this slowly ceased to be so, which is probably why the number of young women presenting to doctors with conversion symptoms has fallen steadily since Charcot's day and why the female predominance has now fallen below 2:1. The frequent coexistence of hysteria and organic disease is also readily explained, for those who are genuinely ill or handicapped—by epilepsy or multiple sclerosis, for example—are the very people likely to have the most difficulty coping with the demands of everyday life, and with the most vivid and recent awareness of the rewards of the sick role. Finally, the predominance of left-sided limb paralyses and anesthetics, first remarked upon by Briquet, is explained, for in a right-handed person this minimizes the handicap without reducing the social impact.

6.2 Implications for Choice of Symptom and Outcome

According to psychoanalytic theory the choice of symptom is determined by its symbolic meaning for

the patient, and doubtless this is sometimes so. Usually, though, it is determined by cultural expectations and the subject's own experience of illness, in themselves or others. The nurse who develops hysterical blindness, for example, had severe conjunctivitis as a child, and the young man who loses the use of his legs had a grandfather who was housebound for years after a stroke.

Just as the development of hysterical symptoms is encouraged strongly by situations in which the balance of the advantages and disadvantages of sickness outweigh those of health, so recovery is encouraged by a reversal of that balance of advantage. This is why the symptom usually fades away if the situation that provoked its appearance resolves itself. If that situation persists, however, or if the inadequacies of the subject are paramount, the advantages and disadvantages of the chosen symptom become important. This is why disabling symptoms, like blindness or inability to stand or walk, have a comparatively good prognosis, whereas those which can be switched on or off as occasion demands, like fits or vomiting, or cause little disability, like tremors, are more intractable.

6.3 Implications for Investigation and Treatment

There are two implications for the investigation of patients with suspected hysterical symptoms, both well known. The first is that medical attention, admission to hospital, and glamorous investigations may easily potentiate the attractions of invalidism. (Indeed, many psychiatrists suspect that the fascinating phenomenon of multiple personality is largely the product of excessive medical interest.) For this reason it is important that the investigations needed to make sure that the patient's symptoms are indeed hysterical are completed as quickly as possible, and not repeated without good reason. The second is that it is immaterial whether or not the patient is aware that he or she is in some sense feigning illness, because the treatment is the same either way. Although the dilemma usually was avoided by assuming unconscious motivation, the traditional medical or psychoanalytic approach should require a distinction between conscious motivation (which is malingering, and so subject to strong disapproval) and unconscious motivation (which is an illness—hysteria—and so worthy of sympathy and treatment) in spite of the fact that it is generally impossible to distinguish the two. Indeed, the patient's degree of awareness often varies from time to time, so that what is initially unconscious becomes conscious, and vice versa.

There are always two components to the management of hysterical symptoms: an attempt to form a psychotherapeutic relationship with the patient, and an assessment of the elements of their social environment which are encouraging or discouraging

invalid behavior. The former is never straightforward, and inexperienced therapists often allow themselves to be manipulated by flattery or coquetry, or end up angrily rejecting the patient because they resent being manipulated, or indeed do both these things in succession. Occasionally it is possible by gentle degrees to lead the patient into a discussion of the emotional predicament from which their symptoms arose, and of the relationship between that predicament and their symptoms. More often there is a sustained denial of emotional difficulties of any kind, and it becomes increasingly clear that the subject is more interested in being a patient than in being cured, and curiously uninterested in the origins of their symptoms.

Arriving at an adequate understanding of the conflicting emotional and social pressures on the patient, both those encouraging and discouraging invalidism, and assessing the possibilities for strengthening the latter, usually involves talking to other key figures in their life as well as the patient. If the patient no longer needs to be ill, they either get better spontaneously, at least in the short term, or do so in response to any treatment that allows them to recover without loss of face. If, on the other hand, there are cogent reasons why invalidism is still more attractive than health, attempts have to be made to modify the attitudes and behavior of those with most influence on the balance of advantage and disadvantage referred to above, and at times this involves devoting more time to a key relative than to the patient. In the past hypnosis was used widely in the treatment of hysteria, and there is no doubt that, thanks to the suggestibility of people with hysterical symptoms, hypnosis is often dramatically successful in the short run. But unless the attractions of invalidism are also tackled, or the underlying predicament has resolved itself, success is usually short-lived.

6.4 The Limitations of Contemporary Understanding

Although this contemporary social and behavioral view of hysterical behaviors explains many otherwise puzzling clinical observations, it provides no

explanation of the mechanisms of conversion and dissociation. The explanatory theories proposed originally by Freud and Janet over 100 years ago have been abandoned, but nothing has yet been offered in their place and the neurophysiology of both phenomena remains a mystery. Indeed, shorn of the original psychoanalytic assumption that unconscious anxiety was being converted into a neurological deficit, the term conversion disorder has lost all meaning. And hysteria itself has been discarded. But as Lewis observed a generation ago, 'a tough old word like hysteria dies very hard.' It may yet come back.
