

F

Face Recognition Models

The human face is a highly meaningful stimulus that provides us with diverse information for adaptive social interaction with people. Our ability to recognize faces is remarkably accurate and long lasting. We are also able to categorize people along a number of visual dimensions including sex, race, and age and can readily interpret facial expression. The challenges associated with encoding and interpreting this information have become evident over the last two decades as psychologists, computer scientists, and cognitive scientists have endeavored to formulate computational models of these processes. The resultant models give insight into the complexity of the problems solved by the human brain in perceiving, representing, and remembering faces. In this article, computational approaches to modeling the perception, categorization, and recognition of human faces will be presented. The properties of the human face as a visual stimulus are described first, followed by definitions of the relevant tasks we perform with faces. The steps involved in modeling these tasks are reviewed next, and representative approaches for modeling individual tasks are discussed. Finally, the article closes with a few open questions in face recognition modeling.

1. The Human Face as a Visual Stimulus

The human face is a complex three-dimensional object defined by the structure of the skull and by the shape, texture, and pigmentation of the overlying skin and tissue. All faces share a basic set of features (e.g., eyes, nose, and mouth, etc.) arranged in a well-defined configuration (eyes above the nose, etc). Individual faces comprise virtually limitless variations on this standard theme. To recognize an individual from a face, we must attend to the information that makes the face unique. To categorize a face we must extract and encode the information that a face shares with an entire category of faces (e.g., male faces), but which distinguishes the category from competing categories (e.g., female faces) (see *Face Recognition: Psychological and Neural Aspects*).

2. The Tasks

'Face recognition' models commonly encompass a range of tasks, including recognition, identification, verification, categorization, and the analysis of facial

expression (see *Facial Expressions*). Face recognition refers to the judgment of whether or not a particular face is 'known.' Face identification refers to the retrieval of information about the 'owner' of the face, such as a name or context of encounter. Face verification refers to a decision about whether a particular face image belongs to a particular individual. Is this person John Doe? Face verification is a common goal of face algorithms developed for security systems.

3. Modeling: A Step by Step Approach

Face recognition models involve: (a) preprocessing algorithms to encode facial 'features' and (b) the application of this information to solve particular tasks.

3.1 Preprocessing Algorithms

3.1.1 Aligning faces. All models that involve the analysis of a three-dimensional object from a two-dimensional image begin with the process of aligning the images into a common coordinate system. This facilitates feature extraction and comparison. Most current face recognition models operate effectively only with frontal images, tolerating only minimal changes in viewpoint. The alignment procedure employed in different models varies both in precision and in the degree of automaticity with which it is accomplished (i.e., by hand or by a computer algorithm). At the most basic level, alignment involves image translation, rotation, and scaling procedures implemented to assure that the eye levels are equivalent and that the centers of the foreheads correspond. More precise alignment is possible with *morphing* techniques that 'warp' individual faces into the 'average face' (Craw and Cameron 1991). To morph a face into another face (e.g., the average face), control points are located on the two faces (usually by hand). These consist of facial landmarks (e.g., corners of the eyes) and supplemental points (e.g., equally spaced points along the eyebrows). Using these points as a guide, each face is warped into the shape of the average face, yielding a correspondence of the control points across all faces. This alignment enables a separable encoding of the two-dimensional shape of the face and the image intensity information. Automated solutions to this correspondence problem have been implemented using all of the pixels or surface samples of

the face rather than just a subset (Beymer and Poggio 1996, Blanz and Vetter 1999). These algorithms employ elaborated optic flow computations and work well on sets of faces for which correspondence is relatively easy to establish, (e.g., faces without hair that are pre-aligned with the translation method). Though difficult to achieve, when successful, complete alignment provides a powerful basis for synthesizing faces with arbitrary shapes and faces composed of intensity composites of other faces (Blanz and Vetter 1999).

A different approach to alignment is represented by the work of Lades et al. (1993) who developed a face recognition algorithm base on the dynamic link architecture. This algorithm combines alignment with identification. The model operates by placing a deformable grid over the target face, sampling the face at the grid vertices. The sampling is done with a series of oriented Gabor wavelets, designed to emulate the orientation specific neurons of visual cortex. The connectors between the vertices are allowed to deform elastically, enabling a resampling of the image until the best fit is obtained. The deformation parameters of this fit serve as the face representation, which is matched to the faces in the database to identify the best match.

3.1.2 Encoding and representing faces. The information in the aligned faces must be quantified in a way that enables recognition, identification, verification, categorization, and the analysis of expression in the model. What are the features of the face? We commonly think of the features of a face as its eyes, nose, and mouth. Descriptions of these features, such as those an eyewitness might provide, are inadequate for communicating enough information about an individual face to distinguish it from competing candidates. Geometrical measures, e.g., distance between eyes, have proved similarly inadequate (Laughery et al. 1981). More recent models have employed relatively raw perceptual codes, including roughly aligned images and three-dimensional surfaces, including pigmentation information. Another code, common since the advent of morphing technology, involves a two-component separable encoding of the two-dimensional face shape and the image intensities. The 'shape' part of this code is defined as the deformation of the control points from the control points in the average face. The 'shape-free' part of the code consists of a 'shape standardized' two-dimensional array of image intensities created by warping an individual face into the shape of the average face.

In current computational and psychological models of face recognition, further analysis of these perceptual codes is carried out using a principal component analysis (PCA) (Sirovich and Kirby 1987; for a review see Valentin et al. 1994). In the US Government's tests of automatic face recognition algorithms between

1994–7, five of the seven algorithms tested used PCA. PCA is a statistical method for describing a set of correlated variables using a smaller number of uncorrelated or orthogonal variables. The uncorrelated variables are called eigenvectors or principal components (PCs), denoted u_i and play the role of 'features' for describing the faces. PCs can be considered features in the sense that any individual face, f , can be expressed as a linear combination of the PCs, $\sum_i w_i u_i$, where the weights are the dot products, $w_i = u_i^T f$, between the faces and PCs. Because PCA is applied usually to images/surfaces, the PCs are also images/surfaces. Thus, individual faces can be synthesized as a linear combination of the PC images/surfaces. In geometrical terms, the PCA creates a multidimensional space in which the PCs define the axes of the space and individual faces are points in the space. The coordinates of a face in the space are the weights that specify the face's value on each PC feature. Note also, that three-layer back propagation networks can extract facial features similarly when they are trained to reconstruct faces through a bottleneck of hidden units. The hidden units of these auto-encoders have been shown to derive rotated versions of the PCs space (Cottrell et al. 1987).

PCA has appeal as a psychological model of face perception and memory for several reasons. First, it is consistent with psychological theories that posit a 'face space' metaphor for human face memory (Valentine 1991). By this metaphor, faces can be thought of as points in a multidimensional space, with the distance between faces a measure of their similarity. At the center of the face space is the average or 'prototype' face. The prototype, a central concept in psychological studies of face recognition, is invoked to explain the role of face typicality in predicting recognition performance. Typical faces, thought to be close to the prototype, are recognized less accurately than distinctive faces. This occurs presumably due to the greater density of faces close to the prototype, causing more confusion among typical faces than among distinctive faces. The prototype is also used as a reference face in creating automatic caricatures. Caricatures can be created by 'moving a face' away from the average in the face space. This results in a more distinctive and recognizable version of the same face.

Second, the features that emerge from PCA are derived from the experience of the model. The role of experience in face recognition performance has been established perhaps most clearly in the phenomenon of the 'other-race effect'—the finding that people recognize faces of their own-race more accurately than faces of other-races. This effect is predicted when the PCA is applied to a majority of faces of one race, and a smaller number of faces of other races. Because PCA derives its features from the statistical structure of the input faces, the resultant features are most appropriate for describing the majority race of faces. Consequently, less distinct encodings of minority race faces

result because these faces are not well characterized by the features extracted primarily from the majority race of faces.

4. Tasks

4.1 Recognition

The quality of the stimulus representation determines the difficulty of the recognition or classification task. With a PCA-based representation, face recognition models can be implemented in a relatively simple way. A face is considered 'known' when an image of the individual was part of the input used to create the PCA space. The most common 'recognition' algorithm implements both recognition and identification. A target face is projected into the space and the distance to all other faces in the space is assessed. The nearest neighbor is chosen as the identity of the target face. Recognition can be implemented by setting a threshold distance, beyond which a target face is declared 'unknown.' An alternative and computationally more expedient algorithm for recognition assesses the representation error incurred by projecting the target face into the space. A threshold tolerance for error is used to determine whether a target face is known or novel.

4.2 Categorization

To categorize faces by sex, race, or age, individual exemplar faces must be assigned to different categories based on visually accessible facial features. Face categorization has been approached with supervised connectionist or neural network classifiers, such as the perceptron (see *Perceptrons*). The models use examples to learn the mapping between face representations and categories. Numerous sex categorization models have been implemented and have been found to perform at or near human performance levels. A similarly structured race classifier has also been implemented, though the imbalance of experience most people have for the faces of different races must be implemented also to model human performance accurately. Finally, little work has been done on categorizing faces by age, though two complementary models of facial aging make use of morphing and caricaturing techniques, respectively. The former simulates aging by morphing individual faces toward the average of older faces (Burt and Perrett 1995). The latter simulates aging by caricaturing the three-dimensional head structure relative to a mean of young adult faces. Surprisingly, this results in an aged face (O'Toole et al. 1997).

4.3 Facial Expression Analysis

Models for categorizing faces by expression have been implemented in ways similar to sex and race classifi-

cation models, but with somewhat less success. These models operate by mapping images of faces on to expression categories using supervised learning techniques. Representations have varied from aligned images, to PCAs of faces preprocessed by the Gabor wavelet filters described previously. Performance has been found to be well above chance, though still short of human performance on a similar task with similar stimuli. Facial expression analysis is currently a very active area of research and more published work on this problem is expected in the near future.

5. Open Questions

Despite the clear successes of face recognition models in the 1980s and 1990s, the problem of recognizing faces from different viewpoints remains an unsolved challenge for models. Though part and parcel of the larger unsolved inverse optics problem of computer vision, the domain of faces may be more accessible due to the specific nature of face recognition as a within category problem. Some promising lines of research have begun and may soon yield new insights into this difficult problem (Edelman 1999).

Facial Expressions

1. Introduction

This article describes one aspect of human communication and behavior—facial expressions. It describes the characteristics of a facial expression and its biological wiring, and then offers a selective history of research on facial expressions that emphasizes the nature vs. nurture debate over the origins of facial expressions of emotions. The article concludes with some current research issues and future directions of facial expression research.

2. Defining Facial Expressions

Of all the forms of human communication, which includes the written and spoken word, body language, and so forth, facial expressions are recognized as among the most salient and influential. Researchers reserve the term ‘facial expression’ for those recurring configurations of facial muscle movements that communicate some thought, emotion, or behavior. This is because not all recurring facial muscle configurations express specific messages. For example, some facial muscle actions that accompany spoken words—such

as raising one’s eyebrows when emphasizing a particular word—may modify those words, but are not messages in and of themselves (e.g., Ekman 1991).

The face can express various thoughts. For example, a person who raises the outer corner of one eyebrow may convey sophisticated skepticism. A person whose eyebrows are pulled up in the middle may convey sympathy for another. A wink can convey that one is kidding. Flashing both eyebrows upward may convey a greeting. Or, lowered eyebrows may convey uncertainty (Eibl-Eibesfeldt 1989). Researchers agree for the most part that these types of facial expressions are learned like language, displayed under conscious control, and their meanings are culturally specific that rely on context for proper interpretation (e.g., Bird-whistell 1970). Thus, the same lowered eyebrow expression that would convey ‘uncertainty’ in North America might convey ‘no’ in Borneo (Darwin 1872/1998).

The face can also express emotions. For example, humans express the emotion of happiness by raising lip corners into what is commonly called a smile. Humans can express sadness by frowning. Besides happiness and sadness, other emotions that seem to have specific facial expressions include anger, disgust, fear, and surprise, and to a lesser extent contempt, embarrassment, interest, pain, and shame (e.g., Ekman 1993, Izard 1991). What makes the facial expression of these aforementioned emotions different from other facial expressions is that there is evidence that these emotions are expressed and interpreted the same across all cultures (e.g., Ekman 1993, Izard 1971). This ‘universal’ production and perception across cultures suggests that those emotions and their specific facial expressions might be determined genetically, rather than socially learned. However, this claim is not without controversy (e.g., Russell 1994).

3. Neuroanatomy of Facial Expression

The idea that facial expressions can be both determined genetically, as in the case of some of the emotions, and learned socially, as in the case of all other facial expressions, is supported by an examination the neuroanatomy of the face. There appears to be two distinct neural pathways that mediate facial expressions, each originating in a different area of the brain; one area for the voluntary, willful facial actions (the cortical motor strip), and the second area for the more involuntary, emotional facial actions (subcortical areas; reviewed by Rinn 1984). This dual origin hypothesis is supported by clinical observations of patients who are paralyzed on one side of their face. When these patients were asked to pose a smile, they could only smile on half their face. Yet when these same patients felt the spontaneous emotion of enjoyment after being told a funny joke, they were able to smile on both sides of their face. Likewise, patients with lesions of the subcortical areas of the brain such

as the basal ganglia have difficulty showing spontaneous, emotional facial expressions; however, these patients are able to move their facial muscles on command. These facial action observations are so reliable that they serve as diagnostic criteria for brain lesions.

4. History of Facial Expression Research

The turbulent history of the systematic study of facial expressions began with the publication of Darwin's book *The Expression of the Emotions in Man and Animals* (1872/1998). In this book, Darwin proposed that humans across all cultures have particular and distinct facial expressions for particular emotions, and that these expressions are produced involuntarily as a result of that emotion. Darwin defined emotions as behavioral and physiological reactions that have helped humans and animals to survive the various life challenges they faced throughout their evolutionary history. For example, the fear reaction assisted humans and animals escape danger, the anger reaction assisted humans and animals to fight rivals, and so forth. Those who possessed these emotional reactions were more likely to live to reproductive age and therefore pass their genes to the next generation (see *Emotions, Evolution of*).

What Darwin argued (and elaborated by others, e.g., Ekman 1991, Izard 1991, Plutchik 1991) is that social animals, such as humans, must communicate these emotions to others in the group because emotions express imminent behavior, such as striking out in anger, fleeing in fear, and so on (see *Emotions, Psychological Structure of*). The facial expression of anger thus becomes the visual signal of this intention to strike. This signal allows others in the group to avoid this person, and thus avoid a potential fight (although others argue that these expressions would deprive an individual of a competitive advantage like the element of surprise prior to an attack, e.g., Fridlund 1994). These facial expressions of emotion were seen as vestiges of an entirely nonverbal human communication system that must have existed in extinct human forms such as Neanderthal, because only modern humans have the throat structures necessary to produce articulate speech. A further clue to this prehistoric human communication comes from the genetically closest living relatives of humans, the chimpanzees, who have a repertoire of facial expressions of emotion that parallel, but are not identical to, human facial expressions of emotion. Thus, current human facial expression of emotion represents more the communication methods of the past genetic history of the species, rather than its present conditions (Brown 1991).

However, much of the empirical work that followed Darwin's book failed to support his notion that there were particular facial expressions for particular emo-

tions. For example, when subjects were startled by firecrackers, embarrassed, or disgusted by having to decapitate a live rat, their most common facial expression shown across all these situations was a smile, even though these subjects were not experiencing positive emotion. Likewise, observations of people outside North America by social scientists cast further doubt; for example, the smile was observed as an expression of uncertainty in Africans but as an expression of sadness in Japanese women (see *Culture and Emotion*). Findings such as these—although there were scattered findings to the contrary—caused scholars to conclude that facial expressions did not provide accurate information as to emotional state (Birdwhistell 1970). Thus, by the early 1960s, social science seemed to conclude that all facial expressions—including facial expressions of emotion—were culturally relative, socially learned, and that there were no universals.

Despite this conclusion, two theorists revived Darwin's ideas about the evolutionary origins of facial expressions of emotion (Plutchik 1991, Tomkins 1962/1963). These researchers took photographs of people posing prototypical emotions such as anger, disgust, fear, happiness, and so on, and found that observers would agree as to which expression represented which emotion. Other researchers found similar results with various European, South American, African, and Asian cultures (e.g., Izard 1971). Proponents of the social learning/cultural relativism perspective counter-argued that the populations upon which this evidence for universality was based were mostly educated, and thus could have learned from various forms of media which expressions represented which emotions (e.g., Birdwhistell 1970). To parry this argument, researchers conducted similar studies with visually isolated peoples whom had limited contact with Westerners, and thus could not have learned these expressions from the media (e.g., the Sadong of Borneo, and Fore in New Guinea). These researchers found for the most part the same pattern of universal expression and recognition of facial expressions of emotion as in the Westernized peoples (e.g., Ekman 1993). Follow up research using a variety of methodological alterations to this basic paradigm found patterns consistent universality throughout the 1970s and 1980s (e.g., Izard 1991). Finally, parallel evidence in favor of universality came from observations of children who were born blind and deaf, and who could not have seen these facial expressions to learn how to express them. These children showed similar expressions of emotion as their sighted counterparts (Eibl-Eibesfeldt 1989).

However, proponents of Darwin's idea were still stuck with the findings that peoples of different cultures sometimes showed different expressions for a given emotion than North Americans. Ekman proposed that the reason this happened was that different cultures learned different rules to regulate their facial

expression of emotion—what he called ‘display rules’ (Ekman 1993). For example, Japanese culture has a display rule that prohibits expression of anger or disgust to higher status people, unlike North American culture. Researchers found that both groups showed facial expressions of disgust when viewing a gruesome film alone. But when in the presence of a high status person, the Japanese group hid their disgust feelings with a smile, whereas the Americans still showed disgust expressions. This concept of display rules seemed to account for why people smiled to such seemingly different events as the death of a loved one, confusion, uncertainty, startle, sexual excitement, disgust, and so on (Ekman 1991). Based on these findings, Ekman (1993) proposed his neurocultural theory of emotions. This theory argued that certain basic human emotions generated particular patterns of physiology and facial expressions, that these facial expressions were universal across all cultures, but that their ultimate expression was modified, exacerbated, suppressed, or masked by social learning processes dependent upon personal, family, or cultural display rules (see *Adulthood: Emotional Development*).

5. Current Facial Expression Research

By the early 1990s, a consensus seemingly emerged in the field of psychology that Darwin was correct after all—that some facial expressions of emotion were universal. This was not a peaceful consensus; social scientists who placed the uniqueness of culture at the forefront of any understanding of emotion were not convinced of universality, based on the observations described earlier (e.g., Russell 1994). Experimental psychology itself issued two challenges to universality in the early 1990s. One challenge suggested that all facial expressions were simply communicative gestures, that is, they are not the result of internal emotional states, but only the result of the social motives of the person within a particular context (the ‘behavioral ecology’ view; Fridlund 1994). The behavioral ecology view found that facial expression, particularly smiling, was related not to felt emotion, but to the presence of others. Proponents of universality counter-argued that not all smiles are the same. They demonstrated that only one type of smile, called the enjoyment smile, is related to the positive emotional experience of enjoyment, as measured through self-report or pattern of brain activity. This enjoyment smile looks different from other smiles in that only enjoyment smiles feature *orbicularis oculi* action (the muscles surrounding the eye that give a ‘crow’s feet’ appearance) along with zygomatic major action (the typical lip corner raising). Failing to note the distinction between enjoyment and other smiles may have been why other researchers found no relationship between smiling and positive emotion (Ekman and Rosenberg 1998).

A second challenge to universality attacked the concepts behind what was meant by universality, as well as the methods used to document universality. These methodological problems—such as biased response forms and preselected facial expressions—when added together may have conspired to bias observers’ judgments, causing them to artificially agree on which facial expression represented which emotion (Russell 1994). Prompted by these criticisms, ensuing experimental research corrected many of the proposed methodological shortcomings, and has so far reconfirmed support for the universality of facial expressions of emotion (Ekman 1994).

Although the issue of the biological vs. social origins of facial expressions of emotion is not fully resolved, what has been impressive is the amount of current research generated by the findings on universality of facial expressions of emotion (Ekman 1993). First, researchers have shown that people who pose and hold these universal facial expressions of emotion begin to experience the particular emotion they are posing—although researchers have debated the exact role of a facial expression in reflecting vs. causing an emotion (e.g., Buck 1988). Regardless, this phenomenon has enabled researchers to document physiologically specific patterns of arousal for specific emotions, and in more than one culture. Second, these universal facial expressions of emotion have been employed in studies of brain activity, leading researchers to discover that there are centers in the human brain that respond specifically to these expressions (e.g., the amygdala responds to fear expressions; Whalen 1998). Third, this work on the universal facial expressions has prompted researchers to examine their origins in children (e.g., Izard and Malatesta 1987). This work has shown that children as young as 12 months of age react differently to their mothers’ expressions of fear versus to happiness; a mother’s fear expression will stop a child’s risky behavior, whereas a mother’s happy expression will not (see *Emotions, Children’s Understanding of*).

These universal expressions of emotion have also shown utility as markers of social and psychological functioning. For example, the presence of enjoyment smiles on the part of a person who has survived the death of their romantic partner predicts successful coping with that traumatic loss. Schizophrenic patients tend to show different, and sometimes fewer or more disorganized facial expressions than normal patients (reviewed by Ekman and Rosenberg 1998). Mothers show different sorts of smiles to their difficult compared to their nondifficult children. The facial expression of disgust or contempt, but not anger, predicts marital divorce (Gottman 1994). Researchers found that these unbidden facial expressions of emotion can occur for very brief flashes, called ‘micro-expressions,’ that under certain circumstances can betray deception (Ekman 1991). Thus, current research on facial expressions has moved away from

documenting the existence of these emotional facial expressions and has moved toward examining the implications of the presence or absence of these facial expressions and their corresponding emotions on human social development, interaction, relationships, and psychopathology.

6. Future Directions of Facial Expression Research

Advances in technology will aid facial expression research by allowing researchers to quickly, validly, and reliably observe facial expressions. This will be helpful to the field because current work on facial expression is extremely time and labor intensive, or suffers from other experimental concerns. For example, visible scoring systems, that require close examination of videotape, can take 60 minutes to analyze one minute of behavior (e.g., Ekman and Rosenberg 1998, Izard and Malatesta 1987). Electromyographic techniques, that use electrodes on the face to measure the faint electrical impulses produced by muscle contractions, suffer from concerns about the salience of electrodes on a person's face affecting the behavior of that person (e.g., Fridlund 1994). In the future, computer based analysis programs will be developed to assess the specific muscle movements associated with facial expressions at a much faster, and more reliable way, than these older methods, without causing awareness on the part of the person being analyzed. This will have the effect of making research on facial expression more accessible to more researchers, which can only help the field progress more quickly than in the past.

There are many questions 'facing' future facial expression research, and space limitations permit only a description of a few. First, researchers will try to clarify the stimuli and processes by which social information elicits an emotion and its expression (the 'appraisal' process; Scherer et al. 2000), as well as the process by which people learn to control their emotional facial expressions. This inquiry might provide researchers with a gateway to understanding better the role of expression in the experience and management of emotions. It will also lead to understanding how perceptions of facial expressions may account for differences in social competence and functioning, or 'emotional intelligence' of adults and children. An offshoot of this work would explore whether professionals and lay people can be trained to improve their accuracy at interpreting emotional expressions, and the implications this has for their relationships. Second, researchers will move toward investigating more interactional research designs that place the facial expression of emotion back into the social context which it is typically embedded, to measure the consequences of such expression in the real world. Third, given that much of the previous work has been with

posed expressions, future work would employ more spontaneous facial expressions. Fourth, with the assistance of technology that allows noninvasive observation of the working brain (e.g., Positron Emission Tomography or functional Magnetic Resonance Imaging), researchers will continue to use facial expressions of emotion to map where in the brain the expressions are perceived as well as where they are generated (e.g., Whalen 1998). Fifth, an examination of these first four future directions will inevitably lead to a better understanding of individual differences in production, control, and recognition of facial expressions, of which there is little work at present. Finally, this work would need to be expanded to cultures other than Europe or North America to assess the relative universality of the process of emotion, its antecedents, attempts to control, and its effect on facial expression (e.g., Ekman 1993).

Research on facial expressions has both paralleled and driven changes in the general assumptions in the field of psychology. The finding that people of all cultures seemed to agree on which facial expressions represented which emotions pushed psychology toward re-examining the biological bases for behavior. But research on facial expressions will continue to be controversial because it exposes the strong feelings of those who believe in the power of social situations to mold all human behavior, expressive or not, and those who believe in the biological origins of some of those behaviors. Thus, debates over facial expressions are really debates about human nature—a debate that has tormented social science from time immemorial. What research on facial expression has done is to help move this debate away from an argument over political beliefs about human nature, and toward an argument over observable data.

Faction: Political

In its broadest construction, a political faction is any part of a political whole. The term has been applied to phenomena ranging from sets of people whose policy preferences tend to align to membership groups that undertake collective action.

In a most famous formulation Madison (Hamilton et al. 1961) defined a faction as a partisan political division of any size, although he qualified the definition to refer to such groups whose aims were 'adverse to the rights of other citizens, or to the permanent and aggregate interests of the community.' Madison viewed factions as the inevitable consequence of political liberty and social diversity, and urged the 'extended sphere' of a federal republic to contain 'the violence of faction.' Madison's treatment of the 'mischief of faction' is often given as evidence for

the American founders' distaste for such commonplace features of representative democracy as political parties and lobbying groups.

For current analytical purposes, Madison's definition of faction is overly broad, in encompassing political parties and interest groups, and overly restrictive in parsing motives. A good, if still broad, definition is that a political faction is a subsidiary part of a political institution, of a political party, a lobbying organization, or a legislature. Unlike political parties within a polity or within a legislature, factions commonly have no legal standing in the institution of which they are part, although they might play an important and enduring role in organizing it. Subgroups that have legal status within institutions are usually designated in other ways, as are the caucuses in the United States Congress and the international political parties in the International Typographical Union. Sometimes analysts identify as factions groupings that are evanescent and happenstantial, for instance a voting coalition on a particular legislative bill or party nomination. Most, however, limit the term to groupings that are enduring and widely recognized. The factional affiliations of Liberal Democrats standing for election to the Japanese Diet, for instance, were routinely reported in the newspapers. The factions within the Democratic Party in West Virginia, while not reported in the press, nevertheless persisted through changes in political administration and party leadership.

In any complex society, a tendency toward faction within political parties and interest groups would seem to be inevitable. Members of parties and groups might be united on the central purposes of the organization but still divided on secondary questions. For decades, the Democratic Party in the United States was loosely united on issues of economic policy but deeply divided into northern and southern factions on issues of race and federal powers, to the point where party allegiances were often superseded by a conservative coalition, an informal alliance of Republicans and southern Democrats, in the US Congress. A common purpose in clericalism still left the Christian Democrats, Italy's confessional party, vulnerable to factions arising from region and class.

Although they are more difficult to observe, similar factional divisions occur in many lobbying groups. At several points in its history, the American Farm Bureau Federation harbored two or three identifiable factions that reflected regional commodity interests. In the 1920s, the Anti-saloon League foundered on a factional division over the question of whether the League ought to emphasize the enforcement of Prohibition in the United States or the promotion of the cause of prohibition abroad.

Considerable evidence exists, however, that some political parties and some interest groups are more prone to faction than others. Political parties in Japan, Italy, and France in the Fourth Republic were

famously factionalized, while parties in Norway, Sweden, and the German Federal Republic were not.

Several conditions appear to promote a tendency toward factional strife in political parties. One factor is electoral domination: factionalization appears more likely in parties that face no real electoral challenge. The Italian Christian Democrats (DC) and the Japanese Liberal Democrats (LDP) are striking both for their enduring factional divisions and their long runs of electoral success—the DC participated in every Italian government from World War II into the 1990s, and the LDP controlled the Japanese Diet continuously from 1955 to 1993. In the American southern states, the electoral threat posed by the mountain Republicans produced a Democratic Party in North Carolina and Tennessee that was appreciably more cohesive than the Democratic Party in states like South Carolina, Florida, Mississippi, and Arkansas, where the Republican Party constituted barely even a nuisance. While counterexamples of dominant parties not rent by faction abound—the Social Democrats in Sweden, the Republicans in Vermont—a considerable body of theory, beginning with the work of Riker (1962) in fact predicts that parties that enjoy more than minimal majorities will be prone to factional disintegration (see *Minimum Winning Coalition, in Politics*).

A second influence on the propensity toward factionalization is the structure of political cleavage within the society (Lipset and Rokkan 1967). In Belgium, class divisions cut across parties that are organized primarily on the basis of language and religion. In Italy, economic and regional differences fueled factions within a confessional party whose *raison d'être* is the establishment of the Roman Catholic Church. In Sweden, by contrast, religious homogeneity and a dominant secularism caused religious disputes to recede well behind the class divisions that are the basis for the political parties (see *Cleavages: Political*).

A third influence on faction is the electoral system. The electoral laws place an upper bound on the number of political parties that can be sustained, a limit equal to one more than the number of candidates to be elected from the constituency (Cox 1997). Accordingly, the electoral laws govern the ease with which factional divisions can progress to outright schism and the formation of new political parties. In the Low Countries of Belgium and the Netherlands, highly proportional representation rules coupled with low election thresholds have produced party systems in which parties and factions morph each into the other with remarkable fluidity. Japan's system of multi-member districts with a single nontransferable vote fostered a half-dozen factions that slated candidates and oversaw the distribution of spoils. The hard limit of a system of single-member districts and plurality voting in the United States forced northern and southern Democrats to stick together, despite

their factional animosities. In the United States, the advent of nominating primaries—creating, effectively, single-member constituencies with plurality voting *within* parties—often limited the number of enduring party factions to two, as in North Dakota on the Republican side or in Louisiana on the Democratic side. In North Dakota, in fact, the more liberal wing of the Republican Party, the Nonpartisan League, split off and joined the Democrats in the 1950s, when two-party competition finally became viable.

The ease or difficulty of schism also contributes to the propensity of interest groups to be ridden with factions. As Hirschman (1970) put it, when exit is costly, members resort to voice. Interest groups that rely primarily on the expressive value of the group's purposes to motivate members seem especially prone to faction (Wilson 1974). Doctrinal purity matters when members are motivated primarily by doctrine. The National Organization for Women, for example, suffered through disputes between a faction that wished to pursue conventional lobbying for the Equal Rights Amendment and a faction that wished to promote social movement activities like direct action. Interest groups that rely upon expressive benefits, moreover, tend also to be prone to schism, because 'purposive' inducements to group involvement are so easy to provide. In the later part of the twentieth century, the 'public interest groups' in the United States multiplied like Protestant denominations, rapidly and schismatically. A dissident faction of the Sierra Club, for example, bolted the organization to form Friends of the Earth; a few years later, a dissident faction of Friends of the Earth created the Environmental Policy Center. In contrast, interest groups that attract members with relatively expensive material benefits like insurance, or interest groups that are able to secure membership through coercion, make it costly for dissidents to exit, channeling what might have been schism into faction. Factional fights within labor unions typically continue intramurally rather than extramurally; the costs a new organization would have to bear to win the right to represent workers in collective bargaining preclude exit. The American Medical Association (AMA) has endured despite tensions between specialists and general practitioners, between doctors in large practices and in small practices, between academics and clinicians, bound by the range of AMA services and by the state powers that have been delegated to the medical societies to regulate medical employment.

The potential for faction in interest groups has long been seen as an important limit on the power and influence of lobbying groups in American politics. Pluralist political scientists identified 'overlapping memberships,' that is, conflicting internal interests, as an important limit on the demands that interest groups might make. During the energy policy debates of the 1970s, for instance, the National Petroleum Refiners Association took no position on crude oil price

regulation, immobilized by conflicts between the small independent refiners and the 'majors.' Likewise, the potential for internal disagreement sidelined many of the large business associations, like the US Chamber of Commerce and the National Association of Manufacturers, in the debates over the extension of the Reciprocal Trade Agreements Act in the 1950s. 'Quasiunanimity,' Bauer et al. (1972) concluded, was a 'premise of action' in lobbying groups. A group that was too extreme in its demands risked disabling internal controversy.

In political parties, factions emerge and recombine to produce change in party systems, as has occurred recently in both Japan and Italy. But factional divisions also hobble parties in the achievement of their policy goals. The most dramatic example is surely the decades-long obstruction of civil rights legislation, a Democratic Party priority since the Truman administration, by the Party's southern Dixiecrat faction. But if factionalism is joined with limited party competition, many argue, the consequences are the more severe. When parties are isolated from the judgment of the electorate, factions dispute not policy direction but the division of the spoils. The extreme factionalization of the Liberal Democratic Party in Japan and the Christian Democratic Party in Italy contributed to the inefficiency, particularism, and corruption of those two dominant parties. But at least the Japanese and Italian factions were relatively enduring and organized. As Key (1950) argued of the Democratic Party in the American southern states, where commonly it was 'every man for himself' in elections, competition between ephemeral factions within a hegemonic party is no substitute for competition between two or more political parties. Political parties develop a stake in their policy reputations that factions commonly do not. Popular control in a democracy requires the clear electoral choices that political parties provide and party factions cannot.

J. M. Hansen

Factionalism

Factionalism refers to dissension between rival subgroups—factions—within a larger social unit. Factionalism can take many forms and has been observed in all parts of the world. It is a basic political process dynamically related to social change.

1. Factions and Organizations

Factionalism, regardless of where it is classified on the conflict continuum, is conflict between factions. Factions are coalitions of persons or subgroups that compete over specific issues within a larger organization or community. The central focus of a faction is the leader who coordinates its activities and recruits its members. Ties between leader and followers are usually personal, although some followers may recruit others on behalf of the leader. The issues about which factions compete are diverse. They generally concern scarce resources the control over which provide power chances, such as economic assets, office and new laws. But they may also involve honor, ideology and behavioral norms. Loosely structured, factions are non-corporate groups that generally dissolve when the particular issues that gave rise to them are resolved. But if the issues remain unresolved, factions may acquire a range of cultural trappings such as property, symbols, ideology and bureaucratic organization. They can then evolve into permanent corporate groups, such as ritual moieties, political parties or other formal associations, for which the term faction is no longer appropriate.

Factionalism takes place within the framework of an established social entity, whether village, school, political party, office, club, kin group, etc., that have clear norms of behaviour. These norms generally include notions of unity, consensus, and cooperation.

The covert maneuvering of factions bent on achieving their own, often self-serving aims, contradict these norms. Hence factionalism has a pejorative connotation. It is seen as subverting organizational rules and goals. Faction members are consequently viewed as disloyal, obstructive persons whose pursuit of narrow, short-term advantage endangers the wider, long-term goals of the organization. The divisiveness inherent in factionalism also hampers the day to day affairs of the organization or community that depend on cooperation. Furthermore, factionalism jeopardizes the good name and image of unity and harmony it seeks to project to the outside world.

2. *The Study of Factionalism*

The study of factions and factionalism developed slowly, shadowing theoretical shifts in the social sciences. Although Linton (1936) long ago suggested that factions presented an interesting but unexplored field, little was done until the 1950s. Political anthropology until then was dominated by the functionalist paradigm elaborated in *African Political Systems* (Fortes and Evans-Pritchard 1940). This viewed politics as maintaining order through consensus, harmony, and balanced opposition. The political groups on which functionalists focused were enduring units, corporate groups. Conflict, if examined, was viewed as reinforcing the social structure. Loosely structured, temporary coalitions such as factions patently did fit into this conception of politics. The theoretical hegemony of Africanist political anthropologists began to be challenged in the 1950s. Not surprisingly, Raymond Firth, given his interest in individual choice, had for some time been uncomfortable with the functionalist paradigm. He and colleagues, who had observed factionalism in Indian communities, were the first to examine factionalism theoretically (Firth 1957). They treated factions as informal counterparts of more formal political formations whose members were recruited according to structurally diverse principles. They also noted that factions tended to become activated on specific occasions and not as regularly recurring features. Other studies of factions and factionalism swiftly followed (Siegel and Beals 1960, Boissevain 1964, 1974, Nicholas 1965, Bailey 1969, Thoden van Velzen 1973, Bujra 1973, Alavi 1973). Most employed a transactionalist perspective, viewing political activity as an arena in which entrepreneurs transact personal relations for political and economic gain. The study of factionalism culminated in the late 1970s with the volume edited by Silverman and Salisbury (1977). This is still considered the definitive work on the subject. Following its publication and the demise of functionalist social science—in which transactionalists played a significant role—academic debate moved on to puzzles related to symbolic, cognitive, and discursive approaches to politics. Factions and factionalism have become accepted concepts

whose characteristics are no longer debated. They are also proving useful to related disciplines (see Brumfiel and Fox 1994).

3. *Issues*

Much of the work on factionalism in the 1960s, although using a transactionalist perspective, continued to be strongly influenced by functionalism. Factionalism was seen as occurring as a result of rapid sociocultural change. Change was seen as coming from the surrounding environment, not as the result of tensions inherent in the community or society in which factionalism arose. Factionalism was generally viewed as occurring because the system's equilibrium was disturbed, and it operated to restore its dynamic equilibrium. Factions were regarded as structurally similar and in balanced opposition. These viewpoints were debated and successfully challenged during the 1970s.

Many of the societies in which factionalism was observed were in fact not subject to rapid social change. But if factionalism was not always a 'result' of change, it seemed always to be 'about' change: changes in power resources, ideology, rules and/or ways of doing things. Factions competed about who was to be boss, about which normative concepts were to be followed, about whose will was to prevail, and thus about which rules were to be followed. Moreover, a closer examination of rival factions revealed that far from being similar or evenly matched, they differed in their access to resources, strategy, tactics, internal organization, ideology, and social composition.

4. *Factions: Structure, Symmetry, and Balance*

Factions often form in opposition to or in defense of some issue or some pre-existing source of power and authority within a community or organization. The distribution of such resources is binary. Some persons have more and some have less. Those with more normally constitute the local establishment that coalesces around a leader or a dominant personage such as a headman, mayor, parish priest, or club president. They and their supporters form the 'establishment' faction. Those who are dissatisfied with the establishment's exercise of its power constitute a category from which a rival or 'opposition' faction can be recruited.

Reports also mention conservative and progressive factions. Because the local establishment normally defends the 'status quo,' from which it derives its superordinate position, it is often labeled as conservative. Since the opposition faction challenges the established defenders of the 'status quo' it is labelled progressive. These labels often do not reflect reality, as when a progressive opposition faction defeats its rival and becomes the dominant, establishment faction.

There is a further reason why opposition factions come to be regarded as progressive. Since they are weaker, they are perhaps more receptive to new resources if and when these become available in the wider society. With these they can challenge their rivals. In rapidly changing societies these may include new government and commercial offices, new laws and new ideologies. Such new resources rapidly tend to change the balance of power. Factionalism thus does not necessarily result from the availability of new resources, as some authors have suggested. Rather, new resources are used in ongoing competitions for power and prestige and tend to escalate the conflict. The use of new resources is not random. A faction will use new resources when it seems likely that they will strengthen its position. It is then labelled progressive, in the sense of favoring change of the 'status quo.'

There is evidence that conflict groups—whether faction, ritual moiety, or political party—differ organizationally. When the opposition consists merely of a category of persons disgruntled with the dominant power elite, they are obviously less organized than the establishment. The internal structure of the local establishment faction, whose members are used to networking to maintain their position, will normally have a more developed exchange circuit than the opposition faction. But if a conflict between the two persists over time, the opposition faction may well become better organized than its rival may. Good organization is a valuable resource and one of the ways a weaker faction can successfully challenge its rival. It is thus more open than the establishment faction to organizational innovation. Because of its superior resources, the dominant faction also tends to be more wasteful. It does not need to husband its resources to the extent that its weaker rival does.

Like most coalitions, factions have core and peripheral members. Core members cluster around the leader and have multiple links to each other. The peripheral members are often linked only to the leader or to a single member of the core group. Where there is a strong core, the faction often acquires some of the characteristics of corporate groups noted previously.

Factions are not necessarily ideologically neutral, as some authors have suggested. The differences between establishment and opposition, like those between conservative and progressive, are not random. They have ideological implications. There is evidence that opposition factions recruit more support than their rivals from weaker or even marginal social categories do. Since opposition leaders usually lack the network ties and material resources that establishment leaders use to recruit followers, they cannot afford to be too particular about the nature of their support. The strength of a faction is usually a function of its size. Just as they often turn to new ideologies and tactics—which because they are new are often viewed as socially unacceptable and subversive—opposition leaders also recruit supporters from among those who are less

influential or are regarded as social or morally inferior. Followers are followers.

Opposition factions consequently often develop or adopt an overarching ideology or symbol to bind their heterogeneous members into a unity. They also often align themselves with political parties that defend the interests of their socially weaker supporters. Most often, opposition factions seek links to parties that embody an emancipatory ideology. Their establishment rivals develop relations with political parties representing vested interests in the wider society. Political parties, on the other hand, also consciously make use of local factions to recruit support at the grass roots level.

5. Conclusion

If factionalism is not necessarily a product of social change, it appears to be always about change. Factions are coalitions that compete for power to determine, and thus to change, what is to be accepted as normal. Rival factions, because they have different access to power chances, are not evenly matched, structurally similar groups. Their asymmetry is fundamental to understanding the nature of factionalism and its dynamic for long term change.

Structural asymmetry and competition for power are also characteristic of class-based conflict groups. This suggests that the line of cleavage between faction, class or party cuts across moral categories and socio-economic classes, not at right angles, as most functionalist and class-oriented analysts postulate, but diagonally. Where the line approaches the vertical, forming conflicting coalitions with a generally even spread across socio-economic classes, it is reasonable to speak of factionalism, in the case of face-to-face groups, and party conflict in the case of conflict on a broader scale. Where the line of cleavage approaches the horizontal, forming conflict groups that are more clearly differentiated according to socio-economic criteria, the term class conflict seems appropriate. But in every case the axis of cleavage must be determined by empirical investigation. It should not be taken for granted.

Factor Analysis and Latent Structure, Confirmatory

Confirmatory factor analysis (CFA) is a quantitative data analysis method that belongs to the family of structural equation modeling (SEM) techniques. CFA allows for the assessment of fit between observed data and an *a priori* conceptualized, theoretically grounded model that specifies the hypothesized causal relations between latent factors and their observed indicator variables. Because population-level equivalence between data and model cannot be proven with sample data, CFA should be viewed as a mainly disconfirmatory technique. That is, CFA facilitates the statistical rejection—or, at best, a very tentative retention—of a specific theory regarding the factor(s) responsible for the observed relations in the data. If, on the other hand, the investigator's intentions are a mostly ungrounded exploration of relations suggested by the data, classical exploratory factor analysis is the more appropriate approach. In this entry, typical steps in a CFA are introduced theoretic-

ally and via example: from model specification and identification, to parameter estimation, data-model fit assessment, and potential model modification. Applied and methodological references are provided for a more in-depth study of CFA and SEM techniques in the social and behavioral sciences.

1. Overview

The term 'factor analysis' describes a host of methods, all of which have the purpose of facilitating a better understanding of the latent, unobserved variables (factors) that underlie a set of directly measurable and observed variables. These factors are often believed to represent constructs, psychological or otherwise, that have a direct bearing on the measured variables; as such they are assumed to motivate (and in turn be inferable from) the pattern of correlations or covariances among those observed variables. In the late 1960s, works by Karl Jöreskog (e.g., 1966, 1967) articulated a method for confirmatory factor analysis (CFA), an application of normal theory maximum likelihood estimation to factor models with specific theoretical latent structures. Such structures could include the *a priori* specification of the number of factors, their orthogonality or obliquity, and which variables had zero and nonzero relations with those factors. This distinguishes CFA from well-known exploratory factor analysis (e.g., Gorsuch 1983, Mulaik 1972) wherein the number and nature of the factors emerge from the observed variables' data through a mathematical algorithm, largely blind to any substantive theory. Most crucial in Jöreskog's CFA work was the provision for a formal statistical χ^2 -test of the fit between the pattern of relations among the measured variables and the theorized factor model, thereby facilitating the disconfirmation or tentative confirmation of an hypothesized factor model. Soon after, Jöreskog and others put forth a more general framework for the integration of measured and latent variables into complex causal networks, serving as the foundation for what is often known as structural equation modeling (SEM). CFA, which may be considered a special case within the more general SEM framework, is the focus of the current entry.

2. CFA Model Specification, Identification, and Parameter Estimation

Suppose an educational researcher wishes to investigate the possibility of a low positive relation between reading and mathematics ability for fifth grade students, which is measured by standardized tests such as the Stanford Achievement Test or the Iowa Test of

Figure 1
Hypothetical CFA model of reading and mathematics ability

Basic Skills. The model shown in Fig. 1 might be hypothesized. Measured variables X_1 through X_6 , shown in rectangles, are believed to be caused by the latent factors ξ_1 and ξ_2 , shown in circles. Here, ξ_1 and ξ_2 represent true latent (unobserved) reading and mathematics ability, respectively, with X_1 through X_3 being standardized reading test measures (Read1 through Read3) and X_4 through X_6 being standardized mathematics test measures (Math1 through Math3). Table 1 includes a simulated variance–covariance matrix for the observed variables X_1 through X_6 based on test data from $n = 1,200$ fifth graders. Our example's focus is the noncausal covariance between reading and mathematics ability, ϕ_{21} . In general, a

covariance is indicated by a two-headed arrow connecting the two constructs, and—because a variance is a covariance of a variable (observed or latent) with itself—it, too, is depicted by a two-headed arrow from the variable to itself.

A factor's hypothesized causal impact on its measured indicator variables is symbolized by an arrow from the factor to the variable with magnitude λ_{ij} , where i denotes the observed variable and j denotes the latent factor. Note that such a model explicitly posits the factors as causing the variables, rather than the variables causing the factors; the latter type of model, in which the factor is characterized as emergent rather than latent, is much less common and beyond the scope of this entry. In many cases, there is no arrow from a factor to a variable, such as from ξ_1 to X_4 ; this implies that Reading Ability has no theoretical causal bearing on the Math1 variable. Finally, to the extent that the factors do not perfectly explain each variable, a residual term, δ , is included as an influential contributor (with its variance shown by a two-headed arrow from δ to itself). This residual might consist of variable-specific measurement error as well as other influences. Thus, each observed variable is the sum of two parts, that attributable to the common factor(s) and that residual part specific to the variable.

The causal relations of the hypothesized model shown in Fig. 1 may be expressed as a system of six regression-like structural equations:

$$X_1 = \lambda_{11}\xi_1 + 0\xi_2 + \delta_1 \quad (1)$$

$$X_2 = \lambda_{21}\xi_1 + 0\xi_2 + \delta_2 \quad (2)$$

$$X_3 = \lambda_{31}\xi_1 + 0\xi_2 + \delta_3 \quad (3)$$

$$X_4 = 0\xi_1 + \lambda_{42}\xi_2 + \delta_4 \quad (4)$$

$$X_5 = 0\xi_1 + \lambda_{52}\xi_2 + \delta_5 \quad (5)$$

$$X_6 = 0\xi_1 + \lambda_{62}\xi_2 + \delta_6 \quad (6)$$

Table 1
Simulated data and selected parameter estimates for the reading and mathematics ability model in Fig. 1

ξ_2	0	0	0	0.75*	0.60*	0.85*
R^2	0.49	0.53	0.62	0.56	0.35	0.73
Data-model fit indices						
$\chi^2 = 16.98$, $df = 8$, $p = 0.030$				CFI = 0.996	SRMR = 0.016	RMSEA = 0.031

Note. * $p < 0.05$

Equivalently, these equations can be represented in matrix form, as in

$$\begin{bmatrix} X_1 \\ X_2 \\ X_3 \\ X_4 \\ X_5 \\ X_6 \end{bmatrix} = \begin{bmatrix} \lambda_{11} & 0 \\ \lambda_{21} & 0 \\ \lambda_{31} & 0 \\ 0 & \lambda_{42} \\ 0 & \lambda_{52} \\ 0 & \lambda_{62} \end{bmatrix} \begin{bmatrix} \xi_1 \\ \xi_2 \end{bmatrix} + \begin{bmatrix} \delta_1 \\ \delta_2 \\ \delta_3 \\ \delta_4 \\ \delta_5 \\ \delta_6 \end{bmatrix} \quad (7)$$

That is,

$$\mathbf{X} = \mathbf{\Lambda}\boldsymbol{\xi} + \boldsymbol{\delta} \quad (8)$$

where $\mathbf{X}$ is a column vector of observed variables, $\mathbf{\Lambda}$ is a matrix of factor loadings, $\boldsymbol{\xi}$ is a vector of latent constructs, and $\boldsymbol{\delta}$ is a column vector of residuals.

The implication of Fig. 1 and the accompanying structural equations is that the population variance-covariance matrix for the X variables, $\boldsymbol{\Sigma}$, is a function of (1) the λ_{ij} loadings in matrix $\mathbf{\Lambda}$, of (2) the variances and covariance between the latent factors in a matrix $\boldsymbol{\Phi}$, and of (3) the variances and covariances among the residuals in a matrix $\boldsymbol{\Theta}_\delta$ (note that in Fig. 1 all residual covariances are zero as implied by the absence of two-headed arrows between the δ terms). More specifically, if all model parameters (loadings, variances, and covariances) are contained in a single column vector $\boldsymbol{\theta}$, the population variance-covariance matrix of the observed variables that is implied by the model and its parameters, $\boldsymbol{\Sigma}(\boldsymbol{\theta})$, is given by

$$\boldsymbol{\Sigma}(\boldsymbol{\theta}) = \mathbf{\Lambda}\boldsymbol{\Phi}\mathbf{\Lambda}' + \boldsymbol{\Theta}_\delta \quad (9)$$

A vector of parameter estimates $\hat{\boldsymbol{\theta}}$ can be derived so that the model-implied variance-covariance matrix $\boldsymbol{\Sigma}(\hat{\boldsymbol{\theta}})$ is as similar as possible to the observed variance-covariance matrix $\mathbf{S}$ provided that model identification has first been ensured. To this end, each parameter in a model must be expressible as a function of the variances and covariances of the observed variables. When a system of such relations can be uniquely solved for the unknown parameters, the model is just-identified. When multiple such expressions exist for one or more parameters, the model is over-identified; in this case, a best-fit (although not unique) estimate for each parameter is derived. If, however, at least one parameter cannot be expressed as a function of the observed variables' variances and covariances, the model is under-identified and some or all parameters cannot be estimated on the basis of the data alone. This under-identification might be the result of the researcher attempting to impose a model that is too complex relative to the number of variances and covariances of the observed variables. Additionally, empirical under-identification might arise when unfortunate estimates for select parameters (e.g., values of zero for factor covariances) render subsets of

model parameters inestimable. Fortunately, in most CFA applications, it suffices to ensure that (1) the number of parameters to be estimated, p , does not exceed the number of variances and covariances of the observed variables, c , and (2) each latent factor has an assigned unit of measurement. To accomplish the latter condition for the model in Fig. 1, we set the factor variances to unity (alternatively, for each of the two factors we could have specified one of the factor loadings to equal unity, thereby setting each factor's units equal to that observed variable). The model in Fig. 1 is over-identified with $c = 6(7)/2 = 21$ non-redundant observed (co)variances and $p = 13$ parameters to be estimated: one covariance between the two latent factors, six variances of the error terms associated with the observed variables, and six factor loadings.

Given that a model is just- or (preferably) over-identified, sample estimates can be obtained through a variety of estimation methods. These include maximum likelihood and generalized least squares, both of which assume multivariate normality and are asymptotically equivalent, as well as asymptotically distribution-free estimation methods that generally require a substantially larger sample size. These methods iteratively minimize a function of the discrepancy between $\mathbf{S}$ and $\boldsymbol{\Sigma}(\boldsymbol{\theta})$, where $\mathbf{S}$ is the unrestricted variance-covariance matrix of the observed X variables and $\boldsymbol{\Sigma}(\boldsymbol{\theta})$ is the model-implied variance-covariance matrix reproduced from the iteratively changing parameter estimates. The standardized maximum likelihood estimates of key parameters in the reading and mathematics ability model are presented in Table 1. Before focusing on our example's main parameter estimate (ϕ_{21}), however, we should consider whether or not there is any evidence suggesting data-model misfit, any statistical—and theoretically justifiable—rationale for modifying the hypothesized model, or any indication of factor unreliability.

3. Data-Model Fit Assessment and Model Modification

One of the advantages of CFA is the ability it offers to assess the quality of the fit of the data to the model. A multitude of measures exists that assist the researcher in deciding whether to reject or tentatively retain an *a priori* specified over-identified model (see Marsh et al. 1988, Tanaka 1993). In general, measures to assess the fit between the variances and covariances observed in the data and those implied by the model can be classified into three categories: absolute, parsimonious, and incremental. Absolute fit indices are those that improve as the discrepancy between $\mathbf{S}$ and $\boldsymbol{\Sigma}(\hat{\boldsymbol{\theta}})$ decreases, that is, as the number of parameters, p , approaches the number of nonredundant observed variances and covariances, c . Examples of such measures include the model χ^2 statistic that tests the

stringent null hypothesis $H_0: \Sigma = \Sigma(\theta)$, the standardized root mean-square residual (SRMR) that roughly assesses the average standardized discrepancy between observed and model-implied variances and covariances, and the goodness-of-fit index (Jöreskog and Sörbom 1996) designed to evaluate the amount of observed variance-covariance information that can be accounted for by the model.

Parsimonious fit indices take into account not just the overall absolute fit, but also the degree of model complexity required to achieve that fit. Indices such as the adjusted goodness-of-fit index (Jöreskog and Sörbom 1996), the parsimonious goodness-of-fit index (Mulaik et al. 1989), and the root mean-square error of approximation (RMSEA, Steiger and Lind 1980) indicate greatest data-model fit when data have reasonable absolute fit and models are relatively simple. Finally, incremental fit indices such as the normed fit index (Bentler and Bonett 1980) and the comparative fit index (CFI, Bentler 1990) gauge the data-model fit of an hypothesized model relative to that of a more restrictive baseline model with fewer parameters.

The three types of fit indices together help the researcher to converge upon a decision regarding the CFA model's acceptability. In our example, the significant $\chi^2 = 16.98$ ($df = c - p = 8$, $p < 0.05$) indicates that the observed variance-covariance matrix would occur rarely if our model correctly depicted the true population relations. This absolute fit statistic, however, is notoriously sensitive to very small and theoretically trivial model mis-specifications (e.g., slight amounts of error covariance) under large sample conditions. As such, other fit indices are generally preferred for model evaluation. According to Hu and Bentler (1999), CFI values of 0.96 or greater together with SRMR values less than 0.09 (or with RMSEA values less than 0.06) point to acceptable data-model fit. The indices in Table 1 suggest no appreciable data-model inconsistency given the Hu and Bentler cut-off criteria.

After the data-model fit has been assessed, a decision about that model's worth must be reached. Acceptable fit indices usually lead to the conclusion that no present evidence exists warranting a rejection of the model or the theory underlying it. This is not to say that the model and theory have been confirmed, much less proven as correct; rather, the current factor model remains as one of possibly many that satisfactorily explain the relations among the observed variables. On the other hand, when fit indices indicate a potential data-model misfit, one might be reluctant to dismiss the model entirely. Instead, attempts are often made to modify the model *post hoc* so that acceptable fit indices can be obtained. Such modifications could include the addition of cross-loadings, allowing a given variable to load on multiple factors, or of error covariances in which variables' residuals are allowed to covary in order to reflect some

potential variable relation above and beyond that motivated by the factor structure itself.

Most CFA software packages will facilitate such model 'improvement' by providing modification indices (Lagrange multiplier tests) indicating what changes in the model could reap the greatest increase in absolute fit, that is, decrease in the model χ^2 statistic. While such indices constitute a potentially useful tool for remedying incorrectly specified models, it seems imperative to warn against an atheoretical hunt for the model with the best fit. Many alternative models exist that can explain the observed data equally well; hence, attempted modifications must be based on a sound understanding of the specific theory underlying the model. Furthermore, when modifications and re-analyses of the data are based solely on data-model misfit information, subsequent fit results might be due largely to chance rather than true improvements to the model. Modified structures therefore should be cross-validated with an independent sample whenever possible. If a new sample is not available but the initial sample is large enough, one can randomly split the sample into calibration and validation subsamples and compute Cudeck and Browne's (1983) cross-validation index. When the initial sample is too small, Browne and Cudeck (1989) also offered a single sample alternative, an estimate of the expected value of the cross-validation index. From the analysis of the model in Fig. 1, none of the modification indices suggested changes to the model that would result in a significant improvement in data-model fit (i.e., a significant decrease in the model χ^2 statistic); thus, we did not report them in Table 1.

Before drawing conclusions regarding the relation between reading and mathematics ability, the question of the 'quality' (i.e., reliability) of the factors should be addressed. Traditionally, this has been accomplished (a) by focusing on the reliability of scores from individual indicator variables, R^2 (i.e., the proportion of variability in an observed variable that can be accounted for by the underlying factor) or (b) by assessing the reliability of scores from linear composites of the indicator variables (e.g., Miller 1995, Raykov 1997). More recently, Hancock and Mueller (2001) suggested a measure (coefficient H) computed from the standardized factor loadings that can be used to assess the reliability of a latent construct itself as reflected by scores from multiple observed variables. One of coefficient H 's advantages over traditional construct reliability measures is that it is never less than the best indicator variable's reliability (R^2), thereby drawing information from all indicators in a manner commensurate with their own ability to reflect the construct. For the current example, $H = 0.79$ and $H = 0.82$ for the reading and mathematics ability constructs, respectively, while the R^2 values for the respective factor's indicator variables in Table 1 range between 0.49–0.62 and 0.35–0.73. Thus, the two factors exhibit reasonable and satisfactory levels of

construct reliability since about 80 percent of their variance is explainable by their respective indicators. Table 1 also lists the standardized factor loadings, that is, the estimates of the λ_{ij} parameters in the Λ matrix that indicate the strength and direction of the *a priori* specified causal influences of the latent factors on the observed variables. All factor loadings are positive and significantly different from zero.

Finally, our primary research question can be addressed. The CFA estimate of the correlation between the two latent constructs reading and mathematics ability is 0.51 and significantly different from zero. This estimate indicates a low to moderate positive association between the two constructs of interest, as hypothesized.

4. Conclusion

Confirmatory factor analysis has become established as an important analysis tool for many areas of the social and behavioral sciences. It belongs to the family of structural equation modeling techniques that allow for the investigation of causal relations among latent and observed variables in *a priori* specified, theory-derived models. The main advantage of CFA lies in its ability to aid researchers in bridging the often-observed gap between theory and observation. For example, an instrument might be developed by creating multiple items for each of several specific theoretical constructs (Fig. 1). Instead of analyzing data with an exploratory factor analysis (where each item is free to load on each factor) and potentially facing a solution inconsistent with initial theory, a CFA can give the investigator valuable information regarding the fit of the data to the specific, theory-derived measurement model (where items load only on the factors they were designed to measure), and point to the potential weakness of specific items. CFA is best understood as a process, from model conceptualization, identification and parameter estimation, to data-model fit assessment and potential model modification. As opposed to exploratory methods, CFA's strength lies in its disconfirmatory nature: models or theories can be rejected, but results might also point toward potential modifications to be investigated in subsequent analyses.

Numerous CFA examples exist in the various disciplines covered in this encyclopedia. The reader might consult (a) in education: O'Grady (1989), Stevens (1995); (b) in psychology: Asmundson et al. (2000), Byrne (1993); (c) in sociology: Alsup and Gillespie (1997), Mulvey et al. (1992); and (d) in health: Galassi et al. (1992), Windle and Dumenci (1999). Some of the more widely used and state-of-the-art SEM software packages for conducting CFA are LISREL (Jöreskog & Sörbom 1996), EQS (Bentler 1997), and AMOS (Arbuckle 1999). Popular textbooks on CFA and more general SEM include Bollen (1989), Hayduk (1987), Loehlin (1998), and Mueller

(1996). Social science journals that publish many CFA and SEM applications and methodological developments include: *Educational and Psychological Measurement*, *Multivariate Behavioral Research*, *Journal of Experimental Education*, *Psychological Methods*, *Sociological Methodology*, *Sociological Methods and Research*, and *Structural Equation Modeling: A Multidisciplinary Journal*.

Factor Analysis and Latent Structure: IRT and Rasch Models

In education and the social sciences, we often ask subjects to respond to a set of items (questions, statements, or tasks) on survey forms, self-report inventories, and mental tests, that are coded as discrete—often dichotomous—variables. In many settings it is natural to think, in analogy with factor analysis (see *Factor Analysis and Latent Structure: Overview; Factor Analysis and Latent Structure, Confirmatory*), that there is one or more continuous latent variables for each subject—such as political agency, extrovertedness, or ability in some area of mathe-

matics—that can be measured or estimated using the positive and negative responses to these items. Item Response Theory (IRT), and specializations such as the Rasch Model, refer to a set of statistical modeling and estimation tools for making inferences about one or more continuous latent variables from this kind of multivariate discrete data.

1. Introduction: the Rasch Model

As an example, consider a test of transitive reasoning in school children (e.g., Sijtsma and Verweij 1999). An item may consist of three rods, A, B, and C, of differing lengths. The child is given evidence that $\text{Length}(A) < \text{Length}(B)$, and $\text{Length}(B) < \text{Length}(C)$, and is asked to deduce a relationship between $\text{Length}(A)$ and $\text{Length}(C)$; his or her answer is scored 1 if it is correct and 0 if it is incorrect. Let us say that J such items, involving different types of objects and attributes (balls of varying weight, disks of varying area, etc.) and different numbers of objects, make up a test given to N school children. If the scored responses were continuous we might build a two-way additive ANOVA model in which child i 's response to item j , X_{ij} , is the sum (or difference) of the child's achieved transitive reasoning level, and the item's innate difficulty, as determined by the attribute on which objects are compared and the number of objects being compared.

However, since the responses are dichotomous $X_{ij} = 0$ or 1, we need a model specifying the probability that $X_{ij} = 1$, in terms of the child's transitive reasoning ability and the item's difficulty. One of the earliest such models, developed by the Danish mathematician Georg Rasch (Rasch 1960), specifies

$$P_j(\theta_i) \equiv P[X_{ij} = 1 | \theta_i, \beta_j] = \frac{\exp(\theta_i - \beta_j)}{1 + \exp(\theta_i - \beta_j)},$$

$$i = 1, \dots, N, j = 1, \dots, J \quad (1)$$

where θ_i represents child i 's transitive reasoning level, and β_j represents the difficulty of the item: as the latent variable θ_i increases, the probability of getting the item right increases, and as the difficulty parameter β_j increases, the probability of getting the item right decreases. The Rasch model, together with similar models using different forms for $P_j(\theta_i)$ developed by Jane Loevinger (Loevinger 1948) and Frederic M Lord (Lord 1952), became the core of what is now item response theory.

On the logit scale, the Rasch model has exactly the two-way additive ANOVA structure we sought:

$$\text{logit } P_j(\theta_i) = \ln \frac{P_j(\theta_i)}{1 - P_j(\theta_i)} = \theta_i - \beta_j.$$

We further assume local independence among item responses, i.e., all X_{ij} are conditionally independent,

given θ s and β s. Letting x_{ij} denote the observed values of X_{ij} , we may write the likelihood for the Rasch model as

$$P[X_{ij} = x_{ij}, i = 1, \dots, N, j = 1, \dots, J | \theta_1, \dots, \theta_N; \beta_1, \dots, \beta_J] = \prod_{i=1}^N \prod_{j=1}^J P_j(\theta_i)^{x_{ij}} [1 - P_j(\theta_i)]^{1-x_{ij}}. \quad (2)$$

An up-to date account of the Rasch model and its various extensions is given by Fischer and Molenaar (1995), to whom we also refer for historical notes and references.

The Rasch model in Eqn. 1 has the interesting invariance property that the odds ratio comparing two items j and k is

$$\frac{P_j(\theta_i)}{1 - P_j(\theta_i)} \cdot \frac{1 - P_k(\theta_i)}{P_k(\theta_i)} = \exp \beta_k - \beta_j$$

independent of θ_i . Hence in our example, the ‘difficulty’ of two items involving different transitive reasoning settings can be compared, in principle, using any convenient sample of subjects regardless of their transitive reasoning level (in practice, subjects still contribute at least ‘small sample bias’ to the estimated β s). Similarly, the odds ratio comparing two subjects is independent of the item difficulty parameters. These two invariance properties are instances of ‘specific objectivity,’ a property Rasch considered important in defining a measurement model and from which Eqn. 1 can be derived (see Fischer and Molenaar 1995). The Rasch model is also closely related to the Bradley–Terry model of paired comparisons. Consider two items j and k for which $\beta_j < \beta_k$. For any subject i who got only one item right, it follows from Eqn. 1 that the probability that the easier item was correct is

$$P[X_{ij} = 1 | X_{ij} + X_{ik} = 1, \theta_i, \beta_j, \beta_k] = \frac{\exp(\beta_k - \beta_j)}{1 + \exp(\beta_k - \beta_j)} \quad (3)$$

independent of θ_i ; this is exactly the Bradley–Terry model with parameters $\phi_j = -\beta_j$. The lack of dependence on θ_i on the right can also be used to construct empirical tests of the Rasch model, since the probability in Eqn. 3 can be estimated without assuming the Rasch model and should be the same in any subpopulation of subjects in which the Rasch model applies.

2. Estimation in the Rasch Model

Two estimation methods are traditionally associated with the Rasch model, joint maximum likelihood (JML) and conditional maximum likelihood (CML).

One can maximize Eqn. 2 jointly in the θ s and β s, by numerically solving the ‘normal equations’ obtained by setting all partial derivatives of the logarithm of Eqn. 2 equal to zero; the maximizing values $\hat{\theta}_i$ and $\hat{\beta}_j$ are called joint maximum likelihood estimators (JMLEs). However, the JMLEs turn out to be *inconsistent*, or asymptotically biased: suppose we are primarily interested in estimating β_j s; it need not be the case that each $\hat{\beta}_j$ converges to β_j as we increase the subject sample size N , keeping the number of items J fixed. Indeed, as N increases, more θ_i s are also added to the model: intuitively, some information must be expended on estimating them, and there is not enough information left over to improve the estimates of the β_j s. One solution to this problem is to exploit the fact that in the Rasch model, a sufficient statistic for each θ_i is subject i ’s total number correct score, $X_{i+} = \sum_{j=1}^J X_{ij}$. If the likelihood in Eqn. 2 is divided by the joint likelihood for the observed x_{i+} s, the resulting conditional likelihood contains only the β_j parameters, and the conditional maximum likelihood estimators (CMLEs) $\hat{\beta}_j$ obtained by maximizing this new likelihood are consistent (asymptotically unbiased) as N grows and J stays fixed. For this reason, CML estimates are usually preferred over JML estimates. Additional details are provided by Andersen (1980), whose earlier work demonstrated the inconsistency problem with JML, and established consistency of CML for the Rasch model.

Another approach to solving the inconsistency problem with JML is to assume the θ_i are independent random effects following a common (discrete or continuous) distribution $f(\theta | \lambda)$. Integrating over θ_i for each subject yields the marginal likelihood

$$\prod_{i=1}^N \int \prod_{j=1}^J P_j(\theta_i)^{x_{ij}} [1 - P_j(\theta_i)]^{1-x_{ij}} f(\theta_i | \lambda) d\theta_i \quad (4)$$

and maximizing this with respect to β_j s and λ (using an E-M algorithm, for example) yields what are called maximum marginal likelihood (MML) estimates $\hat{\beta}_j$ and $\hat{\lambda}$. These MML estimates are also consistent (asymptotically unbiased). The method based on Eqn. 4 can be interpreted as an empirical Bayes method; it also links the Rasch model directly with other latent variable approaches such as factor analysis, where the latent variable θ_i is treated as an unobserved random variable, or equivalently as completely missing data (see *Factor Analysis and Latent Structure: Overview*).

Finally, it can be shown that under Eqn. 4, the marginal distribution of the data follows a log-linear model for the 2^J table of the form

$$\ln p(x_{i1}, \dots, x_{iJ}) = \alpha - \sum_{j=1}^J \beta_j x_{ij} + \sum_{k=0}^J \gamma_k \chi(x_{i+} = k)$$

where $\chi(S) = 1$ if statement S is true, and 0 otherwise. This is the log-linear model of quasisymmetry; the connection between the Rasch model and the quasi-

symmetry model has been independently discovered innumerable times in the literature. Lindsay et al. (1991) give a reasonably complete account of the connection with quasisymmetry and consequences for the identifiability of the distribution $f(\theta|\lambda)$ in a semiparametric formulation of Eqn. 4.

3. Parametric IRT

Other parametric IRT models have been developed for situations in which the Rasch model does not fit, while retaining the ideas of dichotomous ($X_{ij} \in \{0, 1\}$) or at least polytomous ($X_{ij} \in \{0, 1, \dots, K-1\}$) item scores, a unidimensional (or low-dimensional) latent variable θ_i characterizing subjects, a low-dimensional parameter β_j characterizing items, and local (conditional) independence of all item responses X_{ij} given all parameters. An accessible review of developments in parametric IRT in the 1960s, 1970s and 1980s is given by Hambleton et al. (1991).

A simple generalization of the Rasch model that is often useful for dichotomously-scored items,

$$P_j(\theta_i) = \frac{\exp[\alpha_j(\theta_i - \beta_j)]}{1 + \exp[\alpha_j(\theta_i - \beta_j)]} \quad (5)$$

is called the two-parameter logistic (2PL) model. In the 2PL model, the slope parameters α_{jk} are called 'discrimination parameters,' and they control the Fisher information for estimating the θ s. Again, the location parameters β_j play the role of 'difficulty parameters'; they also determine the value of θ maximizing the Fisher information. The three-parameter logistic (3PL) model adds a nonzero lower asymptote to Eqn. (3), to model random or exchangeable response behavior by low- θ subjects. Further generalizations, discussed in the next several paragraphs, are treated at length by Fischer and Molenaar (1995) and van der Linden and Hambleton (1997).

Additional covariates and other structures can be incorporated into these models as regression terms. For example, in the linear logistic test model (LLTM), the difficulty parameters β_j in the Rasch model are rewritten as linear combinations of K basic parameters η_k with weights q_{jk} , and

$$\text{logit } P_j(\theta_i) = \theta_i - \sum_{k=1}^K q_{jk} \eta_k.$$

The matrix $Q = [q_{jk}]$ is usually obtained as a regression model matrix from *a priori* analysis of the items; for example, in the transitive reasoning example described in Sect. 1, the q_{jk} might indicate what kind and how many objects were used for each item. By contrast, multidimensional compensatory IRT models decompose the unidimensional θ_i parameter into an item-

dependent linear combination of underlying traits, e.g.,

$$\text{logit } P_j(\theta_i) = \sum_{a=1}^D \alpha_{ja} \theta_{ia} - \beta_j.$$

For example, mathematics word problems may involve both a math component, θ_{i1} , and a verbal component θ_{i2} in different proportions in different problems, as determined by the discrimination parameters α_{ja} . In some settings, the α_{ja} may be fixed *a priori*, like the q_{jk} in the LLTM model, and in other settings they may be estimated analogously to factor loadings in Factor Analysis. Multiplicative or conjunctive IRT models combine unidimensional models for components of response in a product $P_j(\theta_i) = \prod_a^D P_{ja}(\theta_{ia})$ where $P_{ja}(\theta_{ia})$ are parametric unidimensional dichotomous response functions. The usual interpretation is that the $P_{ja}(\theta_{ia})$ are probabilities of correctly performing component skills or subtasks, which must be done in conjunction in order to generate a correct response to the item itself; this model is sometimes referred to as the multicomponent latent trait model (MLTM).

Probit versions of all the above models, in which the logit function is replaced with $\Phi^{-1}(p)$, the inverse standard normal distribution function, are also in use. Aside from a trivial rescaling of the parameters, there is little difference in practice between the probit and logit models; the choice depends mostly on computational expedience.

IRT model can also be extended to handle polytomous or multcategory items, $X_{ij} \in \{0, 1, 2, \dots, K-1\}$, in much the same way that logistic regression models are extended polytomous data: in the 'graded response model' (GRM) the cumulative logit, $\text{logit } P[X_{ij} > c | \theta_i, \beta_j]$, is linear in θ_i ; in the 'sequential model' (SM) the continuation-ratio logit, $\text{logit } P[X_{ij} > c | X_{ij} > c-1, \theta_i, \beta_j]$, is linear in θ_i ; and in the 'partial credit model' (PCM) the adjacent-category logit, $\text{logit } P[X_{ij} = c+1 | X_{ij} \in \{c, c+1\}, \theta_i, \beta_j]$, is linear in θ_i . Again, probit reformulations of these models are straightforward. When the discrimination parameters are all non-negative, the cumulative response curves in any of these models is nondecreasing (Hemker et al. 1997), a condition referred to as 'monotonicity.' By contrast, IRT formulations of direct-response probabilistic unfolding models, also known as proximity models or parallelogram models, have unimodal response curves that peak near the location β_j of the item.

As was the case for the Rasch model discussed in Sect. 2, JML estimates for IRT models are relatively easy to set up but generally inconsistent (asymptotically biased); CML methods can be used when simple sufficient statistics are available. MML methods based on applying an E-M algorithm to Eqn. 4, with $P_j(\theta_i)$ redefined according to one of the above

First level: $X_{ij} \sim P(\theta_i; \beta_j)^{X_{ij}} [1 - P(\theta_i; \beta_j)]^{(1-X_{ij})}$,

$$i = 1, \dots, N; j = 1, \dots, J$$

Second level: $\theta_i \sim f_i(\theta|\lambda_f)$, each i

$$\beta_j \sim g_j(\beta|\lambda_g), \text{ each } j$$

Third level: $\lambda_f \sim \phi_f(\lambda_f)$

$$\lambda_g \sim \phi_g(\lambda_g)$$

Figure 1

Two-way hierarchical structure for N individuals and J dichotomous response variables. Factors in the first level are independent and are multiplied together to form a likelihood for the response data matrix $[X_{ij}]$. Factors in the second and third levels are also independent, and covariates and special structure for the latent variables and item parameters may be introduced in these levels

parametric forms, are most common, however. The recent development of Markov Chain Monte Carlo (MCMC) integration methods for Bayesian statistics (see *Markov Chain Monte Carlo Methods*) provides an alternative to these methods. Patz and Junker (1999) sketch a general MCMC methodology for parametric IRT models, and Johnson and Albert (1999) survey a range of related applications from a working Bayesian statistician's perspective.

The IRT toolbox has been pushed forward in recent years by the needs of both large-scale educational assessment surveys (e.g., Johnson et al. 1994) and cognitively based assessment models (e.g., Nichols et al. 1995). To accommodate finer structure in the latent space, as well as to incorporate subject and item covariates in the model, it is useful to reformulate the IRT framework as a two-way hierarchical Bayes structure for N individuals and J response variables, as in Fig. 1. In addition to the item response functions $P_j(\theta_i) = P(\theta_i; \beta_j)$ in Fig. 1, f_i and g_j are prior distributions on the latent variables θ and item parameters β respectively (both of which may be multidimensional), and λ_f and λ_g represent sets of hyperparameters needed to specify these prior distributions. The model in Fig. 1 is expressed for dichotomous items but can be generalized easily to polytomous items or combinations of item types, incomplete data, and so forth (e.g., Patz and Junker 1999). The MML formulation dis-

cussed in the previous paragraph is obtained by taking $f_i(\theta)$ to be a single population distribution not dependent on j for the latent trait, and taking g_j to be flat priors not depending on j for the item parameters.

4. Nonparametric IRT

Nonparametric IRT refers to several related methodologies for working with item response data without fully committing to any particular well-known family of parametric item response theory models. Some topics in nonparametric IRT are considered in van der Linden and Hambleton (1997) and Boomsma et al. (2001), and several current issues are surveyed in a special issue of *Applied Psychological Measurement* (Junker and Sijtsma 2001).

Modern nonparametric scaling methods include the 'essential independence' (EI) approach of Stout and his students and colleagues (e.g., Stout et al. 1996), and the Mokken scaling approach (e.g., Hemker et al. 1995); both methods are related to Cronbach's alpha bound on reliability. Mokken scaling is very good at finding groups of items that are highly discriminating among subjects; Stout's methods tend to identify groups of items that narrowly satisfy LI/EI, M, and U better. Ramsay (e.g., Ramsay 1996) has developed computational tools for estimating item response functions nonparametrically, and for visualizing the dimensionality of θ in terms of the surface in the J -dimensional unit cube generated by the joint likelihood for $X_{i1}, \dots, X_{iJ}$ as θ_i varies.

5. Some Applications

Parametric and nonparametric IRT methods are routinely used to assess the quality of individual items and sets of items in educational measurement work (Linn 1989) and to elucidate experimental design and statistical estimation issues when performances of examinees who sit for different versions of the same exam must be compared; such work goes under the name test equating. A similar problem arises in the scoring of sequentially-designed, computerized adaptive tests (e.g., Sands et al. 1997). IRT modeling has also elucidated research into the assessment of sociological bias (differential item functioning) on standardized test items (Holland and Wainer 1993) and the detection and diagnosis of subject outliers (Meijer 1996). Related work includes the study of rater effects (e.g., Patz et al. 2000) and matrix-sampling and the incorporation of group effects and other item and subject covariates in educational assessment survey work (Johnson et al. 1994).

In the broader social sciences and related areas, IRT has also played a substantial role. The Rasch model has long been applied in social survey work; see, for example, Duncan (1985). The Rasch model and other

IRT models can also be applied to model subject heterogeneity in estimating a closed population from multiple-recapture census data (see *Censuses: History and Methods*); Fienberg et al. (1999) recently surveyed this methodology and compared Bayesian IRT models with standard log-linear models in this context. Applications to multiple outcomes of designed experiments and to panel data are indicated in the volumes by Fischer and Molenaar (1995) and van der Linden and Hambleton (1997). Sijtsma and Verweij (1999) apply nonparametric IRT to scale construction in developmental psychology; and Nichols et al. (1995) collect many applications of IRT and related Bayesian inference network models (see *Bayesian Graphical Models and Networks*; Mislevy 1996) in cognitive diagnosis. Applications of parametric and nonparametric IRT to psychiatric scales include Gibbons et al. (1985), Santor et al. (1995) and Kim and Pilkonis (1999). In biostatistics Legler and Ryan (1997) use IRT to model multiple physical outcomes in the study of birth defects.

6. Summary

Item response theory (IRT) has grown from its roots in postwar mental-testing problems, through intensive use in educational measurements in the 1970s, 1980s, and 1990s, to become a mature statistical toolkit for modeling of multivariate discrete response data using subject-level latent variables. Applications of IRT can be found throughout the social sciences and related areas, from education, psychology, economics, and demography to medical research.

Most parametric IRT models would be recognizable by modern statisticians as mixed-effects multivariate generalized linear models, but IRT has benefited from interaction with all parts of the statistical community. Almost any assessment phenomenon—from between-subject dependence due to institutional or sociological factors, to behavioral aspects of raters, to the analysis of item responses in terms of requisite subject or item features—can be expressed in the hierarchical mixture/Bayes modeling framework of Fig. 1, because of its conceptual simplicity. Recent advances in computation, and MCMC methods in particular, have made it possible to estimate a vastly wider variety of these models than would have been imaginable even in the early 1990s however the more complicated models typically also make higher sample-size demands. Nonparametric IRT approaches also rely on computationally intensive methods, including spline and kernel smoothing and bootstrap techniques, to estimate and test probability inequalities, stochastic ordering properties, and similar features of the models. Questions motivating both parametric and nonparametric IRT modeling inevitably involve identifying the phenomena that are worth detailed modeling, and seeing if the computational and data collection

machinery can be pushed to be informative about reasonable models of these phenomena.

Hambleton et al. (1991) provide a fairly straightforward introduction to IRT in educational testing; Andersen (1980) presents the Rasch model in the context of other statistical models for the social sciences; and Fischer and Molenaar (1995) and van der Linden and Hambleton (1997) provide modern technical accounts. A broad range of current research issues in IRT is collected in Boomsma et al. (2001).

B. W. Junker

Factor Analysis and Latent Structure: Overview

The terms factor analysis and latent structure refer to two aspects of essentially the same problem. Both are concerned with statistical problems in which some of the variables are latent, meaning that they are unobservable. Information about the latent variables has, therefore, to be obtained indirectly through indicators, also known as manifest or observable variables. The terminology of the subject reflects the diverse origins of the subject accumulated over almost a century. 'Factor' in this context is a synonym for latent variable. From a theoretical perspective, the only distinctive thing about a latent variable model is

the presence of unobservable variables. In all other respects the normal methods of statistics apply.

Indeed, a latent variable problem can be regarded as a standard statistical problem in which the data on the latent variables are missing. There is no essential difference, for purposes of analysis, between a problem in which some of the data are never obtained and one in which some are lost.

1. Introduction

Latent variables arise mainly, but not exclusively, in the social sciences. This is because social science often deals in concepts which are constructs rather than the directly measurable variables which are typical of physical sciences. The earliest example, and still one of the most important, is general intelligence or 'g.' This goes back to Spearman (1904) and was constructed to describe the variation among individuals in what appeared to be common to a wide range of mental tests. Psychology and sociology abound in such latent variables. Attitudes as well as abilities are all spoken of in the discourse of these subjects as things which occur in varying amounts and which, therefore, appear in the theory as quantitative variables. In economics, variables like business confidence play a similar role. It could be justly claimed that the aspiration of these subjects to be regarded as sciences depends on the success with which latent variables can be quantified.

Latent variables can be classified into several types. Many, like intelligence, are conceived of as continuous in which case we are looking for a scale on which individuals can be located. In other contexts it is more appropriate to think of the latent variable as categorical. In that case individuals are supposed to belong to one of several classes which may or may not be ordered. What is true of the latent variables is, of course, true for the manifest variables and the only essential difference between the various methods is in the types of variables for which they are appropriate.

A convenient way of displaying the relationship between the methods is to introduce the fourfold classification of Table 1. We classify the manifest and the latent variables as metrical or categorical. In the former case we mean that they take values on some

Table 1
Classification of latent variable methods

	Manifest variables	
	Metrical	Categorical
Latent variables		
Metrical	Factor analysis	Latent trait analysis
Categorical	Latent profile analysis	Latent class analysis

continuous or discrete scale of measurement; in the latter, that they fall into categories.

This classification is not exhaustive. It does not, for example, include cases where both kinds of variable occur among the manifest (or latent) variables. Neither does it distinguish between continuous and discrete metrical variables or between ordered and unordered categorical variables. Nevertheless, it does cover the most widely used methods on which this overview focuses.

2. Historical Perspective

Factor analysis was invented by Spearman (1904) for the specific purpose of operationalizing the notion of general intelligence. He remained wedded to the view that there was a single dominant latent variable of human ability which he named 'g' which accounted for most of the variation in observed performance. Thurstone (1947) emphasized the multifactorial approach and, for that purpose, generalized Spearman's treatment to allow for several factors. Factor analysis was ahead of its time in two senses. First, it was a sophisticated multivariate technique introduced long before the statistical technology required was available. In consequence, its development was somewhat idiosyncratic and its separation from the statistical mainstream gave it an alien appearance which persists to this day and still causes suspicion and misunderstanding. Second, it is a computer intensive technique whose full potential could only be realized with the arrival of the powerful electronic computers since the 1980s. This lack distorted the early development of the subject by the need to concentrate on the search for computational shortcuts.

Latent structure analysis, which covers the remaining cells of Table 1, was introduced by Lazarsfeld after the Second World War, with a view to applications in sociology. A book-length treatment, by Lazarsfeld and Henry (1968), has held the field for many years as the definitive source of information but has now been superseded by a new generation of books of which Heinen (1996) is both recent and comprehensive.

Latent structure analysis came on the scene half a century after factor analysis, and in a different disciplinary context. For that reason there was, until very recently, little cross-fertilization between the two fields. When viewed from a level of sufficient generality, the methods are essentially the same.

In the postwar era more powerful methods became available but the whole field largely has remained a set of distinct subspecialisms each with its own literature and technology. It is over 40 years since Anderson (1959) pointed out that all latent methods shared a common conceptual framework but his insight has been slow to yield its full potential. The classification of methods as given in Table 1 was made the basis of

a common approach in Bartholomew (1984) the culmination of which is to be seen in Bartholomew and Knott (1999).

3. The Basic Conceptual Framework

First, we describe the key ideas in nonmathematical terms and then, in the following section, express them more precisely. The central idea on which the treatment is based is that of a probability model in which all variables are represented by random variables. This is so natural to the modern statistician as to pass without comment, but this was not so at the time when factor analysis was being developed. Even today the notion is not always clear. A statistical model is, essentially, a statement about the joint distribution of a set of random variables. Model-building is the process of specifying that distribution.

The discussion is based on a simple example. Consider the case of arithmetical ability and suppose that this varies from one individual to another along a one-dimensional scale but cannot be observed directly. Test items are chosen which depend on this particular skill, and are administered to a large sample of subjects. Our problem is to see whether our hypothesis about the existence of a single latent variable is correct and, if so, to provide a means of locating subjects on that scale on the evidence of their test score.

A simple intuitive approach, which has been used in the educational world for generations, is to add up, or average, the scores for any individual and treat the average as an approximation to the value of the underlying latent variable for that individual. From this it is a short step to a rudimentary model according to which the observed score is equal to the 'true score' plus a random deviation. The deviations will tend to cancel out on addition. All latent variable models can be regarded as elaborations of this basic idea.

The first step is to specify how the observed score should vary when the value of the latent variable is fixed. The next is to deduce what the joint distribution of the scores ought to be when there is no variation. The final step is to introduce the distribution of the latent variable(s)—the true scores. Together these give the overall distribution of the scores which can then be compared with the observed distribution. If the two are in agreement the model is supported, if not it must be replaced with something better.

The second stage in the model building exercise is more problematical. By definition, a latent variable can never be observed so its distribution cannot be observed either. The choice of prior distribution is thus a matter of convention. If it is chosen to be normal, that is equivalent to agreeing to adopt a scale which renders the distribution normal.

All of the models covered by Table 1 have these two elements: (a) a statement of how the scores vary when

the latent variable(s) is fixed and (b) a convention about the form of the distribution of the latent variable in the population from which the sample of those tested has come. Once these two things are known probability theory provides the means to go in the reverse direction and deduce how the latent variable would vary if the observed score were to be fixed.

4. Formal Statement of the Conceptual Framework

The last section set out the key ideas underlying all latent variable models. Here they are expressed more formally in mathematical terms. The nonmathematical reader who is interested only in specific models may pass immediately to the next section.

Denote the set of indicators by the p -vector $\mathbf{x}$. Its elements $x_1, x_2, \dots, x_p$ may be continuous or categorical. The latent variables are denoted by the q -vector $\mathbf{z}$. In the example above there was only one latent variable, arithmetical ability, but in general, there may be several.

Any model must specify, completely or partially, the joint probability distribution of $\mathbf{x}$ and $\mathbf{z}$ denoted by $f(\mathbf{x}, \mathbf{z})$. The distinctive thing about this kind of model is that the values of $\mathbf{z}$ can never be observed. For this reason everything must be expressed in terms of the distribution of the observable variables $\mathbf{x}$. The relationship between the two is

$$f(\mathbf{x}) = \int f(\mathbf{x}, \mathbf{z}) d\mathbf{z} \quad (1)$$

Here and subsequently equations will be written as if the variables were all continuous—hence the integral in (1). This is purely for convenience and the translation needed to cover other cases does not affect the logic of the argument. The next step is to write

$$f(\mathbf{x}, \mathbf{z}) = f(\mathbf{z})f(\mathbf{x}|\mathbf{z}) \quad (2)$$

This decomposition provides us with the two elements to which the description of the last section referred—namely a statement of how the manifest variables would vary if $\mathbf{z}$ were known, given here by $f(\mathbf{x}|\mathbf{z})$, and the prior distribution of $\mathbf{z}$. If both parts of (2) can be specified, $f(\mathbf{x})$ can be determined and thus the way is open to estimate any parameters of the model from a likelihood function constructed from $f(\mathbf{x})$. To scale $\mathbf{z}$, that is to find value for $\mathbf{z}$ for an individual with a given $\mathbf{x}$, the posterior distribution given by

$$f(\mathbf{z}|\mathbf{x}) = f(\mathbf{z})f(\mathbf{x}|\mathbf{z})/f(\mathbf{x}) \quad (3)$$

is needed. A scale value, or factor score, for a particular $\mathbf{z}$ can then be found by using some measure of location of its posterior distribution such as $E(z_i|\mathbf{x})$.

This program is deceptively simple. It merely maps out some of the consequences of regarding $\mathbf{x}$ and $\mathbf{z}$ as

random variables. To turn it into a model we have to specify $f(\mathbf{z})$ and $f(\mathbf{x}|\mathbf{z})$. Here we face a fundamental problem because the decomposition of (3) is not unique—there are infinitely many possible pairs each leading to the same $f(\mathbf{x})$ and hence indistinguishable empirically from one another.

The choice of $f(\mathbf{z})$ is resolved by appealing to the fact established above that $\mathbf{z}$ is a latent variable and hence that it can be constructed to have any convenient distribution. For instance, as a matter of convention one may choose the z s to be standard normal and mutually independent.

The core of the model-building exercise centers on the choice of the conditional distribution $f(\mathbf{x}|\mathbf{z})$. This has to be considered in the context of individual problems but there is one further simplification which applies to all models. This simplification involves making explicit what is already implicit in our formulation. The fact that the x s are supposed to be indicators of $\mathbf{z}$ implies that the x s will be mutually correlated—because of their common dependence on some, at least, of the z s. Hence, if $\mathbf{z}$ were to be fixed, the source of those correlations would vanish. Conditional on $\mathbf{z}$ the x s would then be independent. If this were not so it would be inferred that there was at least one other z , not already included, giving rise to the correlations remaining. Sufficient z s therefore have to be included in the model to eliminate the correlations after conditioning of $\mathbf{z}$. It then follows that

$$f(\mathbf{x}|\mathbf{z}) = \prod_{i=1}^q f_i(x_i|\mathbf{z}) \quad (4)$$

This is often referred to as the assumption of conditional (or local) independence but it is not an assumption in the usual sense. It is, rather, a statement of what is meant by saying that $\mathbf{z}$ explains the interdependence of the x s. It is, essentially, a definition of q as the smallest integer for which an equation of the form (4) can be constructed.

How this may be done in particular cases will be shown in the following section, but there is an important general principle which offers a fruitful way forward. Distributions of the exponential family are widely used in statistical modeling because they lead to estimates with highly desirable properties such as sufficiency. They provide a rationale for many of the most important models used in statistics, such as generalized linear models (see *Neural Networks and Related Statistical Latent Variable Models*).

Essentially the same properties can be utilized here. They are set out in the chapter on the General Linear Latent Variable Models in Bartholomew and Knott (1999). The essential idea is to make what is called the ‘natural’ or ‘canonical’ parameter of the one-parameter exponential family distribution a linear function of the latent variables. If that is done it turns out that the posterior distribution of $\mathbf{z}$ given $\mathbf{x}$ of (3) depends

on the x s only through q linear combinations of the x s which we may write

$$X_j = \sum_{i=1}^p \alpha_{ij} x_i \quad (j = 1, 2, \dots, q) \quad (5)$$

This is a remarkable result which justifies the common practice of 'estimating' latent variables from sums, or weighted sums, of the indicators. Technically speaking the X s are sufficient for $\mathbf{z}$ in the sense that, if we know $\mathbf{X}$, there is no further information in the data about $\mathbf{z}$.

5. Special Cases

5.1 Factor Analysis

This is the oldest and most widely used latent variable method. It is usually written

$$\mathbf{x} = \boldsymbol{\mu} + \boldsymbol{\Lambda}\mathbf{z} + \mathbf{e} \quad (6)$$

where $E(\mathbf{z}) = E(\mathbf{e}) = \mathbf{0}$, $\text{cov}(\mathbf{e}) = \boldsymbol{\Psi}$, a diagonal matrix, $\text{cov}(\mathbf{z}, \mathbf{e}) = \mathbf{0}$ and $\mathbf{z} \sim N(\mathbf{0}, \mathbf{I})$. An equivalent way of writing it, which conforms more closely to the general treatment above, is to specify the conditional distribution of $\mathbf{x}$ given $\mathbf{z}$ as

$$\mathbf{x} | \mathbf{z} \sim N(\boldsymbol{\mu} + \boldsymbol{\Lambda}\mathbf{z}, \boldsymbol{\Psi}) \quad (7)$$

which makes it clear that $\mathbf{z}$ influences $\mathbf{x}$ only through its mean which is linear in $\mathbf{z}$. The marginal distribution of $\mathbf{x}$ is $N(\boldsymbol{\mu}, \boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \boldsymbol{\Psi})$ and it is from this that the parameters $\boldsymbol{\Lambda}$ and $\boldsymbol{\Psi}$ must be estimated. The matrix $\boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \boldsymbol{\Psi}$ is sometimes referred to as the covariance structure.

Fitting the model consists in determining that $\boldsymbol{\Lambda}$ and $\boldsymbol{\Psi}$ which make the fitted and observed covariances of the x s as close as possible. This can be done without invoking the distributional assumptions at all since the covariance structure derived from (6) is the same, regardless of the assumptions about the form of the distributions of $\mathbf{z}$ and $\mathbf{e}$. However, without some such assumption nothing can be said about goodness of fit or the sampling variation of the estimators.

Posterior analysis allows the distribution of $\mathbf{z}$ given $\mathbf{x}$ to be determined, which for the factor model is

$$\mathbf{z} | \mathbf{x} \sim N(\boldsymbol{\Lambda}'\boldsymbol{\Sigma}^{-1}(\mathbf{x} - \boldsymbol{\mu}), (\mathbf{I} + \boldsymbol{\Lambda}'\boldsymbol{\Psi}^{-1}\boldsymbol{\Lambda})) \quad (8)$$

where $\boldsymbol{\Sigma} = \boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \boldsymbol{\Psi}$. As predictions of $\mathbf{z}$ given $\mathbf{x}$ we can use the mean values of this distribution, replacing the parameters by sample estimates.

5.2 Interpretation and Rotation

Interpretation of factors involves procedures which are common to all linear latent variable models. They

are most familiar in the context of factor analysis so, although treated here, their generality must be emphasised. The problem may arise in two forms. If there is some idea of what factors to expect (as in the arithmetical ability example above) the question is how to recognize them. If, on the other hand, the analysis is purely exploratory, further guidance is needed on how to assign meaning to any factor that is found. The essential idea is to look at the relationships between the latent and manifest variables. This is facilitated by noting that the element λ_{ij} of $\boldsymbol{\Lambda}$ may be interpreted as the correlation between x_i and z_j . Manifest variables which are highly correlated with z_1 say, have a lot in common with z_1 which, in turn is highly influential in determining those x s. It must then be asked what it is that those x s have in common with one another which they also share with z_1 . Interpretation is often facilitated by a process known as rotation. Thus far the treatment has supposed that there was only one solution to the problem of fitting the model. In fact there are infinitely many models which all predict the same covariance structure. These solutions can be generated from one another by a procedure known (because of its geometrical interpretation) as rotation. Each such solution represents an equivalent way of describing the latent space, but some may be easier to interpret than others. For example, a solution for $\boldsymbol{\Lambda}$ which has, at most, one nonzero value in each row implies that the x s have been divided into disjoint groups, each group depending on a single latent variable. That latent variable is then interpreted in the light of what that subset has in common.

5.3 The Latent Class Model

If the latent space consists of a finite (usually small) set of classes and if the manifest variables are also categorical the bottom right cell of Table 1 applies. The commonest case is where the manifest variables are binary. If there are c classes the prior distribution $f(\mathbf{z})$ becomes a discrete probability distribution over the classes, η_j being the probability of belonging to class j . In this case these probabilities can be treated as unknown parameters to be estimated. For convenience, the two values which each x_i takes are coded as 1 and 0, the conditional distributions $f_i(x_i | z)$ consists of two probabilities: $\Pr\{x_i = 1 | z\}$ and $\Pr\{x_i = 0 | z\}$. The natural choice for the distribution of x_i is the Bernoulli distribution written as

$$f_i(x_i | j) = \{\pi_i(j)\}^{x_i} \{1 - \pi_i(j)\}^{1-x_i} \\ x_i = 0, 1 \quad j = 1, 2, \dots, c \quad (9)$$

The joint probability distribution of $\mathbf{x}$ is then

$$f(\mathbf{x}) = \sum_{j=1}^c \eta_j \prod_{i=1}^p \{\pi_i(j)\}^{x_i} \{1 - \pi_i(j)\}^{1-x_i} \quad (10)$$

This can be used to construct the likelihood function from which the parameters may be estimated.

Posterior analysis for this case is concerned with allocating individuals to latent classes after $\mathbf{x}$ has been observed and this is done easily by substituting into (3). This gives us the probability that an individual with observed vector $\mathbf{x}$ belongs to each of the classes.

The number of parameters in this model increases rapidly with c and serious problems of identifiability arise if there are more than four or five classes. Also the standard errors of the parameter estimates increase rapidly as c increases.

5.4 Latent Trait Models

These models were devised, primarily, for use in educational testing where the latent trait refers to some ability. There is, thus, usually one latent variable, representing the ability, and many indicators. These are often binary, corresponding to the response to the item being 'right' or 'wrong.' This has become a specialized field, often referred to as Item Response Theory (IRT) with a literature and notation of its own (see *Factor Analysis and Latent Structure: IRT and Rasch Models*). The model may also be used in other fields, such as sociology, where it may be more appropriate to introduce several latent variables.

A latent trait model with binary x s is similar to a latent class model. The prior distribution is now continuous and will usually be taken to be standard normal. The response variables will still be Bernoulli random variables but now they depend on the continuous latent variable(s). Since the Bernoulli distribution is a member of the exponential family the appropriate form for $\pi_i(z)$ turns out to be

$$\text{logit } \pi_i(\mathbf{z}) = \alpha_{i0} + \alpha_{i1}z_1 + \alpha_{i2}z_2 + \cdots + \alpha_{iq}z_q \quad (11)$$

Other versions of the model in which the logit on the left hand side of (11) is replaced by $\Phi^{-1}(\cdot)$, the inverse standard normal distribution function, are widely used and give similar results to (11) but they lack the sufficiency properties. If $j = 1$ and the α_{ij} s are the same for all i , the model is a random effects version of the Rasch model (see, e.g., Bartholomew 1996). In the latter the trait values are taken as parameters rather than random variables so, in the strict sense of classical inference, the Rasch model is not a latent variable model.

5.5 Other Models

The latent profile models of Table 1 have been omitted because they have found relatively little practical application. It has also been shown by Molenaar and

von Eye (1994) that they are virtually indistinguishable from factor models because they have an equivalent covariance structure. Neither have we considered hybrid models in which manifest and latent variables may be mixed type—discrete or continuous. The advantage of our general approach is that it lends itself to the treatment of all such models. This approach has been exemplified by Moustaki (1996) and is capable of further development.

6. Relationship between Latent Variables

In much sociological research the interest is not so much in the latent variables as individual entities, but in the relationships between them. The interrelationship of manifest variables is a major subject of investigation in social science using techniques such as path analysis, regression, log-linear analysis, and graphical models. It is natural to extend these models to include latent variables. This has given rise to linear structural relations modeling which can be implemented using widely available software such as LISREL, AMOS, and EQS (see *Factor Analysis and Latent Structure, Confirmatory; Latent Structure and Causal Variables*).

In essence, such models have two parts: (a) a measurement model which supposes that each latent variable is linked to its own set of indicators through a factor model and (b) a structural model which specifies the (linear) relationships among the latent variables. Such a model is fitted by matching the observed and theoretical covariance matrices. A much more general framework which allows a wider range of models is provided by Bartholomew and Knott (1999). Although these methods are very widely used, serious questions have been raised about the identifiability of the models (Anderson and Gerbing 1988, Croon and Bolck 1997, Bartholomew and Knott 1999). These authors have suggested that it may be better to separate the measurement and structural parts of the analysis. This can be done by constructing 'estimates' of the latent variables and then exploring their interrelationships by the traditional methods used for manifest variables.

7. Future Developments

The advent of massive computer power has changed the practice of multivariate analysis radically, and of latent variable analysis in particular. The limiting factor is no longer computing power but of getting data of sufficient quality and quantity to fit the very complicated models which the theory provides and computers can handle. The precision with which models with many parameters can be estimated is

often very low unless the sample size runs into thousands. This makes it all the more important to estimate the sampling variability of the estimates of the parameters on which the interpretation depends. Traditionally this has been done by finding asymptotic standard errors but these can be very imprecise. However, it is now possible to supplement these results by resampling methods such as the bootstrap.

There are other fields in which latent variable models are used which currently exist in isolation. An obvious generalization is to latent time series. Some work has been done for the case where the latent process is a Markov chain. In this area the term 'hidden' is used instead of 'latent' which helps to conceal the family connections (see *Neural Networks and Related Statistical Latent Variable Models*) (for an introduction see MacDonald and Zucchini 1997). An application in a more traditional time series context will be found in Harvey and Chung (2000). Also, there is work by economists on unobserved heterogeneity as it is called which, essentially, involves the introduction of latent variables into econometric models.

False Memories, Psychology of

A false memory is a mental experience that is mistakenly taken to be a veridical representation of an event from one's personal past. Memories can be false in relatively minor ways (e.g., believing one last saw the keys in the kitchen when they were in the living room) and in major ways that have profound implications for oneself and others (e.g., mistakenly believing one is the originator of an idea or that one was sexually abused as a child). False memories arise from the same processes as do true memories and hence their study reveals basic mechanisms of memory. This article describes empirical research investigating false memories and a theoretical approach—the source monitoring framework—for integrating the findings and guiding further investigation.

1. Selected Early Research

Psychologists have long been interested in memory distortions. A classic example from the 1930s is Bartlett's report of studies in which he told people a folk tale from an unfamiliar culture and asked them to recall it from memory. He noted that the memory errors people made brought the story more in line with their own culturally determined expectations. Another is Carmichael, Hogan, and Walter's demonstration that how forms are labeled influences how they are remembered. For example, people's reproductions from memory of two circles connected by a straight line were more likely to include a curved line if the form had been labeled as 'eyeglasses' than if it had been labeled as 'dumbbell.' Still another is work in the late 1950s and early 1960s by Deese (1959) and by Underwood (1965) demonstrating that people are very likely to falsely remember an item (e.g., needle) if they had earlier been presented with related items (e.g., thread, haystack, sharp).

In the 1970s, studies from a number of laboratories highlighted the fact that such memory distortions do not only occur for unfamiliar materials such as folk tales, or lists of words or pictures—they are a byproduct of our everyday understanding of, and memory for, information and events. For example, Bransford and Johnson's (1973) work on comprehension and memory demonstrated that recalling information often depends on engaging constructive processes by which information is related to prior knowledge or schemas at encoding. For example, memory for a sentence such as 'the haystack was

important because the cloth ripped' was much better when the idea of a parachute had been recently activated than when it had not. However, this work also showed that people are more likely to falsely claim that stories included information that was only inferred based on prior schemas or knowledge. People who heard a story that included the information that 'the spy threw the secret document into the fireplace just in time because 30 seconds longer would have been too late' were later likely to claim that 'the spy burned the document.' Thus distorted 'remembering' of information that might be, but is not necessarily, true (e.g., the spy could have been hiding the document in a fireplace that was not lit) is the potential downside of the intelligent, active processing of information.

Such findings led Johnson and Raye (1981) to suggest that memory distortions like those described above reflect errors arising from imperfect reality monitoring processes that are an integral part of remembering: that is, people sometimes confuse the information they generate during the initial encoding, the retention interval, or subsequent remembering of an event for information that came from the event. Reality monitoring is a special case of the more general ongoing function of source monitoring—making attributions about the origin of activated information in mental experience (Johnson et al. 1993). Thus, source monitoring errors include both confusions between internal and external sources and between various external sources (e.g., attributing something that was imagined to actual perception, an intention to an action, something read in a tabloid to a television program, an incident that occurred in place A or time A to place B or time B).

Of course, how serious any of these memory distortions are depends on what is at stake. A clear case where it matters is eyewitness testimony. In the 1970s, E. Loftus launched an influential research program investigating the impact on event memory of information that is suggested between the time of a witnessed event and the time people are required to 'testify.' In one study, people saw a film of an automobile accident and were asked some questions, including 'About how fast were the cars going when they smashed into each other?' Other people were asked the same question except that the words 'smashed into' were replaced with the word 'hit.' On a memory test a week later, the people in the first group were more likely to mistakenly say 'yes' to a question about whether they had seen broken glass in the film. To take another example from the Loftus laboratory, after seeing a film, participants were asked 'How fast was the white sports car going when it passed the barn while traveling along the country road?' Other participants were asked the same question without mention of the barn. In fact, there had been no barn in the film, but those people who had the barn mentioned in the question were later more likely to say that they had seen a barn in the film. Both of these examples likely

involve source monitoring errors—the former a confusion between a self-generated inference based on the supplied information that the cars 'smashed into' each other and the latter a confusion between what was read and what was seen.

In sum, generation, elaboration, and integration of information across individual experiences from different sources reflects associative, imaginative, and reasoning processes that are necessary for all higher-order, complex thought. But, this very capacity for creativity makes us vulnerable to having false memories.

2. *Source Monitoring*

Perhaps the most comprehensive theoretical account of false memories to date is provided by the source monitoring framework (SMF) proposed by the present author and her colleagues. According to the SMF, it is not the case that memories are found (or not found), but rather that mental experiences are attributed to memory (or not) by ongoing judgment processes. The SMF further highlights several key aspects of these memory attributions:

(a) Memory attributions are based on various qualitative characteristics of the mental experience. For example, perceptual, spatial, temporal, or emotional details typically are taken as evidence that a mental experience reflects a true memory.

(b) Memory attributions are influenced by the embeddedness of the mental experience. Embeddedness depends on such factors as the availability of supporting memories, consistency with knowledge and beliefs (e.g., plausibility), and coherence of the information, and agreement with the reports of others about the event.

(c) Memory attributions are made according to flexible criteria (which qualities are considered and how they are weighted, how much evidence of any given type is needed). Hence, what may be taken for a memory under one set of circumstances might not be under another.

(d) Goals, beliefs, and motivational and social factors influence what characteristics are looked for, how much embedding occurs, and which criteria are applied.

According to the SMF, false memories occur because the mental experiences arising from events of different sorts (e.g., imagination and perception) overlap in characteristics (they are imperfectly differentiated) and because the processes that make judgments about these mental experiences are also imperfect (i.e., they not only operate on imperfectly differentiated data, they are not always fully engaged, they sometimes overweight nondiagnostic evidence or employ inappropriate criteria, they are subject to social influences, etc.). As do most theoretical accounts of false memories, the SMF assumes that the as-

sociative, constructive, elaborative, and integrative processes that are central to human perception and thought contribute information that may become a candidate for misattribution. However, the SMF has emphasized that these processes alone do not produce false memories. Rather, false memories arise when the products of these processes are taken *to be* memories. That is, it is not the fact that associations and other elaborations occur that produces false memories—for example one can make an inference and later attribute it to an inference, or imagine an event and later correctly attribute it to imagination. Survival would be difficult, if not impossible, if there were no differences between the memory records of things that happened and things we imagined, or between activities we observed or participated in and activities we only read or heard about. Fortunately, the imperfect system people have is usually good enough, and perhaps even has some advantages over a perfect system (e.g., life satisfaction may be higher when we remember things as better than they were, social relations may be better when we agree on a common account of events, or generalization between similar situations may be faster when we are not concerned about where inferences come from).

Some theorists (e.g., Gardiner, Jacoby, and Kelley) have proposed that there are two distinct types of memory experience, ‘Knowing and Remembering,’ or ‘Familiarity and Recollection,’ and have shown that errors often result from misattribution of familiarity which can sometimes be corrected with recollection. Within the SMF, these would represent ends (or a coarse categorization) of a continuum of mental experiences. Also, in the SMF, both true and false memories can be associated with a sense of familiarity and with a sense of recollection.

3. Investigating True and False Memories

Evidence for the propositions in Sect. 2 comes from laboratories in many countries working in many domains (the SMF can be thought of as a way of unifying this evidence), including work on familiarity-based attributions, cryptomnesia, the phenomenal qualities of memories, suggestibility, rehearsal, schema effects in memory, the impact of emotion, motivational and social effects in memory, interpersonal reality monitoring, and imagination. Several illustrative findings are briefly outlined here.

3.1 Memory Characteristics

When participants are asked to make ratings of the qualitative characteristics of their memories, memories for real events tend to have more perceptual and emotional detail than memories for imagined events. Moreover, when they are asked to justify why they

believe their own (or someone else’s) memory they invoke these characteristics or are influenced by them. Manipulating these characteristics influences the accuracy of source monitoring. For example, if participants have imagined a word in another person’s voice they are later likely to claim that person said the word. If they have seen a magnifying glass, they are likely to say they have seen a physically similar item that they only imagined (e.g., a lollipop). Furthermore, features are ‘borrowed’ or cumulated across modalities. For example, hearing the sound of a dog barking increases subsequent claims that an imagined dog was seen. In some experiments, people are as likely to claim to ‘remember’ their false as their true memories and to be as confident (or more so) about them. However, in several experiments using more detailed rating categories (e.g., asking for specific ratings of visual and auditory detail, emotional qualities) false memories were on average somewhat less vivid or detailed than true memories.

3.2 Evidence and/or Criteria used in Source Monitoring

Attribution processes are subject to task and social demands. If people are induced to, or have the opportunity to more carefully evaluate their memories, the probability of false memories decreases. Ways to decrease false memories include avoiding leading questions, asking people to explicitly consider the possible sources of their memories rather than simply asking about one source, having them rate the qualitative characteristics of their memories, and public as opposed to private remembering. Presumably, these manipulations decrease the degree that people will rely on a single type of information (e.g., familiarity or perceptual detail) and increase consideration of, and retrieval of, additional potentially useful information.

3.3 Rehearsal and Imagination

Thinking about events can increase the vividness of imagined events, the probability people will claim imagined events occurred, and their confidence that an event occurred. Imagining events can also make similar perceived events seem to have occurred more frequently. Furthermore, inducing subjects to generate images of suggested information increases later source misattributions.

3.4 Attention

Emotional self-focus or distraction during encoding or remembering can result in decreases in source accuracy without necessarily decreasing memory that an event

occurred. Such findings emphasize that memory 'strength' (in the sense of probability of recognition or recall) is not a perfect predictor of source memory. People can have strong memories for information for which they have only vague source cues, or strong-but-wrong source cues.

4. Are Some Memories Immune to Distortion?

In 1977 Brown and Kulick proposed that there is a class of 'flashbulb memories'—accurate, long lasting, and detailed—for highly significant, emotional events (e.g., where one was when one heard that Kennedy was assassinated or that the Challenger space shuttle exploded). However, subsequent research has shown that, like ordinary memories, these memories are subject to distortion.

The question of whether some memories might be immune to distortion resurfaced in the 1980s and 1990s, prompted in part, by high profile legal cases that involved either children's testimony in sexual abuse cases (e.g., *New Jersey vs. Michaels*), or adults' testimony about recovering previously repressed memories that they were sexually abused (e.g., *Ramona vs. Ramona*; *Martinelli vs. Diocese of Bridgeport*), or witnessed crimes (e.g., *People vs. Franklin*). Such cases greatly broadened the interest among the research community in the processes of memory distortion and the number of published papers related to memory distortion increased dramatically.

A central issue in discussions about these cases has been to what extent the findings and principles arising from laboratory research apply to real life, especially to traumatic memories. Some clinicians and authors of popular self help books encourage individuals experiencing psychological problems to freely imagine what might have happened to them as children and to think about why such events might have been likely. Although intended to help clients, the potential consequences of such practices are clearly problematic from the perspective of the SMF. Such practices encourage the client to generate details that may not be accurate, embed false information in a web of supporting knowledge and beliefs, and to adopt weak criteria for what constitutes evidence for a memory. At the same time, the conditions of laboratory studies cannot mirror those of real-life traumatic situations. Thus some have suggested that experimental results and some theoretical ideas do not always apply. They claim that certain classes of traumatic memory, including childhood sexual abuse, are unlikely to be false because the associated emotion is evidence of their authenticity.

Although there are obvious ethical limits to the types of laboratory situations that researchers can set up, researchers have demonstrated that false memories can be created for entire, complex, salient, and

emotionally significant events—inducing both children and adults to believe that they remember autobiographical events that never happened. The general procedure in some of these studies is to obtain reports of actual events from a relative of the participant and then query the participants about these events. Embedded in the list of real events is a false event that did not happen to the participant. After reading the accounts and, especially after being encouraged to think about the events, some participants claim to remember the false event. For example, Loftus and Pickrell induced adult participants to remember being lost in a shopping mall as a child. Hyman and colleagues induced participants to remember being taken as a child to the hospital for an ear infection. These false memories can contain quite specific details not provided in the relative's account. Similarly, Ceci and his colleagues have found that some children will provide compellingly vivid accounts of complex events (e.g., having their finger caught in a mousetrap), particularly after repeated questioning about the event. Spanos and colleagues demonstrated that adult participants could also be led to report memories from infancy. For example, participants were told that, because they have good visual skills, they were likely to have been born in a hospital that hung mobiles over their cribs and then they were 'age regressed' to recover the memories. Groups that were hypnotized and groups that were not both reported a high incidence of 'infant memories.' Spanos and colleagues suggest that memories of past-life identities, UFO abductions, and satanic ritual abuse are similarly likely to be created in a social context where authoritative or trusted sources make such events seem plausible, create the expectation that the individual has had such experiences, and use techniques such as generating imagery or repeated questioning to facilitate recovery of such hidden memories. Ofshe has also argued that induction of hypnotic or dissociative states, in combination with specific suggestions from authority figures, can result in false memories and provided a chilling account of a criminal investigation in which leading questioning techniques induced a man to confess to the sexual abuse of his children.

Of course, it is quite difficult to isolate particular factors contributing to false autobiographical memories in these relatively complex, emotionally salient situations. Nevertheless, overall the results of these studies appear to reflect the processes proposed and they increase confidence in the generality of laboratory findings. Repeated questioning or thinking about an event increases the details that are remembered or confidence in the memory. Encouraging participants to embed a 'memory' in other supporting personally relevant details increases false memories. Individuals with high imagery ability seem to be more susceptible to induced false memories, presumably because they embellish more or create representations that are more like perceptions. In some studies, individuals who

score high on tests of hypnotizability or dissociative experiences are also more susceptible, perhaps because these individuals are high in imagery ability or easy to coax into using lax criteria for assuming something is a memory.

Studies that induce false autobiographical memories highlight the fact that remembering often takes place in a social context that can be a source of false information, can provide occasions for repeating and embellishing 'memories,' and can coax people to ignore the doubt that is an important cue during normal source monitoring. Therapy is itself a social context that potentially can have these characteristics. In 1995, Poole in the US and Lindsay in Canada, in collaboration with UK researchers Memon and Bull, reported results of a survey of therapists in the US and UK: 25 percent of the sampled therapists who work with adult female clients believe 'that recovering memories is an important part of therapy, think they can identify clients with hidden memories during the initial session, and use two or more techniques to help such clients recover suspected memories of [childhood sexual abuse].' They note that such techniques may be used with caution by many therapists, but that other therapists may be unfamiliar with the cognitive literature on processes of memory distortion, and may underestimate their own influence. As professional books and journals and, especially, the popular press, have provided wider exposure to theoretical issues and research findings, therapists are likely becoming better informed for making judgments about which techniques to use. Importantly, however, not only therapists, but also police officers, lawyers, social workers, parents, and many other trusted authorities (e.g., talk show hosts, Internet sites) are in a position to influence how people search and evaluate their memories. There is no reason to believe that memories cannot be accurate (they often are quite accurate in both laboratory and more naturalistic studies), and appropriate cueing and some conditions of social remembering can facilitate memory as well. Nevertheless, the potential for memories to be false is clear and the mechanisms of distortion are generally understood. Recent work has been directed at developing interview techniques for reducing false memories in both children and adults.

5. The Prefrontal Cortex and Source Monitoring

Based on the evidence that memory involves constructive and reconstructive processes (including the self-generation of retrieval cues, setting criteria, and evaluation of activated information), one would expect the region most associated with reflective or executive processes—the prefrontal cortex (PFC)—to be important for episodic memory, especially distinguishing between true and false memories. And, indeed, damage to PFC often produces memory deficits, including deficits in self-generated retrieval

necessary for autobiographical recall, increases in false recognition of related distracters, and, in some cases, clinically significant confabulation. Source memory deficits (and resulting false memories) are more likely in children (whose frontal lobes are slow to develop) and in older adults (who are likely to show increased neuropathology in PFC with age). PFC dysfunction may play a role in schizophrenia, which sometimes includes severe source monitoring deficits in the form of delusions. Furthermore, in cognitive tasks given to neurologically intact young adult participants, increasing the cognitive load (having the participant simultaneously engage in a secondary task) disrupts performance more on tasks requiring source identification than on tasks simply requiring old/new recognition. Presumably, the extra load taxes the recruitment, organization, and integration of cognitive component processes necessary for source identification that are subserved by PFC.

A few studies have directly examined the brain activity associated with true and false memories. These studies show that there is overlap in the brain regions activated for correct recognition of old items and recognition of semantically related lures, as would be expected based on the behavioral evidence of their confusion. However, evidence also suggests that the similarity of the brain activity associated with true and false memories depends on how people are tested (e.g., with targets and lures randomly intermixed or in separate lists). This is consistent with the idea that what people are looking for as they are remembering will influence the qualities of their memories.

6. Conclusions

Autobiographical memories are narratives that are influenced by expectations before events ever happen and by rumination after the fact. These narratives are also influenced by other experiences (photographs, other people's accounts, and even unrelated events) and our goals and motives at the time of remembering. False memories arise from the same encoding, rehearsal and source monitoring (memory attribution) processes that produce true memories; thus one can never be absolutely sure of the truth of any particular memory. Of course, in many contexts, minor (and even major) distortions are of little practical consequence. There may even be some advantages to certain kinds of false memories (e.g., remembering a vacation as having been more pleasant than it was). However, there are other contexts in which it does matter whether memory is accurate—when distorted memories result in consequences that are clearly undesirable from the personal (e.g., mistakenly believing one was a victim), social (e.g., giving erroneous testimony about someone's actions), or professional (e.g., appropriating someone else's ideas) perspectives. Furthermore, certain conditions of psychopathology or

brain damage result in clinically significant increases in false memories and beliefs—confabulations and delusions. Hence understanding the mechanisms underlying true and false memories can potentially help reduce their occurrence under everyday circumstances (e.g., in therapy, in police interrogations, in scholarship) and help specify more completely and assess cognitive dysfunction in clinical populations.

Familial Studies: Genetic Inferences

The twentieth century may be described as the century of genetics. It began with the rediscovery of Mendel's work by Johannsen (1903) and ended with the completion of the Human Genome Project (HGP). *Nature* (2001, 409) published the *Initial sequencing and analysis of the human genome* by The Genome International Sequencing Consortium and *Science* (2001, 291) published similar sequencing by Celera. The twenty-first century, particularly its first half, will see a spate of work related to gene manipulation and genetic disorders. We can confidently look forward to substantial developments in our understanding of our species.

We fear that even in the post-HGP era, some of the twentieth-century errors relating to inferences from genetic analyses of familial data will be repeated and some more will be added. Indeed, McGuffin et al. (2001) say 'The most solid genetic findings about individual differences in human behavior come from quantitative genetic research such as twin and adoption studies that consistently converge on the conclusion that genetic variation makes a substantial contribution to the phenotypic variation for all behavioral domains.' The conceptual and mathematical errors in behavior genetic models, therefore, need to

be known widely. Behavioral traits are also described as 'complex' traits (McGuffin et al. 2001, Carroll 2001). Feldman and Lewontin (1975) define a complex trait as one whose frequency of occurrence cannot be analysed in terms of simple genetic hypothesis. We prefer Mather's (1949) description of such a trait as 'polygenic' as it indicates clearly the basic genetic hypothesis. This article is concerned with the inheritance of a polygenic trait. It will: (a) explain the nature of the statistical model used for the statistical analysis of a polygenic trait, (b) show that heritability is not defined in the presence of assortative mating, (c) explain Galton's ideas about nature-nurture contributions and their extension in the twentieth century, (d) clarify some confusions about correlation and regression, (e) discuss heritability, and (f) show that behavior geneticists use incorrect formulas in model fitting. As an example, we choose Devlin et al. (1997) because it was published in *Nature*, and show that the formulas they used were incorrect. We state why Fisher's (1918) formulas are wrong and point out the deficiencies of Jinks and Fulker (1970). We explain why phenotypic, that is, observed variance of a trait cannot be partitioned into genetic and environmental components. Finally, we state how the research in genetic disorders should progress.

1. Mathematical Models in Biology and Medicine

There is a long tradition of using mathematical models in medicine and related areas. For example, Cullen (1983) divides his book *Mathematics for the Biosciences* into four major areas: (a) physiology and medicine, (b) ecology and population, (c) fisheries and oceanography, and (d) genetics. Roach (1984) in *Mathematics in Medicine and Biomechanics* has chapters on blood modeling, oxygen transport, nerve modeling, etc. Mathematical models have also been used in epidemiology, neurophysiology, cardiovascular simulation, tubercular skeleton, body fluids, kidneys, etc. All these models are type I models and have proved very useful in medical research. Recently, type II models to estimate the heritability of a trait have been introduced in familial aggregation studies. We give a brief description.

A Type II model is also known as the Components of Variance model. Its basic structure is: observed value = constant + linear function of *random* variables + residual. Residuals are assumed to have 0 mean and σ^2 variance (the assumption of normality of residuals is required for tests of significance). Here, we sample the variables at random from all the variables that affect a disorder. The problem is that we may not know all variables that affect it. Therefore, random selection of variables is very important. Our interest lies not in the mean effect of a factor but in the contribution it makes to the total variance. Thus, the aim is to divide the total (phenotypic) variance of a

disorder into the sum of variances due to factors. Numerical analyses for type I and type II models are similar and this may cause confusion in the minds of some nonspecialist researchers. We emphasize that no treatment of a disorder can be deduced from a type II model.

2. Heritability

In genetics, narrow heritability (h^2) and broad heritability (H^2) are strictly defined. h^2 = additive variance/phenotypic variance and H^2 = genetic variance/phenotypic variance. Additive variance is the variance of additive values and genetic variance is the variance of genetic values. The genetic value of an allele at a locus is defined as the regression of the phenotypic values on genotype and the additive value is defined as the regression of genetic values on genotype. Thus, both additive value and genetic value at a locus *are statistical constructs*. We can calculate phenotypic variance directly from phenotypic values. We cannot, however, calculate additive or genetic variance directly, as neither additive nor genetic values are known (Capron et al. 1999). Geneticists have devised various methods for estimating h^2 and H^2 . For example, if we know *beforehand* that a trait is under genetic control, then assuming random environment and random mating with respect to a trait, h^2 = corr. (mid-parent, child).

Jensen (1969) used the concept of heritability for analysis of IQ data. Since then an enormous literature on heritability has built up. Layzer (1999) questions the assumption that phenotypic measurement = genetic component + an environmental component, as 'every phenotypic trait is a *function* of genetic and nongenetic variables.' Feldman and Lewontin (1975) said: 'As we show below, the partition of the causes of variation is really illusory and the analysis of variation can not really separate the variation that is the result of genetic segregation. *The genetic variation depends on the distribution of environments and the environmental variance depends on the distribution of genotypes*' (italics added).

We agree with these criticisms but the nature of our criticism is slightly different. We believe that heritability is not defined when the population mates assortatively with respect to the trait. Fisher (1918) showed that assortative mating will introduce association between similar alleles and, thereby, destroy independent segregation of alleles. This association will also destroy the linearity of regression on which the definition of additive values is based. We do not know how to define additive value at a locus when a population is at equilibrium under assortative mating. Moreover, it can be shown that assortative mating will also create association between additive and dominance deviations at different loci. Thus, in the presence of assortative mating narrow heritability is not

defined. Fisher (1951) did not approve of the concept of heritability.

Nonrandom environment also causes problems. The trait is then associated with environmental variables. It can be shown, if assortative mating continues, it will create association between genetic alleles and environmental factors. The additive and genetic values cannot now be defined. Fisher may have known this and assumed random environment (see Kempthorne 1969). Moreover, few of us are capable of identifying all aspects of environment. To equate environment in genetic studies with the number of cars, or the number of rooms, or the number of books in a family home, etc. is simplistic (see Sect. 10). If a researcher wishes to study the effect of books, cars, or rooms on a trait, they should use a Type I model. Heritability analysis is a genetic cul-de-sac. It suggests no remedy for a disorder. With high H^2 one can only argue incorrectly, as Jensen (1969) did, that intervention programmes are useless.

Concerning comparisons between two groups using heritability, we agree with Feldman and Lewontin (1975) that 'the concept of heritability is of no value for the study of differences in measures of human behavioral characters between groups' (see also Thoday 1973).

3. Type II Model Fitting on Twin Data

This section is in two parts: (a) Galton's ideas, and (b) later attempts to divide the phenotypic variance into nature and nurture components.

3.1 Galton's Nineteenth-century Ideas

Galton was not aware of Mendel's work. His main interest lay in Eugenics, that is, the improvement of the white 'racial' stock. He invented the concept of correlation. He was well-off and endowed the Galton Laboratory for National Eugenics to propagate eugenics. Karl Pearson was its first Director. He devised the commonly used formula for product moment correlation following Galton's concept of correlation. Galton thought that the difference between concordances of monozygotic (MZ) and dizygotic (DZ) twins on a trait gave an indication of genetic (nature) effects on that trait. Galton's views have had a powerful effect in genetics and social sciences. His *law of familial regression* has been used to 'prove' that a trait is determined genetically.

Galton's method of concordance is explained in textbooks on genetics (e.g., Snustad et al. 1997 and Hartl and Clark 1997, etc.). In exercise 15-6 Levitan (1988, p. 361) asks: 'What can be said about the relative roles of heredity and environment in the following studies?' and lists a number of studies with respective MZ and DZ concordances. The first on the list is

tuberculosis (TB). The ratio of MZ and DZ concordant twins are 202/381 and 187/843. Perhaps he expects the students to compare the two concordances and conclude that heredity plays a major role in causing TB. This, indeed, was the 'scientific' view of the researchers in the field of TB based on analysis of familial data until the late 1950s (Capron et al. 1999). We now know that this is not the case.

Vogel and Motulsky (1996) give a similar table (6.22, p. 237) with larger sample sizes. They also calculate the statistics 'MZ higher than DZ.' Its highest value, 2.9, is for leprosy and the second highest, 2.56, is for TB. They say, 'In Western Europe, for example, leprosy disappeared during the seventeenth and eighteenth centuries without any therapy, only due to improvement in living conditions. *There was probably little or no influence of genetic changes*' (p. 237, italics added). They then claim that 'Analysis of discordance can shed some light on genetic versus environmental factors in disease.' They are obviously wrong. The only reasonable conclusion from these data is that the concordance method has no value in genetics. Note that heritability, as defined above, cannot be estimated from concordances.

3.2 Nature–Nurture Methods in the Twentieth Century

Researchers in twin studies soon realised the deficiencies of Galton's method and devised new methods to estimate nature–nurture contributions. Holzinger (1929) gave an index $H^2 = (r_{mz} - r_{dz}) / (1 - r_{dz})$ in terms of intraclass correlations between MZ and DZ twins. Nichols (1965) proposed an 'improved' index $I = 2(r_{mz} - r_{dz}) / r_{mz}$. In these formulas r_{mz} and r_{dz} are the phenotypic correlations between MZ and DZ twins, respectively. Obviously, neither of these formulas estimates h^2 or H^2 . Jensen (1967) realised this and published his formula for estimating broad heritability, H^2 from twin data in the PNAS. He began by stating a complex 'generalized formula' but did not say where it came from. That formula has *no* theoretical basis. After 13 steps he stated the formula $H^2 = (r_{mz} - r_{dz}) / (1 - \rho_{dz})$ where ρ_{dz} is the genetic correlation between DZ twins. Comparison of Jensen's and Holzinger's formulas shows that Jensen had replaced the phenotypic DZ correlation r_{dz} with the genetic DZ correlation ρ_{dz} . We do not know the value of the genetic correlation ρ_{dz} . Jensen (1967) got himself into a circular situation.

How did he remove the circularity? He claimed that we could find ρ_{dz} ($= \rho_{oo}$, the genetic correlation between offsprings) by using the formula $\rho_{oo} = (1 + \rho_{pp}) / (2 + \rho_{pp})$ where ρ_{pp} is the genetic correlation between parents on the trait, and gave Li (1955, Chap. 13) as reference for the formula. It does not appear there and has no genetic basis. Clearly, circularity remains. One now needs an estimate of h^2 to obtain ρ_{pp}

from r_{pp} . When Jensen's formula was used to calculate heritability in England's largest study of twins, Vetta (1977) was able to inform the researchers that this formula is not correct. Their response was 'It follows that the formula ought not to be perpetuated' (Adams et al. 1977).

The quest for a formula for estimating heritability from twin data continues. Vogel and Motlusk (1996, p. 769) said 'Twin data can be utilised as an alternative way to get heritability estimates.' As to how it can be done, they said 'An empirical way ... is to calculate alternative estimates from the same (twin) data to determine how well they coincide.' They made a number of unrealistic assumptions and developed formulas for finding h_1^2 and h_2^2 . They then claimed that H^2 lies between h_1^2 and h_2^2 . We cannot commend their formulas.

4. Correlation and Regression Tell Us Nothing about Cause and Effect

The formulas given in the last section use MZ and DZ correlations. Geneticists borrowed the concepts of correlation and regression from statistics. Confusion regarding their significance permeates the scientific literature. For example, Lawrence and Jinks (1973) said: 'This tendency for like to beget like, or in statistical terms, for the stature of parents and offspring to be positively correlated, is a sure sign of genetic determination.' The concept of regression to the mean originated with Galton's (1869) law of filial regression. He noticed that the children of tall parents were, on the whole, not as tall. He called it regression to the mean. He thought that a trait showing regression of progeny mean on mid parental value must be genetically determined. Jensen (1969) discussing some results on IQ says: 'None of these findings is at all surprising from the standpoint of a genetic hypothesis, of which an intrinsic feature is Galton's "law of filial regression."' Eysenck (1975) wrote 'There is no mention (in Kamin's book, 1974), for instance, of the remarkable regression effects which provide such a striking proof of inheritance, as well as making possible estimates of heritability' (see also Eysenck 1976).

This confusion has now entered the area of familial aggregation. We give two examples. Tsuang et al. (2000) found that 'In the Huntington's disease probands with psychosis, the onset of psychosis correlated with the onset of the neurological symptoms of the Huntington's disease.' From this correlation they concluded: 'Patients with Huntington's disease and psychotic symptoms may have a familial disposition to develop psychosis.' Perusse et al. (2000) used a familial correlation model and concluded 'that familial/genetic factors are more important ...' Behavior geneticists Neale and Carden (1992, p. 99) said: 'In other words, genotypes and environments are not

measured directly but their influence is inferred through their effects on the covariances of relatives.'

It is remarkable that despite Fisher's (1924) efforts, confusion persists. Fisher, discussing the phenomenon that children of tall parents are, on average, less tall said: 'This phenomenon has been called "regression to the mean" a use of the term regression quite different from the *technical meaning of the term* explained previously' (italics added). He suggested some reasons for this (see also Vetta 1975). Statisticians know that correlation or regression, in absence of other evidence, tell us nothing about cause and effect. Fisher put it elegantly (p. 196), 'To begin with, these statistics (regressions) do not prove that daughters inherit their height from their fathers; if they prove that they will equally prove that fathers inherited their height from their daughters, which is absurd. What they prove is that the heights of fathers and daughters are influenced by the same causes and it is generally agreed on *quite other grounds*, that the important cause of this similarity is that daughters have a great deal in common with their fathers in their hereditary constitution' (italics added). Thus, familial correlations, covariances or regressions on a trait should not be used to estimate genetic contribution, that is, h^2 or H^2 unless one is absolutely certain, on quite other grounds, that the trait has a genetic component.

Some behavior geneticists use path coefficients (Wright 1921). A path coefficient is a standardized regression coefficient. We do not discuss path analysis. We do not believe that a regression coefficient with or without the help of a diagram can assist us in resolving the problem of cause and effect.

5. Development of Modern Genetics

Modern genetics was developed by Fisher, Wright, Haldane, and Dobzhansky, among others, in the early part of the twentieth century. Fisher was a brilliant geneticist, as well as a brilliant statistician. His 1918 paper *Correlation between relatives on the supposition of Mendelian inheritance* is a comprehensive paper on quantitative genetics. It is difficult to read and almost impossible to understand. It is the basis of most of the model-fitting work in behavior genetics. It is, therefore, important that one understands the assumptions he made and the consequences of their failure.

6. Fisher's (1918) Correlation Formulas are Incorrect

Vetta (1976) showed that Fisher's (1918) correlation formulas are incorrect. He gave two reasons that may have led to the error. A third reason is that Fisher's basic assumption for his model was that the contribution of terms of third and higher degree of smallness are negligible as compared with the con-

tribution of terms of second degree of smallness (which are associated with variances). This assumption is valid only under random mating and not under assortative mating. The terms of third degree of smallness do make a contribution to covariances but the contribution of the terms of fourth and higher degree of smallness is, indeed, negligible. P-c and sib correlation formulas obtained by taking the contribution of terms of third degree of smallness into account meet the criteria discussed above.

7. Fisher's Model in Behavior Genetics

Behavior genetics is a relatively young science (Hirsch 1967). One of the major problems was the existence of genotype-environment interaction for most behavioral traits. There was no method of estimating it and Jinks and Fulker (1970) devised one. Their method was hailed as a breakthrough. It was used by Jensen (1970) and was extended to the multivariate case by Eaves (1972). In 1975 Vetta found that there was an algebraic error in their paper. When this error is corrected their method is useless. This was made known immediately to Professor Jinks and his colleagues. Despite this, Fulker and Eysenck (1979) said 'We can test directly for some form of genotype-environment interaction.' This is not true. In the rest of their paper Jinks and Fulker used Fisher's (1918) *incorrect* formulas to analyze data on some behavioral traits. Their paper is probably the most cited paper in behavior genetics. Eysenck (1979) says 'This book is the first to base itself entirely on these new methods.' Some behavior geneticists regard it as 'seminal' (Martin et al. 1989, p. 5). We disagree.

Most behavioral traits involve assortative mating. Behavior geneticists use incorrect formulas when they fit assortative mating models. Devlin et al. (1997) supplement Bouchard and McGue's (1981) correlations with correlations from twin studies published after 1981. They said: 'IQ heritability is not well characterized.' On the basis of past analyses Herrnstein and Murray's (1994) believed 'that IQ heritability is at least 60 percent, and is probably closer to 80 percent ...' (p. 470). They predicted that this will give rise to dysgenic trends and a cognitive caste will emerge. Devlin et al. (1997) aimed to show that a cognitive caste will not emerge. Using incorrect formulas, they obtained estimates of 0.34 and 0.48 for narrow and broad heritability respectively. They argued that, in view of these smaller estimates, a cognitive caste will not emerge. Actually, a cognitive caste will still emerge but over a longer period of generations, if IQ is a genetic trait. McGue (1997, p. 417) said that Devlin et al.'s analysis follows 'a long line' of analyses. Behavior geneticists keep on analyzing essentially the same data and obtain estimates of heritability of IQ to suit the occasion.

Devlin et al. (1997) wrote expected covariance formulas for different kinships. Each formula had a

genetic and an environmental component. The genetic part of their covariance formulas for dizygotic twins and sibs is $1/2 (1 + r\sigma_A^*) \sigma_A^2$. The genetic part of their parent-child covariance formula is $1/2 (1 + r) \sigma_A^2$. In these formulas, σ_A^2 is the additive variance of the trait, σ_A^* is its standardized additive variance, and r is the phenotypic coefficient of assortative mating. As stated earlier, in the absence of dominance these genetic parts should be equal. Therefore

$$(1 + r\sigma_A^*) \sigma_A^2 = (1 + r) \sigma_A^2 \quad (1)$$

Simplifying, $r\sigma_A^* = r$. This gives, $\sigma_A^* = 1$. But σ_A^* is always < 1 as it is the additive part of the phenotypic variance (except for the trivial case when only additive variance is present). These formulas are not correct. Similarly, their formulas expected covariances of dizygotic twins, siblings reared together, and siblings reared apart are not correct (Table 1, p. 469). Their model is, therefore, useless.

8. Statistics and Behavior Genetics

A recently borrowed concept from statistics is 'shared environment.' McGuffin et al. (2001) said that the second striking finding of behavior genetics is that the contribution of environment 'tends to be of the nonshared type, that is, environmental factors make people different from, rather than similar to, their relatives.' What is 'nonshared' environment? Neale and Cardon (1992, p. 15) said 'The environment between families is sometimes called the *shared environment*.' Thus, within family environment it is the 'nonshared environment.' Behavior geneticists in their analyses of variance of observed data may have found that, for some traits, within-family variance $>$ between-family variance. We do not believe that this justifies their claim.

A statistician working on a designed two-factor component of variance model will have three types of data; (a) observed values, (b) levels of factor I, and (c) levels of factor II. A behavior geneticist only has observed values from an observational study. He makes up for the lack of data (b) and (c) by calculating kinships covariances. He then equates calculated covariances to expected covariances, under assortative mating. His expected covariance formulas are invariably wrong. He then makes various claims which, in our view, cannot be justified.

9. High Heritability and Change in the Population Mean of a Trait

The concept of heritability is surrounded with many misconceptions. One such misconception is: if the heritability of a trait is high then environmental changes have little or no effect on its mean. When with high H^2 , the mean value of a trait changes appreciably,

some geneticists are at a loss to explain the change. For example, see Vogel and Motulsky's (1996, p. 239) discussion of the 'recent increase in stature.' There has also been a secular trend in IQ during since the 1970s. A secular trend in presence of high heritability deserves serious consideration. Fisher (1918) showed that a polygenic trait is normally distributed. The mean and variance of a normal distribution are, however, independent, that is, the factors which affect variance do not affect mean. Therefore, H^2 , the ratio of two variances, does not affect the mean. This is true in industrial production. We do not believe it is true for a genetic trait. The factors that contribute to H^2 , that is, genes, must also affect the mean of the trait. Genes, however, do not determine secular trend. We should, therefore, consider alternate explanations, for example, genes only provide possibilities; the trait has no genetic component; all genes for the trait are 'fixed,' therefore, the variance is due to 'environmental' factors, etc.

10. Can Genetic and Environmental Effects be Separated?

A designed statistical experiment could separate effects of factors on a disorder. Designed experiments are not possible on human beings. Moreover, we shall not be able to sample from all genotypes and all environments. In the absence of designed experiments, the genetic and environmental variances *cannot* be separated. Fisher (1918) did separate the genetic and environmental variances relating to height by assuming random environment. We do not believe that this assumption is viable. It is noteworthy that Fisher never really returned to the subject of this paper. Actually, the concept of 'evolution by adaptation' implies complex relationships between genotypes and environments. The history of human evolution may be divided into two periods: the first period when Homo Sapiens tried furiously to adapt to the then existing environment and the second, when they tried to control it. We are now far into the second period. We do not know the bygone environment to which our bodies adapted. We agree with Fisher (1930) that a species is defined only *in* an environment. Change this environment a little, the species will try to adapt. Change it too much and the species may not be defined. Therefore, research aimed at finding the genetic and environmental components of human behavior has no scientific content.

11. The Future?

McGuffin et al. (2001) envisage a new science of behavior genomics. We suspect that as the unscientific nature of behavior genetic analysis becomes known,

researchers will eschew heritability analysis. HGP has made the identification of a genetic disorder easier. If, for example, a large number of individuals suffering from a disorder have mutation at a locus as compared with the normal type, this provides some evidence of the genetic nature of the disorder. Heritability analysis is useless as it relates to a population and not an individual. To find remedies for genetic disorders, type I models are useful. Venter (2001, *The Independent*, February 12) succinctly summarizes our view when he says, HGP indicates 'to me that we are not hard wired. The idea that there is a simple deterministic explanation—that is: we are the sum total of our genes—makes me as a scientist, want to laugh and cry.'

Families and Households, Behavioral Demography of

The last half of the twentieth century has seen the study of household and family develop into a major subspeciality in demography, rivaling in scope and interest more traditional subfields, such as mortality–morbidity, fertility, migration, and urbanization. The study of households and families introduces a new order of complexity into demography since (a) the focus is now on a set of interrelated individuals rather than on the isolated individual or on a population aggregate described by summary measures, and (b) the balancing equations for these residential and kinship units involve several events other than those in the fundamental demographic equation (population change = births – deaths + in-migration – out-migration). Changes in households and families must be related also to marriage, cohabitation, divorce, separation, home-leaving of young adults, as well as other forms of exit and entrance to the group (e.g., the entry of an elderly parent or some other relative). The household may be viewed as a resultant of many individual behaviors.

There are more fundamental complications relating to household and family identity: it is clear when a particular individual begins (birth) and ceases to exist (death), and there is individual continuity over the lifetime. By contrast, it often is not at all clear when a particular household or family begins or ends. Households, unlike individuals, can split apart into two or more smaller households (fission), or can merge to form larger and more complex units (fusion). This fundamental problem has been not solved so much as finessed by extensive data-collection and analysis of *individuals in terms of their family and household statuses and the events changing their statuses*.

But progress has been considerable, particularly with the advent of large-scale social surveys containing event and status history data on marriage, family, and household (individual event-histories are much more common than histories of households or families).

These data have allowed the description and analysis of individual family life-histories and changing household statuses, based on real cohort data. These newer studies stand in contrast to the synthetic approach of the original 'family life-cycle' studies, based on census data (cross-sectional) and sometimes misleading. Recent work has documented a proliferation of family and household behavioral sequences, overturning the stereotypical view of the 'family life-cycle,' based on averages or medians (a development anticipated by Höhn 1987).

Another important breakthrough is the work of Zeng et al. (1997), who have developed accounting equations for a number of specific family household types, equations that can be applied using routine census and vital registration data. The model produces detailed household projections by size and type of household that are consistent with population projections by age, sex, and marital status.

Review articles and summary volumes on the demographic approach to households include: Burch (1979), Bongaarts (1983), Bongaarts et al. (1987), Keilman et al. (1988) and van Imhoff et al. (1995). Work in behavioral household demography, of course, has not occurred in disciplinary isolation, and should be viewed in the context of parallel or overlapping efforts in family sociology, household economics, anthropology, and demographic history.

1. The Definition of 'Household'

The central idea of the household concept is that of *coresidence*: a household is a group of persons who 'live-together' day-to-day, or an individual 'living alone.' In demographic usage, the operational definition of this concept has tended to follow census practice, with households defined in terms of persons occupying a separate housing or dwelling unit (house or apartment), or, less often, the persons who participate in a common domestic economy. The housing unit approach provided a convenient basis for census enumeration (first identify housing units and then enumerate the people usually residing in each), and later, for modern large-scale sample surveys.

1.1 Households and Families

Whereas the *household* is defined in terms of *coresidence*, the *family* is defined in terms of *kinship*, which in turn is based on marriage, descent from a common ancestor, or social fiction (adoption or other forms of 'fictive kinship'). Ryder (1987) has aptly termed these, respectively, the residential, the conjugal, and the consanguineal dimensions of intimate relationships among individuals (see also van Imhoff

et al. 1995). This distinction is not always made in everyday language, however, and the concepts and reality overlap: a household consisting of persons related by kinship is also a family, but such a household seldom contains all of an individual's close kin, the so-called 'extended family.' Modern census practice often used the term *family* to refer to a group of related persons living together (more properly called a *census family*), a usage encouraged by and reinforcing a Western cultural tendency to view the small, nuclear family group as 'the family'—other kin are 'relatives.' Historical and comparative studies of household and family have forced a clarification and refinement of census concepts to take into account the greater complexity of household and family patterns, as have more recent developments such as cohabitation or the joint custody (and split coresidence) of children following divorce. In general, the single word *family* is ambiguous, and should always be related to context, and qualified as necessary with such terms as *nuclear*, *extended*, *census*, *economic*, etc.

1.2 Large Households

The majority of households are relatively small, consisting of groups such as a couple and their children, a small group of students sharing an apartment, or an individual living alone. Such households often are referred to as *private households* in contrast to *institutional households* such as boarding schools, prisons, chronic-care hospitals, mental institutions, convents, or seminaries. There is no inherent limit to the size of private households, but their average size seldom exceeds six, and in urban-industrial societies is closer to three.

In modern census practice, private households can contain boarders, lodgers, or servants, but an arbitrary numerical limit on such members is set, beyond which the household is considered institutional.

1.3 Limitations and Criticisms

The modern household concept does not deal easily with social realities such as residential *compounds*, clusterings of separate but closely related (in terms of kinship or economic activity) households, often physically distinct, occupying a separate farm or walled or fenced space. An example from a polygamous society would be the compound containing a man and his several wives and children, the latter occupying separate huts and eating separately. Laslett (1982) has suggested the term *houseful* for European cases where several smaller nuclear families (some related, some agricultural workers or servants) occupied a well-defined farmstead.

In contemporary urban societies, census practice reveals virtually nothing about relationships among separate households even when such relationships are frequent and close. For example, an older couple and two grown children, all occupying separate apartments in the same neighborhood, or even the same building, would be reckoned simply as three households, with no census item even hinting at their close ties. Relationships are counted within but not across households. It is of interest that this census practice was codified around the middle of the twentieth century, at a time when social scientists, especially family sociologists, were emphasizing (in retrospect exaggerating) the isolation of the nuclear family in modern urban societies. These limitations of the census have been rectified in part by large social surveys including information on numbers and types of kin, on kin location, and on kin interaction.

A related problem has been noted with use of the phrase *living alone* to refer to one-person households. Accurate enough in terms of census housing-unit concepts, its connotations can be misleading with respect to the degree of social integration or isolation of the occupants.

These and other concerns have led some to more or less reject the household concept as ethnocentric or culture-bound, and too limited, artificial, and abstract. But an increasingly popular view of scientific methodology (see, e.g., Giere 1999) reminds us that all scientific concepts (models, theories) are abstract—therefore, limited and artificial—and are better judged in terms of their analytic usefulness for the study of particular problems. The household clearly is the relevant unit for much consumer behavior (from buying a house or renting an apartment to routine purchases of food or clothing), demographic decision making (e.g., migration), and much of our day-to-day intimate social interaction and support, including the intimacy of couples and the continuing care of infants and young children. Thus, housing analysts and planners still are major users of household projections, as opposed to ordinary population projections. And the household remains a major focus for family sociology and for microeconomics (notably the Chicago school of the ‘new household economics’), even as they have broadened their view to encompass such economic realities as intergenerational transfers and such psychological realities as ‘altruism.’

Even so, the household concept needs refinement and extension to take more account of the fluidity of household membership and its ‘fuzziness,’ as more persons can realistically claim membership in two households: children in joint custody arrangements, ‘commuter marriages,’ Caribbean-style ‘visiting relationships,’ and ownership of second homes. Residence will increasingly be seen as a multidimensional concept, with different households fulfilling different household functions for the same individual. The census convention of a one-to-one correspondence

between individuals and households will not be abandoned entirely, but formal and behavioral demographic analysis will of necessity go beyond it.

2. Late Twentieth-century Trends and their Demographic Determinants

The generalization is sometimes advanced that twentieth-century households have tended to become smaller and less complex. The generalization regarding size almost certainly is valid, that regarding complexity less clearly so. Households have tended to become smaller in large measure because on average they contain fewer minor children, consequent to widespread fertility decline. If the total fertility rate is two or below, the typical nuclear family household (husband, wife and own children) will contain three or four members or fewer. Only populations that retain traditional high fertility levels, and perhaps other features of traditional family structure, still report average household sizes of five or six persons and above.

Other factors are at work. In highly urban-industrial populations, smaller average households also have resulted from such factors as the rise of independent living of women (lone mothers, earlier home-leaving of women) and the elderly (widows and widowers), and the splitting of households following divorce. Also relevant in some societies has been the decline of live-in servants and of boarders or roomers. But these latter trends, unlike fertility decline, differ considerably across societies, depending on cultural traditions relating to coresidence with nonnuclear kin. In Japan, for example, the norm requiring taking in elderly parents remains strong. In Italy, adult children tend to remain in the parental home until marriage. Paradoxically, these familistic patterns are facilitated by low fertility, with a small nuclear family leaving space for young adults and elderly who might otherwise be crowded out. Mitchell et al. (1989), for example, show that in Canada number of siblings is an important determinant of age at leaving the parental home. These examples underline the point that household-formation behaviors feed back on one another.

In many western societies, rising rates of divorce and of nonmarital cohabitation have led to considerable fluidity in household formation, particularly among young adults and among older persons following divorce or widow(er)hood. Looking to the future, one might anticipate even greater flexibility in household arrangements, including among the elderly, as individuals develop broader repertoires of behavior based on early experience as children and young adults.

The older stereotype identifying large households with complex households of extended kin must give way to the view that smaller households can also be more rather than less complex, given greater degrees

of freedom to add members due to reduced domestic demands of smaller numbers of minor children. Like many other demographic behaviors, household formation and dissolution now show more heterogeneity in most dimensions except size.

In most societies, coresidence of kin has been lessened by high rates of migration, and the consequent location of kin in different, sometimes distant, communities. In urban-industrial societies, this includes urban-to-urban labor migration as well as retirement-related migration of the elderly. In developing societies, a major factor is rural-urban migration and, in some cases, high rates of overseas migration. Kinship contacts persist, but they are attenuated by distance.

3. Behavioral Theories of Household Dynamics

As with other demographic behaviors, explanation of household dynamics must be partly formal, partly behavioral. But unlike other demographic behaviors, accession to or relinquishment of a household status is not a unitary behavior. In traditional terms, an individual may become a household 'head' by setting up his or her own household, by being widowed or divorced, by the departure of one's last child (if already widowed or divorced), and so forth. It is this fact that has made the fitting of so-called 'household headship' curves relatively intractable: they are the resultant of too many different behaviours (Corner 1987). A theory of household formation must, therefore, in some sense be a theory of marriage, divorce, fertility, mortality, home-leaving, etc.—all combined in some meaningful way.

3.1 Microeconomic Theories of Household Formation

In this field, as in demography generally, economics has had considerable theoretical influence, notably from the works of the 'Chicago School' and from empirical studies of household formation, especially the rise of one-person households. Becker (1981) viewed marriage and household formation in terms of a traditional sexual division of labor, with husband and wife coming together for practical economic advantage in a 'household economy.' Women tended to remain in the home performing domestic tasks, while men entered the labor market for wages, both pursuing comparative advantages associated with differential earning potential. Davis (1984) called this arrangement the 'breadwinner' system, and associates it with the Victorian era. Prior to that, on family farms or in small enterprises, both husband and wife worked to support the family economically.

Clearly, such a system no longer prevails in Western urban-industrial societies, as women have entered the

labor market in force, pursuing careers throughout their adult lifetimes. In some contexts and especially among young adults, women often appear to have the advantage in terms of employment and income, as work requiring physical strength has declined in importance. Women are not as dependent as formerly on men for their economic well-being, and are more able to establish their own households. At the same time, the costs of maintaining desired levels of consumption have risen, so that having more than one wage-earner per household is advantageous. Thus, both members of a couple are apt to work, bringing in more income but foregoing the real economic advantages of Becker's household division of labor, even if not along traditional lines. There still are economic rationales for marriage and coresidence, but they are somewhat different than in earlier times.

A central notion in economic analysis of the household is that there are economies of scale to be gained by coresidence—in the provision of housing, utilities (heat, lighting, etc.), food and meal preparation, and consumer durables such as stoves, refrigerators, or automobiles. A *leitmotiv* in the economic literature on households is that rising levels of living have led to the purchase of greater privacy and independence, with a sacrifice of economies of scale associated with the sharing of living quarters.

In their influential article (*Privacy, Poverty and Old Age*, Beresford & Rivlin (1966)) began a research tradition of empirical research on 'living alone' in one-person households. The aim was to explain the rise in the 'propensity' to live alone, that is, the rise in age-sex-marital status specific rates of living alone, notably among older women and young adults of both sexes. The central explanatory idea was that high real income was being used to purchase more household 'privacy,' viewed as a luxury in the technical economic sense, but a luxury that had always been desired. In keeping with the tenor of economic thinking of the times, any possible shift in 'tastes' or values relating to household arrangements was played down.

Further research tended to qualify a pure 'income' explanation. Clearly, individuals would not live alone if they literally couldn't afford it. But older women, for example, lived alone in greater numbers partly due to new social programs (social security, government pensions, old-age assistance), created in response to demand or felt need, based in turn on new ideas about individual independence. The larger explanation was social and political as well as economic. Similarly, among young adults, the pursuit of independence from parents often has been intense, with youth leaving affluent homes to live in relative squalor, a pattern documented in path-breaking research based on the Survey of Labor and Income Dynamics (SLID), one of the first major longitudinal surveys (Hill & Hill 1976).

Many of these household dynamics can be related to a general breakdown of traditional patterns of age-sex

stratification (the 'decline of the patriarchy'), in the family as well as society at large. Women, older persons, children, and young adults have sought and been accorded rights and perquisites formerly reserved to the middle-aged male. This has led to greater competition *within* households for scarce household goods such as personal space, quiet, privacy, and freedom of movement (Burch 1985).

In the West, these developments clearly are bound up with a strong cultural strain towards individualism and with its full expression in situations of affluence. Whether others societies will follow is unclear (McDonald 1992). Similarly, in the absence of affluence individualism may be sacrificed, as coresidence is sought for economic reasons—the *estrategias de sobrevivencia* emphasised by the Latin American social demographic school.

In addition to economic and cultural factors, early research by Sweet (1977) and by Kobrin (1976) focused attention on a demographic supply factor in the choice of household statuses: to the extent that coresidence continued to be seen as a family matter, even an act of relative intimacy, one's options for coresidence were limited by the number and availability of suitable kin. Sweet succinctly noted that an older widow cannot live with a child if she has no living children.

3.2 Demographic Theories of Household Formation

Ermisch (1988) has developed and empirically tested what might be called a two-part model of household formation, one in which 'demographic influences on household formation and composition can be separated from their economic influences ...' (p. 24). In this approach, demographic events of marriage, birth, death, and home-leaving lead to the formation of 'minimal household units' (childless unmarried adults, lone parents with children, childless married couples, married couples with children). These 'minimal household units' then distribute themselves into distinct household arrangements in response to socioeconomic factors. The model is not meant to imply that household formation literally occurs in two temporally ordered stages, but is seen only as an analytic convenience.

Burch & Matthews (1987) have proposed a decision-making model that is nearly the opposite of Ermisch's—with couples or individuals giving priority to a choice of household living arrangement, and then deciding on demographic behaviors (marriage, fertility, etc.) accordingly.

Only detailed descriptions of decision-making processes over individual life courses would clarify the order of demographic and household decision-making in reality. Until now, adequate survey data are limited to events, not the decision processes that underlie them. And, of course, some changes in household status are not chosen by the individual: spouses or

partners die or separate; grown-up children leave home; circumstances dictate taking in an elderly parent. The question then is one of inertia v. choice of a different arrangement.

Whether an integrated theory of household dynamics is possible is a moot question. But some contemporary philosophers of science (Giere 1999) would urge us not to worry on that score. Theory is seen as consisting of a large collection of theoretical models pertaining to the household, some useful for some analyses, others useful for others—theory as a toolkit, rather than as 'truth.' And the household dynamics literature is now rich with such tools.

3.3 Household Formation and 'Social Capital'

Since the 1960s, theories of demographic behavior have been subject to strong—some would say excessive—influences from neoclassical microeconomics, with various demographic choices viewed as resulting from rational and forward-looking individual assessments of costs and benefits ('lifetime utilities'). Sociologists and psychologists, among others, have objected that the economic perspective provides a narrow and unbalanced view of human behavior and social structure, and have tried to extend the core microeconomic model to deal with human realities such as emotions, social norms, and social and cultural systems (leading economists of demographic behavior also attempted such broadening, as in Becker's concern with altruism, or Easterlin's with 'psychic costs' of fertility control). A recent attempt has been the introduction into the study of fertility of concepts of 'social interaction,' 'social influence,' and 'diffusion' (Bongaarts & Watkins 1996, Montgomery & Casterline 1996).

But there have been few efforts (and no successes) at constructing a theoretical scheme that does not retain microeconomic ideas at its core—perhaps a reflection that when all is said and done, a good deal of human behavior and social structure is at base purposive and rational. Clearly this is the case with households, which serve a number of purely utilitarian functions: provision of shelter, heat, physical security, sleep; storage of personal property; and the purchase, preparation, and consumption of food. But households also meet nonmaterial needs, as the locus of various forms of companionship and intimacy, social support, and the formation of 'social capital.'

A programmatic article on this concept by Astone et al. (1999) seems destined to shape behavioral research in household demography for some time to come. These authors call for a reorientation of family and household demography around the concept of *social capital*—defined as resources of an individual that derive from his or her social ties (p. 2)—with that concept reinserted into the context of social exchange theory, from which it emerged. 'The formation of sexual partnerships, the birth and rearing of children, and both intra-generational and inter-generational

transfers constitute major forms of investment in social capital in virtually all societies' (Astone et al. 1999, p. 203). Clearly, their concern is with both households and families (including extended kinship networks) as these have been defined earlier.

This perspective raises a number of interesting questions regarding contemporary household patterns in urban-industrial societies' in general whether they have moved too far in the direction of solitary living—what Kuznets (1978) referred to as 'the apartness of adults,' with associated sacrifices of both economic and social-psychological benefits of coresidence. More specific questions might include the following: Do persons in one-person households suffer from a lack of enduring social ties, or are the four walls of a house or apartment relatively unimportant as social boundaries? Do children suffer from growing up in households with only two adults, as compared with those containing aunts or uncles, or grandparents—do they grow up with a more limited repertoire of behaviors; or, are the limitations of the household offset by increased social interaction with adults at 'daycare.' Are households in which one member of a couple (whether a woman or a man) remains at home performing 'domestic' tasks better off in terms of 'social capital' formation even if household income is lower?

The study of these and other questions pertaining to household and family structure might be strengthened by focus on issues widely viewed as 'social problems.' That is, the development of household and family demography might benefit not just from theoretical reorientation as suggested by Astone et al. (1999) but also by greater attention to real-world social problems.

Families and Households, Formal Demography of

‘Family and household demography’ differs from traditional demography in that it explicitly recognizes and studies *relationships between individuals*. In traditional demography, the core processes of birth, death, marriage, divorce, and migration are typically studied as occurring to individuals in isolation. In contrast, family and household demography studies how these processes occur to multiple persons interacting with each other. In doing so, additional relevant processes like entering or leaving co-residence are also studied. In short, relationships between individuals are the central focus of family and household demography. This article outlines the main subfields within the broad area of family and household demography, as well as the most important formal concepts.

1. Classification by Subject Matter

Three types of relationships between individuals can be distinguished (Ryder 1987):

- (a) *Consanguineal* relationships run via the fundamental parent–child relation. Any two persons sharing a common ancestor, i.e., linked by a sequence of birth events, are said to be related by blood.
- (b) *Co-residence* relationships are between persons living together. A foolproof definition of co-residence does not exist (think, for instance, of student housing, lodgers, or part-time households), but ‘sharing roof and manger’ is not bad for a start.
- (c) *Conjugal* relationships are between individuals who are married to each other. In fact, living together in marriage is a special form of co-residence. To many people, the bond of marriage is so special that it is (almost or fully) put on the same footing as the consanguineal bonds mentioned under (a). In modern societies, the traditional marriage is gradually replaced by cohabitation (consensual unions). In these societies, ‘being married’ is more and more replaced by the more neutral ‘living together as a couple,’ which includes both formal marriages and consensual unions, and frequently also includes homosexual cohabitation. The United Nations. Statistical Division (1998) ex-

plicitly recommends: ‘Couples living in consensual unions should be regarded as married couples’ (p. 67).

The broad field of family and household demography studies all these links between individuals, in their own right but also in relation to other demographic processes (e.g., migration of household, mortality patterns in kin groups). Within the broad field, several subfields can be identified, according to the type of relationship on which they concentrate:

- (a) *Demography of kinship* studies links of type (a) and (c).
- (b) *Demography of households* studies links of type (b), but also of type (c) since ‘living together as a couple’ is a special form of ‘living together’ (see also *Families and Households, Behavioral Demography of*).
- (c) *Demography of the family* studies the simultaneous links of type (a) and (c), on the one hand, and of type (b), on the other: a family is a group of co-resident kin.
- (d) *Demography of marriage* studies links of type (c).

2. Data Issues

The data sources for household and family demography are the same as for demography in general: censuses, population registers, surveys (in kinship studies, genealogies are also sometimes used). However, *definitional problems* are particularly strong in household and family data.

There are two sets of definitional problems. The first relates to criteria for establishing *whether or not a certain relationship exists* between two persons. Examples of such problems include:

- (a) Two persons (e.g., a mother and a student child) live together during weekends only. Do they belong to the same household?
- (b) Two persons form a household. How to judge whether they ‘live together as a couple’?
- (c) Two students live in an apartment, occupying separate rooms but sharing kitchen and bathroom. Do they count as one or as two households?

The second group of definitional problems relates to criteria for *classifying households and/or family into categories*, like those used in published household statistics. Examples include:

- (a) A woman lives with her 30-year old son. Should this household be termed a lone-parent household?
- (b) A lone mother cohabits with a new partner. Is this a ‘couple with children’ household, or rather a ‘one-parent family plus other(s)’?

Such definitional degrees of freedom result in actual definitional differences, the consequences of which are potentially very large (Keilman 1995). Therefore, demographers must be well aware of the precise definitions underlying their household and family data. In descriptive studies, definitional differences can seriously distort international or intertemporal

comparisons. In modeling exercises, it is crucial that model parameters are derived from data that are definitionally consistent with the variables in the model. In order to stimulate international comparability of household and family data, the United Nations has specified detailed, extremely useful recommendations for data collection, definition, and tabulation in population and household censuses (United Nations, Statistics Division 1998).

3. Unit of Analysis

A major problem in the formal demography of families and households is whether the group or the individual should be taken as the primary unit of analysis. Almost by definition, the behavior of the individuals within the group are highly interdependent. Therefore, analyzing the behavior of the group cannot be done without proper account of the characteristics of its members; conversely, analyzing the behavior of the individual cannot be done without proper account of the characteristics of the group (including those of the other individuals in the group).

Today, most family and household demographers agree that it is most convenient to work at the level of *individuals*. The main reason for this is that, unlike individuals, groups do not have a clearly defined origin and destination in time since members can enter and leave all the time. Thus, modern practice is to define a group in terms of its members and the relationships between them, rather than defining individuals in terms of the group to which they belong.

Because of strong interdependence of within-group behavior, proper modeling of individual family or household members' behavior requires sufficient information on the characteristics of the other individuals involved. In microlevel data, this implies the inclusion of *pointers* or reference variables to other individuals in the dataset, with sufficient detail on the type of the relationship to that other individual. A main advantage of such data is that it can provide very rich descriptive information on different family and household types, as opposed to standard census breakdowns by just a few main categories.

Naturally, when using sample survey data, proper account should be given to the representativeness of the data at different units of analysis. For example, a random sample of individuals is *not* representative at the household level, since large households will be over-represented. Weighting schemes must be used to correct this and other potential distortions.

4. Models in Family and Household Demography

A model is a simplified, quantitative description of reality. In family and household demography, models provide a formal description of the quantitative relationships between family or household charac-

teristics and their demographic determinants and consequences (Bongaarts 1983).

At the heart of any modeling exercise lies the specification of the *state space*: the representation of the components of the system of interest. At the level of the *individual*, the state space consists of a number of characteristics or attributes (e.g., age, sex, position in the household, age of spouse, number of children), each of which can take a certain value. At the population level, the state space consists of all possible combinations of attribute values: it is a breakdown of all individuals comprising the population by relevant characteristics.

The ultimate purpose of model building is to obtain an understanding about this multidimensional breakdown of the total population. A classical demographer is satisfied with a breakdown by age and sex. A marriage demographer would want to add at least 'marital status' as an additional variable. A kinship demographer would want to add a complete breakdown by number of living children, grandchildren, siblings, parents, and so on. A household demographer would want to have, next to age and sex, variables like household size and household type, in a classification that is sufficiently detailed for the research or policy problem at hand. All these demographers have in common that they want to understand why an observed population breakdown is how it is; how particular changes in behavior (for example, total fertility level) would change this breakdown; or how the currently observed breakdown will develop over time (forecasting).

The particular problem in household and family models is that the relevant state space is potentially very large and complicated. This has forced family and household demographers to sacrifice all kinds of descriptive, behavioral, and/or conceptual detail. Evidently, the result is that existing household and family models reflect a wide range of different modeling strategies. Three important classes of these strategies are discussed in the sections below.

4.1 Severing the Link

As said before, family and household demography is all about relationships between individuals. A particularly important type of 'sacrifice' frequently made by family and household demographers is to discard most of the information on the characteristics of the individuals *with whom* a particular relationship exists. For example, in the case of a marriage model, a woman aged 40 and married to a man aged 42 is classified as being a married woman aged 40: the information about the age of the husband is discarded. Without discarding, the total population would require a table of $2 \times 100 \times (1 + 100) = 20,200$ cells (2 sexes, 100 age groups, 1 for nonmarried, 100 for married by age of spouse); with discarding, a table of $2 \times 2 \times 100 = 400$ cells is sufficient (2 sexes, 2 for

nonmarried vs. married, 100 age groups). In other words, a frequently used modeling strategy is to collapse all information on all individuals to whom person x has relevant relationships into just a few attributes of person x , thus in fact ‘severing’ the explicit link to those related individuals.

An example of this ‘severing the link’ strategy is provided by marital-status models of the multistate type (see *Multistate Transition Models in Demography*). Here, individuals are classified by sex s (m for men, f for women), age x , and marital status i , where i can take the following values: N for never married, M for married, D for divorced, W for widowed. The development over time of the population is described in terms of *events*, which are changes in the attributes of the individual members of the population. For example, next year’s 31-year old married female population is given by (ignoring migration):

$$\begin{aligned} P(f, 31, M, t+1) = & P(f, 30, M, t) \\ & + E(f, 30, N, M, t) + E(f, 30, D, M, t) \\ & + E(f, 30, W, M, t) - E(f, 30, M, D, t) \\ & - E(f, 30, M, W, t) - E(f, 30, M, \text{dead}, t) \end{aligned}$$

where $P(s, x, i, t)$ denotes the population at the start of year t of sex s , age x , in marital status i , and $E(s, x, i, j, t)$ denotes the number of individuals of sex s and age x who during year t experience an event from position i to position j . The various numbers of events depend on the size of the relevant population at risk of experiencing the event, and on the rate at which individuals in the population at risk experience the event. For example, the number of women who marry for the first time at age 30 in year t , i.e., $E(f, 30, N, M, t)$, equals the product of two factors: the number of never-married 30-year old women $P(f, 30, N, t)$, and the first-marriage rate for 30-year old women $M(f, 30, N, M, t)$.

Given a full set of age-, sex-, origin-, and destination-specific rates, the population by age, sex, and marital status can be projected forward in age and time. Also, a marital-status life table can be calculated. However, a crucial characteristic of this model is that marital-status events for one sex are essentially independent of the demographic situation for the other sex. As a result, in this model it is not guaranteed that the resulting population flows for men and women will be mutually consistent. For example, the number of married men having a divorce should equal the number of married women having a divorce, but there is no mechanism in the model to ensure this equality. This problem is known as the *two-sex problem* in nuptiality models (Keilman 1985a). It is a direct consequence of the fact that the explicit link between marriage partners is missing. There are several solutions to the two-sex problem, each of which introduces fresh problems:

(a) To restore the link between marriage partners. This greatly expands the state space, since married

persons must be simultaneously classified by own age *and* by the age of their spouse. It also greatly complicates the modeling of numbers of events, since rates must be defined for all combinations of male *and* female ages and marital statuses (see also *Population Dynamics: Two-sex Demographic Models*).

(b) A slightly different way of restoring the link between marriage partners is to recast the model in terms of *microsimulation*. See Sect. 4.2.

(c) To concentrate on one sex (usually: women) only. This is convenient, but obviously unrealistic.

(d) To introduce an adjustment mechanism, by which aggregate numbers of events (i.e., aggregated over all ages) are forced to satisfy certain requirements. For example, if the model initially produces 1,000 male divorces and 800 female divorces, male divorces are adjusted downward and female divorces upward to result in, say, 900 divorces for each sex. Such procedures are called *consistency algorithms* (Keilman 1985b, Van Imhoff 1992). Although such algorithms can be given a satisfactory behavioral interpretation, they nevertheless have an artificial ring and are certainly rough approximations only.

(e) A combination of the previous two ‘solutions’ leads to consistency algorithms that are one-sex dominant. For example, in a female-dominant marital status model, the total number of male divorces is determined by the female married population and female divorce rates.

Marital status models are by no means the only models in which ‘severing the link’ leads to consistency problems. All household and family models which are of the multistate type suffer from essentially the same problem.

4.2 Macro- vs. Micromodels

In principle, an algebraic representation of a model can be manipulated to study the model’s properties. If the model is not too complicated, it could be analyzed in this way. Because family and household models easily get quite complex, analytic models are rare in family and household demography. A good example of an analytic model (although valid under a number of quite restrictive assumptions only) is the kinship model of Pullum (1982).

For more complex models, analytic manipulation becomes infeasible, so that *numerical simulation* methods have to be used to study the implications of the model. Here, two fundamentally different strategies can be distinguished: *macrosimulation* vs. *microsimulation* (Van Imhoff and Post 1998; see also *Microsimulation in Demographic Research*).

In macromodels, numbers of events (e.g., ‘first marriages to women aged 25’) are obtained by applying rates (e.g., ‘first-marriage rate for 25-year old women’) to a *group* of individuals of a certain size (e.g., ‘number of never-married women aged 25’). In

micromodels, events are obtained by applying probabilistic decision rules (Monte Carlo experiments) to *individual persons*, separately for a number of individual persons. To follow the example of first marriages: for each individual never-married woman aged 25 in the database, draw a random number between 0 and 1; if this random number is less than the first-marriage probability, the woman is deemed to marry, otherwise she remains unmarried.

In macrosimulation, the calculations are carried out in terms of the cells in the aggregate cross-classification table: for each cell, the model should evaluate how the number it contains will change over time. Microsimulation, on the other hand, does its calculations in terms of the individual records: for each individual, the attribute vector is updated according to the specifications of the model and the results of the Monte Carlo experiments. The storage and retention of information in microsimulation occurs via a *list* of individuals and their attributes; in macrosimulation this is done via the aggregate cross-classification *table*. If there are K attributes and M_i categories for attribute $i = 1 \dots K$, the table at the macrolevel consists of $M_1 \times M_2 \times \dots \times M_K$ cells; in contrast, at the microlevel a total population of N individuals can be described by a matrix with $N \times K$ cells. For most applications where a relatively large number of attributes is considered, the size of the aggregate table is much larger than the size of the list. This is particularly the case in household and family models, where characteristics of the individuals to whom relationships exist need to be included. In macromodels this would lead to incredibly large tables.

In micromodels, contrary to macromodels, it is quite easy to keep links between individuals intact, simply by including in the individual records of the database some reference numbers (pointers) to other records (persons) in the database. As a result, the consequences of an event that is simulated for one person can be easily determined and updated for the other persons involved. Thus, the two-sex problem or more generally the consistency problem discussed in the previous section is more or less 'automatically' solved in micromodels. The other side of the coin is that, for events that involve creating a *new* link between individuals, a matching problem has to be solved (e.g., if a woman is simulated to marry, a concrete husband must be identified).

Another main advantage of microsimulation is that it can provide very *rich output*. The output of a microsimulation model consists of a database with individual data that can be aggregated in an almost infinite number of ways. Compare this with the situation in macromodels, where the aggregation scheme is fixed once the model (i.e., the state space) has been specified. Apart from detailed cross-sectional counts, the microsimulation database can also be used to construct longitudinal information, e.g., in the form of individual biographies.

In short, microsimulation offers three main advantages that are of particular relevance in family and household demography: it can handle a large state space; relationships between individuals can easily and explicitly be retained; and it provides richer output.

This does not automatically imply that microsimulation is the ideal methodology for family and household modeling. As always, these advantages are bought at a cost, and the cost can be heavy. The most important drawbacks of microsimulation are twofold: first, the model results are subject to random variation, and the degree of this randomness gets larger as more explanatory variables are included; second, it takes a lot of time and effort to construct a concrete microsimulation application.

4.3 Dynamic vs. Static Models

Populations change over time, and so do household and family structures. Thus, if a model is to describe this change, it must always contain the *time* element in one way or another. In this sense, all demographic models are dynamic by definition. However, there are many ways in which time can be included into a model. Merely adding an index t to all model variables and parameters hardly warrants the term 'dynamic.' A truly dynamic model should not only specify what the system looks like 10 years from now, but also how the system is supposed to get from here to there. In other words, the *processes* that underlie the changes in the system variables should be explicitly included in the model. In a truly dynamic model, the focus is on the *events* of formation and dissolution of relationships between individuals. The LIPRO household model belongs to this category (Van Imhoff and Keilman 1991, Van Imhoff 1995).

In contrast, *static* models do little more than compare household and family structures at different points in time, thus essentially treating the underlying processes of household and family formation and dissolution as a black box. The classical headship ratio models belong to this category. The headship ratio is the proportion of household heads in a population category, e.g., '80 percent of all 40-year old males are head of a household.' If from a population forecast (see *Population Forecasts*) we know that the number of 40-year old males will increase from 1,000 to 1,500, and we extrapolate that the headship ratio for 40-year old males will increase from 80 percent to 90 percent, then it follows that the number of households headed by a 40-year old male will increase from 800 to 1,350. With headship ratios for all ages and both sexes, a full population forecast can in this way be easily converted into a forecast of the number of (private) households. Several generalizations of the classical headship ratio model exist (Kono 1987). However, they all suffer from the disadvantage that the headship ratio is a static concept: the model cannot tell us why the current ratio of 80 percent will increase to 90 percent.

In a way, the dynamic vs. static issue is gradual rather than fundamental. For instance, if a demographic forecaster hypothesizes that marriage rates will fall by 10 percent between now and 10 years into the future, one could argue that the marriage component of the model is static since the demographic forecaster does not specify *how* the marriage rates are going to fall. Similarly, the headship ratio method is generally termed static since the changes in age-specific headship are not explicitly specified; however, the changes in the age-specific population size to which these headship ratios are applied *are* explicitly modeled, so the headship ratio model is dynamic at least to some extent.

In fact, leaving some model variables static rather than 'truly' dynamic is an effective strategy to reduce the complexity of the model. The decision of where to stop making variables dynamic is governed by the fundamental tradeoff between information intensity on the one hand, and the capacity to make meaningful predictions on the other. This tradeoff must be faced in every effort of modeling human behavior.

The household model used by Statistics Netherlands for its official household forecasts for The Netherlands is a nice example of a carefully constructed mixed dynamic-static household model (De Beer 1995). This model consists of two layers. The first layer is a multistate marital status model, producing forecasts of the population by age, sex, and marital status. In the second layer, each combination of age, sex, and marital status is distributed over various *household positions* (e.g., living alone, with partner, as lone parent, as dependent child, etc.), using household position proportions which are extrapolated into the future. The rationale for this strategy is that the available statistical data are sufficiently reliable to allow a dynamic approach to nuptiality, but do not warrant a dynamic treatment of household formation and dissolution. The resulting model is dynamic to the extent that household events are related to nuptiality behavior.

Families as Educational Settings

1. Introduction

Children's education is viewed here in broad terms, reflecting not only academic standing in the formal setting of school, but also general cognitive development. In that vein, family influences on children's educational progress are myriad, as family provides the primary context for children's development and also reflects the broader societal and cultural contexts within which the family is embedded. Both change and continuity in family influences are noted during infancy, early childhood, and the school years.

2. Early Research

Much of the early research in family influences on children's educational progress examined ways in which academic outcomes were related to demo-

graphic characteristics such as parent marital status and education, ethnicity, birth order, and socioeconomic status. This early work revealed consistent, moderate relationships between most of these factors and children's cognitive development. In particular, more positive educational outcomes were found in families where the parents' marriage remained intact, where parents were better educated and had higher income, and for children who were first- rather than later-born. Psychologists and educators have noted that such group comparisons, which have been labeled 'social address' (Bronfenbrenner 1979), are less informative than research which identifies the processes underlying these group differences. Four categories of process variables are summarized here: parental beliefs, instruction from parents and siblings, structuring of the home environment and family life, and parents' behaviors outside the home.

3. Parental Beliefs

Parents' beliefs affect children's educational outcomes both through their influences on parental behaviors and on children's developing beliefs. For instance, a parent will speak to her 6-month-old daughter more often if she believes the infant can benefit from 'conversations' with an adult partner. Parents' beliefs also shape the developing beliefs of their children, many of which serve a motivational role for the child. For instance, a child whose father conveys that a failure was due to lack of effort rather than lack of ability will be more likely to persevere on a future task. Three types of parental beliefs are described here: parents' educational aspirations for their children, attributional beliefs about the reasons underlying academic outcomes, and beliefs about child rearing.

3.1 Parents' Educational Aspirations

Most parents have expectations for their children's performance in school and eventual educational attainment. Both aspirations regarding the child's future education level and projections of what specific grades a child will obtain are frequently highly optimistic. Thus, for instance, many parents who themselves have failed to complete high school expect that their own children will be college graduates.

It is clear that children's competencies inspire parents' aspirations (i.e., parents have higher expectations of more competent children). In general, the research literature also indicates an independent effect of parent expectations on children's achievement: Parents with more ambitious aspirations have, on average, children who excel academically and who are more likely than other children to pursue higher education (e.g., Okagaki and Frensch 1998). Parents who value education and who have high aspirations

for their children are likely to foster achievement striving in their children and to provide a supportive learning environment in the home. Another way in which high parental expectations foster children's educational development is through the degree of challenge parents provide in learning situations.

3.2 Parents' Attributional Beliefs

The classic work of Rotter (1966) and Weiner (1979) demonstrated that individuals vary in their beliefs about the reasons underlying success and failure, and that future performance is related to these beliefs. When failure is attributed to an internal controllable factor such as effort, the individual is more likely to persist than if the failure is attributed to lack of ability or an external factor such as teacher preference or luck. Conversely, a belief that success is due to the internal factors of high ability and hard work is likely to foster persistence. Attributional beliefs are thus posited to influence children's outcomes largely through their motivational effect on children's persistence in the face of failure and/or challenging tasks.

Much of the research in parents' attributions has entailed cross-cultural investigations of ethnic or national differences in children's academic achievement. This work shows that Asian parents are more likely to attribute their children's academic outcomes to effort than are parents of European cultural heritage; these beliefs are then presumed to lead to academic superiority of Asian students over European American students, particularly in math. Although considerable evidence has supported the notion that children's beliefs influence their achievement striving, particularly in the face of failure, it is unclear that beliefs explain cross-national differences in achievement. European parents are more likely than European Americans to espouse ability attributions, yet children's math achievement in a number of European countries is higher than in the USA. Cultural variations in beliefs are undoubtedly confounded with other cultural and national differences such as schooling characteristics.

3.3 Parents' Beliefs about Child-rearing

Parents' beliefs about child-rearing also contribute to the educational qualities of the home environment. These beliefs include parents' views of optimal ways to socialize children (e.g., discipline practices, how and to what extent autonomy is fostered) and age-related expectations of children's abilities. A substantial body of literature indicates more positive cognitive and social outcomes for children whose parents show warmth while exhibiting firm yet flexible control, a style called democratic parenting by Baldwin (1955), and later described by Baumrind (1973) as authoritat-

ive parenting. Authoritative parents rely primarily on reasoning as a discipline tool rather than punishment and view their children's good behavior as the primary goal of their parenting rather than obedience. Thus, parents who value their children's autonomy, and whose knowledge and beliefs are consistent with an authoritative parenting style are more likely to foster educational progress in their children, as marked by school grades, low incidence of discipline problems, and healthy self-esteem. However, some recent research indicates cultural variation in the relationship between parenting style and children's outcomes, both in the importance of autonomy encouragement and the possible detrimental effects of harsh discipline.

Parents vary tremendously in their beliefs about children at different ages. For instance, some parents expect that 18-month-olds can be potty-trained, whereas other parents are nonplussed when the three-year-old continues to have 'accidents.' By the same token, some parents expect their three-year-olds to master rudimentary concepts of number and quantity that other parents would not expect before the age of seven. Although parents may not be conscious of many of these beliefs, they nevertheless shape everyday activities in the household, family rules, and the messages children are given—both blatant and subtle—regarding their abilities. For example, parents who believe that an eight-year-old is capable of planning are more likely than other parents to expect their child to pack his/her school lunch, select weather-appropriate clothes, and budget time to include homework, soccer practice, and leisure in a given evening.

Research in this area has indicated that a U-shaped function operates; expectations that are either too low or too high are not optimal for the child. According to Vygotsky's concept of scaffolding (1978), parents foster children's cognitive progress when they provide graduated cues that enable the child to function at a level slightly beyond what the child could perform independently. A parent who persistently has low expectations is unlikely to challenge the child to progress further. On the other hand, expectations that are too high (e.g., attempting to teach algebra to an average kindergartner) are equally unlikely to enhance the child's development.

4. *Instruction by Parents and Siblings*

Parent beliefs affect child outcomes primarily through their impact on parent behaviors. One type of parent behavior that shapes the educational quality of the home is parent instruction. In addition, siblings are an important source of information for young children. Instruction from parents and siblings are discussed here together. From birth onward, parents and siblings are a very important source of children's knowledge. The parent's early language use guides the

development of the infant's ability to distinguish among phonemes. The toddler observes an older sibling's interactions with friends and imitates that behavior later in other social situations. A young adolescent acquires concepts of social stereotypes through his parents' conversation at the dinner table.

Family influences are readily evident in a child's acquisition of specific skills and knowledge about the world. Thus, for example, a child whose parents are swimmers will probably learn to swim, and the child of musicians is likely to know more about music than peers from nonmusical families. Family also provides the primary context for children's cognitive development in less obvious ways. Through everyday conversations and activities with family members, children acquire concepts of schemas (e.g., what a visit to the doctor's office entails), grammar, and mathematical concepts (e.g., the early distinction between 'one' and 'more;' how to fairly divide the last piece of cake). Children learn memory strategies (e.g., where can I put my show-and-tell item so I won't forget it tomorrow morning), meta-cognitive knowledge (I can't concentrate on my homework while big brother is listening to that music), and problem solving (How should I clean up this spilled sugar?).

Some instruction from family members is verbal; other 'instruction' is nonverbal, communicated through body language and mood, or is modeled through behavior that the child later imitates. Instruction that takes place in the home is markedly different from that found in the school setting, in that it is largely unplanned, informal, and context-grounded, rather than the planned, formal, and context-independent instruction that occurs in school. Most instruction in the home occurs spontaneously based on the specific events, feelings, and needs of a given moment in the family life. Because it is so highly context-dependent, this instruction from siblings and parents provides the basis for most of the child's knowledge and skills of how to survive in the day-to-day world.

5. *Structuring of the Home Environment*

In addition to their beliefs and instruction, parents shape the educational qualities of the home environment in important ways through their choices regarding the physical qualities of the home and the child's activities. The well-established relationship between socioeconomic status and children's academic success has been attributed in part to substantial material differences in the home environments of children. Space, availability of developmentally appropriate games and toys, warm and responsive caregivers, and exposure to cognitively stimulating adults and new experiences have all been found to be related to later IQ or school achievement. A child's needs change with age. For instance, a supportive

home environment for infants includes a responsive mother and appropriate play materials, whereas in mid-childhood emotional climate of the home and child's participation in the family are associated with higher school achievement (Bradley et al. 1988).

In addition to the physical and social characteristics of the home environment, the lifestyle choices that parents make for their children determine on a day-to-day basis the educational experiences of the children. These lifestyle choices include how children spend their time outside of school; parental supervision of homework; the amount of television the child is permitted to watch; the extent to which play with peers is monitored; and so forth. All of these factors are related to children's school achievement. Differences in the educational outcomes of children of divorce versus intact marriages is now attributed in part to reliable differences in the home environments and daily activities of these groups of children. Single parents, who on average must survive on a lower income than couples, have fewer material and emotional resources to devote to their children. Thus children in single parent households are more likely than peers in two-parent households to have little adult supervision during after-school hours, to interact with parents who are stressed, and to shoulder heavy domestic responsibilities at an early age. These qualities of the home environment rather than parental marital status have the strongest influence on children's cognitive and emotional outcomes.

6. Parents Outside the Home

The child's development occurs within a multilevel ecological framework (Bronfenbrenner 1979). In addition to the microsystem level, where the child is involved in all interactions (e.g., family, school, church), other settings influence the child's development. At the mesosystem level, microsystem interactions occur without the child's presence (e.g., a parent attending a school open house). The exosystem, in turn, is comprised of those settings which never include the child, but which nonetheless influence the child. Two of these broader settings are discussed here: parents' employment (an exosystem influence) and parents' involvement in the child's school (a mesosystem influence).

6.1 Parental Employment and Children's Development

Early investigations in parent employment and children's outcomes were mostly group comparisons aimed at determining whether or not maternal employment had a detrimental effect on children. These investigations indicated no differences in quantity or quality of parenting systematically related to maternal

employment status. More recent research has identified process variables related to parent employment that have both positive and negative influences on children.

According to scarcity or stress theory, parents have a limited amount of time and energy, and parental employment is deleterious to children's developmental outcomes to the extent to which it decreases parents' time, energy, and patience. Stress theory reflects a strong trend in the USA and many other industrialized nations: Namely, in spite of the impressive technological advances of the past century, most parents work harder than ever (Schor 1991). Particularly as maternal employment rates have increased, the everyday lives of children have become harried. Thus one consequence of parental employment for children is the resulting stress associated with parental employment-related absence, whether that absence is actual or psychological, as stressed parents are preoccupied, tired, and impatient. A second consequence of demographic changes in employment patterns is that children spend a greater amount of time with other caretakers. Therefore, parents' selection of day care for infants and preschoolers, and their choices of after-school activities for school age children have real impact on children's developmental outcomes.

Parental employment can also benefit children's educational progress. On the one hand, parents gain in self-esteem, competency, and social support (as well as income) through their employment; these benefits for parents may translate into benefits for children. Mothers who are employed in professional positions serve as positive role models for daughters. In addition, parents' work characteristics are related to the quality of their parenting. Parents who enjoy their work, who are socially rewarded for it, and who are intellectually challenged in the work setting are more likely to show warmth and greater flexible but firm control with their children than parents who have less satisfying employment (Greenberger et al. 1994).

6.2 Parents' Involvement in Schooling

Formal education is an important part of the everyday lives of children and—along with family—is the most important source of children's educational progress in most countries. Therefore, parents' attitudes toward school and involvement in school activities have long been studied as an important factor related to children's educational progress. Parent involvement in children's formal education is positively related to their children's achievement: Parents of higher-achieving children tend to have more positive attitudes toward school, attend school functions, volunteer at their children's schools, and know teachers better than parents of lower-achieving children. Some theorists have pointed out that families of higher socioeconomic status are more comfortable with the cultural milieu of

schools, and thus find it easier to approach teachers and school administrators than families of lower socioeconomic status. These barriers to parent involvement are even greater when parents represent an underprivileged minority group and have had previous contacts with school officials that were negative (Clark 1983).

7. Current Research Directions

The home is one setting embedded within broader societal, cultural, and generation settings. Much current research examines how the family is changing due to changes in demographic factors such as parent employment, poverty, divorce and remarriage, and migration. Current research also emphasizes cultural variations in family life, both in terms of similarities and differences across groups, and in understanding what is optimal for children's healthy development (e.g., Okagaki and Frensch 1998). Finally, current research seeks to better understand family as an educational setting within a developmental framework, studying both the ways in which family influences change across childhood and the long term effects of early enhancement or insult.

Family and Consumer Sciences: United States

Family and Consumer Sciences is the study of relationships among individuals, families, and communities and the social, economic, political, biological, physical, and aesthetic environments in which they function. An early widely accepted definition stated:

... in its most comprehensive sense (it) is the study of the laws, conditions, principles and ideals which are concerned on the one hand with man's immediate physical environment and on the other hand with his nature as a social being, and is the study specifically of the relations between those two factors (Lake Placid Conference 1902).

Themes which characterize the field include (a) holistic, systems approach to the study of individuals, families, and communities, (b) interdisciplinarity as the field draws knowledge from the social, behavioral, and life sciences, from technology and engineering, and from the arts and humanities, and (c) integration and synthesis of concepts as they are applied to well-being. A continuum from discovery and integration of knowledge through its application in practical settings also is a defining characteristic of the field.

Most of the work of the profession fits this characterization; however, degrees of emphasis on particular elements and the desire to communicate that emphasis through nomenclature has led to the use of a variety of names. This is most evident in the naming of colleges in higher education institutions in the United States. Human ecology, human sciences, human environ-

mental sciences, human resources, as well as family and consumer sciences are used to designate this field of study in the academy.

Family and consumer sciences is mission-oriented. As a profession, field of study, and critical science, the mission of family and consumer sciences is 'the empowerment of families to function interdependently and the empowerment of individuals to perform family functions' (Green 1996). The mission-oriented nature of family and consumer sciences is reflected in statements about areas of leadership for the profession, to wit:

- (a) improving individual, family, and community well-being;
- (b) impacting the development, delivery and evaluation of consumer goods and services;
- (c) influencing the development of policy; and
- (d) shaping societal change; thereby enhancing the human condition ('The Conceptual Framework for the 21st Century' 1994).

1. Definition and Body of Knowledge

Family and consumer sciences is the study of relationships among individuals, families, and communities and the reciprocal relations of family to its human-created and natural environments. Specific elements in the body of knowledge have varied somewhat over time. A task force of individuals from many of the organizations linked to family and consumer sciences began updating the specification of the body of

knowledge in 2000. The work of this group is incorporated in Fig. 1, which depicts the core concepts in family and consumer sciences (Baugher et al. 2000).

1.1 Basic Human Needs

A primary expectation of families in most societies is that they work toward meeting basic human needs. Abraham Maslow's conceptualization summarizes these needs as physiological needs (food, shelter, clothing), safety (security and the absence of fear), love and belongingness (human emotions connecting individuals in human systems), self-esteem (sense of competence and respect for self), self-actualization (achieving one's human potential) (see Paolucci et al. 1977).

Starting from the center of this model and moving outward, three interdependent concepts are represented: individual well-being, family well-being, and community vitality. Subsumed within these concepts, but not delineated, are multiple specific areas of research within family and consumer sciences. These concepts also represent the mission-oriented nature of family and consumer sciences. Together, the three areas reflect the ultimate concern of family and consumer sciences to enhance the quality of life.

1.2 Individual Well-being

Individual well-being refers to the promotion of a person's physical and mental health, knowledge and

Figure 1
Core concepts in family and consumer sciences

skills, values, and civic responsibilities. Research in this domain may be as basic as studies to understand human metabolic processes and human genetic make-up, personality traits, or self-esteem as reflected in the selection of apparel. Application of this concept is reflected in numerous family and consumer sciences programs to increase knowledge and skills and foster more effective personal functioning.

1.3 Family Well-being

Family well-being is concerned with the development and dissemination of knowledge designed to empower families to meet the basic human needs of their members and engage in processes that build sustainable viable communities. Roles, responsibilities, and functions of the family have predominated the concerns of family and consumer sciences rather than structure (Green 1996). This is reflected in the definition of family adopted by the American Association of Family and Consumer Sciences. Family is defined as 'two or more persons who share resources, share responsibility for decisions, share values and goals, and have a commitment to one another over time' (Bivens et al. 1975, p. 26).

In a statement on the 'intellectual ecology' of family and consumer sciences Green (1996) identifies the substantive core of family and consumer sciences as family functions. The family functions framework addresses the role of families in meeting the needs of its members (i.e., basic human needs). In the developed economy and contemporary society of the United States, there is great interdependence of families and other systems in producing the goods and services to meet these needs. Accreditation documents of the American Association of Family and Consumer Sciences have delineated these aspects of human needs in relation to the near environment that are of concern to family and consumer sciences (see Council for Accreditation 1995). The following concepts would generally be found in such a listing:

- (a) Family systems, including economic, social, cultural, political, and demographic factors; family dynamics and roles;
- (b) Interdependence of families and communities;
- (c) Human development across the life course;
- (d) Resource development and management, including production, consumption, disposition, management and decision-making;
- (e) Human nutrition and food in the development, health and wellness of individuals, families, and communities;
- (f) Design and changing technology in relation to the development of home, community, and work environments that are supportive of consumers and families;
- (g) Role of apparel and textiles in meeting the physical, social, and aesthetic needs of consumers and families.

1.4 Community Vitality

Community vitality fosters interdependency and collaboration designed to enhance the well-being of individuals and families. This concept may apply to those who reside in a specific locality or to groups who perceive themselves as a community based on shared interests and beliefs. Technology makes it possible to sustain community vitality in cyberspace. Community vitality can encompass the global community.

1.5 Systems Theory

A system is defined as interrelated elements having functional unity within a larger system. 'Ecosystem' is the regular interdependency of organisms within their environment. The basic concepts found in systems theory are development, relationships, interdependence, and reciprocity. The fundamental theoretical framework that gives family and consumer sciences its dynamic and integrative nature is family ecosystems. Paolucci et al. (1977) define family ecosystems as follows:

Family members, their external environments as perceived by them, and the web of human transactions carried out through the family organization constitute the basic elements of the family ecosystem. One fundamental characteristic of the family ecosystem is that it is made up of a collectivity of interdependent but independent parts working together to achieve a common purpose. Each element (organism and environment) is interrelated (p. 15).

Human ecology theory is congruent with family ecosystems, and human ecology theory is often identified as the theoretical foundation of family and consumer sciences. Bubolz and Sontag (1993) identify the uniqueness of human ecology theory as its 'focus on humans as both biological organisms and social beings in interaction with their environment' (p. 419). The use of the human ecological perspective is found in many social science disciplines and applied fields.

1.6 Life-course Development

The concept of life course refers to a sequence of socially defined, age-graded events and roles that individuals enact over time (Elder 1998). Life-course thinking appears in most of the behavioral sciences scholarly literature after the 1960s.

As understood in life-course theory, human development is a co-active process in which social, cultural, psychological, and biological influences interact over time in the context of culture and social structures (Elder 1998). The concept of life-course development for individuals has been extended in family and consumer sciences to families, which also are observed to have experiences and characteristics described as life course events. An understanding of

life-course development is important in family and consumer sciences because environments in which families function, and families themselves, change over time.

1.7 The Professional Context

As shown in the model, principles of professional practice are a part of the core concepts of family and consumer sciences. Brown and Paolucci (1979) identify three criteria for identity as a profession:

(a) A profession is oriented toward providing a service;

(b) The service involves intellectual activity, including practical judgment, which requires that the professional master theoretical knowledge related to the work;

(c) Members in the profession seek to assure that work within the profession is morally defensible both in nature and in the quality of performance.

Family and consumer sciences includes courses and experiences to facilitate a professional orientation with regard to ethics, valuing diversity, critical thinking skills, working in partnerships, and advancing policies that support the well-being of individuals, families, consumers, and communities.

1.8 Synergistic/Integrative Approach

Family and consumer sciences claims as one of its distinguishing characteristics a 'synergistic, integrative nature' (Council for Accreditation 1995). The overlapping circles, dotted lines, and arrows in Fig. 1 depict this interplay among concepts. Addressing issues of wellness, for example, in the context of multiple factors rather than as isolated elements is the essence of the synergistic concept. For example, a dietitian needs to understand that obesity and impending cardiovascular disease are not just a matter of nutrition. Obesity is probably related to cultural food patterns, economic resources, and family relationships.

The integrative focus entails recognizing the interrelatedness of individuals, families, and consumers with their environments. In the example, the absence of sidewalks and parks with walking trails in a community may be a barrier to the state health agency's goal of reducing obesity through fitness programs.

2. Specializations and Family and Consumer Sciences

Like a chameleon, family and consumer sciences is perceived differently by observers depending on the context and the 'colors' highlighted in that context. In

the mid-twentieth century, Lee and Dressell (1963) observed three conceptions of the field, as follows:

(a) a single field with a broad general perspective and a number of specialties;

(b) a unified field with subspecialties embedded in the home and family;

(c) a collection of disciplines with no unifying theme or 'anchor.'

Families may be recognized as the basic social unit of society, but technology and changing social norms increasingly influence how family functions are carried out. In economically developed countries, such as the United States, the household produces only a small portion of the goods and services it consumes. The family has become increasingly a managerial unit.

As family roles changed and new technology, products, and services emerged, specializations developed related directly to the family or derived from the functions of the family (e.g., providing food, shelter, nurturance, clothing, and reproducing children and culture) (Bailey and Firebaugh 1986). Some specializations developed around certain human issues (e.g., nutrition, dependent care of the young and the elderly, housing). Other specializations focus on the application of knowledge in business, industry and agencies (e.g., restaurant management, interior design, marriage and family therapy). Certain specializations may or may not be found in family and consumer sciences academic units. At the turn of the twenty-first century, examples of the three conceptions of family and consumer sciences can still be found in academic units in the United States.

3. History

Family and Consumer Sciences evolved from home economics. Home economics emerged at the turn of the twentieth century in the context of the progressive reform movement. The organizers of the home economics movement were educated women and men who deplored the problems associated with urban crowding, child labor, malnutrition, immigration, and lack of education; but they also believed that the application of scientific knowledge could improve the daily lives of people and the policies of public agencies and employers (Stage 1997, Vincenti 1982). They organized courses to improve nutrition and the management of resources in public schools and neighborhood organizations in Boston and New York City. They launched campaigns to reform corrupt practices of landlords, employers, and businesses. They advocated for responsible 'municipal housekeeping' in which government would improve living conditions and citizens would be involved in governing bodies.

The educational innovations of the 1860s, such as the creation of land-grant universities through the Morrill Act of 1862 (whose express purpose was to educate the children of the common folk), offered

opportunities for higher education where they were not previously available. Home economics became a major point of entry for women into public higher education. The 'second Morrill Act' was passed in 1892, authorizing institutions of higher education for black citizens in the Southern States. The home economists who worked in the Extension Service and in the Southern schools and colleges worked in a segregated system with few resources (Harris 1997). Despite these constraints, their efforts greatly improved the daily lives of their constituents and offered career opportunities to those with formal education.

In 1899 began a series of meetings at the Lake Placid Club at Morningside, New York, for the expressed purpose of uniting efforts in the study of the home under one name and to organize a body of knowledge (see Brown 1985 and Lake Placid Conference Proceedings 1902–8). The proceedings record lively dialogue about nomenclature and content. Home economics was adopted as the name of the discipline. Ellen H. Swallow Richards, a chemist and the first woman graduate and first woman faculty member at the Massachusetts Institute of Technology, emerged as a zealous leader for academic programs, demonstration and outreach projects, research, and professionalization of the field (Hunt 1942, Stage 1997). Ellen H. Swallow Richards is generally identified as the 'founder' of the home economics movement.

The growing strength of home economics in terms of students enrolled, organizational structure, and public policy advocacy is documented in Pundt (1980). She describes the first decade after the founding of the American Home Economics Association in 1909 as 'continuing the struggle of the new discipline to define itself and find a rightful place among the more orthodox disciplines of a college or university ...' (Pundt 1980, p. 25).

Ideas about the modernization of family roles and the application of science in the home took a central place in home economics during the first quarter of the century. Behavioral sciences greatly influenced home economics teaching about child development and parenting, and child rearing was integrated into the home economics curriculum (Grant 1997). Principles from industrial engineering were applied to work simplification and design in the kitchens of America. Home economists were called upon during the 1930s to help families meet the devastation of the Great Depression. An outcome of these efforts was that nutrition and dietetics achieved a secure place in home economics curriculum and outreach programs (Babbitt 1997).

Dramatic changes in social roles, attitudes, and organization at mid-century and beyond prompted a series of conferences—New Directions (1959) and New Directions II (1975), the French Lick Conference (1961), the Eleventh Lake Placid Conference (1973), and Home Economics Defined (1979)—as the field engaged in a 'search for identity' (Brown 1985). The

focus of most of these conferences and 'white papers' was the purpose and subject matter central to the field (Simerly et al. 2000).

In 1975, a definition of home economics was published in *New Directions II*:

The study of the reciprocal relations of family to its natural and man-made environments, the effects of these singly or in unison as they shape the internal functioning of families, and the interplay between the family and other social institutions and the physical environment (Bivens et al. 1975, pp. 26–27).

The Scottsdale Conference held in 1993 examined the mission, breadth, scope, and name of the field (Simerly et al. 2000, Stage and Vincenti 1997). The outcome of the meeting was the recommendation of the name Family and Consumer Sciences for the field, which was subsequently ratified by the sponsoring organizations. A systematic statement of the basic beliefs, assumptions, professional practice, and areas of focus was developed (The Conceptual Framework for the 21st Century 1994).

4. Research Methods

Research in family and consumer sciences covers the entire spectrum from empirical studies using survey research methods, experimental laboratory studies, historical analysis, qualitative research such as case studies and personal narrative, needs assessments, and evaluation studies. Both 'basic research' (i.e., research conducted for the sake of testing theory, or to study phenomena with no expectation of a utilitarian outcome) and 'applied research' (i.e., research directed toward the solution of specific problems) are found in family and consumer sciences (Touliatos and Compton 1988). Intervention projects based on experimental design are used to test the efficacy of programs aimed at behavioral change.

Certain research methods tend to be associated with specializations within family and consumer sciences. For example, nutrition, food science, and textile research tends to be conducted in laboratories using basic or experimental research methods. While animal models have long been used to study diet-related diseases, studies with human subjects are becoming more prevalent. Population studies based on the methods of epidemiology are employed in assessing the extent of dietary diseases.

Areas in textiles and apparel such as fashion merchandising and international trade adopt a variety of research methods ranging from historical analysis, psychometrics, and secondary data analysis. Textile scientists concerned with the environmental impacts of processing conduct field studies and operate pilot plants to investigate their research questions.

Demography is concerned with human population and changes over time, thus it plays a major role in

social sciences and history. Family demography has traditionally been used to study macrolevel family patterns, but as life-course events are increasingly matters of choice, the importance of both macro and microlevel understanding is recognized (Teachman et al. 1999). Demographic methods are used to study housing, family economics, marriage, and fertility.

Research in family studies relies heavily on cross-sectional surveys and quantitative analysis. Data for these studies may be collected through interviews or self-administered questionnaires. Longitudinal analysis based on panel studies of the same subjects provide insights about families and their behavior over time. Acock (1999) observes that advances in computer technology and software facilitate the analysis of quantitative data which was not possible as recently as the 1970s.

Observational studies either in clinical or laboratory settings or the 'naturalistic' setting of the home are used to study family interaction. Qualitative methods are increasingly accepted as legitimate for the study of family and consumer issues. Qualitative family research uses content analysis of in-depth interviews, documents and other artifacts, and case studies (Rosenblatt and Fischer 1993). Qualitative studies are especially useful in the study of meanings, perceptions, and other subjective phenomena.

The mission-oriented nature of family and consumer sciences creates a close affinity for action research. The primary objectives of action research are solving problems and improvement of practice, but increased knowledge is also a potential outcome (Touliatos and Compton 1988). Participatory action research incorporates the indigenous knowledge of the community. Valuing such knowledge is important in facilitating societal change.

5. Outreach and Application

The Hatch Act, passed in 1887, provided funds to the States to establish agricultural experiment stations at the land-grant universities. The goal was solving practical problems. The Smith-Lever Act was passed in 1914, creating the Cooperative Extension Service. This provided the institutional vehicle for disseminating the research results from the universities and encouraging citizens to adopt practices to improve their living standards (see Babbitt 1997, Firebaugh and Redmond 1996, Harris 1997). The Cooperative Extension Service was a unique creation of higher education in the United States. It continues to have the most access to the most people through its network of county-based education programs.

The tradition of taking knowledge to the people has been modified through the years and adopted by family and consumer sciences programs, and many related social and behavioral sciences, in all types of higher education institutions. Community-university

collaboration in identifying and addressing the problems facing families and youth in the United States is creating effective programs and solutions to many of these problems (Chibucos and Lerner 1999) and increasing the value of outreach scholarship within higher education (Lerner and Simon 1998). Limitations of space preclude a comprehensive review of the multitude of models and programs in which family and consumer sciences is in partnership with other disciplines and with constituents in the application of knowledge to address quality of life issues of the twenty-first century.

6. The Future

Family and consumer sciences has evolved with growing sophistication in research methods, proliferation of specializations within the field, use of new technologies for dissemination of knowledge, and advocacy for policies to protect families and consumers. The field, however, has remained focused on its mission. Fidelity to its mission and responsiveness to change are expected in the future.

Application of knowledge to persistent practical problems has characterized family and consumer sciences. The list of accomplishments is vast: the school lunch program, delineation of requirements for nutrients, standardization of clothing sizes, best practices models in dependent care, Truth in Lending and Truth in Saving legislation, to name a few. New issues present themselves in the twenty-first century. Most of these issues are complex and require multiple perspectives. More collaborative projects across the disciplines and with community groups can be expected in the future. New guidelines in federal and foundation funding, designed to foster a closer integration of research and application, will encourage family and consumer sciences researchers and practitioners to engage in more collaborative outreach efforts.

Increased availability of information through the Internet and rising education levels of the population are expected to change the focus of professional practice from an orientation of being an 'expert' to being a 'facilitator.' The holistic family ecosystems theoretical framework and the integrative, synergistic orientation of family and consumer sciences will provide a comparative advantage for practitioners working in the 'information society.'

Deliberations about the nature of family and consumer sciences as a discipline are sure to continue. Conceptualizations about the body of knowledge (Baughner et al. 2000), discourse on the nature of the discipline (Brown and Paolucci 1979), and attempts to clarify and unify the discipline and the profession (Green 1996, Simerly et al. 2000) are echoes of the discussions at the Lake Placid Conferences. Such examination of family and consumer sciences will foster its future vitality and relevance as a field of study and a profession.

Family and Gender

The relationship between gender and the family has been a contested issue in the social sciences. Much of this controversy arises because even to speak about gender is, deliberately or inadvertently, to raise the issue of equality between men and women. Moreover, the issue of equality between the genders, in turn, is intimately linked to the paradoxical treatment of the family in classical liberal political thought (Eisenstein 1981).

1. The Classical Liberal Legacy—Patriarchal Antipatriarchalism

Classical liberal theory is one of the constitutive elements of modern society. Liberal political ideas emerged against the background of the collapse of the feudal social order and the emergence of a society based on market relations. Liberalism simultaneously promoted the ideals of freedom and equality, and strict separation between a public and a private realm. However, classical liberalism's assertion that principles of equality and freedom should be limited to the public realm has led many later thinkers to see the transformation of power in private family households as the last remaining objective of an incomplete revolution.

The most celebrated exponent of classical liberalism, John Locke, developed his doctrine in opposition to the doctrine of patriarchalism—a Latin term meaning the rule of the father. The patriarchalist Sir Robert Filmer had justified the absolute rule of the monarch by analogy to the 'divine and natural' authority of fathers over their households. In Filmer's social world, no distinction was drawn between the public and the private capacity of the king. King James I, for example, was expected to finance his own government from the revenue generated by his own estates, crown lands, and customs.

Locke opposed Filmer precisely because Filmer conflated the political and the familial. In Locke's view each institution had a separate purpose. Family, as an institution dealing with the rearing of dependent children, was organized around the inequality of parent and child. In a market society, politics, by contrast, was concerned with the coordination of independent individuals; that is to say, it was organized around the principle of equality. Thus, Locke rejects patriarchal doctrine, acclaiming the principle of public equality between reasoning adults, while at the same time endorsing patriarchy as the appropriate logic of the private realm of the family.

Locke and his contemporaries excluded women from the public realm because they assumed that rationality was an exclusively male characteristic. Locke recognized women's role in procreation and the preparation of children for political life but assigned these activities to the private sphere. Furthermore, Locke believed that a 'wife's subordination to her husband had a "Foundation in Nature" and that the husband's will must prevail in the household as he is naturally "abler and the stronger"' (Pateman 1989, p. 121).

Classical liberalism's legacy, among other things, is a continuing tension between the antipatriarchal demand for equality associated with rule by consent in public life and the creation of a separate private sphere still based on patriarchal prerogatives. This tension has given rise to a demand for equality between the genders, even in the private sphere of the family. Indeed, the family has often been seen as a key institution and, in some cases, the very locus of patriarchal rule (Hartmann 1981). However, the demand for gender equality has different variants depending on different analyses of the significance of the family for the subordination of women.

2. Liberal Feminism—Escaping the Doll's House

Liberal feminists accept broadly the classical liberal idea that citizenship is based on participation in public institutions, especially the (labor) market. Furthermore, liberal feminists also to a great extent accept that what happens at home is a private matter to be negotiated between husband and wife. Consequently, theorists of this persuasion argue that the key to women's subordination is the restriction of women to the private sphere.

Liberal feminism urges women to be like Nora, the heroine of Henrik Ibsen's play *The Doll's House*, and throw off domesticity and participate fully in the labor market, competing with men for the economic and social rewards available through paid work. It assumes that the traditional domestic division of labor, where the man is the provider and the woman the homemaker, follows from the fact that the homemaker is more dependent economically on the provider. It is the

dependence of the housewife on her husband, and not her gender, that is responsible for the sexual division of labor. The implication of this doctrine is that once women achieve economic independence, gender equality in the home will follow automatically.

From the perspective of liberal feminism, women's legal rights to property, including property in their own person, is the first step in the emancipation of women. Liberal feminism broadly accepts the proposition that contemporary advanced industrial societies are meritocratic, and that women as a group are not innately less talented or less diligent than men but are denied opportunities simply because of their sex. It shares with neoclassical economics the belief that discrimination distorts the market mechanism and produces undesirable outcomes, while disagreeing with the neoclassical economists' presumption that discrimination is an infrequent occurrence. Liberal feminism views wage discrimination and sex segregation of occupations in the labor market as a mechanism designed to exclude women from the labor market. Liberal feminist doctrine lies behind much of the legislation on antidiscrimination and equal opportunity. Discrimination against women, claims liberal feminism, often arises from stereotyped expectations.

These gender stereotypes and prejudices are often learned in the family. Like structural functionalist theory in sociology, liberal feminism sees the family as an institution that specializes in socialization. Children learn gender roles in the family, using role models available to them that are 'reinforced' by the wider society. Characteristically, liberal feminism implies that the inequitable influence of gender roles can be reversed by simply giving girls better role models, establishing equal opportunity in education, and encouraging high achievement aspirations. The mother's role in the traditional domestic division of labor models poor achievement aspiration to daughters but it is not itself a source of constraint. The fundamental gender neutrality of the domestic division of labor, which liberal feminism presumes, can be justified on two distinct bases, either on the claim that the current organization of the family is an economically rational specialization of roles, or on the basis of the exchange theory of power.

Households, according to economist Gary Becker (1981), allocate their resources of time and money rationally between the spheres of market work, non-market work, and leisure. Individuals specialize in those tasks for which they have a 'comparative advantage'; a decision based on relative productivities. Becker claims that small biological differences, such as lactation, give women an advantage in child rearing. Men become more productive at market work because gender specialization leads them to invest in their capacity to earn (human capital), through education and on-the-job experience. This leads to a situation where men's wages are generally higher than women's,

and any extra allocation of men's time to housework would oblige them to forgo a greater amount of income. By contrast, the 'shadow price' or opportunity cost of women's time spent in unpaid work at home is lower, because the cost of income forgone is smaller. This somewhat circular reasoning leads to the claim that men have a 'comparative advantage' in paid work, while women have a 'comparative advantage' in unpaid work. Because each member specializes in activities where their advantage (productivity) is greatest, and they pool and exchange the rewards of these separate activities, the household is said to benefit from 'gains of trade.' Assuming an equitable distribution of these gains, the household that specializes is collectively better off than the one that does not. The asymmetry in the allocation of domestic work in the family is seen as a freely chosen and rational response to the biological differences plus inequalities in the labor market. The contribution of discrimination to gender inequality in the labor market is de-emphasized, since neoclassical economic theory implies that discrimination should erode in competitive markets. The allocation of domestic tasks will become symmetrical if the barriers to women's economic emergence are removed, and their labor market situation becomes similar to that of men.

Sociological exchange theory does not require the assumption that everyone in the household strives to increase the household's joint welfare. On the contrary, it assumes that whoever brings the most valuable resources to a marriage can expect to be able to bargain for some kind of compensation in the form of release from menial activities. In the traditional family, the wife provides domestic labor in return for economic support. The fact that housework and child care are done by women follows, according to exchange theory, from her inability to contribute socially recognized resources, such as money, to the relationship. In other words, responsibility for housework and child care falls to her because she contributes significantly less money rather than because she is a woman. Improve the labor market position of women, argue liberal feminists, and the inequities in the domestic division of labor will disappear.

If liberal feminists allow for any 'stickiness' in patterns of family organization this is attributed to a process of lagged communication and the learning of new sex role expectations. Women must acquire the techniques of assertiveness that allow them to negotiate their relationships with their partners. Men must learn to accept new domestic responsibilities and become 'new fathers.'

3. Other Forms of Feminism

Other forms of feminism view the family as a key site in the determination of gender equality. Nonliberal

feminists have drawn attention to how the privatization of family life contributes to the subordination of women in two key respects. First, women's unpaid work around the home is private, unseen, and devalued. Moreover, the pattern of the distribution of resources is hidden from view. Second, by definition, privacy screens family relations from view, allowing domination, including physical forms of coercion, to displace rule by consent. In addition, modern family relations have been seen as the crucible in which gender identity is forged.

Since the 1940s it has been popular to view the family as a 'haven in a heartless world'—a secluded refuge from the ruthlessly impersonal world of market relations. However, according to its critics, this liberal view of the family as refuge relies on two propositions: the separation of home and work, and the idea that only market work is work.

Nonliberal feminists challenged the presumption of economics (before the development of Becker's new home economics)—that the family household is purely a site of consumption—pointing to the valuable stream of goods and services produced in the home. In place of the separation of home and work, feminists substituted the distinction between paid and unpaid work. In the traditional division of labor, the male provider returns from market work ('a hard day at the office') to seek comfort and rest at home. For his homemaker spouse, however, the home is the site of her work.

Just how nonmarket work (performed in private homes) became virtually invisible, even to social scientists, would make a fascinating study. It is possible, however, to make explicit some of the social conditions that make this illusion possible. In pre-modern times, households were largely self-sustaining (consuming mostly goods produced at home) and most work was nonmarket work. However, as soon as market exchange becomes the dominant principal of economic organization, most things start to be bought with money. A labor market develops where people buy and sell the capacity to work for a stipulated amount of money (a wage). Money becomes the universal measure of value. Since mothers and housewives receive no pay for their work, it is seen as valueless, as not actually work at all. By the middle of the twentieth century the idea of housework as an instrumental labor process had disappeared so thoroughly that most celebrated social theorists of the time thought that wives and mothers specialized in 'expressive' behavior (Parsons and Bales 1955).

In contrast to the gender-neutral theories of the allocation of unpaid work favored by liberal feminists, other varieties of feminism place great emphasis on the fact that unpaid work is allocated on the basis of gender, so that housework and child care continue to be 'women's work.' Women, not men, interrupt their careers to raise a family. Indeed, men with families are more devoted to careers than single men. Studies of the time devoted to unpaid work show that women

still do an overwhelming proportion of laundry, cleaning, cooking, and the physical care of children. The same studies show that men continued to specialize in mowing the lawn and polishing the car, and their chief contact with children is in the context of play.

Even when both partners are in full-time employment the sex segregation in unpaid work tasks does not diminish. The idea that gender relations within the family make it difficult to reassign the sex-stereotyped domestic responsibilities lies behind the anxiety about women performing a 'second shift' (Hochschild and Machung 1989).

Although responsibility for key domestic tasks is allocated to women, all members of the family enjoy the benefits of domestic work—live in clean dwellings, eat home-cooked meals, wear laundered clothes, receive emotional nurturance, etc. Although society as a whole depends on the reproduction of acculturated individuals, the costs of the activity of mothering, such as loss of lifetime earnings, reduced autonomy, and greater exposure to poverty, predominantly are borne privately by mothers.

The recognition of these facts about the distribution of domestic labor brings under suspicion the key presumption of the 'rational' specialization thesis, namely joint family welfare. These suspicions are reinforced by research into the relationship between women's share of family income and consumption of market goods. If families work to maximize their common (unitary) utility and pooled resources, then their consumption will be determined by total family income alone, and not by who earns or controls income. However, there is mounting evidence that, independent of the amount of total family income, increasing women's share of family income changes family expenditure patterns. The increasing women's share of family income results in greater expenditure on goods and services preferred by women (women's and children's clothing, restaurant expenditures) (Lundberg et al. 1997). Taken together, this evidence suggests that neither the sexual division of labor nor the distribution of market and nonmarket goods and services is consensual.

This raises the prospect that the family as an institution is constituted by systematically unequal exchange between the genders. Indeed, significant numbers of feminists believe that men as a social group actively or passively resist the reallocation of responsibility for domestic tasks because, as beneficiaries of this unequal exchange, it is not in their interests to change (Delphy and Leonard 1992).

Recognition of resistance leads feminists to explore the basis of capacity to resist, or to say the same thing in different words, to seek out the sources of male power. While liberal feminists tend to see men's dominance of the public sphere as the key to their power, radical feminists have often sought the basis of male power in family relations.

A simple, and long neglected, form of male power is physical coercion. The rise of second-wave feminism toward the end of the 1960s was accompanied by a growing recognition of the shocking extent of domestic violence. The significance of this kind of coercion is probably greater than the recorded incidence of violent acts, because in most social systems it is the threat of violence (terror) rather than direct acts of physical coercion that intimidates people into acquiescence. Susan Brownmiller used a similar logic when she claimed that rape is 'a conscious process of intimidation by which all men keep all women in a state of fear' (1975, p. 15). Emphasizing the crime of rape focused attention on the fact, a legacy of classical liberal thinking, that in most jurisdictions rape within marriage was not a crime in the middle of the twentieth century.

Domestic violence, and rape within marriage in particular, is so unexpected (even shocking) because they contradict the notion that family relations are relations between consenting equals. Much of the debate around sexual harassment and date rape also centers on the issue of consent. In classical liberal terms, it has become natural for us to allow the standards of liberty and equality developed as principles applying only to the public sphere to spill over to the private sphere. Many writers argue that the contemporary family is based on the progressive democratization of intimate relations.

Most social scientists believe that few systems of power can rely on coercion alone, and that the routine exercise of power must be seen as somehow legitimate. Sociologists believe that power is most successful when it becomes domination, that is, when it operates with the apparent consent of the dominated. Among the ideas that can be used to legitimate domestic inequality, a few have received the most consistent theoretical attention. The first is to present it as consensual and beneficial. Opponents of the 'rational' specialization thesis argue that this doctrine serves as an apologia for patriarchalism at home. The second focus has been the devaluation of women's work. Devaluation generally consists of diminishing the perceived importance of something, failing to recognize its true worth. The extreme case of devaluation is complete invisibility—which was a notable feature of the treatment of household productive activities as 'expressive' rather than 'instrumental.' The third idea that has received attention is the association of domestic work with femininity and its obverse, the association of masculinity with market work. Gender identity, many claim, is a major support for patriarchalism in the family and a significant obstacle to the achievement of gender equity.

The idea that the activities typically associated with women have been devalued has led to both attempts to revalue women's work, for example, through comparable worth campaigns, and attempts to reconsider the relationship between equality and difference. At

one level this has involved positive emphasis on 'women's values' (sensitivity, caring, and nurture) in opposition to the male values of competition, self-centeredness, aggression, and violence.

The celebration of difference has often been accompanied by an intellectual exploration of the socially constructed nature of gender identity which has taken priority over an analysis of family relations. Theories about language, and more broadly discourse, have been used to argue that signs used to represent things are arbitrarily self-referential. Self-referential because the meaning or one word is defined in terms of its relationship to other words—for example, 'light' is the opposite of 'dark,' while 'many' is defined against the background of the concept of 'one.'

It follows from this approach that the most powerful thing a social analyst can do is to deconstruct the discursive practices through which the social world is portrayed. The political objects of these more recent postmodern varieties of feminism have been representations of women and men, their bodies and relations in the various media of cultural transmission. Feminist theory has moved away from a preoccupation with things to emphasis on the salience of words and other cultural symbols.

Of course, the method of deconstruction can and has also been applied to the texts of feminist theory itself. This has made it problematic to assume that a political movement, with common objectives, can be rooted in a single category called 'women.' There has been an emerging sensitivity to the idea of difference among women, especially between 'women of color' and 'white middle-class feminists.' Hooks (1984) has argued that, for black American women, the family has been a source of solidarity and resistance to white racism and therefore less oppressive to black women than white American women. This emphasis on difference has been combined with a hostility derived from postmodernism to grand narratives or 'totalizing' conceptions. Generally, this has resulted in a political agenda that celebrates multiple identities, plastic sexuality, and diversity of household types ranging beyond the currently known groupings of family household.

From this perspective, sexual identity is an arbitrary cultural or social product. Gender identity, however, is seen as among the elements that contribute, in the deepest sense, to the conception of what one is. In 1978 Nancy Chodorow drew on a variant of Freudian psychodynamic theory (object relations theory) to explain gender differentiation and the different personality traits of adult men and women. Chodorow argued that because women are currently responsible for the primary care of children, this situation creates deeply internalized, unconscious desires in sons and daughters that reproduce male dominance and female mothering. When women 'mother,' all children have an initial attachment to and identification with a female. Because boys have a carer of a different sex,

achieving gender identity encourages emotional separation from the mother. Individuating from a female carer encourages boys to define their masculine gender identity that emphasizes difference from and rejection of femaleness, identification with emotionally absent (non-nurturing) males. For girls, raised by a same-sex carer, gender identity and individuation are not as mutually reinforcing. Thus, males grow up with an internalized need to emphasize separation and with misogynistic tendencies to define themselves in opposition to whatever is female; females grow up with a desire for emotional connection, including mothering. Chodorow draws the heartening conclusion that if men were to 'mother,' and therefore become more like women, this would change the masculine psyche. Chodorow's proposal to create greater gender equity ultimately turns on reforming the nurturing relations in the family.

Interest in the formation of gender identity, especially masculinity, has increased since Chodorow wrote *The Reproduction of Mothering*, using a different framework for understanding the process which places more emphasis on the role of culture and less on family relations. The most prominent alternative approach is social constructionism. In social constructionist variants, 'gender is not fixed in advance of social interaction, but is constructed in interaction' (Connell 1995, p. 35). It encourages study of the construction of masculinity in everyday life, acknowledges the existence of significantly different masculinities, and emphasizes the contradictory and dynamic nature of gender. This framework presupposes that Western culture typically valorizes the masculine over the feminine. The sexual division of labor at home has been viewed as a scaffold for the construction of gender identities.

4. Conclusion

The relationship between families and gender continues to be the subject of dispute in the social sciences. The 'linguistic turn' in the study of gender relations has directed attention to the most general cultural determinants of the gender identity of family members. The economic significance of nonmarket work has directed fresh attention to the process of home production. The classical liberal values of freedom and equality have proven themselves to be irrepressible, and although the split between the public sphere and the private sphere has endured, it has proven difficult to limit the demands for equality purely to the public sphere.

Family and Kinship, History of

This article discusses the emergence and development of the historical study of the family and interprets them in the larger context of social history. It addresses the following issues: the emergence of the field of family history; household structure; developmental perspectives; kinship; the family's interaction with the process of industrialization; family strategies; and future directions in the field of family history.

1. *Emergence of the Field*

Recent historical research on the family has revised some widely held myths about family life in the past, as well as generalizations about the impact of the grand processes of social change on the family and society. Family history has complex roots in both the historical demography of the early 1960s and the 'new social history' of the same period. Particularly in the United States, it has shared with the latter a commitment to reconstructing the family patterns of ordinary people and viewing them as actors in the process of change. Contemporary historians of the family have sought to reintroduce human experience into historical research and to emphasize the complexity of historical change (see Hareven 1971, 2000a, Tilly 1987). Hence, research in the history of the family explores previously neglected dimensions of human experience such as growing up, courting, getting married, bearing and rearing children, living in families, becoming old and dying. The formidable goal has been to understand the family in various contexts of change and at different points in historical time. In short, the historical study of the family represents an effort to understand the interrelationship between 'individual time,' 'family time,' and 'historical time' (Elder 1978).

Before systematic historical research on the family began, various social science disciplines had generated their own myths and grand theories about continuities and changes in family behavior in the past. Sociologists in particular argued that, in preindustrial societies in the west, the dominant household form had contained an extended family, often involving three co-resident generations, and that the 'modern' family—characterized by a nuclear household structure, family limitation, the spacing of children, and population mobility—was brought about by industrialization. Associated with these generalizations was also the popular myth that industrialization broke up traditional family patterns and community life. By providing a perspective on change over time, as well as on family behavior within specific social and cultural contexts in discrete time periods, historical research on the family has led to the rejection of these assumptions and to the resulting questioning of the role of industrialization as a major watershed in this field for

American and European history (Wrigley 1972, Goode 1963).

Over the three-and-a-half decades of its existence, family history has moved from a limited view of the family as a static unit at one point in time to an examination of the family as a process over the life course of its members; from a study of discrete domestic structures to the investigation of the nuclear family's relations with the wider kinship group; and from a study of the family as a separate domestic unit to an examination of its interaction with the worlds of religion, work, education, correctional and welfare institutions, and with processes such as migration, industrialization, and urbanization (Vinovskis 1977, Hareven 1982).

As research in this field developed, new findings and approaches have led to the revision and augmentation of the pioneers' approaches. Efforts to explore decision-making processes within the family have led to an investigation of strategies and choices that individuals and family groups make. The life-course approach has added an important developmental dimension by focusing on age and cohort comparisons in ways that link individual and family development to historical events. Research also expanded chronologically to cover antiquity, and geographically to encompass southern Europe, eastern Europe, the Mediterranean, Japan, China, and Latin America, in addition to Western Europe, North America, and Japan. The cumulative impact of studies in the history of the family has been to revise simplistic views of both social change and family behavior (Reher 1997, Andorka 1994, Plakans and Wetherell 1999, Todorova 1997, Halpern et al. 1996, Hayami and Uchida 1972, Kuroso 1996, Lee and Campbell 1997, Lee and Feng 1999, Borges 1992, Kuznesof 1997).

The emergence of the history of the family as a special area of inquiry received its major impetus from the publication of Philippe Aries's *Centuries of Childhood* (1960 in French and 1962 in an English translation). Aries argued that childhood as we know it originated only in the early modern period and that its discovery was closely linked to the emergence of the 'modern' or conjugal family, in which parents' private relationships with their children were more important 'than the honor of a line, the integrity of an inheritance, or the age and permanence of a name' (Aries 1962, p. 393). By linking the 'discovery' of childhood to transformations in family and social structures as well as economic and demographic changes, Aries inspired a whole generation of scholars.

Along another line of research, historical demographers in France in the early 1960s provided family historians with a powerful 'new weapon' for the analysis of demographic processes. Louis Henry and Pierre Goubert had developed a family reconstitution technique in the 1950s. Using genealogies, and marriage, baptismal, and death records from parish registers, this method enabled demographers to recon-

struct aggregate patterns of fertility, nuptiality, and mortality for vast numbers of people and, in some instances, over several generations (Henry 1953).

From the 1960s on, historical demography and family history in France developed into two parallel but interrelated streams. One continued to concentrate on demographic analysis, along the lines of Henry and Goubert; the other, influenced by Aries, anthropology, and the French social history tradition, integrated demographic analyses with patterns of family and sexuality, linking community and social and cultural variables with *mentalité*, as exemplified in the work of Emmanuel LeRoy Ladurie (1978), André Burguière (1987), Jean-Louis Flandrin (1976), and Martine Segalen (1991), among others. Family reconstitution subsequently became a powerful tool in the hands of the Cambridge Group for the History of Population and Social Structure.

Established in 1964, the Cambridge Group adapted the family reconstitution method to English parish registers, while also pursuing analysis of seventeenth-century nominal household registers. Wrigley found in the decline in fertility in the seventeenth century and in its recovery in the eighteenth century, evidence that rural births and marriages responded to changing economic conditions. He concluded that the demographic transition involved a change 'from a system of control through social institution and custom to one in which the private choice of individual couples played a major part in governing the fertility rate' (Laslett 1977, Wrigley and Schofield 1981).

Such demographic analyses for France and England, and subsequently Sweden, Austria, Germany, and The Netherlands, revealed that, in the pre-industrial period, people married later than had been generally assumed, couples practiced some form of family limitation and child spacing as early as the seventeenth century, households were predominantly nuclear rather than extended, and preindustrial populations experienced extensive geographic mobility (Laslett 1965, Goubert 1977). Late marriage served as a method of family limitation. It was also closely related to the expectation that a newly wed couple would establish a separate household and be self-supporting, while continuing to contribute to their families of origin. Linking late age at marriage to the nuclearity of the household, John Hajnal (1965) developed his model of the 'West European Marriage Pattern,' which served as the basic model for the analysis of West European families until it came under criticism. Hajnal claimed that marriage patterns in historic Europe could be differentiated with a line drawn approximately from St. Petersburg on the Baltic Sea to the Adriatic Sea. West of this line marriages tended to be relatively late (late 20s) for both sexes, and substantial portions of the population did not marry at all. East of this line, marriage for both sexes was relatively early (late teens) and marriage was nearly universal. He identified the 'western' pattern as

the 'European' pattern and suggested that the 'eastern' pattern was shared by many developing countries (in the 1960s).

2. Household Structure

Using nominal census records, Laslett found evidence of continuity in nuclear household structure in England, at least since the sixteenth century. A landmark volume published by Laslett and Wall (1972), containing articles on household structure for various countries, including Japan, concluded that pre-industrial households in Western Europe and North America affirmed these findings and dispelled the previously held assumption that industrialization brought about a nuclear family form. Although Laslett's early work emphasized the persistence of a nuclear 'family,' the major unit discussed was the household, not the family. A household is not identical with a family, since the domestic group may include nonrelatives as well. Nor is a 'family' restricted to the household, since extended family ties transcended the household unit (Goody 1972, Hareven 1982).

Subsequent studies showed that co-residence with extended kin tended to increase, not decrease, after the 'industrial revolution,' because of the need of newly arrived migrants to industrial cities to share housing space (Laslett and Wall 1972, Hayami and Uchida 1972, Anderson 1971). David Herlihy (1987) and Richard Smith (1979), respectively, traced a nuclear household structure in medieval Tuscany back to the twelfth century, as well as in England; and, in the medieval village of Montailou, LeRoy Ladurie (1978) found a variety of forms of family structures in the *domus* (household), ranging from ordinary nuclear families to various complex configurations. Household structure varied over the life course of its members, in relation to the economy and migration.

Such early discoveries also led to the formation of new generations and stereotypes: by combining the findings about the nuclearity of the household with the Hajnal thesis on the Western marriage pattern, Laslett developed a typology of the 'western family,' which he characterized as having a simple nuclear household; a relatively late child-bearing age; a relatively narrow age gap between husband and wife, with a relatively high proportion of wives older than their husbands; and the presence in the household of 'life cycle' servants unrelated to the family with whom they were residing. By contrast, he characterized the South European and Mediterranean family type as having complex household structures and early marriage, in which nuclear households are formed by the breakup of extended ones, rather than through marriage (Laslett 1977). These typologies, along with the Hajnal thesis, later came under criticism. David Kertzer refuted the thesis that links early female marriage to joint household organization as a characteristic of the

'South European' family pattern. He showed variability in household structures in Italy, depending on types of landholding and sharecropping. Similarly, Haim Gerber, on the basis of his analysis of urban Turkish households in the seventeenth century, questioned stereotypes of the traditional 'Middle Eastern family' (Kertzer and Hogan 1989, Gerber 1989).

In New England, when interpreted in the context of economic and social institutions (such as landholding, inheritance, religion, community structure, and religion), demographic patterns served as the backbone of complex family and community analyses. In his analysis of household and family structure in colonial Andover, Massachusetts, Philip Greven revealed the power relations between fathers and sons and the limits of the sons' autonomy based on inheritance. He found that households were primarily restricted to members of the nuclear family and nonrelatives, but a 'complex web' of family connections reinforced by proximity of residence, often on the same land, permeated the community (Greven 1970). Demos, in his study of colonial Plymouth, Massachusetts, used family reconstitution, the analysis of nominal census records and a great variety of other sources to reconstruct family and community patterns (1970). He also found a predominance of nuclear households, but these differed considerably from contemporary ones. Families were larger then and included nonrelatives, such as servants, apprentices, and boarders and lodgers in the households. Age configurations were also different; in some families, the oldest child in the household would be an adult while the youngest was still at the breast.

A major critique of early studies of household structure was their reliance on 'snapshots' in the household schedules listed in the census at one point in time. On the basis of his reconstruction of peasant households in the villages of Heidenreichstein in northern Austria in 1763, Berkner (1972) provided evidence that household structure changed several times over the course of the family's life, as it moved through its cycle—from a stem family to a nuclear one, and later to a stem family again, in relation to inheritance. Households were not static. At the same time, Demos' reconstruction of the stages of the life cycle in Plymouth demonstrated dynamic movements of individuals within and across families and households, in relation to the religious and cultural prescriptions of Puritan society (Demos 1970).

The presence of 'life cycle' servants—young men and women in their teens who lived and served in other people's households in the transitional period between leaving home and marrying—which Laslett found in English villages, as well as the presence of other unrelated individuals in the household, proves the remarkable flexibility of households in the past. Nuclear households included nonrelatives such as servants, apprentices, boarders and lodgers. Similarly, in nineteenth-century American urban households,

Modell and Hareven (1973) found a high proportion of boarders and lodgers, who provided important substitutes for children who had left home. Households expanded and contracted over the life course and in accordance with the family's needs.

3. *Developmental Perspectives: The Life Course*

The discovery of boarders and lodgers in nineteenth-century households and of the overall fluidity of household structure led historians of the family to search for a framework that would allow them to capture the movement of individuals through various household forms over their lives and the changes in the composition of the family and the household under various historical conditions. The family cycle model, which was used originally to identify changes in family structure, became unsatisfactory, because the stages of the family cycle were derived from contemporary American middle-class families, and were *a priori*. As Glen Elder explained, the family cycle identifies stages of parenthood rather than the more dynamic aspects of individual transitions into and out of various family roles (Elder 1978).

Dissatisfaction with the family cycle model led historians and sociologists to develop the life-course approach, which has introduced a dynamic dimension into the historical study of the family, and has moved analysis from a simplistic examination of stages of the family cycle to individuals' and families' timing of life transitions in relation to historical time (Hareven 1978, Elder 1978). According to the life-course paradigm, the pace and definition of the timing of life transitions, such as starting work, leaving home, and getting married, are determined by their social and cultural context. On the familial level, timing involves the synchronization of individual life transitions with collective family ones (Elder 1978). For example, using both demographic evidence and prescriptive literature, Modell, Funstenberg, and Herschberg found a major historical change in American society over the past century, from the 'erratic' timing of life transitions governed by collective family needs to more individualized timing in conformity with age norms (Modell et al. 1976).

Life-course research also illuminates the links between behavior and perception. While the actual timing of life transitions can be reconstructed from demographic records, its meaning to the individual and family members undergoing these transitions hinges on the examination of qualitative, subjective sources (Neugarten and Hagestad 1976, Bourdelais 1993, Hareven and Masaoka 1988, Hareven 2000b). A life-course perspective has also made an important contribution to the study of kinship by directing attention to the changing configurations of kin with whom individuals 'travel' together over their lives. Such configurations are formed and re-formed; they

change in their composition, in their relationship to the individual and the nuclear family, and in relation to each other over the life course.

4. Kinship

During the second decade of the development in the field of family history, kinship ties outside the household received increasing attention. Rather than being isolated, nuclear households were embedded in extended kinship ties outside their confines. Members of the nuclear family were engaged in various forms of mutual assistance, collaboration, and rituals with extended kin. Even though aging parents did not generally reside in the same household with their married adult children, they lived in the vicinity, often on the same land (Greven 1970, Berkner 1972, Smith 1979, Sabean 1998).

For nineteenth- and twentieth-century urban populations, Anderson (1971) and Hareven (1982), respectively, have documented the central role of family members and more distant kin in organizing migration from rural areas to industrial cities, in facilitating settlement in urban communities, and in helping migrants adapt to new working and living conditions. In her study of late-nineteenth- and twentieth-century textile workers in Manchester, New Hampshire, Hareven found that kinship networks in communities of origin were reinforced by the back-and-forth migration of individual members, and the transfer of resources. Following 'chain migration' routes, villagers who went to work in industrial communities spearheaded migration for other relatives by locating housing and jobs. Those who remained in the communities of origin often took care of aging parents and other relatives who stayed behind (Anderson 1971, Hareven 1982). Hareven found that despite the scale of the modern factory system, workers' kinship networks cushioned the adaptation of immigrant workers to new industrial working conditions. Kin acted as brokers between the workers and their industrial employers. Rather than disrupting kinship ties, migration often strengthened them and led to the development of new functions for kin in response to changing economic and employment conditions in response to the requirements of the industrial system (Hareven 1982).

5. The Family's Interaction with the Process of Industrialization

An examination of the family's interaction with the process of social and economic change enables us to understand more precisely what occurred internally within the family and how such changes were accomplished on a societal level. It provides new insights into the process of industrialization and urbanization,

into how labor markets functioned, and how industrial work processes and labor relations were organized. Historical research on the family has led to the rejection of simplistic models of social change, especially of modernization theory. How the family both initiates change and adapts to it and how it translates the impact of larger structural changes to its own sphere are crucial questions for the understanding of the process of social change.

The important principle underlying these questions is a view of the family as an active agent. The family planned, initiated, or resisted change; it did not just respond passively. Historical research over the past two decades, highlighting the family's role as an active agent, has led to revising questions such as 'What was the impact of industrialization on the family?' to 'What was the family's impact on the industrial system?' (Hareven 1982, c.f. Goode 1963). The question has been further cast into a more complex form: Under what circumstances was the family more able to control its destiny and to affect the larger social processes, and under what circumstances did the family succumb to declining markets, changing modes of production, business cycles, and other external forces?

The family had a central role in charting the transitions to various modes of industrial production by following diverse routes: from a rural economy to a proto-industrial or industrial one, or from a rural economy directly to an industrial one. In all these cases, while following its own priorities, when possible, the family facilitated the advance of industrialization by releasing the labor force needed for the newly developing factories and by organizing migration to industrial centers (Smelser 1959, Tilly and Scott 1978, Quataert 1985). The family's interaction with the industrial system has received attention from studies of family production systems in artisanal and proto-industrial settings and the study of family and work in the context of large industrial enterprises.

Proto-industrialization was a household-based form of production in the countryside and in some urban areas in England, France, Belgium, Switzerland, and Austria, from the seventeenth to the nineteenth centuries that preceded the 'industrial revolution.' It was characterized by the production of goods in local cottages for a capitalist employer who sold the products in external markets. Rudolph Braun (who first identified these patterns in Switzerland) and other historians developed a model of demographic behavior they claimed was typical of 'proto-industrial' families. This consisted of earlier age at marriage, higher fertility, and delays in children's departure from the home, all of which were conducive to maximizing a family labor force. Marriage formed the key to the spread of the cottage industry, because it led to the formation of a new nuclear family unit, which was also a 'unit of labor' (Braun 1974, Mendels 1972, Medick 1976).

In the 1980s and 1990s, the demographic model of proto-industrialization has come under criticism. On the one hand, scholars have questioned whether demographic behavior associated with proto-industrialization had been sufficiently widespread to warrant such generalizations. They found that demographic behavior in response to new economic conditions 'differed according to the environment (i.e., land ownership, social structure, and inheritance) and the exact nature of the economic change which took place' (Gutmann and Leboutte 1984, p. 589). Regional variation, interaction with the local agricultural structure, as well as the type of cottage industry (whether weaving or spinning), made a difference (Mitterauer 1992).

Like research on the family in proto-industrial regimes, the study of family in the factory system has provided considerable evidence documenting the family's role as an active agent in its interaction with the process of industrialization. Such research effectively undermined the theory of 'social breakdown' that had haunted sociology and social history. According to this notion, migration from rural to urban centers had led to the uprooting of people from their traditional kinship networks. The pressures of industrial work and urban life caused a disintegration of the family unit, and adaptation to industrial life stripped migrants of their traditional culture (Parsons 1955, Wirth 1938).

Historians and sociologists alike have challenged the theory of social breakdown, by providing contrary evidence. Neil Smelser, in his pioneer study of the family in the early stages of industrialization in Britain, documented the recruitment of entire family groups as work units in the early textile factories. Fathers contracted for their children, collected their wages, and were responsible for their performance in the factory. Entire families depended on the factory as their employer; the factories, in turn, depended on the recruitment of family groups to maintain a continuous labor supply (Smelser 1959). Anderson documented a continuity of recruitment in family units and in the vital role of kin among workers in the textile industry in Lancashire, England, at least through the middle of the nineteenth century. The practice of family members working together in the factory was carried over into the United States, as the factory system developed there, and was still present among immigrant workers in the twentieth century. The very success of the early industrial system depended on the recruitment of labor along kinship lines (Anderson 1971, Hareven 1982). As mentioned above, Hareven's study of family and work in the Amoskeag Mills in Manchester, New Hampshire, has documented the active role of the family and the kinship group in relation to the industrial corporation. It showed that the family type most 'fit' to interact with the factory system was not an 'isolated' nuclear family, but rather one embedded in extended kinship ties (Hareven 1982).

The functions that kin fulfilled in their interaction with the factory system were not merely archaic carryovers from rural society but a selective use of pre-migration patterns of kin assistance patterns in response to the needs dictated by industrial conditions. The encounter of immigrant workers with the modern factory system led neither to the abandonment of pre-migration family traditions, nor to a rigid adherence to them. Rather, the workers adapted their customs and social organization to the new conditions they confronted. In doing so, they addressed the factory system on its own terms. The family selected those aspects of its pre-migration culture that were most useful in coping with industrial conditions and adapted them to new needs. These patterns of selectivity called into question the linear view of social change advanced by modernization theory. Family behavior did not modernize at the same pace as workers' conduct in the factory. The family was both a custodian of tradition and an agent of change (Hareven 1982).

6. *Family Strategies*

To better understand the family's role in these processes of social change, it is necessary to examine how families charted their strategies in relation to external opportunities and constraints. Family strategies involved both the decisions individuals or families made and the actual timing of such decisions in relation to opportunities and constraints. Strategies included, at times, calculated trade-offs in order to find employment, achieve solvency, buy a house, facilitate children's education or their occupational advancement, control or facilitate a child's marriage, save for the future and provide for times of illness, old age, and death. Strategies were part of a larger life plan. As people encountered new circumstances, they modified and reshaped their plans and strategies in the context of their own culture and traditions (Hareven 1990).

As research on family strategies developed further, the concept also underwent important revisions. Under the influence of feminist historians, the question was raised: 'Whose strategies are family strategies?' This question is still part of an important research agenda about the process of decision making within the family, particularly concerning women's participation. Recent research suggests, though, that there may have been a considerable variation along gender-lines and among family members in the forging of strategies.

7. *Future Directions*

The multidimensional research effort in family history has produced impressive results and identified new

lines of investigation. Research still needs to pursue established topics that have not received sufficient attention, including the family's relationship to social space and a more systematic study of the family's relationship to religion, the state, and the legal system.

There is a need for more systematic studies of the 'edges' of family life, such as solitary individuals, orphans and foundlings, and the process of family breakdown through divorce or death and of family reconstitution through remarriage. A second direction is the forging of more systematic linkages between demographic behavior and household structure with internal family dynamics; a closer integration of the study of the household with nonresident kin; a more careful linkage of kinship and household patterns with various processes such as work and migration; and the relationship between demographic and family patterns with cultural dimensions.

In addition to this specific agenda, the larger questions of historical changes in the family over time still need to be explored systematically in several directions: First, if industrialization did not cause the emergence of 'modern' family behavior in Western Europe and the United States, what did cause it? One plausible explanation that has been advanced is the commercial revolution of the sixteenth and seventeenth centuries. This does not explain, however, the existence of nuclear household patterns in the Middle Ages. While Stone (1977), like Aries, dated the emergence of the 'modern family' in the late seventeenth and early eighteenth centuries, Shorter placed it in the late eighteenth, and early nineteenth centuries. Carl Degler (1980) dated the emergence of the American modern family in the late eighteenth or early nineteenth centuries as well. Following in Aries's footsteps, Stone, Shorter (1976) and Degler have focused on the rise of 'affective individualism' as the major criterion of 'modern' family life. They generally agreed that the 'modern family' is privatized, nuclear, domestic, and based on emotional bonding between husband and wife, and between parents and children. The correlates of its emergence were the weakening influence of extended kin, friends, and neighbors on family ties and an isolation of the family from interaction with the community. There is some disagreement and, at times, lack of clarity about which class initiated these changes. Aries, Stone, and, more implicitly, Degler viewed the bourgeoisie and the gentry as the vanguard, while Shorter assigned a crucial role to peasants and workers.

Related to the emergence of the family as a private, intimate entity is the widely accepted interpretation that this transformation was based on the family's surrender of earlier-held functions of production, welfare, education, and social control to other institutions and its withdrawal into domestic privacy has become one of the standard clichés of family history and sociology. We need to understand the process by which these functions were transferred to other insti-

tutions. A systematic exploration of the family's relationship to public agencies and institutions—specifically institutions of education, welfare, and social control, after the transfer of its functions—will help historians escape the trap of viewing the family as an isolated domestic entity.

Historical studies in Europe in the 1990s have emphasized an integrated view of the family both as a private entity and an object of the state. *The History of Private Life*, under the general editorship of Philippe Aries and Georges Duby, which focuses primarily on French society, deserves particular attention. The fourth volume, *From the Fires of Revolution to the Great War*, edited by Michelle Perrot, presents the experiential history of the family in relation to public life. The authors view the family's private life and sexuality as inseparable from the state (Perrot 1990).

As further research continues to emerge, it becomes necessary to develop a comprehensive model of change in family behavior that does justice to its complexity. The most important dimension still absent from studies of long-term changes in the family involves more systematic distinctions by social classes, rather than generalizing for the entire society on the basis of the middle class. We need a more detailed understanding of the historical process by which other classes adopted middle-class family behavior, if indeed that was the case, and of what class differences have survived such a process. How did patterns of family behavior that first emerged in the middle class transfer to other classes in society and by what processes? Equally important, at the end of that process, had rural and working-class families really adopted middle-class family forms, or did differences persist underneath apparent similarities?

The question about when and how change takes place needs to be raised again. Various strands of change in family history still need to be traced individually to the point of their culmination as visible transformations. The process is rendered more difficult by the fact that not all the strands undergo change at the same pace. Since the family is not a monolith, different members within it may initiate change or accept change at different points. For example, women were agents of change in certain areas of family life, such as in the practice of family limitation, while men were innovators in others. Even children were innovators in certain areas. They may have brought literacy into the family, new perceptions of behavior they learned in school or new work habits and new technologies. Thus, when we examine the family's role in the process of social change, we need to differentiate among the respective roles of members within the family, in interacting with these processes. This is an important task for future decades.

Family and Psychiatric Illness/Family Therapy

The term family therapy refers to the involvement of family members in the treatment of the patient. One participating member, as in the case of a spouse or

partner, is sufficient to justify the use of the term. Family members included in the therapy may share the same household with the patient or live apart, and may be seen by therapists with or without the patient. Family therapy was introduced as a means of altering family relationships that were believed to contribute to the development of the patient's illness. Recently, interventions have been mounted to help relatives cope better with long lasting illnesses without any implication that they have played a part in their causation.

1. Theories of Family Causation of Schizophrenia

Schizophrenia is one of the most severe mental illnesses and although relatively uncommon, affecting 1 percent of the population, can cause lifetime disability. Its causes are still unknown, although there is strong evidence for a contribution from inheritance (see *Mental Illness, Genetics of*). This evidence was scanty in the 1940s when psychoanalysts began to identify features of parental behavior that they linked to the development of schizophrenia. One of the earliest papers was by Hajdu-Gaines (1940), based on his psychoanalysis of four women with schizophrenia. He characterized their mothers as cold, rigorous, and sadistic and their fathers as soft, indifferent, and passive. Fromm-Reichman (1948), when discussing the problems patients with schizophrenia pose in psychoanalysis, coined the term 'schizophrenogenic mother,' which became common currency among psychiatric professionals. Coming from a similar background, Lidz et al. (1957) studied 14 families with a member suffering from schizophrenia and concluded that the parents' marriages were either unbalanced in terms of power ('marital skew') or exhibited an emotional distance between the partners ('marital schism'). Bateson et al. (1956) developed a theory that the irrational thinking of people with schizophrenia was induced by exposure to contradictory messages from their parents. They worked on the theory and came up with the term 'the double bind' that was an early formulation of catch 22. The double bind was defined carefully as a contradiction within the verbal content of a message, or between the words used and the feelings expressed. In addition, the recipient of the message is not allowed to comment on the contradiction (the doubling of the bind). Like Fromm-Reichman's term, double bind rapidly infiltrated the psychiatric vocabulary, and indeed went beyond into usage by the lay public. The basis of its popular appeal was in fact its greatest weakness as an explanation for the origin of schizophrenia, namely the fact that it was recognized immediately as occurring in everyday interchanges.

All the foregoing theorists were American, but Britain produced its own charismatic figure, R. D. Laing, who achieved popular fame during his lifetime. His formulation of schizophrenia was that it was a

completely understandable response to the family's efforts to drive one of its members mad (Laing and Esterson 1964). He believed the family selected one of its number as a scapegoat to bear the brunt of the family's emotional tangles. His ideas also spread far beyond his colleagues to be taken up by young people in particular, who found the role of being their parents' victim immensely appealing. A film based on his theory, called *Family Life*, was a popular success.

All four theories described above are flawed for the same reason: they were developed from clinical experience with highly selected groups of patients, and were not subjected to scientific tests of their validity by their originators. This would have entailed developing reliable measures of the phenomenon described, e.g., cold, rejecting mothers; double bind messages; and comparing their occurrence in representative samples of families of people with schizophrenia and in control families. One pair of theorists did just this: Lyman Wynne and Margaret Singer. Like Bateson's group, they focused on distorted communication in the family, only they developed an extensive schema for rating varieties of what they termed 'communication deviance.' Using this method to rate transcripts of subjects' speech they were able to distinguish parents of people with schizophrenia from parents of people with other psychiatric disorders and from normal subjects with uncanny accuracy (Singer and Wynne 1966). The results were so striking that they demanded replication and Hirsch and Leff (1971) attempted to do this using a British sample. They learned to make ratings of communication deviance reliably and assessed transcripts of parents of patients with schizophrenia and of parents of patients with neuroses. The former scored significantly higher than the latter but there was substantial overlap in the scores of the two groups. Thus, the parents of people with schizophrenia do seem to have an increased tendency to communicate in an unclear fashion, but this finding by no means proves that this lack of clarity induces schizophrenia in their offspring. An equally plausible explanation is that deviant communication in the parents is a manifestation of the genes they share with the ill family member. As a consequence of shared inheritance, 10 percent of parents of people with schizophrenia develop the illness themselves.

The theories presented address different parental qualities: their emotional responsiveness, the balance of power in their relationship, their ability to communicate. Each group of theorists has tended to formulate schizophrenia in terms of the particular abnormality they have focused on in the parents, rather than starting with a generally agreed concept of the nature of the illness. For example, Bateson's group conceptualized schizophrenia as a disturbance of logical thinking, while Laing saw it as an attempt to escape from the role of victim. In fact schizophrenia produces pervasive disturbances in the entire mental life of the sufferer: thinking, feeling, perception, and

communication may all be affected. None of the theories accounts for all the varied manifestations of this puzzling condition.

2. Family Therapy

2.1 The Introduction of Family Therapy

Family therapy developed initially in relation to schizophrenia, fuelled by the widely held view among psychiatric professionals that parents induced the illness in their offspring. Experienced psychoanalysts brought their expertise to bear on families caring for a person with schizophrenia. This in itself was an unconventional use of psychoanalysis, which was traditionally centered on the relationship between the analyst and a single client. Although scientific evaluations of this adaptation of psychoanalysis are almost nonexistent, the pioneers realized after some years that they were making little impact on the illness. Rubinstein (1974), one of the most respected therapists in the field, wrote that 'One of our earliest preconceptions, which proved to be unwarranted with the passage of time and our increase in experience, was that schizophrenic behavior could easily be modified if we treated the family conjointly, and if we helped the members sort out some of their distorted interpersonal dynamics.' The disillusionment of therapists with this work can be documented by calculating the decline over time in the number of papers on schizophrenia in one of the premier journals dedicated to family therapy. In the first volume of *Family Process*, published in 1962, exactly half the papers were concerned with schizophrenia. By 1975, the proportion of papers dealing with this condition had dropped to 10 percent, and by 1990 to 6 percent.

While psychoanalytic therapists turned their attention to families with other types of problems, a few charismatic individuals continued the work with schizophrenia, developing their own approaches and techniques, which often departed radically from the tenets of psychoanalysis. Therapists who are convinced of the value of their work rarely submit their efforts to scientific evaluation and no rigorous studies have been conducted of these individualistic therapists.

2.2 Shift from Schizophrenia to Other Diagnostic Groups

The focus of family therapy shifted to disorders of children, such as bedwetting, tantrums, and school refusal. These disturbances proved to be much more responsive to a family approach than schizophrenia, partly because there is not likely to be a biological basis to these behavioral problems, and partly because

children are much more under the influence of their parents than young adults. This point is underscored by the results of family therapy for eating disorders. This has beneficial results when the patient is a child or adolescent, but is less effective for adult patients, who do better with individual therapy (Russell et al. 1987).

2.3 The Influence of Systems Theory

While psychodynamic approaches to family work continue to have their adherents, they have been eclipsed by the rise of systemic family therapy. This was based on systems theory as enunciated by Bertalanffy (1968). The family is conceptualized as a system that attempts to maintain its integrity by responding to change in one part of the system with compensatory changes in other parts. Homeostasis, then, is the overriding concern of the family system (Jackson 1957). When a child develops a disturbance such as bedwetting, this is seen as compensating for a disturbance between other members of the family, say a conflictual relationship between the parents. When the parents bring the child for treatment, the child's symptoms are taken to signify dysfunction in the family system as a whole. For this reason the individual presenting for treatment is often termed the 'designated patient,' with the implication that this person has been selected by the family (unconsciously) as a messenger to the health professional that the whole family is in need of help. There is an echo here of Laing's view of the person with schizophrenia as the scapegoat for the rest of the family.

2.4 Family Therapy Approaches

Structural family therapy was developed by Minuchin and co-workers and entailed a basic assumption about the way in which a normative family should function (Minuchin 1974). The therapist takes an active role in trying to mold the family as closely as possible to this ideal image. As it involved a view of the father as the head of the household, it was criticized as gender biased and ethnocentric. In response to this, structural therapists now request families to state how they would like to function, and then help them to achieve the necessary changes, thus incorporating cultural sensitivity.

Strategic therapy, by contrast with systemic therapy, takes the presenting symptom at face value and involves a narrow focus and a time-limited intervention. An important innovation of strategic therapists is 'reframing,' in which the problem as presented by the family is reformulated, often changing its negative connotations into positive ones. This can free the family from established patterns of behavior and enable them to respond to the 'problematic' member in a different way.

Systemic family therapy received a boost from a group working in Italy who became known as the Milan School. The key therapists were Selvini Palazzoli, Boscolo, and Cecchin. They introduced innovative techniques such as paradoxical injunctions, and focused on patients with eating disorders and with schizophrenia (Selvini Palazzoli et al. 1978). They developed an interviewing technique of circular questioning, which has become recognized by family therapists as a useful tool. An example would be the therapist asking one member to describe the relationship between two other family members. This will produce responses from all concerned and will prompt the therapist to formulate the next question. This process makes evident to the family the circularity of interaction, as hypothesized by systems theory. The fame of the Milan therapists was such that clients came to them from all over Italy. This made follow-up very difficult and no convincing outcome research has been conducted on their patients.

2.5 Research on Family Therapy

In fact systemic formulations about the family's contribution to mental illness are difficult, though not impossible, to test scientifically. A number of instruments have been devised to measure the ways in which family members function when together, but these are not entirely satisfactory in grappling with the problem, since when several people are interacting they produce a vast amount of data. As an example, Mishler and Waxler (1967) recorded interactions between two parents and a single offspring. The recording, transcribing, coding, and scoring of the interviews required 129 hours of staff time for every hour of interview. For this reason greater success has been achieved by focusing on specific aspects of family interactions. The introduction of videotaping of family sessions, allowing replay, pausing, and slow motion, facilitated the study of interactions in great detail. One of the most productive lines of research has developed from the use of a measure of relatives' emotional response to a sick family member, known by the term Expressed Emotion (EE).

3. Relatives Expressed Emotion

This assessment instrument was introduced to investigate one of the consequences of deinstitutionalization (e.g., see *Deinstitutionalization, Psychiatry of*). In the UK it was found that patients discharged from psychiatric hospitals to live with close relatives were more likely to be readmitted than those who went to live with more distant kin or with landlords. George Brown, a sociologist, had a hunch that it was to do with the emotional relationship between patients and their close relatives, and with Michael Rutter, a child

psychiatrist, developed a technique to measure these. It is based on a semistructured interview with the relative enquiring about the patient's behavior and symptoms in the previous three months. The interview is audiotaped and ratings are made later from the tape. These depend partly on what the relative says and partly on the way their voice is used to convey emotion. The key ratings are of critical comments, reflecting how angry the relative is with the patient, hostility, representing rejection of the patient, overinvolvement, comprising overprotection and overidentification, and warmth.

3.1 Relatives EE and Schizophrenia

The initial studies were of patients with schizophrenia, since this was the most common diagnosis in patients discharged from long-term hospital care (Leff and Vaughn 1985). It was found that relatives' negative emotions—critical comments, hostility, and over involvement—were each associated with a greater likelihood of the patients to relapse. Consequently, they were combined into an index of Expressed Emotion (EE) and relatives were classified as high or low EE. In most parental households both parents were congruent in being either high or low EE. When they differed in their ratings, the highest rating was taken as characterizing the household. By contrast with the ratings of negative emotion, warmth was associated with a better outcome for the patients. Thus, it appeared that the family members could influence the course of schizophrenia either in a positive or a negative way.

The early studies of EE aroused a great deal of interest since they demonstrated that family members' emotional relationship with the patient could be measured reliably, and furthermore that these relationships appeared to determine the outcome of the patient's illness. It should be emphasized that, unlike the theories of causality reviewed above, it was not claimed that high levels of EE antedated the appearance of schizophrenia or played any part in its etiology. If there was any causal influence, it was on the subsequent course of the illness once it was established. Many groups have replicated the link between EE and the outcome of schizophrenia, with the result that it is now one of the best evidenced associations in psychiatry (Butzlaff and Hooley 1998). These replications have been carried out in a number of languages and cultures, including India, China, and Japan, showing that the association is independent of variations in family structure and function.

3.2 Family Interventions for Schizophrenia

The research on relatives' emotional responses and schizophrenia led to a revival of interest in working with the families of such patients. However the

approach was quite different from that of the earlier generation of therapists. Instead of viewing the family as pathogenic and in need of treatment, the new attitude was one of respect for the carers and a genuine desire to work with them as allies in the struggle against the illness. This in itself was revolutionary since for decades family members had been subject to vilification and rejection by mental health professionals. Instead of the patients being scapegoated by their families, as Laing had claimed, it was the relatives who were treated as scapegoats by the professionals. Relatives were denied information about the patient's illness on the grounds of confidentiality, which unnecessarily hindered their attempts to understand what was happening to the patient. Partly as a response to this treatment, relatives formed national organizations, such as the National Schizophrenia Fellowship in the UK and the National Alliance for the Mentally Ill in the US. This development raised the profile of relatives, gave them access to political power, and increased their confidence in dealing with professionals (e.g., see *Mental Illness: Family and Patient Organizations*).

Controlled trials of family interventions for schizophrenia began to appear in print in 1978 and over the next two decades more than a dozen such studies were published (Lam 1991). They all employed the same design, namely a comparison of family intervention plus antipsychotic medication against medication alone. This design reflects the important assumption that antipsychotic medication is an essential basis for the treatment and maintenance of a person with schizophrenia, but that working with the family to improve the management of the condition confers an added benefit. Indeed, this series of studies provided strong evidence for that proposition. Patients' relapse rate over one year was reduced from an average of 50 percent with medication alone to 20 percent or less by the addition of family interventions.

Despite a multiplicity of names, the interventions share much in common. They all start with an educational program which conveys to the family information about the causes of schizophrenia, the symptoms, the likely outcome, and the treatment and management. This is followed by instruction in problem solving, improving communication, reducing the intensity of negative emotions, utilizing the family's natural support networks, and developing realistic expectations for the patient. The general aim of the approach is to build on the family's strengths and to facilitate their mutual co-operation in coping with the illness.

3.3 Testing Systems Theory

Some programs were delivered by sessions in the family's own home, a radical departure from traditional family therapy, in which treatment often took place in a special clinic room equipped with a one-way

mirror to allow the whole team to monitor the interactions between therapist and family. Home visits are an effective way of engaging families, as well as enabling the therapists to observe families in their natural surroundings. These advantages have to be weighed against the extra staff time taken up by travel. Other programs set up groups for relatives that were run by professionals on the same lines as the family sessions. Voluntary organizations for families often establish self-help groups, but when they invite professionals along it is to provide information and not to institute therapy. Indeed they reject the term 'family therapy' as implying that relatives are pathological and in need of treatment themselves.

One American therapist, Bill McFarlane, based his program on multifamily groups that included patients as well as relatives. He has produced some evidence that these are more effective than groups comprising only relatives (McFarlane et al. 1993). Relatives groups provide the opportunity to test one of the basic tenets of systems theory, namely that altering one part of the system can effect change in the entire system. In the course of evaluating family interventions for schizophrenia, Leff et al. (1989) compared the effectiveness of family sessions with a relatives group from which patients were excluded. They found that relatives who attended the group showed a significant reduction in EE and this was accompanied by a lowered relapse rate for the patients. Hence, altering one component of the system, the relatives, led to the desired change in another component, the patient.

3.4 Relatives EE and Other Illnesses

Since the original research on schizophrenia, the measurement of EE has been applied to a variety of other conditions, both psychiatric and physical. In the realm of psychiatry, high levels of EE have been found in relatives of patients with manic-depressive psychosis, depressive neurosis, dementia, learning difficulties, alcoholism, eating disorders, and post-traumatic stress disorder, and in families in which children have suffered physical or sexual abuse. High EE has been found to be linked with outcome in all these conditions, with the exception of dementia and learning difficulties. In the domain of physical illness, high EE attitudes have been recorded in relatives of patients with epilepsy, heart disease, diabetes, inflammatory bowel disease, and Parkinson's disease. From this it appears that high EE attitudes can develop in response to any long-standing or recurrent illness, be it psychiatric or physical. However, an association with outcome is much stronger for psychiatric than for physical disorders. Regarding the latter, only for diabetes has a link been demonstrated and the evidence is equivocal.

It seems from this series of studies that the emotional attitudes of family members have a much greater

impact on people suffering from disorders with an emotional basis than on people with physical illnesses where there is a demonstrable pathology. The exception might seem to be schizophrenia, in which brain abnormalities have been demonstrated (e.g., see *MRI (Magnetic Resonance Imaging) in Psychiatry*). However, a high proportion of patients with schizophrenia experience depressive symptoms and they are responsive to the same adverse events in their life as are people with a depressive illness. Hence, the underlying brain disorder does not negate their sensitivity to the social environment.

4. Couple Therapy for Depression

Marital therapy, as it used to be called before marriage went out of fashion, has a long history, and developed to help couples resolve their relationship difficulties or to part amicably. In the UK, a voluntary organization, Relate, trains counselors in the skills needed for couple therapy. However, there is not usually an identifiable psychiatric illness in either member of the partnership. In recent years, a small number of studies have tested the value of couple therapy for people with a depressive illness. In most of these, couple therapy has been compared with cognitive therapy, a treatment of known effectiveness for depression that focuses on the individual patient. In general, couple therapy has been found to be as effective as cognitive therapy for improving depression, but has stronger effects on the couple's relationship.

A recent study tested couple therapy against the best possible regime of antidepressant medication for depressed patients who were in a stable relationship. Both treatments were continued for one year and then stopped, after which the subjects were followed up for a further year. This design was chosen because most treatments in use improve depressive symptoms: the challenge is to reduce the liability for the symptoms to recur. The couple therapy was given by two systemic therapists who focused on the relationship between the partners as being the means by which the depression was maintained. The patients who received couple therapy showed a greater improvement in depression than those assigned to medication, and this advantage for couple therapy persisted over the second year after treatment had been stopped (Leff et al. 2000). Hence, changing the relationship between patient and partner was more effective both for treatment and prevention than altering the biochemistry in the patient's brain.

5. The Family as a Therapeutic Resource

Since family therapy was first introduced, there has been a major shift in professional attitudes from holding relatives responsible for the patient's illness to

viewing them as allies in a struggle to help the patient overcome symptoms and disabilities. Alongside this sea change, western families have been altering in their composition, structure, and function, requiring a greater flexibility in professional inputs. Several schools of family therapy have developed, each with their own distinctive concepts of the family, and have introduced novel techniques. Not all of these have proved their worth, but the emerging evidence of family influences on the course of a wide range of psychiatric disorders is a spur to test existing methods of working with families and to develop innovative ones.

Family and Schooling

There is an obvious difficulty in considering relationships of the family to other institutions at a time when it is changing rapidly and radically in structure, functions, and internal dynamics. While some investigations have addressed aspects of those changes, much research on family–school relationships does not take account of them. Perhaps this research is more properly regarded as providing information on homes, which can encompass a variety of family types, rather than on families.

Up to relatively recently, the family took major responsibility for the care, education, and training of children. In it, children acquired skills to deal with day-to-day tasks, including those of work. During the Industrial Revolution, as work moved into factories and became more specialized and skilled, and knowledge accumulated, homes could no longer provide children with the required knowledge and skills, and the need for an institution dedicated to formal learning arose. Increases in migration, industrialization, and urbanization served to underline the need, and so nations came to accept education and training in school as their responsibilities.

Children still spend most of their waking time outside school, however, and it would be surprising if the continuous influence of the family, both before children enter school and when they are attending school, did not play a major role in their learning. Although one would expect families and schools to play complementary and mutually reinforcing roles in children's education, they may not always do so

because of differences in their goals, structure, demands, activities, values, and the competencies they foster. When these differences are large, children may experience a serious dysfunction in socialization when they go to school, which will affect their ability to adapt and to learn. To deal with this problem, concerted efforts have been made in several countries in recent years to increase parents' involvement in the formal education of their children.

This article provides a summary of the findings of research that indicate that children's home circumstances are related to school learning. Proposed explanations of the findings are presented. Finally, programs to increase parental involvement in the education of children living in families and communities characterized by high rates of educational failure are considered.

1. The Findings of Research on Family Characteristics and Children's School Learning

Research on the family factors that influence children's development, much of it in the context of policies of providing equality of educational opportunity, has been carried out since 1900 in several disciplines: education, psychology, sociology, economics, and behavior genetics. There has been little integration of the work across disciplines.

Findings of the empirical studies can be summarized in eight general conclusions (Kellaghan et al. 1993, White 1982): (a) level of socioeconomic status (or social class) is positively but not very strongly related to children's performance on measures of scholastic ability and achievement. Children from high socioeconomic status homes tend to perform better than children from low socioeconomic status homes; (b) differences in cognitive skills between children from varying socioeconomic and ethnic backgrounds are in evidence before children go to school; (c) the gap between children from different backgrounds widens as children progress through school; (d) the length of time a student spends in the education system is a function of the socioeconomic status of the student's family. This is so even for students of the same level of general scholastic ability; (e) in countries in which secondary schools are differentiated, major selection in terms of socioeconomic background occurs at the point of transfer from primary to secondary school. Students from high socioeconomic backgrounds tend to transfer to an academic type of secondary school which will lead to third-level education, while children from low socioeconomic backgrounds tend to go to technical, vocational, or 'short-cycle' schools; (f) variables which describe the ethos and teaching style of families predict students' academic achievement better than do measures of the socioeconomic status of families. Thus, what parents do is more important

than their status; (g) children's learning benefits from parental involvement. Such involvement is more likely to occur if parents construe their role as involving activities related to children's education, and if they believe that involvement will have a positive influence on their children and will be welcomed by schools (Epstein 1991, Hoover-Dempsey and Sandler 1995); (h) many studies reflect a low negative correlation between family size and educational abilities, achievements, and attainment. Increased spacing between children tends to reduce the decrement associated with increase in family size, while the effects of size are more marked in homes in which the father has a low occupational level.

Methodologies have been employed which reject the 'objective' quantitative approach of empirical studies, adopting the view that since acts imply purposeful constructions by actors, they can only be understood from the actor's point of view. In this context, ethnographic and case study procedures have been used to explore individuals' 'interpretations' of home-school relationships (see Marjoribanks 1991). The approach is supported by the findings of psychological research that perceptions of family supports are better predictors of personal adjustment than are actual supportive behaviors provided by network members (Pierce et al. 1996).

Research on the effects of variation in family structure and function on children's school learning does not provide clear-cut findings, which is not surprising, given the complexity and variety of the conditions being investigated. It is, for example, difficult to design studies that will isolate the effects of family circumstances (e.g., divorce, maternal employment, blended families, lone parenting) from the effects of many conditions frequently associated with these circumstances. One consistent finding, however, is that lone parenting is often associated with school problems for children when the parent (usually a mother) is young, financially poor, and poorly educated (Kellaghan et al. 1993).

Changes in family structure, which are associated with a decrease in the monitoring and supporting of children's behavior by parents and other adults, and in which the cultivation of one's own well-being replaces interest in others, are perceived by some commentators to have a negative impact on children's educational development (see Coleman 1987). The changes are represented as reflecting an erosion of 'social capital' (see Sect. 2).

2. Explaining the Family's Influence on Children's Development

Using a concept analogous to financial capital, the term 'cultural capital' has been used to conceptualize some of the influences of families, and the communities

in which they are embedded, on children's academic development. It exists in three forms: in cognitive and noncognitive competencies derived from past experiences (particularly familial ones) which actively organize future experience; in an 'objectified' state in cultural goods (pictures, books, instruments); and in an institutionalized state (educational qualifications). Language forms an important part of cultural capital since, in addition to being a means of communication, it provides, together with a richer or poorer vocabulary, a system of categories, which enables one to decipher and manipulate complex logical and aesthetic structures (Bourdieu 1986).

Separate strands of research in education (Kellaghan et al. 1993) and in psychology (Moos and Moos 1994) have identified a number of behaviors and conditions in the family that contribute to cultural capital: (a) modeling (in use of complex language; in planning and organization to ensure that time and space are well structured and used; intellectual-cultural orientation in activities; moral-religious emphasis); (b) providing motivation and reinforcement (encouraging and rewarding school-related activities and independence in decision-making); (c) holding high academic aspirations and expectations; (d) providing direct instruction (guiding and supporting academic work; helping with homework); and (e) ensuring that the activities engaged in are developmentally appropriate.

A number of points have been made about cultural capital: (a) its value will vary with the 'markets' in which it can be used advantageously; (b) capital required for success in school is defined by the dominant social groups in society; (c) ability or talent is the product of an investment of time and cultural capital; and (d) the notion of cultural capital helps explain the unequal scholastic achievement of children originating from different social classes. If you bring the right kind of capital to school, you will do well. If you do not, you are likely to find yourself at an academic, social, and ideological disadvantage in most schools (Bourdieu 1986).

In separate, but mutually supporting research in psychology and sociology, interpersonal relationships have been identified as another area in which the family's influence on children's development can be discerned. In psychology, the focus is on cognitive aspects of support (that incorporate expectations about how others will respond when assistance is needed) and on actual supportive behavior (Pierce et al. 1996). Sociologists, on the other hand, speak of 'social capital,' which is perceived to inhere in the structure of relations between and among individuals and organizations. Three forms have been identified: shared obligations and expectations; useful information that is passed between members of a social network; and a value or norm consensus between adults, coupled with a willingness to monitor behavior and enforce norms that control and shape children's

activities. These conditions are seen as contributing to the development in children of basic attachments, attitudes, willingness to make certain efforts, and concepts of self, all of which work to children's advantage when they go to school. A variety of individuals and organizations can help children with these developmental tasks: siblings, grandparents and other members of the extended family, neighbors, churches, and various social and cultural groups (Coleman 1987, Garbarino et al. 1997).

These explanations of the factors in social and familial contexts that affect school learning do not help us understand how it is that children from the same family can differ considerably in their success at school. The answer would seem to lie in the fact that, although certain aspects of children's genetic endowment and environment (inside and outside the home) are shared by children in a family, other aspects are unique to each child. It may be that non-shared influences (e.g., the specific treatment of a child by parents and siblings) contribute more to variation in children's characteristics than family variables that are common to all children (e.g., socioeconomic status, general parenting style) (Rowe 1994). The complexity of the interaction between genetic and environmental factors becomes obvious if it is the case that compared to their less 'able' counterparts, genetically more 'able' parents create more stimulating environments, and genetically more 'able' children take a more active role in shaping their environment.

3. Home-School Partnerships

Recent efforts to improve home-school relationships may be attributed to concern about achievement levels in schools, sometimes arising out of the results of comparative international studies of achievement; the limited success, despite considerable investment, of efforts, such as 'Headstart' in the USA and similar programs elsewhere, to raise significantly the educational achievements of children living in areas described as economically and socially disadvantaged; and realization of the contribution that factors outside the school in homes and communities, particularly in the early years, make to the development of competence in children, a realization that was inspired by evidence relating to the importance of early childhood experiences, and of the effects of home background on achievement.

In the USA, there is a long tradition of involving parents and communities in children's formal education in, for example, parent-teacher associations. In Europe, the situation is more complex because of differences between countries in legal arrangements and ideology. However, in many countries, recent efforts, in some cases supported by legislation, go well beyond traditional parent-teacher associations in the role they propose for parents, involving them in

curriculum decision-making, and in teaching and learning activities in the classroom (e.g., as classroom assistants) or in the home (e.g., in developing children's skills in problem solving and language, and in supervision of homework). Many of the efforts are directed towards families in 'disadvantaged' areas, where children face economic, educational, and social problems, and are considered to be at risk of educational failure, school dropout, and intergenerational poverty. As is the case with family-support initiatives in general, programs are designed to improve the developmental capacity and educational options available to families. They are based on a variety of models and approaches, have few theoretical frameworks, and vary in the extent to which empirical evidence is available on their effectiveness.

Most programs can be described as instrumental-technical, in that they are designed to provide parents with a range of skills that are considered relevant to their children's education. Alternative approaches are based on an interpretative paradigm, which, recognizing the uniqueness of parents' experience, attempt to facilitate them in interpreting and understanding that experience. Yet other approaches go a step further, again helping parents interpret their situation, but to do so critically in the context of presumed determining social structures and ideologies (e.g., Morgaine 1992).

One of the mechanisms used in the USA (Becker et al. 1997) and in the UK (Bastiani and Wyse 1999) to involve parents requires them to sign home-school contracts. Such agreements describe, among other things, the reciprocal responsibilities of schools, parents, and students in relation to student learning and school discipline.

A number of problems associated with efforts to promote partnerships have been identified: (a) despite rhetoric regarding choice, partnership, and parents' role as 'primary educators,' many efforts mirror the traditional home-school power relationships that they were designed to alter; (b) in many cases, schools limit the involvement of parents, denying them any real input into the construction of 'shared understandings'; (c) many approaches are based on an implicit view of parents as being inadequate in parenting skills, or as being 'hard to reach'; (d) many parents are untouched by the partnership, and remain distanced and alienated; (e) when involvement is based on contracts which require agreement before a student will be admitted to a school, only families with a certain level of commitment may enrol their children; (f) the extent of parental influence depends on parents' social, cultural, and material resources; (g) finally, strategies generally fail to reach fathers (Vincent and Tomlinson 1997).

While evaluations of individual initiatives to improve family involvement have reported a variety of effects on parents and children, it is difficult to generalize about the effectiveness of home-school

partnerships because of variation in the goals of programs, in the situations in which programs are delivered, in the delivery of services, and in the recipients of services.

4. Conclusion

Research has gone a considerable way in identifying family characteristics that are associated with children's successful school learning. We may expect future research to be more interdisciplinary, to focus more on individuals' perceptions of family-school relations, to attend to the role of individuals' unique nonshared attributes and experiences, and to support the development of parent involvement programs that are based on the concept of equality of the partners.

Family, Anthropology of

At intervals during the last 50 years, anthropologists have pointed out the deficiencies of the concept of the family as an analytical tool (e.g., Fortes 1958, Yanagisako 1979, La Fontaine 1985). One of the more recent, Robertson, starts with an account of the importance of the idea of the family in Western culture; later, he draws attention to social scientists' 'fixation on the family' (1991, p. 154). These two phenomena are undoubtedly connected. An account of anthropological understandings of the family must distinguish between its significance in Western society and its use in the comparative analysis of social life. Comparing the two may then expose the fundamental ethnocentricity of the concept and its weakness in cross-cultural analysis.

1. The Family in Western Society

The significance of the family in Western societies is obvious in daily life. Children in primary school are asked to describe their families as a writing exercise and politicians vie with one another to be 'the party of the family.' Christianity, the majority religion of Western society, celebrates the Holy Family and its priests proclaim the duty of Christians to emulate it in their domestic life. The terms used by members of a family for one another are not applied to any other relatives and the relationships they designate are seen as unique. The family encloses the private life of individuals and, as the building block of society, is given equal weight with the public institutions of the state, since the division into public and private is one of the fundamental social distinctions in Western culture. Yet this important institution is also the subject of controversy. There are arguments over the past and future of the family, over whether it is universal or merely an adaptation to the modern world, over the possibility of its decline and the effect on it of political and economic measures. The family is not taken for granted.

Despite its importance, the word 'family' has no clearly defined meaning. In twentieth century England, for example, in ordinary speech it may evoke any one of a cluster of meanings, depending on context (Harris 1983, p. 31). As well as parents and children, 'family' can mean: a network of kin ('all the family'); a succession of related people ('the family has lived here for 400 years'); children ('they have not brought the family with them'); birth status ('he comes from a good family'); household ('children leave the family as they grow up'); relatives generally ('she has no family in London'); etc. It is difficult to claim that any of these meanings is the 'true' meaning and others merely metaphorical usages, although some people might claim that the unit of parents and children is the primary sense of the term. However, there is evidence to show that this narrower meaning is relatively recent in English history. Davidoff and Hall (1987) trace its importance to the rise of the industrially based middle-class in the nineteenth century.

Three elements are *interrelated* in complex ways in the various uses of the word family: marriage, relatedness, or kinship and domestic or household organization. Each usage of the term carries different combinations of these elements. The 'elementary' or 'nuclear' family, as social scientists label parents and children, combines all three and it is this form that carries such symbolic weight in twentieth-century Western culture. At some point in the history of anthropology each of these three features has been used separately, and effectively, in cross-cultural comparison (see *Marriage; Kinship in Anthropology; Household in Anthropology*). The three principles are quite distinct in the abstract but separating them in analysis is not easy. However, it is the confusion between, for example, kinship and residence or marriage and parentage that causes problems in using 'the family' as a technical term.

In the West marriage is the foundation of 'the family.' As a legally established relationship the marital tie may be contrasted with the 'biological' links between parents and children or between siblings, which are referred to as blood ties. In Western societies marriage entails co-residence, although this is not a universal consequence of marriage (e.g., Fortes 1949). Where the norm is for a newly-married couple to set up their own household as in much of North America and Western Europe, this qualifies the newly-married couple to be referred to as a 'family' in anticipation of the children that are expected to follow. The death of a spouse or a divorce are individual breaks in the expected pattern but remarriage 'reconstitutes' the family once more.

The centrality of relatedness to the notion of family can be seen in the fact that not all residential units qualify to be called families. Individuals living on their own, boarding schools, prisons, and colleges are never referred to as families, nor are groups of unrelated people sharing a flat. In the case of the last three, this

may indicate that children are essential to a family, but children's residential homes are not considered families either. It is the nature of the ties among them that qualifies people who live together to be called a family.

The relationships internal to a family are thought of as emotional bonds, permanent ties that reflect ideals of sharing and altruism by contrast with the short-lived rational contracts of the market or the self-serving nature of political alliances. The authority of parents over children and the role of the father as 'head of the family' are believed to derive from the reproductive functions of the family and to reflect the 'natural' differences of generation and gender within it. The assumption that living together is necessary for the family to fulfill its reproductive function underlies the interchangeability of 'family' and 'household.'

However, Western cultures also make implicit distinctions between families and households. Where children are expected to leave the parental household at adulthood, this may, like the death or divorce of parents, be said to 'break up' the original family. Nevertheless, married adults continue to be related to their parents and siblings by genealogical ties that may be referred to collectively as belonging to a 'family,' although one which is not a household. Husband and wife belong, as offspring, to distinct 'families' that the marriage can be seen as linking. Individuals are thus members of at least two 'families': one in which they are children and (usually) siblings and one in which they are parents and spouses. Sociologists have labeled these the family of origin and the family of procreation, which emphasizes the different methods by which the focal individuals are recruited, birth and marriage; the labels incorporate the folk view. From a more analytical perspective the network of genealogical ties linking individuals can be seen as cross-cut by living arrangements that group them into different households.

Other usages of the term 'family' used in a variety of contexts show different combinations of kinship and residence. The term extended family may be used to refer to all individuals linked genealogically but not living together, giving this use of the term 'family' a purely kinship connotation, unlike its use to mean close kin who do live together. Alternatively, a large number of related households in one community may be referred to as an extended family, making their common locality a significant factor. Finally, 'extended family' may mean large households containing three or more generations, which can still be found in some rural communities in Europe. All these uses of the term are also current in academic works (e.g., Janssens 1993, 1fn).

The range of meanings that attach to the concept of the family make clear its great importance in Western culture. However, its complexity also raises a series of problems when it is used to analyze other societies. Simplifying the concept by identifying one or other of

its component elements as fundamental has not solved the problems in cross-cultural analysis but has preserved the idea that 'the family' is a useful concept.

2. The Family in Anthropological Analysis

The issues with which the anthropology of the family have been associated reflect Western notions. At the outset the focus was on marriage. In the nineteenth century, the scholars who developed anthropology regarded monogamous lifelong marriage as characteristic of 'civilization,' the culmination of human evolution. The Western family was a late development not to be found among peoples who represented earlier stages of the evolutionary process. These latter were characterized by plural marriage and a failure to understand the nature and significance of biological links. Nineteenth century evolutionism has long been recognized as lacking a sound empirical basis for its conjectures, but the idea that the present form of 'the family' is a product of social changes over time was not entirely abandoned. It survived in modified form in the view that the present form of 'the family' is a product of modernization, of capitalism, or of industrial society and in the myth that Europe's peasant forebears all lived in extended families.

By the middle of the twentieth century, some anthropologists argued instead that the family could be said to be universal. The basis for this contrary view was the assumption that 'the family,' so far from being associated with marriage in a particular cultural form, was based on a universal, natural function: reproduction. It was this biological 'fact' that formed the basis of the family, a view widespread in the societies from which anthropologists came. 'The family,' a couple with their children, might be incorporated in various different domestic arrangements, but was itself a biological 'given.' Whether any individual society recognized this or not depended on their culture, a view not unlike that of the evolutionists. Malinowski, an early proponent of this functional view, nevertheless cautioned that '...the essential features of the individual family...depend upon the general structure of a given society...' (1913, p. 6). More boldly, Murdock (1949) proclaimed the nuclear family to be universal, a co-residential unit with 'sexual, economic, reproductive, and educational' functions. His conclusions depended on the application of the label 'family' to a wide variety of social units that were not strictly comparable. The procedure showed all too clearly the looseness of the term.

Anthropological arguments over the incest taboo paralleled those over whether the family was a biological or social entity (La Fontaine 1990, pp. 20-43). The view that the incest taboo reflected a natural avoidance of sexual relations between related people assumed that incest referred to sexual relations within the 'nuclear family'; these relationships were such that

sexual attraction naturally did not arise. Other anthropologists pointed to documented cases of sexual prohibitions of an identical nature involving relationships outside the 'nuclear family,' as was also the case in Western society. Incest taboos, considered as total systems of prohibitions, varied widely cross-culturally, and could not therefore be considered biologically determined or 'natural' (Goody 1956). The later development of sociobiology resulted in claims that the taboo could also be observed to exist among the higher primates and was therefore genetic, rather than a feature of human family relations. This and other forms of biological determinism were vigorously contested (Schneider 1965, Sahlin 1976); in particular it was pointed out that paternity cannot be identified among higher primates and among human beings it is always socially determined. Few social or cultural anthropologists now accept that the incest taboo is universal, but the ideas that among close kin it is only rarely broken and that incest is 'unnatural' remains. At the end of the twentieth century, evidence that breaches of the incest taboo were infrequent but not rare in Western societies became public knowledge there. This offered proof that the 'taboo' was neither genetic nor unbroken. The reality of incest was not easily accepted, whether by the public at large or by social scientists, showing that the assumptions underlying it and also entailed in the concept of the family were deeply rooted in Western culture.

Knowledge of the variation in incest prohibitions came from the study of kinship systems that expanded rapidly in the middle decades of the twentieth century. The development had a further impact on views of the family. A solution to the theoretical problems raised by the data on domestic organization was to distinguish between 'the family' as a reproductive unit and the household or domestic group. One of the earliest to do this was Fortes (1958) who used the term domestic group, referring to the 'family' as the reproductive nucleus within it. His distinction emphasized a number of contrasts between the concepts: 'the family' consists of parents and children, whereas the domestic group might include more than two generations; the family is recruited through marriage and kinship ties, whereas many different kinds of tie may draw individuals into living together. The family is concerned with social and physical reproduction, the domestic group 'is essentially a householding and housekeeping unit' (Fortes 1958, p. 8). According to Fortes, the changes in the size and structure of domestic groups that can be observed in a particular society do not reflect breaches of any 'rule of residence' as had previously been thought, but derive partly from the effect on household constitution of the political and economic structure but also from the developmental cycle of growth and maturation in the reproductive nucleus. These processes and the cultural reactions that they entail are the driving force behind household changes.

Fortes' distinction also drew attention to production as a household activity. Property rights and labor needs were shown to influence the form of the domestic group as much as the developmental cycle of the reproductive core. Households were shaped by the demands for different kinds of labor associated with their subsistence activities and the association of related people within different households concerned economic viability as well as kinship obligations. Goody went further and showed that interpersonal relations in the 'reproductive core' were also affected by these factors (Goody 1956). Marxist anthropology subsequently attempted to construct different modes of domestic production and reveal the power structures entailed in them, but these largely ignored reproductive processes.

Distinguishing 'family' from 'household' avoided rather than solved the problems inherent in the concept of the family (La Fontaine 1985). The notion of the family as a reproductive unit conflates child-bearing and child-rearing with co-residence so that in effect the family is actually defined by residence, a return to the Western folk concept (Smith 1973). It is not surprising that some anthropologists have subsequently reverted to using family and household indistinguishably. The distinction also maintained the segregation of domestic kinship from the network of kin as a whole, which was particularly misleading where spouses were chosen from among them.

The French anthropologist Lévi-Strauss' revolutionary approach to kinship disposed of some of these questions. He argued that exchange of goods and of women, not biological reproduction, was the basis of social life. Hence, marriage rules are integral to the wider social structure, not merely the basis of the family or a means of recruitment to households. Systems where marriage with relatives was the ideal showed how the patterns of distribution of women in marriage constituted social structures. His 'atom of kinship' (1958 (1963)) contained the same elements as 'the nuclear family,' but rearranged so as to emphasize the relation between a man and his wife's brother created by marriage. Moreover its elements, pairs of opposites, reflected the oppositions in systems of thought, the deep structure of culture.

Under the rather more materialist influence of feminism, anthropologists in the 1970s showed how the 'natural' processes of childbirth seemed to be very widely used to symbolize women and legitimize their subordination to men. Within the domestic sphere, also associated with women, the division of labor was seen as reflecting the natural capabilities of men and women; the products of their labor were shared with their children. However, the distribution of goods and the allocation of labor within the household actually reflected its internal power structure rather than a pooling of family resources or a 'natural' division of family labor. The realities of power were presented as unquestionable by being associated with the natures of

men and women. Concepts of nature were thus shown to be more than mental constructs; they were also intimately bound up with the social distribution of power and authority, which they helped to reproduce. The 'family' was revealed as a similar social representation legitimizing household organization (Harris 1981).

Both of these approaches stimulated research into the meanings of folk concepts and into local systems of knowledge (Barnes 1973, Harris 1981, Carsten 1997). The social constructions of the person in folk theories made it clear that whatever the common physical nature of human beings, it is perceived through these culturally variable understandings. The image of shared blood or common physical substance are only two among many ways of representing relatedness and the concept of the family is a folk concept among others.

While Levi-Strauss' structuralist approach undoubtedly revealed the significance of cultural understandings of the world, he was not interested in distinguishing between the meanings drawn from the analysts' own Western culture and those of the societies they were studying. Recognition of this ethnocentricity led to a wholesale rejection of such oppositions as domestic and political, natural, and social that underpinned the notion of the family and kinship (Schneider 1984, Carsten 1997, p. 20). Others accepted that certain distinctions might be culturally specific, but argued that the topic of relatedness could be approached through the folk concepts of the society studied (Carsten 1995, p. 225). This left 'the family' as a Western folk concept, limited in its usefulness to an understanding of the West.

A final strand in late twentieth century anthropological thinking on 'the family' has been contributed by research in Europe and on issues of public concern (La Fontaine 1990, Simpson 1998). While there is a general acceptance that the concept of the family is analytically unhelpful, the term continues to be used. Thus, Segalen and Zonabend, having noted that under the influence of anthropology the 'overfluid' concept of the family has been replaced by analytical concepts such as household and kinship (1987, p. 112), then use 'family' unreflectively and do not discuss why or in what sense. Rather than refer to kinship networks established after divorce, Simpson retains the term family, though qualifying it as 'the unclear family.' He argues for the study of divorce, not as a social problem or a symptom of general breakdown, but as the reorganization of interpersonal relationships in new forms of kindred. His rejection of 'the family' as a theoretical model is explicit, but his continued use of the term implies, as does that of Segalen and Zonabend, an attachment to certain connotations of it that have yet to be explored. The concept of the family may have been discarded from the repertoire of many anthropologists but it is too soon to regard its relegation to the scrap-heap as final.

J. S. La Fontaine

Family as Institution

The family is one of the foundational social institutions in all societies, although the definition of ‘the family’ varies from place to place and from time to time. Thornton and Fricke (1989, p. 130) suggest an inclusive definition that provides a good starting point: ‘family [is] a social network, not necessarily localized, that is based on culturally recognized biological and marital relationships.’ In most times and places, families were responsible for production, distribution, and consumption of commodities, for reproduction and socialization of the next generation, for co-residence and transmission of property. And families generally still are. This article examines the structure of the contemporary family and changes in that structure. It describes alternative family forms and it looks at the processes producing families and dissolving them.

1. Family Mode of Social Organization

Under the family mode of social organization, kin groups pooled resources, including their labor, specialized in particular tasks, coordinated their activities, and connected to the larger community as a unit. This family mode of social organization is often associated with agricultural production, but it appears in a wide range of economic environments (Thornton and Fricke 1989).

The family mode of social organization has altered, however, with other, far-reaching social changes,

including the rise of the market economy, vast increases in productivity with concomitant increases in real income (Fogel 2000), urbanization, changes in ideology toward greater individualization (Lesthaeghe 1983), and changes in the structure of education. All of these changes have shifted decision making and social control away from the family, toward the individual or toward other social institutions. As families have less control over the time and resources of children, they are less able to influence marriage choices—whether, when, and whom to wed. As more people support themselves through wage-based employment rather than through work on a family farm or small business, families have less stake in the property and family connections that a potential marriage partner brings and young adults acquire more autonomy in marriage choices (Caldwell et al. 1983). Urbanization and electronic communication have made the family a less important source of companionship and entertainment now than when most people lived on farms or in villages (Burch and Matthews 1987).

In developed industrial societies such as the USA, the family retains responsibility for reproduction, socialization, co-residence, and transmission of property across generations. It is the main unit of consumption and often also produces considerable amounts of goods and services. Families provide care and support for both the young and the old. Although older adults receive financial transfers and access to medical care from the government in many societies, family members still provide the vast majority of their help and support (Logan and Spitze 1996) and children are almost entirely dependent on their families for financial, emotional, and instrumental support.

2. Structure of the Family

In the USA and many industrialized societies, the structure of the family looks quite different than it did in the mid-twentieth century. In fact, fewer people live in families as traditionally defined and more live in nonfamily households. The rise in nonfamily living can be traced to earlier nestleaving by young adults (Goldscheider and Goldscheider 1993), to delayed marriage and to nonmarriage, to continued high rates of marital disruption with lower rates of remarriage (Cherlin 1992), and to increases in independent living at older ages (Michael et al. 1980). In 1998, 15 percent of all people lived in nonfamily households, 10 percent alone (US Bureau of the Census 1999, Table 16), compared to 6 percent in nonfamily households in 1950 (US Bureau of the Census 1955).

3. Marriage

In the USA, men and women are delaying marriage into their mid-to-late twenties, often entering a cohabitation first. Divorce rates are high and stable, but rates of remarriage have fallen, so that a larger

proportion of adults are unmarried at the beginning of the twenty-first century than in the past. In 1970, unmarried people made up 28 percent of the adult population. In 1996, 40 percent of all adults were unmarried. Seventy-one percent of women born in the early 1950s had married by age 25, compared to 54 percent of those born in the late 1960s (Raley 2000). In fact, the shift away from marriage has been so dramatic for blacks that now a majority of black men and women are not married, compared to about a third of white men and women (Waite 1995).

Similar changes in marriage patterns have taken place in most European countries; recent cohorts are marrying at older ages and over a wider range of ages than in the past. In addition, European countries differ substantially in marriage ages. The Nordic countries of Sweden, Denmark, and Iceland show the highest average ages at marriage for women (around age 29) and the Eastern European countries of Bulgaria, the Czech Republic, Hungary, and Poland the lowest (around age 22). Since societies with relatively high age at marriage also tend to be those in which many people never marry, this diversity suggests that marriage is a more salient component of family in some European countries than others (Kiernan 2000).

Countries in Europe also show a great deal of variation in the proportion of women in marital unions. Marriage is most common in Greece and Portugal, where over 60 percent of women aged 25 to 29 are married, and least common in the Nordic countries, Italy, and Spain where a third or less are.

Age at marriage also seems to be rising in many countries in Africa, including the northern African countries of Egypt, Sudan, Morocco, and Tunisia, and in Kenya, Mauritania, Nigeria, Senegal, Togo, Uganda, and Zimbabwe. Countries in northern Africa also show a rise in age at first birth that is not apparent in the rest of Africa, suggesting an increase in nonmarital childbearing in those countries in which age at marriage is rising (van de Walle 1993). The proportion of women who are currently married is 55 percent in Morocco, 61 percent in Kenya, 58 percent in Haiti (both formal and informal unions), 68 percent in Indonesia, and 63 percent in Bangladesh (Macro International 2000).

4. Cohabitation

Declines in marriage are closely linked to increases in cohabitation, although it is difficult to untangle the nature of the association. In the USA cohabitation has become an increasingly common step in the courtship process; only seven percent of the women born in the late 1940s cohabited before age 25 compared to 55 percent among those born in the late 1960s (Raley 2000). Most couples begin their intimate life together by cohabiting rather than by marrying, so that the form of the union has changed more than its existence. But even when we consider both marriage and cohab-

itation, young adults are less likely to have formed a union now than in the past. Among young women born in the early 1950s about a quarter had not formed a union by age 25, compared to a third of those born in the late 1960s (Raley 2000).

Although a number of European countries have experienced similar increases in cohabitation, some have experienced much more and some much less. Cohabitation is strikingly common in the Nordic countries of Denmark, Sweden, and Finland, and France also shows fairly high levels, with about 30 percent of the women aged 25–29 in cohabiting unions. A group of countries that includes The Netherlands, Belgium, UK, West and East Germany, and Austria shows moderate levels of cohabitation—from 8 to 16 percent of women aged 25–29 are in this type of union. And in the Southern European countries and Ireland cohabitation is rare with less than three percent cohabiting among women aged 25–29 (Kiernan 2000).

In many European countries, women typically are in either cohabitational or marital unions by their mid-to-late twenties. However, over 60 percent of Italian women and 50 percent of Spanish are single, neither cohabiting nor married at these ages, compared to around one in three Portuguese and Greek women. In the Nordic countries and France, about a third of women aged 25–29 are cohabiting, a third are married, and a third are single. Marriage is much more common than cohabitation in all other European countries (Kiernan 2000).

5. Unmarried Childbearing

Changes in marriage have played a central role in increases in unmarried childbearing, which has reached historically unprecedented levels (Bachrach 1998); in 1996 32.4 percent of all births and 44 percent of all first births in the USA occurred to women who were not married (Ventura et al. 1999). But over a quarter of unmarried mothers are cohabiting with the child's father at the time of the birth so their children are living in 'intact,' if unmarried, families (Bumpass et al. 1995).

The proportion of births to unmarried women depends on the share of all women who are married, the fertility of unmarried women, and the fertility of married women. Marital fertility is relatively low in the USA and many European countries. Where nonmarital fertility is also low, as it is in Spain, Italy, and Japan, total fertility is substantially below replacement, but those low-fertility countries with fairly high levels of nonmarital childbearing, like the USA and France, tend to have higher total fertility (Rindfuss et al. 2000).

Unmarried childbearing varies substantially among racial and ethnic groups in the USA. The percentage of births to unmarried women is highest for black women (69 percent), and lowest for Chinese Americans (7 percent), with whites intermediate between

these two extremes at 26 percent. Rates of unmarried childbearing also vary a good deal within Hispanic origin groups, with rates for Puerto Rican women approaching rates for blacks (59 percent), whereas rates for Cuban-origin women (24 percent) approximate those of non-Hispanic whites (Ventura et al. 1999).

As we might expect from differences in the proportion of women who are single and in the proportion in cohabitational unions, unmarried childbearing also varies dramatically across countries in Europe. The Nordic countries, which have a high rate of cohabitation, also have quite high percentages of births to unmarried women; in Norway, for example, 46 percent of births at the end of the twentieth century occurred to unmarried women, most of whom were cohabiting. More than half of births in Sweden and almost half in Norway occur to unmarried women. At the other extreme, only 10 percent of births in Spain, 8 percent in Italy and 3 percent in Greece are to unmarried women. Countries such as Ireland, Belgium, Germany, Portugal, and The Netherlands fall in between (Rindfuss et al. 2000). The social implications of unmarried childbearing depend on both the extent to which these births take place within stable, socially recognized cohabiting couples, like in the Nordic countries, and the extent to which social welfare programs cushion the financial impact on the family of having a single parent. Where few supports for single parents exist, as in the USA, children in these families do less well than children raised in two-parent families, but even under these circumstances, most children raised by single parents are happy and successful as adults (Amato and Booth 1997).

6. Marital Disruption and Union Dissolution

A substantial proportion of all marriages end in divorce or separation due to marital discord. The divorce rate, which reflects the number of divorces in a year relative to the number of married people, rose continuously for more than a century in the USA and many similar industrialized countries, then leveled off at a fairly high level in about 1980 (Goldstein 1999). In the USA, the best estimates suggest that around half of all marriages will be disrupted (Cherlin 1992). The marriages most likely to end include those with no children, with children from a previous union or older children (Waite and Lillard 1991), marriages begun at a young age, and marriages between partners with relatively low levels of education (Martin and Bumpass 1989).

Although high divorce rates make marriages seem unstable, other types of unions are much more likely to dissolve. Cohabital unions show quite high chances of disruption, with a quarter ending in separation within three to four years compared to only five percent of marriages, according to one study (Wu and Balakrishnan 1995). Many cohabitations become

marriages, but these show lower stability than marriages not preceded by cohabitation (Lillard et al. 1995).

7. Alternative Family Structures

The married, two-parent family has been the most common family form in the USA and other industrialized countries for some centuries. But even at the height of the married couple family, many people lived in other types, most often due to the death of one member of the couple before all the children were grown (Watkins et al. 1987). When death ended many marriages relatively early in life, remarriage and stepfamilies were common, as were single-parent families caused by widowhood. The rise of cohabitation and nonmarital childbearing have meant that unmarried-couple families and never-married mother families are now common alternative family forms.

8. Sex

In spite of the sexual revolution, marriage circumscribes the vast majority of sexual relationships. Almost all married men and women are sexually active and almost all have only one sex partner—their spouse. Unmarried men and women have much lower levels of sexual activity than the married, and frequently have no sex partner at all. Cohabiting couples are at least as sexually active as married couples, but are much less likely to be sexually exclusive (Laumann et al. 1994). Thus, the married couple remains the locus of the vast majority of sexual activity.

9. Working Families

Perhaps as dramatic and far-reaching as the alternations in the structure of the family are the changes in the way its members use their time. In the early 1960s in the USA, among those in the prime working ages most married couples followed the male breadwinner/female homemaker model; 56 percent had only one earner. The dual-income family was uncommon—both spouses worked full-time in 21 percent of married couples. By 1997, only a quarter of married couples had one earner. In 44 percent of married couples both spouses worked full-time, and in another 24 percent one worked full-time and one part-time. The shift toward the dual-worker family was even more dramatic for couples with children (Waite and Nielsen 2001). Even by the beginning of the 1970s, most children living with a single parent did not have a parent at home full-time; now most children in married-couple families do not either.

Many public commentators and some scholars of the family argue that the family is in decline and under siege from legal, economic and social change (Popenoe 1993). As evidence, they point to low marriage rates,

high divorce rates, low marital and high nonmarital fertility. And this evidence is compelling, as far as it goes. But most adults are married (although it is a second marriage for many), most have children, most rate their marriage as very happy and place a high value on family life, and most have only one sex partner—their spouse. Most single parents raise happy and successful children. This evidence suggests that the family remains a key social institution, even in its altered state.

Family Bargaining

1. Introduction

The concept of bargaining refers to a particular approach to decision-making in situations of conflict. Such conflicts could be resolved in other ways: dictatorially, for instance, through the use of force or authority, or democratically through majority vote. Bargaining, on the other hand, refers to the attempts

by the different parties to a dispute to threaten, cajole, or persuade others to settle it in their favor. Bargaining takes different forms because it occurs in different contexts. This article reviews different social science approaches to the analysis of bargaining in the specific context of family-based households and the insights they provide into its distinctive features. Two broad approaches will be distinguished: the neoclassical and the 'institutional.'

2. *Neoclassical Economics and Household Decision-making*

Neoclassical economists tend to explain human behavior through abstract mathematical models and econometric approaches to data analysis. They therefore place considerable value on 'parsimony,' or the ability to explain complex phenomena through a very limited set of variables. This is evident in early models of household decision-making which assumed it to be the responsibility of the household head, acting as 'benevolent dictator': 'benevolent' because he was assumed to take account of the welfare of all members in his decisions and a 'dictator' because he was able to impose his decisions on them (such models implicitly assumed a male household head, an assumption which is often but not invariably appropriate). However, while this dual assumption considerably simplified attempts to model household decision-making, it ruled out the possibility that power and conflict might have any role to play in the process (Becker 1981)

Two bodies of empirical evidence challenged this representation of household decision-making. The first showed that access to resources by individual members influenced the allocation of intrahousehold resources, suggesting that household decision-making processes were susceptible to the economic leverage exercised by different members (Thomas 1993, Hoddinott and Haddad 1995). The second documented phenomena such as domestic violence as well as systematic inequalities in household welfare along age and gender lines (Momsen and Townsend 1987), further undermining the assumption of conflict-free, welfare-maximizing, decision-making. Bargaining models of household decision-making emerged in response to such evidence. Their starting premise was that individuals cooperated to form households because the resulting benefits exceeded those obtainable from living alone. Where members had conflicting views about certain decisions, they might seek to bargain over the final outcomes. However, not all members had equal bargaining power and bargaining models largely were concerned with establishing the determinants of differentials in bargaining power within the household. These were seen to depend on the kind of 'threats' that different members could make in order to influence the decision-making process. The ultimate threat available was the threat of

'exit,' which in the context of the household, implied withdrawal from its membership.

However, the credibility of such a threat depended on the kind of resources that members were able to command as individuals rather than as household members. Initially, the 'threat' position was equated with access to individual economic resources, for instance, labor market earnings. It was expanded subsequently to include aspects of the social context which were likely to impinge on the threat positions of individuals as social groups. For female members, for instance, individual threat positions might be influenced by sex ratios in the relevant marriage market, laws concerning alimony/child support settlements, women's ability to return to their natal homes after marital breakdown, and the cultural acceptability of outside work.

Quantitative tests of bargaining models supported the assumption that individual economic characteristics, such as wages and incomes, as well as broader structural factors, such as legal provision relating to divorce settlements, did influence decision-making outcomes within the household (Hoddinott and Adam 1998, McElroy 1990, Schultz 1990, Jones 1986). They confirmed the feminist argument that, by and large, male household members exercised greater bargaining power than females, a reflection of their higher earning capacity as well as gender asymmetries in the legal structure. They also confirmed anthropological findings that men used their stronger bargaining position to claim a disproportionate share of household resources for their own consumption as well as more leisure (Dwyer and Bruce 1988). They pointed to the importance of women's access to paid employment for helping to shift the balance of decision-making power within the household. However, the insights provided by economic models have been limited by their focus on the economic determinants of bargaining power and their failure to consider its social dimensions. Yet it could be argued that it is its social dimensions which most help to distinguish the process of bargaining within the family from bargaining in any other arena of social life.

3. *Institutional Approaches and Family Bargaining*

Institutional approaches to household bargaining refer to attempts by nonneoclassical economists, sociologists, and anthropologists to account for the specificities of the household as an institutional form. These see households as an institutional response to the human need for long-term stable environments in which to bear and bring up children, to care, and be cared for, through sickness, disability, and old age and to plan for the future in a world characterized by uncertainty. What gives the household its institutional advantage in achieving these goals is the close inter-

twining of emotions and interests that characterize its relationships. Despite the different forms households take in different parts of the world, its relationships are generally familial. Its members are related by blood or marriage, they have lived together over considerable periods of time, they care for each other, and in any case, trust each other more than they trust strangers.

However, cooperative behavior within the household is not left entirely to the spontaneous impulse of members. It is also underwritten by a series of 'implicit contracts' that spell out the claims and obligations of different members to each other. Given the importance of the activities carried out within the family to the reproduction of social life in the wider society, these contracts typically embody social norms and beliefs about the meaning of the family in different cultural contexts. And given the importance of gender relationships in the key activities of the family, contracts between women and men within the family typically embody social norms and beliefs about gender differences in the wider society.

As long as household members have more to gain from their membership of the household than from going it alone, they have an incentive to abide by the terms of intrahousehold contracts, including its rules about decision-making. However, when these gains are less certain, how household members respond, whether or how they seek to achieve more favorable outcomes, will depend on what they are stand to gain from such action compared with what they stand to lose. Institutional approaches to cooperation and conflict within the household differ from neoclassical approaches in two important ways. First of all, they explain the rationale for cooperation within the family in affective and contractual terms rather than purely instrumentalist ones. Household members do not make decisions and seek to bargain as unrelated individuals, differentiated only by their resource endowments, but as members of families, with ascribed roles and responsibilities. Familial connections also mean that what individual members value about their membership of particular households, and hence what they stand to lose, cannot be captured by a materialist calculus alone. Nelson (1996), for instance, suggests that along with concerns with material well-being, household members will also seek to balance their need for 'affiliation,' the need to love and belong, with the value they attach to 'agency,' the capacity to define and act in their own interests. These different dimensions of well-being often involve trade-offs so that an individual may gain greater 'agency' by withdrawing from the household but have to sacrifice affectivity or material well-being.

At the same time, there may be situations where members may feel strongly enough about a decision to seek to influence its outcome. Because such action can, in certain cases, lead to open conflict, the likelihood of it happening will be determined partly by the extent to which the member, or members, in question feel able

to jeopardize their membership of the household, in other words, on the strength of their fall-back positions. The second important difference between institutional and neoclassical approaches to bargaining relates to how they conceptualize differences in fall-back positions. While the primary focus of neoclassical approaches has been on differences in individual economic resources, institutional analysis emphasizes the much wider range of constraints and possibilities which reflect the household as a specific institutional form and create social differentials among individual members, or categories of members. These points have been articulated most clearly in the literature dealing with the gender dynamics of household decision-making and will be elaborated by drawing from this literature.

4. Gender and the Structure of Constraint

Neoclassical approaches to household economics tend to treat differences in resource endowments as the product of individual efforts or as 'given' by genetic features like the sex of individuals. Institutional approaches, by contrast, suggest that these differences are influenced significantly by social rules and norms which prescribe the distribution of resources, the division of labor and responsibility for decision-making within the household. While it is largely men who are favored by these rules and norms, gender inequalities vary considerably across societies, leading to wide variations in whether, and how, women have influence in household decision-making. For instance, most inheritance laws and customs favor male members of family but vary considerably in how they treat women. In some societies, women can own land and property in their own right. In others, they have rights of access or use, but only as members of particular households. In yet others, they are effectively property-less. Similarly, social norms tend to assign primary responsibility for domestic work to women in most societies, but vary considerably in whether they permit women to engage in economic activities as well. In societies that practice female seclusion, for instance, women are proscribed culturally from undertaking public forms of employment. They are consequently likely to be far more dependent on male members of the household, and their capacity to influence household decision-making processes correspondingly curtailed, compared with societies where women have a socially-sanctioned role in production.

Finally, there are also cross-cultural variations in the access that women enjoy to extrahousehold social networks which will also influence the extent to which they are dependent on their immediate household members for provision and security. For example, in the Indian context, the ability of women to retain contacts with their natal families after marriage has been found to be an important factor in determining

the degree of agency they are able to exercise within marriage.

These variations in the contractual relations of the family create very different sets of gender interests in different social contexts and very different possibilities for women, as the subordinate category, to pursue their own interests. In contexts where women have recognized access to resources and economic opportunities, as in parts of sub-Saharan Africa, the relationship between spouses is often characterized by an overt bargaining element. Attempts to infringe on women's economic autonomy can result in open conflict, often ending with women leaving their husbands to set up their own households. By contrast, in many parts of South Asia, where women are denied access to critical productive resource or the ability to engage in economic activities, there is less scope for overt bargaining with more powerful male members. Conflicts are likely to be suppressed and dissent expressed covertly through what have been described as the 'weapons of the weak': deception, manipulation, and subversion.

5. *Gender and the Structure Of Preferences*

Neoclassical approaches to household decision-making do not pay a great deal of attention on what motivates people in their behavior. It is assumed that each member will have their individual preferences, depending on what gives them 'utility' or satisfaction. Because these are subjectively determined, they will be idiosyncratic to individuals and distributed randomly across the membership. However, evidence that women tend to behave in systematically different ways from men within the household, that they are more likely to put the collective interests before their own and to allocate resources under their jurisdiction to collective, rather than individual forms of consumption, has been given different explanations.

One set of explanations focus on differences in interests and fallback positions. Thus, although women often appear to give value to the collective well-being over their own as a result of prevailing ideologies of maternal altruism, Whitehead's (1981) work in Ghana leads her to suggest that such altruism often contained a dimension of self-interest. Women's fortunes are bound up with the fortunes of the household collectivity to a larger extent than those of men and their longer-term self-interests better served through altruistic forms of behavior which helped to preserve household solidarity. According to Agarwal (1997), evidence from South Asia that women tend to subordinate their own well-being to the well-being of others reflected their awareness of the weakness of their fall-back positions and a resulting caution in acting overtly in their own self-interest. An alternative set of explanations suggest that these differences in behavior reflect actual differences in the values and

priorities, differences which in turn reflect social definitions of gender identity. Social norms and beliefs do not simply determine gender differences in resource endowments; they also justify and legitimate these differentials by ascribing very different aptitudes and dispositions to men and women, differences which are internalized by them as aspects of their gender identities.

For instance, studies in the US and Europe suggest that the processes of socialization through which men and women acquire their gender identities tend to stress agency and 'separative' notions of selfhood for men, and affiliation and 'connected' notions of selfhood for women (Chodorow 1978). In the South Asian context, it has been argued that gender identities are linked to differentiated notions of individual self-worth (Sen 1990). Women are seen to accept the lesser status accorded to them by a society and to define their own sense of well-being in terms of the well-being of other family members.

If men and women within the family have different values and preferences, bargaining can take the form of trade-offs between different dimensions of individual well-being noted earlier. Thus, a wife may agree to love, honor, and obey her husband in exchange for his promise to love, honor, and protect her: both value affiliation but the wife trades some amount of agency in return for material security. Alternatively, a husband may accept greater agency for his wife (and perhaps less for himself) by agreeing to her paid employment but only on condition that she does not neglect the housework and hence his material comforts. However, these negotiations and trade-offs will not be conducted on equal terms because the gender differentials in values and priorities do not have symmetrical implications for the bargaining process. If women do indeed attach greater value to affiliation or less value to their own self-worth, it is likely to work to men's advantage in situations of conflict. First of all, women will be less willing to disrupt household solidarity by open expression of dissent. Second, even if they do decide to engage in explicit bargaining, they will find it harder to hold out for their own self-interest or to threaten to use the exit option, if things do not go their own way.

6. *Conclusion*

Institutional approaches to family bargaining differ from neoclassical bargaining approaches because they focus on households as sets of social relationships, rather than a collection of individuals, on the structural determinants of bargaining power rather than the individual, and on the role of norms and values in shaping preferences rather than taking preferences as given. They consequently offer important insights into the specificities of households as social institutions and into what makes bargaining within the family different from bargaining in other arenas of life. Because

families are constructed around relations of unequal, but intimate, interdependence, power within the family is rarely exercised in a naked form. Violence, and the threat of violence, exist, but more often, men are able to resort to the authority vested in them in their capacity as household heads or as primary breadwinners to protect their own interests. The association of authority with male roles within the family explains why decision-making roles are not reversed automatically in households with unemployed husbands and employed wives or where women earn more than their husbands.

Equally, however, despite their stronger fall-back position, men within the family do not always get their own way. Bargaining processes within the family encompass forms of 'threats' as well as 'persuasions' that cannot be reduced to the economics of fall-back positions. They reflect the fact that the family is an intensely personal arena of life and that family relationships are suffused with feelings and emotions to a much greater extent than any other institution in society. Because families are based on ideologies of affectivity and shared interests, bargaining within the family rarely takes the form of open self-interest. Instead, it is conducted as negotiations over meanings and interpretations of, for instance, what constitutes the collective interests of family members, what their proper roles and responsibilities should be, and the basis of claims on collective household resources.

This means that, despite their subordinate position, women have a valuable resource on which they can draw in devising their bargaining strategies: their intimate knowledge of other family members, of their feelings and emotions, as well as their values and priorities. This knowledge can be translated into various forms of 'threats,' including persistent complaining, ridicule, withdrawal into silence, and withholding sex from husbands. Alternatively, they may employ more persuasive tactics. These may be discursive in form, for instance, appeals to shared interests in children's welfare as the justification for pursuing some preferred course of action. Or they may be more practical, involving strategies of 'wielding and yielding,' trading concessions in some areas in some areas to win concessions in others.

However, the fact that, despite the weakness of their fall-back positions, women are able to engage in a variety of bargaining maneuvers to achieve their priorities, should not be taken to negate the importance of improvements in their fall-back positions. Such improvements can bring about qualitative transformation in the asymmetries of the bargaining process. They can, for instance, lead to more open forms of bargaining between equals in place of the covert tactics that make up the 'weapons of the weak.' They can also open up for negotiation and contestation of aspects of household inequality that were previously considered nonnegotiable, for instance, in the domestic division of labor.

Research is needed to establish which are the most critical opportunities and constraints which make up women's fall-back position in different societies, how changes in these opportunities and constraints come about, and what role can be played by policy and public action to facilitate the right kind of changes. Women's paid activities has been found to be one of the most consistent predictors of their capacity to exercise agency within the household, both in advanced industrialized countries as well as in poorer ones. However, their ability to take advantage of employment opportunities is itself a matter for bargaining and negotiation, particularly in societies which practice female seclusion. The fact that women have, nevertheless, been able to do so suggests that other factors also came into play in negotiating these opportunities. Economic resources are important, but they may require changes of the kind brought about by enabling policies and social movements before their transformatory potential can be realized.

In addition, research is needed on the pathways by which changes in the wider structures of constraints and opportunities transform the unequal interdependencies of the family. It is possible that they will vary considerably according to local beliefs and values. In cultures that are strongly individualist in their outlook, women may use improvements in their fall-back position to seek greater independence, perhaps exercising their exit options. On the other hand, in cultures that emphasize collective values, they may prefer to bargain for greater equality in decision-making, the democratization of household structures. Attempts to evaluate the transformatory potential of different kinds of change in women's fall-back position will 'misread' the nature of the process if they are premised on an inappropriate set of values.

Family Business

Family business is an interdisciplinary field involving all professionals who advise, study, and work in family firms addressing their structural and transitional problems. Family firms are companies of various sizes controlled by one or more owners tied by family relationship or solid alliances (see Corbetta 1995, Aronoff et al. 1996, Neubauer and Lank 1998). Even if this control-based definition is widely accepted, some authors propose others based on the owners' managerial involvement. Other authors do not consider either firms controlled only by the founder or those controlled by unrelated partners as family businesses. Another group tends to identify family businesses with small and medium-size enterprises where the overlapping of family and firm is particularly high. Whichever the accepted definition may be, it includes

various types of family firms that can be classified using different dimensions. Family business specialists' fields of origin are equally varied and include such disciplines as business, law, psychology, sociology, and history.

A study carried out on the articles published in *Family Business Review* from 1988 to 1997, shows that over 70 percent of the academic articles were written by authors in the field of business management (Dyer and Sánchez 1998). In this discipline, family business literature mainly overlaps with studies on entrepreneurship and management issues in small and medium enterprises (SMEs) (see *Entrepreneurship*). However, it distinguishes itself from such studies on at least three levels. First of all, family business literature investigates family firms' evolution from succession to the founding owner up to following stages in which the firm may have become very large and even public but it may still be controlled by one or few families tied by family relationship or solid alliances (Gersick et al. 1997). Second, family business management literature deals with the entrepreneur's characteristics and entrepreneurship training and developing processes in a peculiar way.

On one hand, these topics are always related to owning families' characteristics and dynamics, and on the other hand much more attention is devoted to the issue of how to pass on entrepreneurial capabilities rather than on how to start a new venture. Finally, family business literature deals with topics that are not investigated by the streams mentioned previously, such as managing the ownership group, governing the family firms and managing the family–firm relationship.

Family businesses are dynamic systems that include two subsets, the family and the firm, which are characterized by their own evolutionary patterns and are linked to each other by many dynamic relations. Hence a scholar may be considered a scholar at family business when they deal with the whole system: a psychologist interested in parents–children relationships addresses family business issues only when they consider how these relationships' dynamics impact the way the business operates. A business management scholar interested in strategy deals with family business only when investigating the relationships between the owning families' structure and evolution and business continuity.

1. Origins and Development of Family Business

Even if some family business articles appeared in the 1950s, 1960s, and 1970s, only at the beginning of the 1980s was family business born as a field acknowledged by a number of North American scholars and practitioners. A fundamental contribution was made by a management researcher (Richard Beckhard, Management and Organization Behavior Professor at

MIT Sloan School of Management for more than 20 years), by a psychology researcher (Harry Levinson, professor at the Psychiatry Department at Harvard Medical School), and by a consultant (Léon Danco, CEO of the Center for Family Business in Cleveland). In the mid-1990s they have been recognized publicly as family business pioneers and interviewed in the 1994 *Family Business Review* issue (Vol. 2) dedicated to the field's history; in these interviews they all admit to how difficult it was to make the scientific community accept the existence of family business as a special discipline.

Until then business and family (and related studies) had been dealt with as two separate, autonomous fields: it was difficult to convince scholars in either that it would be useful to get acquainted and cooperate. Moreover, the first studies in family business were case descriptions without any interpretative framework, which made it even more difficult to open a scientific debate. Finally, most family business professionals were practitioners at that time; as such, they were not well respected as researchers by the scientific community. Further, they were not very committed to publishing in order to share their knowledge and experiences with others.

Generally speaking, family firms traditionally have been considered—and not only by academics—as a residual of the past to overcome, beginning from the study by Berle and Means (1932) who considered separation between ownership and control as a fundamental condition of development for modern economies. Not surprisingly, the media were used to dealing with family businesses only to highlight how disputes among family owners or nepotistic behaviors negatively impacted the business.

In 1984 something of decisive importance in the development of family business occurred: a group of North American scholars and practitioners, coordinated by Barbara Hollander, gave rise to the Family Firm Institute (FFI). By means of its various services, FFI has become a special forum for knowledge sharing and development. Particularly, annual conferences and the *Family Business Review*—founded by Ivan Lansberg in 1988—have been fundamental tools that helped develop theory and practice. In the leading article of the first issue, Lansberg himself provided significant data about how early the stage of the field's development was: according to a study conducted on the Social Science Citation Index from 1977 to 1987, only 53 articles had been published in the US on family business issues, as compared with the 813 on entrepreneurship.

In 1990, the Family Business Network (FBN) was founded in Europe. Despite its different membership policies (there are more family business members and less professionals), FBN fulfills a similar mission by spreading family business knowledge and fostering a scientific and cultural debate on this topic.

The increasing number of monographic issues on family business published in such reviews as *Organi-*

zational Dynamics (summer 1983), *Business History* (October 1993), and *Entrepreneurship Theory and Practice* (N. 1, 1994) shows that rising attention has been devoted to this new discipline by scholars in other fields as well.

In the US and in other parts of the world, some universities followed the increasing interest on the part of scholars and other stakeholders towards family business. Nowadays more than 100 universities and business schools in the world offer specific research and training programs on family business issues (Aronoff 1998). Most of these programs have been developed in family business centers, which—even if they are often based in management departments—usually get contributions from various disciplines.

Different factors have persuaded individuals and institutions to invest resources in exploring family business. Among these is the diffusion of data about the importance of family businesses in modern economies, evidence that family firms can grow big and cannot just be identified with SMEs, and consciousness of the difficulties for family firms to last beyond the first generation. Depending on the adopted definition, family firms represent from 30 percent to 70 percent of the GDP in the main industrialized countries, and above all, they seem to be the enterprises with the highest rate of growth in employment.

Looking into the future, family business seems to be in a delicate phase. In order to gain importance in the academic context this new discipline needs to be acknowledged from an institutional point of view as well; for this reason, a key challenge—at least in Europe—is to increase the number of universities and business schools that create chairs in family business. Probably this will happen mainly in management departments, as it occurred in the closely related field of entrepreneurship.

Concerning the practitioners' sphere, the family business field is growing very rapidly, with many advisors coming from a variety of professions and entering the field. The main problem in the near future is the difficulty in defining the minimum standards necessary to qualify people as family business professionals. The FFI is working on a research project that started with identification of four major content areas—Behavioral Science, Finance, Law, and Management Science—and is going on with the definition of fundamentals that competent family business advisors, consultants, and educators should know to work effectively in those subfields.

2. Research Areas and Achieved Results

Family businesses are a composite world including different archetypes. Many authors have proposed classification criteria. According to a widely accepted distinction there are family firms owned and managed either by a single owner or by two or more siblings or

by cousins' teams. A fourth archetype consists of those family firms where equity has been opened up to partners other than the founding family (Corbetta 1995). Usually, changing from one type to the others the company grows in size. But notable exceptions make it impossible to significantly correlate company size with ownership structure. The distinction mentioned here cannot be confused with the generation-based perspective, for example, first generation family enterprises can be controlled either by a single owner or by a sibling partnership or by a cousin consortium.

For every archetype identified, a variety of research topics can be defined, such as:

- (a) family structure and management;
- (b) ownership structure and management;
- (c) company governance;
- (d) company management;
- (e) relations among family, ownership, governance and management; and
- (f) transitions into another type of family business.

Other general topics of research concern the comparison among different types of family businesses, between family and nonfamily businesses (in terms of values, culture, strategies, and performances), among family enterprises operating in different countries, the relationship between enterprises and consultants, and the role of women.

In terms of necessary competencies, many family business scholars believe that most research topics need interdisciplinary team effort; in particular, researchers in management, psychology, and sociology should cooperate to capture the distinctive facets of family business.

2.1 Studies Before the 1980s

The first family business studies mostly concerned founder succession issues, that is either transition from the controlling owner archetype to another or recycling of the same archetype with different actors (Danco 1975). Such studies typically had the following characteristics:

- (a) they concerned small and medium sized firms with simple management structures;
- (b) they took into consideration only the simplest family situations—one founder, one heir—overlooking more complicated but also more widespread circumstances, for example, those of founding partners' teams or those where the transition occurs between multiple founders and multiple heirs;
- (c) they centered their attention on the two people involved in leadership transition—the founder and the heir—without considering other family and business members;
- (d) they almost exclusively dealt with the issue of passing on managerial roles overlooking ownership changes; and
- (e) they considered the family as an obstacle to the effective and efficient management of the firm and

suggested a clean distinction between family and enterprise as an indispensable condition for business continuity.

Even if many of these studies, which were clearly influenced by some streams of rationalism (Hollander and Elman 1988), have been revisited or even become outdated, they have actually achieved some important results. First of all, they have opened up a new, interesting stream by explicitly recognizing the differences—in terms of roles, goals and needs—and the mutual influence between the family and the business. Moreover, these studies suggested some interpretative frameworks still valid today such as: succession considered as a multiphase process and not an event; the difficulties of this transition coming from the variety of roles—parent, owner, and manager—simultaneously played by the founder; the importance of training for people; the need to consider the firm's continuity as a fundamental goal to be achieved to be able to consider generational transitions as successful ones.

Many of the first scholars were focused on small and medium sized enterprises, which made them also study managerialization processes in relation to company growth patterns.

2.2 The Subsequent Studies

In the following years the family business field was consolidated; its boundaries were clarified and new topics were identified. In particular, several contributions concerned the following:

- (a) the definition of family businesses and their classification, going beyond complete overlapping with small and medium sized enterprises;
- (b) the definition of the main dynamic relationships between family and business using interpretative frameworks based on different stages of the firms, people, and families' life cycles (Davis and Tagiuri 1982, Beckhard and Dyer 1983, Gersick et al. 1997);
- (c) succession processes, widening the range of considered situations and variables; and
- (d) new topics such as management of extended families, family business governance, and strategy. Concerning the first topic, numerous studies have been focused either on the role and way of implementing family protocols or on the way of functioning of specific bodies like the family council. With regard to the second topic, attention has been centered on the structure and the functioning of boards of directors (Ward 1991, Neubauer and Lank 1998). On the third topic, interesting contributions have been published on internationalization processes and strategic management in general (Ward 1988).

During this period, scholars have reached a greater consensus about the definition of family business and about the classification of different family firms' archetypes. The field has experienced significant development and has involved scholars from other

disciplines (e.g., finance and corporate governance), which has generated new research opportunities.

One very important achievement is that the family is no longer considered an obstacle to the firm's development. Longitudinal studies of family business cases and quantitative researches definitely have shown that the owning family can be a strong point for the firm as it provides such key factors as long-term orientation, education to entrepreneurship, values, commitment and personal sacrifice, reputation, speed in decision-making, and lower transaction costs (Gallo 1995). Social scientists' studies are considered an important basis to build up theories and models that can be helpful for family business success in the long run. Theories on family life cycles and adult development have been used to analyze family firms' stages of development, which are seen as the joint result of family, ownership, and business dynamics (Gersick et al. 1997). Family systems' theories are used to suggest how to better manage interpersonal relations, communications, and to handle conflicts through their predictable stages in the family business context (Barnes 1988, Kaye 1991). Interpretative models have recently been proposed considering the family just as important as the company as a determinant of family business success; so, both institutions are included in the model at the same level of detail, as purposive social systems transforming resources and constraints into outcomes by interpersonal and resource transactions (Scannel Trent 1999). The same studies have investigated family firms' diffusion by surveying households instead of companies.

Concerning succession, which is still the hottest topic in family business literature, research findings highlight the need to plan the transition: the importance of successors' personal development both inside and outside their own family firms; the critical role of the entrepreneur and of their ability to delegate; the importance of communication; and the useful contribution of nonfamily members either as outside directors or as tutors and mentors to the younger generation. Efforts have been made to broaden the focus of research: a variety of situations has been addressed in addition to the 'simple' one featuring one entrepreneur with only one heir; ownership transitions and their financial implications have emerged as relevant succession topics besides the classical one concerning company leadership. Efforts have also been made to offer deeper insights on the 'classical' issue of succession to the founder. Numerous studies have built upon the existing literature by exploring the complexities that characterize this type of succession as well and that had been overlooked so far. Relationship between founder and the whole organization, and how organizational culture can be created and passed on so as to enable company continuity have been investigated (Schein 1983). The broad range of stakeholders involved besides the founder and the successor involved has been analyzed, highlighting

how each of them may resist coping with the generational transition issue and by this means create obstacles to the whole process (Lansberg 1988). The issue of how entrepreneurial attitudes and capabilities can be learnt and taught has been further explored (Aronoff et al. 1996).

Finally, relevant insights have been provided on family business governance, particularly on the structure and the functioning of boards of directors and on their contribution to company development.

2.3 Future Developments

A recent article that appeared in the *Family Business Review* has identified some trends in family business studies (Aronoff 1998). Succession will remain one of the most interesting areas in the broader perspective of generational transition. A new research topic could concern possible roles for retiring entrepreneurs. Generational transitions will increasingly lead to both owners and family managers' teams; conditions under which such teams can effectively work will be one of the hottest topics in the nearest future. Companies' strategic context is significantly changing because of the impact of new technologies and globalization. Family businesses' capability to compete in such a context will make a relevant research topic as well. Another key issue will be the impact of increasing managerial and financial sophistication on both the culture and behaviors of family businesses. The other topics mentioned by Aronoff concern the roles of women, consultants, and educators.

Interesting developments may also come from the increasing focus on big family businesses that characterizes some studies in progress. Certainly this will lead not only to identifying and offering more sophisticated solutions to the already well-known problems of smaller family businesses, but also to investigating different ways to govern and manage large family fortunes in terms of both personal attitudes and necessary skills.

Studies on family businesses' developmental stages have not yet deeply explored transitions from one stage to another. Relevant insights on this topic could be provided by joint efforts of management and psychology researchers.

Finally, other topics are likely to undergo important developments. We can mention, for instance: comparisons among different archetypes of family firms, among family businesses from different countries, and between family and nonfamily enterprises in terms of resources, strategies, and performances; nonfamily managers' characteristics and roles; family businesses' selling processes; and the impact of some variables on family firms' continuity. Research efforts could also address family values and ownership structures.

Research topics still seem to be driven by both family enterprises and family business professionals, necessary because they are the main sponsors of

research projects. On the other hand, the strong link with family businesses is helpful in making the relationship between theory and practice mutually beneficial. Obviously scholars should avoid focusing on short-term needs and commit themselves to identifying long-term research goals and strategies.

3. Methodological Issues

Practitioners, as it was stated before, have played a predominant role in the formation of family business as a discipline. At least until the early 1980s, as a consequence, research methodologies were not emphasized. Even those scholars who have been in the field from the very beginning were much more concerned in defining boundaries and topics rather than in carrying out methodologically acceptable research projects. In the first issue of the *Family Business Review*, in 1988, only 14 percent of articles were research based. Notably, 64 percent of the articles published in the 10th issue of the same review reported qualitative or quantitative research findings (Dyer and Sánchez 1998).

In any case, family business research still has to cope with at least three specific problems. The first and most important one is that family business, as should be evident, requires that contributions be provided by professionals from different disciplines, particularly social sciences such as sociology, psychology, and business management. On one hand, it is not easy that a single person dominates both; at the same time, interdisciplinary collaboration is not well developed, probably because of the high costs of joint research due to the very different starting points in terms of knowledge, languages, and methodologies. On the other hand, since in many fields radical advances come from collaboration between authors in different disciplines and professions, such collaboration should be strongly encouraged.

The second problem concerns information availability. Entrepreneurs and their families are known to be very reserved and protective of their privacy. Moreover, most family businesses do not have to disclose much information about their structure or about their performances. Researchers are trying to overcome this problem by collaborating with institutions such as banks that can provide family business databases or by designing research projects based on primary sources and making use of interviews, questionnaires, and longitudinal case studies.

The third relevant problem regards the specific need of this field to encourage collaboration between scholars and practitioners. Increasing interest in family business among younger Ph.D.'s is definitely improving the quality of research. Some difficulties could arise as young scholars often focus their attention on topics that are not considered particularly relevant by family businesses, which may hinder communication between academics and other stake-

holders. In other fields such as entrepreneurship, such incommunicability has led to very disappointing results (Brockhaus 1994).

Finally, given the interdisciplinary nature of the family business field, relevant developments might result from the application of theoretical frameworks and analytical tools developed in other knowledge areas such as the system dynamics approach (which might be useful in explaining the dynamics of the family-business system) or the resource-based view (which might lead to a better understanding of the relationships between the business and the family's resources and the firm's performances).

Family Health

The very diversified topic of family health is currently receiving increasing attention from different disciplines and different directions within psychology. This is especially evident in the areas of clinical and family psychology, gender-specific research, and health psychology (see *Health Psychology*). In this article, important theories and empirical results from these fields are summarized in a systematic overview which is divided into the following sections: (a) the bi-directional connections between family dimensions and the health of family members (e.g., the mother), (b) systemic concepts like ‘psychosomatic families’ or ‘family mental health,’ (c) family resources in terms of coping capabilities or ‘salutogenetic’ and regenerative variables of family life, and (d) differential aspects of family health, that is, differences between the developmental stages of the family life course, differences between family structures, and main results from gender-specific research.

1. Introduction

The article will first of all locate the topic of ‘family health’ within some main psychological traditions, before a systematization of the topic is proposed and selected empirical results are described briefly.

The field of family health can be seen at the crossroads between the disciplines of family psychology and health psychology. The connections between health and family factors are numerous, varied, and important. Nevertheless, the fields of ‘family health psychology’ and ‘family systems medicine’ are still in the early stages of development, although family psychology and health psychology are established disciplines (Akamatsu 1992).

Despite the fact that the family is the basic social context in which health behaviors are learned, clinical and health promotion theory and research traditionally have focused primarily on individual behavior. In contrast, family psychology has been studying inter-individual relationships or ‘systems’ from its beginn-

ings. Yet, within health psychology, family systems considerations are currently gaining recognition.

As health is a very important value for most individuals and families, it has always been of major interest within the discipline of family psychology, though not called ‘family health.’ Important contributions in research on family and health can be accredited to family stress research. In the beginning, this field of study focused on the familial crises brought about by major life events. At the same time, studies on the psychological processes of individuals were also ‘pathogenetically’ oriented. Antonovsky’s ‘salutogenetic’ approach offered an alternative to the pathogenetical perspective.

Antonovsky (1979) builds on earlier developments of Humanistic Psychology and the theory and practice of prevention, and he focuses on health-promoting factors and processes as well as on the characteristics of extremely healthy people or systems. In contrast to earlier studies on health and on the family, the current disciplines of family and health psychology are paying more and more attention to these salutogenetic views and models (see Olson and Stewart 1991).

The early notions of optimal family functioning were inferred from experiences with families or family members in treatment. As the practice of family therapy became institutionalized, integrative models of family health were developed increasingly. Generally speaking, theories and models of family psychology that can be regarded as unequivocally salutogenetic, either (a) conceptualize a health ideal of families, or (b) consider health processes within the context of individual or familiar resources that contribute to the state of health of the whole family or its individual members.

In the following sections, health is conceptualized as a state of total physical, psychological, and social well-being, and not only the absence of disease and disability (see Antonovsky 1979). As this definition contains a physical, a psychological, and a social component, it meets the requirements of a ‘biopsychosocial’ perspective in health psychology (see Schwarzer 1997).

Psychological definitions of family point out that a family is a special group of persons living in a close personal relationship, in the past, in the present, and in the future. It is an economic unit bound together by emotional ties (see Schneewind 1991).

In the following, the two topics of family and health are combined and a systematic overview of the field of ‘family health’ is offered.

2. Family Health: A Systematic Overview and Selected Empirical Results

The very diversified subject of family health was dealt with by totally different directions in theory and research, such as stress research or feminist research.

Table 1

Systematic overview of essential facets of family health in theory and research

1. *The family and the health of individual family members or dyads*
 - (a) Family stress and the health of individual family members
 - (b) The family as context for socialization
 - (c) Intergenerational theory of personal development within the family system: the family of origin in its relevance for the current health of its members
 - (d) Influences of a chronically or acutely sick individual upon other family members
2. *The family as resource and health-promoting institution*
 - (a) Family coping; family variables as 'stress buffers'
 - (b) The couple and family as direct resource and source of satisfaction
3. *Differential aspects of stress and health within the family*
 - (a) Gender-specific family psychological research regarding health and stress
 - (b) Different family structures, e.g., two-parent vs. divorce- and stepfamilies
 - (c) Health and stress in different phases of the family life course; intergenerational differences in health variables
4. *Systemic view of family health*
 - (a) Family health in the form of 'family competence' or 'family mental health'
 - (b) Family ideals
 - (c) Health-relevant characteristics of dyads within the family or of family structure
 - (d) Systemic interventions

Note: The numbering 1 to 4 is parallel to the order in the Sects. 2.1 to 2.4

Following the systematic overview in Table 1, some of these different aspects of family health will now be described briefly.

2.1 *The Family and the Health of Single Family Members*

Studying the links between family characteristics and the health of individuals, one has to distinguish whether (a) the effects of certain family characteristics or situations on system members are being considered, (b) the effects of certain individuals on the family, or whether (c) interaction processes and the resulting effects are being taken into account.

Effects of familial characteristics or situations are studied intensively by family stress research. Within this field, the family is viewed as a source of stress or a mediating factor. 'Stress' is considered either as 'life events,' family transitions, caregiving, or economic strains or stressors resulting from family interactions. Furthermore, extremely adverse familial influences such as violence and abuse are examined. All these forms of familial stress can affect psychological and physical health. Yet the extent of negative effects is highly dependent on coping processes and on individual and familial resources (see Sect. 2.2).

The study of familial influences on child development leads one into the very wide field of socialization within the family. Generally, the family is regarded as the main matrix of personality development, laying the foundations for mental health in childhood. From a clinical perspective, there are certain familial factors which put a child's devel-

opment at risk. Some of these risk factors are psychological disorders of a parent, parental delinquency, strong marital conflicts, and poor educational level of the parents. These variables have been found to correlate with emotional and behavioral disorders and academic failure during childhood. Moreover, childhood problems such as 'internalizing disorders' (e.g., depression) and 'externalizing disorders' (e.g., conduct problems) that stem in part from poor caregiving practices, are again strong predictors of mental disorders in adulthood.

What distinguishes effective from ineffective caregiving? Scientists have identified two fundamental dimensions of caregiving that are particularly important for children's adjustment. The first is, how much warmth, nurturance, and acceptance (vs. hostility and rejection) caregivers convey to children. The second is how much control, structure, and involvement (vs. permissiveness and detachment) caregivers display towards their children. Schneewind and Ruppert (1998), for example, demonstrate by longitudinal data that the family's atmosphere with the primary dimensions of positive emotionality, activation, and level of organization is a relevant predictor of family members' emotional, personality, and social development as well as the child's locus of control (see Schneewind 1995). Furthermore, studies have found that the family's emotional expressiveness also plays a role in the development of social competence in children. Intergenerational family systems theory of personal development within the family views well-being within the context of a multigenerational model. The quality and dynamics of these significant relationship patterns are conceptualized as having far-

reaching implications, not only for psychological functioning, but also for physical well-being, ability to cope with stress, and willingness to engage in positive health-related behavior. All of these assumptions are verified empirically. For practical reasons, nearly all of the studies rely on retrospective data, and most of them address only two generations. These studies, which consider the relationships between important psychological dimensions of the family of origin and the current health of family members, find, for example, moderate correlations between the degrees of autonomy and coherence, which were experienced by grown-up members of their family of origin, and their current psychological adaptation. Studies on the role of parental separation and divorce for child development have shown evidence of impairments of a child's social and personality development, mainly during the first year after the parent's separation. But the effects measured have been proven to be minimal, and the differences between children of intact families and divorced families almost vanish as time goes by.

The study of effects of individual characteristics on the family has a theoretical tradition in the field of family therapy, despite the transactional thinking of this systems approach. In earlier family therapy theories, a family in which an individual member became schizophrenic or developed a psychosomatic illness was known as a 'schizophrenic' or 'psychosomatic family.' Virginia Satir's experiential model of family therapy stresses the importance of the individual's self-esteem to the family's overall level of health. There are also empirical verifications of these interrelationships between self-esteem and perceived family functioning (e.g., Heaven et al. 1996).

This direction of effects from an individual's state of health on the couple or familial relationship has also been examined in cases of acute or chronic illness of a child, a parent, or a spouse. Using longitudinal data, Booth and Johnson (1994), for example, demonstrated that health impairments of a spouse diminish the quality of the couple's relationship quality, especially on the part of the sick person's partner. Nevertheless, the couple's or family's coping processes are very relevant for the system's adaptation to the situation.

2.2 The Family as a Resource and Health-promoting Institution

Although the family and its patterns of interaction can be an enormous stressor, scientists also know about the positive and regenerative aspects of the family. These 'family resources' are fundamental for the functioning of every society. They include a large variety of aspects, ranging from material resources, over social support, dimensions of recovery, and familial coping competencies, to 'daily uplifts' within the family's interaction.

An essential part of the health-promoting aspects of the family lies in the regenerative and protective effects of a good marriage or couple relationship (e.g., Gove et al. 1983). Even family status alone (single, married, separated, divorced, or widowed) shows significant connections with emotional well-being and life expectancy (e.g., see Cotten 1999, Gove et al. 1983). Despite a higher percentage of overweight persons among the married, living together with a spouse is on the whole health-promoting, especially for men. But these differences (between the groups and between the sexes) are diminishing currently. Furthermore, relationship quality is a moderating variable in the correlation between marital status and health, so that 'good,' satisfying marriages are more health-promoting (see Ross et al. 1990).

The correlation between socioeconomic status of families and mental and physical health appears consistently in the literature. Thus, the economic benefits within 'dual-income' families can be seen as a resource, as well as the emotional benefits which many women experience when they are working. These benefits could 'buffer' the stress of the 'double burden.'

Individual stress research has shown that the way people cope with stressors such as critical 'life events' is even more important than their occurrence (e.g., see Antonovsky 1979). Furthermore, there is evidence that also on the family level the quality of coping (e.g., with acute or chronic illness), is extremely relevant. Is the family able to 'buffer' the potentially negative effects of the stressor, or does the family use dysfunctional strategies which only serve to worsen the situation? Adequate coping is a resource which can lead to the establishment of other resources, which then can be useful in comparable or totally different situations in the future.

For couples or parents, the emotional support of a spouse is evidently very important (see *Social Support and Health*). Process analyses in the daily life of couples show that only in cases where a relatively high level of spouse support was evident does a decline in work-related stress occur during the evenings. Interestingly, allowing the partner to withdraw has proven to be one of the forms of spouse support (see Repetti 1989).

Furthermore, high quantity as well as quality of marital interactions has been connected with less risk-taking behaviors, such as less alcohol or drug use (see Wickrama et al. 1995). Similar findings regarding families demonstrate that the lifestyle of persons who live in families is more solid and healthier.

2.3 Differential Aspects of Family Health

Especially in the case of traditional role sharing, we expect gender differences in the experiences of family life and—in relation to these differences—in health-relevant variables.

Studies on the situation of the so-called 'dual income' families show that it is the women who experience a 'double burden' and difficulties in coordinating work and family life. In addition, for women the experienced inequality is more strongly connected with their couple satisfaction (see Kluwer et al. 1997). While women more often experience family stress in the form of their spouses' behaviors (e.g., not enough support), men more often feel stressed by their partners' criticism. Furthermore, as women tend to be supporting and do the larger portion of the household tasks, they have less time to 'unwind' after a stressful work day than their husbands (see Repetti 1989).

In summary, studies in Western nations have found that, although men show more risk-taking behavior compared to the more preventive behavior of women (Schwarzer 1997), women nevertheless have less favorable scores of physical and psychological health. This fact is to be seen in the context of the women's work and family roles, and the overload that is so often connected with these (e.g., see Barnett and Marshall 1991). This strain from work, parental, and couple domains has negative effects on women's well-being and health, and on the functioning of the family.

The lower health scores of older persons that were found by a large number of cross-sectional and longitudinal studies (e.g., see Schneewind and Ruppert 1998) can also be linked with family variables. Apart from biological factors, the stress of family transitions, such as disruptions of marital relationships through divorce or death, also bear aversive emotional and immunological consequences.

Another differential aspect of family health is the family structure or type. While it has often been thought that family structure (i.e., intact, divorced, stepfamily) was a key determinant of well-being, especially among children and adolescents, recent investigations have concluded that family process variables, such as conflict dynamics, cohesiveness, and support, are more important (e.g., Heaven et al. 1996; see above). Furthermore, cultural, social, and economic factors have widespread influences on the health of families.

Differential examinations of the different phases within the family life course show that the level of family stress is highest during the adolescent stage of family life, while family cohesiveness and satisfaction is lowest (see Aldous and Klein 1988).

2.4 Systemic View of Family Health

Scientists who are dealing with an overall, systemic concept of family health try to meet the demands of the systemic approach. They look at the topic in a more holistic manner and identify the structures and processes of the 'whole,' the family system which is embedded in other contexts (e.g., society). Conceptions that

consider the health of the whole family are, for instance, the psychological constructs of 'family competence' or 'family mental health' (e.g., see Pruchno et al. 1994), as well as all family ideals.

In terms of 'family health' measures, there are some self-report assessment instruments and additional measures which are designed to quantify the quality of familial functioning from the perspective of an external clinical observer. Questionnaires that consider an overall systemic construct, for example, 'family mental health,' usually found their operationalizations on sum scores of the individual family members as well as on discrepancy scores between them. Families with higher discrepancies in their perceptions of family reality normally have a lower score on individual well-being. Obviously, converging realities in the subjective views of the system members are functional, whereas larger divergences are a characteristic of clinical families.

Another concept which is of interest, not only from a systemic, family-centered perspective, but also from the perspective of health psychology, is the one of 'family health cognitions': but until now, the empirical basis regarding the impacts of family cognitions on the use of health services and on personal health actions is weak and needs further attention.

An example for a family ideal is the 'balanced' family type within the 'Circumplex model' (Olson 1989). These families have relatively high scores in cohesion (but without being 'enmeshed'), and relatively high scores in their capability to adapt to new situations (without being 'chaotic'). These characteristics are connected with better communication, more favorable coping, and higher family and personal satisfaction and health.

A further systemic perspective of family health concerns health-relevant characteristics of the system structure and the characteristics of dyads within the family system. Such a link between systemic-structural characteristics and family health is represented by the variables of generational boundaries and parental coalitions. Clear—yet not too rigid—boundaries between the parental subsystem on the one hand and the children's subsystem on the other have proven to be a characteristic of healthy family systems. Similarly, coalitions between the parents, the 'architects of the family,' are more functional than strong transgenerational coalitions (e.g., mother-daughter).

Furthermore, a systemic view of the whole family's health is practiced in all family interventions, that is, in family-oriented prevention or health-promotion programs and in family therapies. The insight that the health of the whole family should be considered when one member has a symptom was the birth of family therapy. Family health-promotion programs help families to sustain or enhance the social, emotional, and physical well-being of the family system or its members (see Schneewind 1991). These different kinds of family interventions have become well institutional-

ized. Nevertheless, researchers should pay more attention to evaluations of these different family interventions.

3. Conclusions

Family life experiences affect deeply the competence, resilience, and well-being of everyone. The family shapes the quality of our lives, but—to a certain extent—we also shape the quality and health of our families, especially when we become parents.

Research is paying closer attention to salutogenetic family-centered variables of coping and health. Empirical evidence supports this trend. Yet, in the field of research a great amount of work still lies ahead in order clearly to establish an overall systemic view of the family, whereas in the domain of family therapy this perspective has been the major characteristic from the very beginning.

As patterns of marriage and family life are currently changing in the Western world, scientists should be aware that changes in the strength of connections between family factors and health variables can occur. In the case of the association between family status and health variables, a decline in correlations has already been observed.

Although the family is the basic context in which health behaviors are learned, further research studies should well consider the interactions between the family and other social contexts, like peer or work relationships. Influences from the side of these other persons and systems could, for instance, be one possible explanation for the fact that until now studies have found only rather weak links between 'family health cognitions' and health-related behaviors.

All in all, knowledge of the frames for a healthy development from and in families is very relevant for different branches of psychology. The application of this knowledge is especially important for family interventions, such as prevention programs, but also for family politics.

Family Law

1. Introduction

Geertz described law as much a part of the culture of a society as its poetry, painting, or music (Geertz 1983). This profound and illuminating approach to

the patchwork of norms, rules, and institutions by which we regulate our daily lives is nowhere more appropriate than when we consider the regulation of family matters. Here law is at its most social as we move forward to new ways of organizing our households and relationships in a multicultural context. The study and practice of family law has attracted socially minded lawyers and has provided a seedbed for the development of the sociological approach to law now known as sociology of law.

In this short article, I will first lay out the various ways of conceptualizing the role of law in family life as the framework within which the individual, the family, and the state define their mutual obligations, and second examine the implications of these models for the framing and operation of the legal assumptions and instruments which regulate family matters.

As Aubert has pointed out, both law and social science are concerned with social interaction: with rights and expectations, with obligations and sanctions, and with predictability (Aubert 1963). But the same terms are used for different purposes. The lawyer uses a normative framework; she gives directions to her client and expects action to follow. The social scientist, on the other hand, observes and describes, seeking to identify and to explain patterns of behavior. The lawyer interested in family work is often concerned with how people behave in family settings, as well as with the strict applications of legal rules. The social scientist who looks at family law is often policy-aware and interested in the practical implications of the work, as well as in the theoretical analysis. The study and development of family law in many different societies, including Japan, Italy, France, the UK, the USA, Australia, and Poland has been imbued with collaboration between social scientists and lawyers (Murayama 1999, Ronfani 1991, Bastard and Cardia Voneche 1995, Commaille and Singley 1997, Maclean and Eekelaar 1998, Weitzman 1991, Funder 1996, Maclean and Kurczewski 1994). The result is a rich understanding of law in family life.

2. *Families, Politics and the Law*

What do we want from law in the context of family life—as opposed to business life, or economic life, or international relations?

The way we model our answer will depend on our view of the family, of the law, and of the state. Let us take three examples of the interweaving of politics, family life, and the law: an old fashioned liberal democracy, an old democracy emerging from totalitarian rule, and a new democracy emerging into a multicultural society. From these examples, we shall derive our models.

In the predominantly secular UK, discussion of the boundaries between the obligations of individuals to

each other as individual citizens or as members of family groups (however these are defined) usually is couched in economic rather than in moral terms. In times of economic stringency, there is a tendency to retrench public spending and to stress the obligations of families to support their members, and also to extend the ties which carry a duty to support. For example, the obligations of parents who do not share a household with their children will be highlighted and enforced. Such moves are countered by the claims of weaker family members, usually women and children but also the older generation, to establish their right to call on the public purse as individuals, irrespective of their family relationships. In the UK, family forms have changed and diversified as a result, in part, of the increased opportunities to form separate households when housing became more widely available in the late 1960s and early 1970s. We have experienced a divorce explosion and a rise in cohabitation. More older people are forming separate households, more women are working despite limited child care, and more men are unemployed.

'Supporting families' has become a political slogan attracting universal support in the UK, but for a variety of reasons. Family life is seen as an answer to the need for increased social control, particularly of young delinquents, and also as the alternative to public provision of shelter and support. The conservative administration of the Thatcher era was active in passing legislation to increase the visibility and enforceability of private obligations as an adjunct to the rolling back of the welfare state. Thus, the UK saw the paradox of a government committed to 'privatizing' the family and to withdrawing from intervention in family matters but compelled to construct a regulatory framework in order to do so. The Child Support Act of 1989 stands at the pinnacle of this policy. This Act attempted to reverse the widely held assumption that when a couple separate and the breadwinner re-partners and produces a second family, their resources should be mainly available to the household in which they now live and not be directed back to the first set of children. The Act firmly stated that first children must have first call on their absent parent's resources. To achieve this change, the government, which was pledged to reducing the role of the 'nanny state,' was required to take draconian powers of investigation and enforcement.

On the other hand, in Poland between 1945 and 1990, the family had a unique role as the only institution supported both by the ruling Communist Party and by the Catholic Church, for different reasons but with a similar purpose. The family was seen as the institution through which moral values are best transmitted and reinforced, and as a powerful agent of social control. In times of intellectual and spiritual alienation, the family became of primary importance as the place where trust predominated over suspicion and where communication could be frank and open.

When there were shortages, the family functioned as an effective searching, queuing, and allocating organization, providing specialist's support for the group in bringing home goods in short supply, or in helping with access to jobs and housing. Following this period of intense interdependency, it has been suggested that family members may wish to withdraw from this level of closeness and move towards the pure relationships of coupledness, parenthood, and friendship defined by Giddens (Reith Lectures 1999). But if the public welfare provision of care for children and care for the sick and elderly break down, then the family may be needed to replace these functions. Despite the emphasis on individual rights and liberties in the free market after the end of authoritarian rule in Poland, family values remain strong and are reinforced by the Catholic Church, whose wish to restrict divorce and abortion has had a profound impact on family law since 1990. Divorce has been removed to the higher level of the courts, which means a long wait and increased costs to the petitioner. And at the same time, the long struggle in the *Sejm* to restrict the right to abortion succeeded in January 1993 by a narrow margin.

For our third example, let us look to South Africa. Those who prepared the new Rainbow Constitution, which signals the passing of the apartheid regime, have struggled with the question of whether to constitutionalize the rights of the individual to marry the person of his choice and to found a family. The Constitutional court acknowledges that a number of international instruments clearly establish the right to form and live in a family. But although many constitutions expressly defend the family (e.g., Germany, Pakistan, China), many do not (e.g., Austria, India, Singapore, Taiwan). The South African government decided not to constitutionalize family matters, stating that the very nature of the family, particularly in multicultural and multi-faith societies, is so diverse that it is best to leave the fundamental rights and liberties in relation to family life to the basic principles of freedom, security, and choice. 'Then through legislation, the development of precedent in courts, social custom and practice, the different forms of family life will manifest themselves and be appropriately protected. The minute you constitutionalize the family, the courts are obliged to establish a prototype of what is meant by a family, and families take such diverse forms in South Africa that this could impose a straight jacket on future developments.' (Eekelaar and Nhlapo 1999).

3. Modeling Family Law

We have looked at three very different examples of the interrelationship between the political situation, the institution of the family, and family law. Now we will try to draw on these variations to develop a set of models which incorporate the key elements and

illuminate our own choices. We can categorize the family law system according to the level of intervention accorded to the state in family life.

3.1 The Interventionist Model

In societies where the state has a strong and coherent message to communicate, based on a political or religious ideology or world view, we tend to find an interventionist model of family law. The function of the family may be to raise good socialist citizens, as in the former communist countries of Eastern Europe, or to raise good catholic citizens, as in Southern Europe. In the former, divorce and abortion were freely available, gender equality was well developed, citizens were equal in the eyes of the state, and labor productivity required women to be available for work. In the latter, divorce and abortion were unavailable. If the family is seen as a box with walls of varying degrees of porosity, in interventionist societies the box is very transparent and porous, allowing the regulatory system to enter. In this model, the family is less able to function as an institution of civil society but, instead, serves the dominant ideology, whether secular or sacred. Such a system has difficulty providing for a multicultural society and traditionally obscures ethnic differences. Such systems ironed out the differences in family life between the Roma, Turks, Pomacks, and Bulgarians in Bulgaria (Maclean and Kurczewski 1997).

3.2 The Residualist or Minimalist Model

The residualist model lies at the other extreme of our continuum. In this model, the family is seen as the desirable or competent source of nurture, caring, social control, and perhaps moral education. In such a model, the walls of the family box are dense to opaque, and the state does not easily penetrate the private family world. The function of the law is to do no more than protect the weaker members of the family group from violence or neglect. This may be left to the criminal law rather than requiring a special form of intervention through family law. Such a model is not acceptable to feminists, as nonintervention in effect favors the status quo and does not redress the power imbalance characteristic of patriarchal societies (see *Gender and the Law*).

3.3 The Facilitative Model

There is, however, a middle position which may be termed the Facilitative model of family law. Under this approach, family law is required to respect the human rights outlined above and (Eekelaar and Nhlapo 1999) to be based on the underlying principles

of freedom, security, and choice, to enable each individual to develop to the fullest and to accommodate the varieties of faith, ethnicity, and sexual orientation. Such a model would encompass acceptance of cohabitation, same sex marriage, assisted reproduction, abortion, divorce, and remarriage, and maybe polygamy and polygyny.

4. *The Way Ahead*

Whichever model of family law underpins the regulatory system of a particular country or state, there do seem to be some common directions for change. In the 1980s and 1990s, writers on family law identified what became known as the rolling back of family law, that is, the increased reliance on individual decision-making and the removal of a number of matters related to personal relationships from legal intervention. It became less common for legal rules to regulate choice of marriage partner (i.e., the old restrictions from the Judaeo-Christian tradition on marrying the dead wife's sister which conflict with the Moslem requirement to take on responsibility for a dead brother's wife). In many societies, no-fault divorce became a matter of personal choice. But although the couple relationship is coming to be seen more as a matter of choice, and to lie outside the boundaries of legal regulation, the relationship between parents and children becomes more exposed and subject to increasing legal intervention. Where children live in households with parents, the need for protective legislation remains, but the need for regulation of how the household sustains itself is minimal (see *Children and the Law*).

But as couple relationships become divorced from the parenting function, the need for legal regulation of the obligations of parents increases. If two people produce a child, and either never live together or separate, and either or both go on to have other children with other partners, the potentially conflicting obligations between this network of parents and children requires a regulatory structure. We referred earlier to the difficulty in the UK when the Child Support Act in 1991 required a change in the distribution of the assets of the absent parent, requiring him to give priority to the children born first, and not to children currently sharing the new household. This was a hard switch to make, and it aroused great public outcry.

But there is a further aspect of the parent-child relationship which may also give rise to legal regulation in the future. With an aging population, and the rolling back of welfare provisions, we may be looking to adult children to offer more support to their elderly relatives (see *Law and Aging*). After the establishment on a firmer footing of child support, we may need to consider legislating for parent support. Such a development manifests a view of family law as no longer

concerned with moral codes of behavior or political ideologies, but as trying through basic human rights principles to deal as best it can with multicultural and multifaith societies. Family law is developing to deal with personal obligations such as material obligations to support and enable.

At the same time, as the thrust of legislative intent focuses on obligations, rather than on rights, so too there is a move away from lawyers and courts to enforce these obligations. We see a resurgence of interest in paralegal activity and in finding alternative methods of dispute resolution. Mediation and conciliation, which require the individuals concerned to take responsibility for arrangements made in family matters, are expected to reduce levels of hostility and to produce longer lasting settlement. Empowerment of the individual is thought to be well served by these means, together with improved ability to communicate, which will be increasingly important as parents continue to take long-term responsibility for their children while no longer sharing a household.

Finally, as family arrangements become more attuned to individual choices in societies with a more tolerant view of different ways of arranging personal life, the ability to negotiate and to adjust becomes more important than the ability to fight for a particular right. If we continue to move in this direction, then it is probable that family law will become less concerned with adjudication or settlement of disputes, and more concerned with the business of managing change. A separation or divorce will involve less acrimony, and there will be clear directives on how to allocate responsibility for children. Legal intervention in families may come to resemble the technical financial advice of the accountant, rather than the fighting spirit of the old divorce lawyer 'taking the husband for all he's got' or 'making sure she doesn't get away with a penny.' The family law of the past was prescriptive, derived from the allocation of property between marrying groups. The family law of the future will be grounded in human rights and will facilitate the maximization of individual choices about personal living arrangements. It will ensure protection for the vulnerable family member, who is likely to be defined by age and relationship to the labor market, rather than by gender.

Family Planning Programs: Development and Outcomes

1. Demographic Momentum

One of the most important developments of the twentieth century was a huge increase in global population and a massive change in the distribution and age structure of the population. In the second half of the century, differences in birth rates were an important factor dividing the world into developed and developing nations. For a long time there has been compelling evidence that many couples all over the world want fewer children. In most Developing nations with high birth rates, national family planning programs have been established. Some of these programs have been highly successful, but others failed due to controversy, lack of political will, or inappropriate technical advice.

In the twenty-first century the world will divide along a new socio-economic fault line, also largely driven by differences in birth rates. Countries that achieve replacement level fertility by about 2010 are likely to progress economically. Those that do not will face continued rapid, and in some countries unsustainable, population growth. In much of Africa, for example, half the present population is below the mean age of marriage, and even if the fresh cohorts of young people are able to have smaller families, there will be so many new parents that the population will continue to grow. This phenomenon of population, or demographic, momentum occurred in China in the

1960s and 1970s. As a result of rapid population growth, many more Chinese brides were entering the fertile years than were leaving them by death or reaching the menopause. In 1979 China instituted a one-child policy, but even today the country still has one million more births than deaths each month—and therefore a net growth to China's population of one million each month. Since the one-child policy began, China has added more people than live in the whole of the USA.

In order to overcome past failures in family planning, countries that are being overtaken by a new wave of demographic momentum will need to adopt bold new policies. This will be difficult.

2. Why Do People Have Children?

Unlike most other animals, human beings have frequent sex; most of it unassociated with ovulation and often taking place thousands of times more frequently than is required for fertilization. This behavior probably evolved as a social bond linking parents in the arduous task of bringing up a family. In preliterate societies, pregnancies were naturally spaced by hidden physiological mechanisms that suppress ovulation during breastfeeding. In such communities, women averaged 4–6 live-born children in a lifetime, of which approximately half died before they could reproduce. In the modern world, family size has increased because (a) women often only breastfeed for a few months or not at all, (b) puberty occurs several years earlier than it used to, and (c) infant mortality has plummeted. These are the factors that drove the twentieth century's 'population explosion,' and these factors will continue to operate in the twenty-first century.

The simple fact that human beings have sexual intercourse much more frequently than most animals is obvious, yet often overlooked by governments when they are setting family planning policies, or specialists analyzing demographic changes. Many policy-makers continue to focus on factors that correlate with family size, such as education or income, instead of those that cause changes in family size, which, in addition to the age when intercourse begins and patterns of breastfeeding, are the use of contraception and abortion.

Economists often speak of people making rational choices over the costs and benefits of a particular act, such as buying a washing machine. However, as a result of frequent sexual relations between couples, human fertility is in effect perpetually turned on, and such rational choices are not possible. We buy a washing machine when we want one, but if this worked like human fertility, the washing machine would arrive whether it was ordered or not. In the modern world it is possible to have a small family only if the couple have access to contraceptives and abortion. Tragically, as the twenty-first century begins, hundreds of millions of people still find contraceptives geographically, socially, or financially inaccessible, and for even more

women, abortion is available only in dangerous and commonly financially or sexually exploitative circumstances.

3. Changing Attitudes

In 1900 the world was deeply hostile to the public support of fertility regulation. In the US and parts of Europe, the sale of contraceptives was illegal, while in the UK sales were 'under the counter.' Throughout Europe, North and South America, and in all the European colonies, abortion was illegal. Yet doctors and clergymen, who often opposed contraception in public, were beginning to limit the number of children they had. Condoms, spermicides, intrauterine devices (IUDs), and voluntary sterilization were all known in 1900, but were of poor quality and were difficult to acquire. The theory behind the Pill was described in the 1920s, but research in contraception was actively discouraged. When Margaret Sanger opened a family planning clinic in New York in 1916, it was closed by the police. When Marie Stopes started family planning clinics in England in 1921, she had to face stiff criticism and even arson.

The pivotal point in the development of family planning programs came near the middle of the twentieth century. The 1950s saw the introduction of oral contraceptives, the more widespread use of IUDs, and some Scandinavian and eastern European countries introduced liberal abortion laws. Family planning clinics run by non-governmental agencies began to be important in a few developed nations. In 1965, the US Supreme Court struck down the last of the anti-contraceptive laws passed almost 100 years earlier. In 1966 the British reformed their abortion law, and in 1973 the USA Supreme Court (*Roe v. Wade*) made safe abortion legal throughout the country.

In developing nations, non-governmental organizations also took the lead. In 1952 the International Planned Parenthood Foundation (IPPF) was founded to tie these efforts together. In the 1960s, US foundations and the Swedish International Development Agency (SIDA) began to offer money and know-how to help family planning programs in developing nations. The US Agency for International Development (USAID) followed soon afterwards, and finally a number of developed nations joined in offering support.

But there were also problems. Much of the academic community clung too long to outdated paradigms and until 1959 the US National Institutes of Health (NIH) was forbidden to conduct contraceptive research. The Vatican State, which is part of the UN system, successfully blocked the World Health organization (WHO) from offering governments help in family planning until the 1960s. The British representative at the WHO Assembly was ordered by the Foreign Office to not discuss family planning, but eventually India,

Trinidad and Tobago, and the Netherlands (with British support) did succeed in getting a resolution permitting WHO assistance to respond to requests for family planning technical assistance.

In 1968, many Catholics were stunned when Pope Paul published the Encyclical *Humanae vitae* and upheld the 1600-year-old tradition of St Augustine that sexual intercourse was sinful unless it was open to the possibility of procreation. (In a clear demonstration of the fact that theological opinions on reproduction are not necessarily constant, *Humanae vitae* permitted the use of periodic abstinence, or the safe period, which St Augustine in the fourth century had explicitly condemned as immoral.) Today, almost every developed nation, with the exception of the Republic of Ireland and Malta, offers its citizens access to modern family planning. Pills, condoms, safe and effective IUDs, increasing access to voluntary sterilization for either sex, and above all, access to safe abortion has revolutionized the lives of women in developed nations. For the first time in history, they could fit childbearing into a variety of chosen lifestyles and no longer had to spend every month worrying whether they were going to see their next menstrual period. Nearly every developing country has also established some sort of national family planning program. However, the hostility and controversy that had characterized the slow and painful process of family planning in the first half of the twentieth century has not gone away, and many family planning programs in developing nations are deeply flawed and fail to offer the choices required to truly control family size.

4. Family Planning Programs

The development of international family planning movement can be divided conveniently into three phases, each one symbolized by an international population conference organized by the UN.

In the 1950s and 1960s, a few timid, and sometimes frankly unrealistic, efforts at family planning began. In 1951 the WHO responded to a request by the Indian government by advising use of periodic abstinence. (At that time, the Vatican City, as a member of the WHO governing body vetoed more practical methods.) India adopted a formal governmental population family planning program in 1952, but efforts were made to use IUDs on a large scale failed because the health personnel or facilities to support the method were not available. Very different programs began in South Korea (1963) and Taiwan (1959). Here, several methods including voluntary sterilization were offered and safe abortion, although initially illegal, was widely available. New choices were added to the menu of contraceptives as couples showed they wanted them.

These initial efforts were largely brought about by a small number of charismatic, hard-working individuals. They probably had a powerful impact because

they were responding to a deep and long-hidden desire for fertility regulation in groups all around the world. In the US William Draper Jr. led the Population Crisis Committee, badgered Congress, and played a key role in putting the UNFPA together. Reimert Ravenholt became an extraordinarily effective leader of the early USAID programs. Alan Guttmacher led Planned Parenthood/World Population in the US and changed the face of domestic and international family planning. Ottesen Jensen in Sweden and Madam Kato in Japan moved mountains of opposition. Fernando Tamayo, Jae Mo Yang, Dapne Chung, Lady Rama Rao, L. P. Chow and others appreciated the damage rapid population growth was doing to their societies and economies, and launched family planning programs in their respective developing nations. Those most closely involved in putting programs together, whether from developed or developing nations, were universally impressed by the unmet demand for family planning and the opportunity that family planning provided to meet individual, as well as community needs. Many of these early pioneers were also particularly skilled at turning the controversy, which associated their efforts to their own advantage.

The United Nations Fund for Population Activities (UNFPA) was launched in 1969, and the first UN population conference was held in Bucharest, Romania in 1974. Demographers and economists warned against the dangers of rapid population growth. The Bucharest meeting was dominated by the developed nations who emphasized the need for family planning programs. But a number of developing nations, including India, expressed resentment at what they perceived to be the demographic emphasis of the meeting.

However, when it comes to sex and reproduction, people do not always say what they mean, or mean what they say. Although India and China adopted the rhetoric that 'development is the best contraceptive,' almost as soon as the meeting ended China introduced the one-child family and India embarked on a top-down family planning campaign that ended with episodes of coercive sterilization, which brought down the government of Indira Gandhi. The problem in China was that Chairman Mao had denied there was such a thing as a population problem, and this delayed the introduction of a realistic family planning program. As noted, China ended up with an enormous imbalance of young people. No one in China liked the one-child policy but neither has anyone ever come up with a plausible alternative strategy. Had China started a voluntary family planning program just a few years earlier, there is every reason to believe it would have been as successful as Korea, which saw the TFR fall from 6.0 in 1960 to 1.7 in 1990. Indeed, during the 1970s a number of countries, such as Colombia and Thailand, followed the example of Taiwan and South Korea. They forged ahead offering several methods of contraception, they developed non-medical channels

of distribution and they confronted the public health issues of unsafe abortion. Whereas it had taken the USA almost 60 years (from 1842 to 1900) for the total fertility rate (TFR) to fall from 6.0 to 3.5, Taiwan, Columbia, and Thailand all made the same transition in a few years. In 1984 the world community met for a second population conference, this time in Mexico City. Whereas the US had been criticized in 1974 for emphasizing population problems, in 1984 the Reagan administration asserted that population growth was not a serious problem and followed this up with policies in the US. It was now the turn of the developing nations to call for more support of family planning programs.

At the Cairo International Conference on Population and Development in 1994, yet another set of political forces surfaced. Population issues had fractured into five different schools of thought. Women's advocates focused on the needs of the individual, emphasized broader aspects of reproductive health as well as access to family planning, and downplayed demographic forces, often portraying family planning programs as coercive. Those emphasizing socio-economic development focused on the inequalities between North and South and the need to redistribute the world's wealth more equally. Voices from the South harked back to the Bucharest conference, and again used the slogan that 'development is the best contraceptive' to diminish any role for purely population issues. The Vatican continued its hard-line stand against any form of 'artificial contraception' and condemned the use of condoms, even by monogamous couples where a man might have acquired HIV through a blood transfusion. The group who had launched family planning in the 1960s were reduced in numbers, but they maintained a traditional concern about rapid population growth and emphasized that if the unmet need for family planning was met in a respectful way then fertility would fall rapidly. Most groups at Cairo (other than the Vatican) considered the meeting a considerable success because consensus appeared to have been achieved on so broad a range of issues.

The program of action that came out of Cairo underscored the heavy burden of social and cultural injustice that falls on many women in the world. The conference looked at sexually transmitted diseases and AIDS, it condemned female genital mutilation, and it set family planning in a broad context of reproductive health care. With the passage of time, however, the Cairo Program appears more blurred and less satisfactory. One of the weakest parts of the Cairo document were the targets set for finance, which were much too low. A broad agenda not backed up by the necessary budget is a dangerous situation. It is a sad fact that since the Cairo conference, the sum total of human suffering in the reproductive health field has significantly increased. The WHO has raised the estimates of women dying from pregnancy, childbirth,

and abortion from 500,000 to 575,000 a year—more than one a minute. In the countries most heavily affected by HIV/AIDS, reproductive health has deteriorated more in the past five years than in any similar period during the twentieth century. (See *HIV and Fertility; Mortality and the HIV/AIDS Epidemic*.)

5. *Meeting Individual Family Planning Needs*

A great deal is known about how family planning choices can be made available in a poor country. Experience suggests that a 15 percent rise in contraceptive prevalence is associated with approximately one birth less per family. The wider the choice of contraceptive methods and the greater the variety of distribution channels the more rapidly contraceptive prevalence rises. In many countries prevalence has been going up at more than 2 percent per annum. Family planning is a choice and not a therapy, and therefore contraceptives can be distributed responsibly within a community, often outside any clinic-based health system. Unfortunately, the expansion of family planning also continues to be limited by restrictive medical policies. For example, injectable contraceptives could perfectly well be distributed at a subsidized cost by traditional practitioners, injection doctors, and others who provide medicines in rural and shantytown communities. The subsidized sale of contraceptives has proved an effective way of distributing pills and condoms and is almost always more cost-effective than distribution through medical clinics.

Family planning methods vary in their cost-effectiveness. Condoms are relatively expensive, while voluntary sterilization and intrauterine devices often cost the least per couple-year of protection. Probably the most realistic and acceptable way of satisfying the community's need for family planning would be as follows. The government health services would focus on IUDs and voluntary sterilization. Pills, condoms, and injectables would be available in government clinics, but the primary mode of distribution would be through the commercial sector or through subsidized marketing, involving a variety of outlets, from kiosks on the pavement, through chemical sellers and pharmacies, to traditional practitioners and finally trained physicians. Private physicians could offer sterilization and IUDs. The consumers would pay what they can afford and the government would make up the shortfall. Such a scheme has worked exceedingly well in South Korea and Taiwan and needs to be repeated in countries like India or Nigeria.

6. *Abortion*

The Cairo conference was the first UN meeting to mention the health consequences of unsafe abortion. It concluded that 'prevention of unwanted pregnancies

must always be given the highest priority and every attempt should be made to eliminate the need for abortion.' These are goals that most reasonable people support, but it will take a long time to achieve them given the current low levels of funding.

No country has achieved a low birth rate without a considerable number of abortions—whether legal or illegal. Conversely, wherever women have access to safe abortion, fertility has declined to a lower level than where such a choice is not available. Indeed, nearly all countries that have access to safe abortion have reached or passed below replacement-level fertility. Technically, abortion in the first 3 months of pregnancy can be safely preformed in any clean room. Manual vacuum aspiration (MVA) using hand-held plastic equipment costing less than \$20 has proved an appropriate technology in locations from rural Vietnam to urban San Diego, California. The technique can be used to treat patients with botched abortions as well as to terminate an early pregnancy. In Bangladesh, MVA is available for menstrual regulation, approved by the government as a family planning method through approximately 12,000 providers, and it is one reason why the TFR has fallen from almost 7 in 1960 to 3.3 in 1998.

Abortion is an ethical problem, and all modern democratic societies that separate church and state have to find ways to accommodate a variety of sincerely held views on this critically important topic. Some groups may have to learn the hard lesson that toleration is preferable to confrontation.

7. *HIV/AIDS*

By the early decades of the twenty-first century, AIDS will have killed 30 to 40 million people—more than died as civilians and combatants in World War II. Current UN population projections assume that the global population in the twenty-first century will be 400 million less than it would otherwise have been as a result of the spread of HIV/AIDS. This does not imply that 400 million people will die from this disease, but that the approximately 30 million projected to die early in the next millennium will not themselves have children, and the downstream effects of these deaths will be considerable. In most of the worst hit countries of Africa AIDS will slow population growth but it will not halt it.

8. *The Future*

The developing world is approximately halfway through the demographic transition that began in the 1960s. Family planning programs have played a significant, (and some would argue, a major) role in this important change. As the twenty-first century opens, the largest cohort of young women in history is

entering the fertile years. Contraceptive prevalence is rising. Unfortunately, at this time of unprecedented need, attention is being taken away from family planning. There is an increasing demand for subsidized contraceptives to meet the needs of many millions of very poor people, but there is no clear strategy in the donor community to provide the essential commodities required to fulfill this need.

In 1998 the UN population division issued new projections for global population. Demographic projections are 'what if' statements. The UN projections assume a continued fall in fertility, and in regions such as Africa, these are based on the assumption that the needed contraceptives and services will be available. This may not happen, in which case there will either be a 4-fold rise in abortions, or else millions of unintended pregnancies, in which case even the high UN projections will be exceeded. Of the small amount transferred from rich nations to the poor in overseas aid, only between 1 and 2 percent goes to international family planning. With the added burden of AIDS and lack of a coordinated global policy to ensure that essential commodities are available, the world faces a genuine crisis in family planning and reproductive health.

9. Summary

A great deal is known about how to provide effective family planning choices. When people are offered several methods of contraception and access to safe abortion, fertility always falls. However, family planning has a controversial history. Currently, poor countries sometimes lack the will to make realistic services available and rich countries are reluctant to put enough money into needed programs. As a result the world looks destined to become increasingly divided between high fertility and low fertility countries.

Family Planning Programs: Feminist Perspectives

1. Population Paradigms

Since the 1960s and even earlier in some cases, governments and private organizations in many poorer countries have developed and implemented family planning programs. By 1985, 37 governments had established national family planning programs, and an additional 33 countries had significant non-governmental programs with the direct or indirect support of governments (Bongaarts et al. 1990). These efforts were largely driven by fears of rapid population growth, and the reduction of fertility was their highest priority. By the 1990s, however, critics of these programs succeeded in causing, what many have called, a revolution in the rationale for these programs. The human right to autonomy in matters of sexuality and reproduction was proposed by feminists, as the cornerstone for these efforts. As a result of this critique, 180 countries achieved consensus on a new approach to population policies and family planning programs at the United Nations International Conference on Population and Development (ICPD), held in Cairo in 1994.

1.1 Family Planning Programs and the Erstwhile Population Approach

To fully understand the significance of the Cairo accord and the influence feminist thinking had on it, it is necessary to look at the philosophies and practices it replaced. The 1960s, with the advent of new con-

traceptive technologies and an increase in fears of a population explosion, saw a significant increase in support for family programs in both industrialized and Third World nations. In 1967, the United Nations Fund for Population Activities (later renamed the United Nations Population Fund) was established to support population and family planning programs. At the UN population conference in Bucharest in 1974, many policy makers—mainly from Northern nations—viewed unchecked population growth as the root cause of poverty, environmental degradation, and social unrest. Many developing countries resisted this line of thinking, suggesting instead that economic development was a more straightforward solution to societal ills, than family planning. While women's issues gained some attention, they were not seen to be central. Meanwhile, on the ground, family planning programs continued, largely unaffected by the debate at the international forum (Demeny 1985).

At the 1984 Mexico City conference, demographic concerns continued to be the driving force in discussions. However, in a reversal of its previous policy, the powerful US delegation now asserted that population growth had a neutral, not harmful, effect on economic development. Furthermore, anti-abortion politics gained center stage as the US launched an attack on abortion rights (Demeny 1985). Still, family planning programs on the ground continued to be guided by demographic goals and to use mechanistic measures such as reaching target numbers of 'contraceptive acceptors.' These programs' principal strategy was the distribution of contraception, chiefly to married women. Perhaps called population programs more accurately than family planning programs, these efforts usually did not address other health needs, even reproductive health needs.

2. The Feminist Critique of Population and Family Planning

As these programs proliferated throughout the 1970s and 1980s, women around the world began focusing on the negative effects of family planning programs that were based on demographics. While not denying the benefits of family planning, feminists rejected the depiction of women as targets of programs designed to limit births (Pitanguy 1995). The feminist critique concentrated on several aspects of program practices, including their vulnerability to coercion, their low quality, and their sole concentration on fertility regulation to the exclusion of other women's health needs.

The vulnerability to coercion was a major element of the feminist critique. In some countries, health care providers were under pressure to achieve targets or be subject to penalties, and workers pressed people into accepting contraception or sterilization against their

will. With success of family planning programs measured in terms of numbers of acceptors, some agencies and governments devised incentive and disincentive schemes to induce couples to participate in family planning programs. For some time, there was a debate about the fine line separating incentives from coercion. Feminists argued that, while milder than sheer force, the incentive practice is coercive; incentives are aimed primarily at the poor, for whom an economic inducement can be a vital necessity, not a free choice (Hartmann 1995). The Cairo Programme of Action later disavowed incentives.

Furthermore, women—and women were the objects of these campaigns in much greater numbers than men—were given little contraceptive choice. The focus was on sterilization or other modern, provider-controlled, methods of contraception such as the injectable Depo-Provera. The risks of these methods, feminists argued, were largely ignored and even exacerbated as a result of poor screening procedures and the lack of follow-up examinations. Safer methods, such as the condom and diaphragm were neglected, even though barrier methods have the ability to help prevent the spread of sexually transmitted diseases. Indeed, apart from fertility regulation, family planning programs provided little else in the way of services. Furthermore, male contraceptive methods were ignored in the research sphere and male participation was neglected in family planning programs, except for sterilization campaigns in some countries (Dixon-Mueller 1993).

Feminists insisted that family planning programs be comprehensive in nature with the limiting of births being only one item in a wide range of women's reproductive health needs. Other items included skilled care during pregnancy; delivery and postpartum care; prevention of infertility; counseling for sexual dysfunction; safe abortion; prevention and management of sexually transmitted diseases; reproductive tract infections, and reproductive system cancers; and treatment of postmenopausal health problems (HERA n.d.).

Furthermore, feminists demanded that women's health advocates should be represented at all levels of policy and decision making. They also maintained that men's responsibilities in the reproductive realm should not be ignored (Women's Declaration on Population Policies 1992).

Perhaps most central to the feminist critique is the assertion that women have the ability to make appropriate reproductive choices. In the feminist view, reproductive choices belong at the individual level, not with the health practitioner and especially not with the state. Noncoercive family planning programs aim to prevent unwanted fertility—as defined by couples, not by the government or other outside parties—through the provision of competent services that respect dignity and privacy. The essence of the feminists' perspective is the view that reproductive rights are human rights.

Another fundamental premise of the feminist perspective on family planning programs, sees women's empowerment as a desirable goal in its own right, rather than a means to a demographic end. Feminists also emphasize gender equity, including men's responsibilities in sexual and reproductive matters (García-Moreno and Claro 1994).

Articulating these views, women in many countries around the globe began advocating wholesale transformation of the approach to population concerns and the basis for family planning programs. By the time of the 1994 ICPD, an international women's health movement was organized and had developed the expertise and the professional skills needed for influencing policy makers and shaping the paradigm shift on population and family planning (Klugman 2000). 'The Cairo Programme of Action sums up the agenda of priorities which women from all over the world, through their leadership networks, built gradually during the years of preparation for the conference' (Berquó 1997).

3. *The Cairo Programme of Action and the 'Feminist Imprint'*

The Cairo conference ushered in a new era of population policy and family planning programming. Its resulting Programme of Action reflects a clear 'feminist imprint' (Petchesky 1995). The conference document presents a new perspective, in which high rates of population growth are understood as an interdependent and aggravating factor—rather than the cause—of problems such as poverty and environmental degradation. Even more critically, it places women's wellbeing at the center of population policy and points to the human rights of individuals to determine and plan family size. Unlike documents from previous population conferences, the ICPD Programme of Action includes chapters on 'Reproductive Rights and Reproductive Health,' and 'Gender Equality, Equity and the Empowerment of Women.'

Echoing the feminist critique, the comprehensive nature of reproductive health is elucidated in section 7.2 of the Programme of Action, as follows:

Reproductive health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity, in all matters relating to the reproductive system and to its functions and processes. Reproductive health therefore implies that people are able to have a satisfying and safe sex life and that they have the capability to reproduce and the freedom to decide if, when and how often to do so. Implicit in this last condition are the right of men and women to be informed and to have access to safe, effective, affordable and acceptable methods of family planning of their choice, as well as other methods of their choice for regulation of fertility which are not against the law, and the right of access to

appropriate health-care services that will enable women to go safely through pregnancy and childbirth and provide couples with the best chance of having a healthy infant.

While previous population conferences had always seen women's development as a tool for achieving lowered fertility rates, the Cairo Programme of Action places women's empowerment as a worthy goal in its own right. 'The empowerment and autonomy of women,' the agreement reads, 'and the improvement of their political, social, economic and health status is a highly important end in itself' (*Programme of Action*: 4.1). In another clear echo of the feminist critique, the document goes far in its call for gender equality (*Programme of Action*: 4.1):

The power relations that impede women's attainment of healthy and fulfilling lives operate at many levels of society, from the most personal to the highly public. Achieving change requires policy and programme actions that will improve women's access to secure livelihoods and economic resources, alleviate their extreme responsibilities with regard to housework, remove legal impediments to their participation in public life, and raise social awareness through effective programmes of education and mass communication.

4. *Critiquing the Critique*

The feminist critique has its detractors and the outcome of the Cairo Conference was not universally applauded. Vocal critics were mainly religious fundamentalists, especially the leadership of the Roman Catholic Church (Shannon 1994). A much quieter reaction was registered among some demographers and others whose concerns about high rates of population growth led to their dismay at what they saw as the dismantling of population policies (Dixon-Mueller and Gemain 2000). For example, Malcom Potts maintained that the 'flaw in the Cairo process was to move from a well-tested middle ground of supplying family planning to adopting a much broader agenda' (Potts 1995). Jason Finkle and Alison McIntosh claimed that women's groups 'co-opted' the ICPD. The conference, they maintained, was 'not a step forward for the population movement, which for many years has given primacy to efforts to limit population growth' (Finkle and McIntosh 1996).

Even some supporters of the reproductive health paradigm adopted in Cairo found some faults in its processes and outcomes. In a review of responses 'that tend to temper the initial feeling of euphoria surrounding the triumph of the feminist agenda,' Huda Zurayk writes that while a large number of women from Third World countries were present in the ICPD process, 'the strings were definitely being pulled by the well-organized Western feminist groups' (Zurayk 1997). Others, however, point to the significant con-

tribution of Third World—particularly Brazilian, Indian, Egyptian, Nigerian, Mexican, and South African—women to ICPD discourse.

5. Beyond Cairo: The Feminist Critique Moves Forward

After the Cairo Conference, the feminist critique expanded to include a vision of policies, governing not only family planning programs but also the broader panoply of issues related to reproduction and sexuality. One year after the ICPD, in 1995, the United Nations held another of its major international conferences, this time the focus was on women and the venue was Beijing. Again the ensuing conference document, the Beijing Platform for Action, reflected feminist input. While refraining from using the phrase 'sexual rights,' the agreement nonetheless endorsed the basic tenets of such rights, and placed them within a human rights framework. 'The human rights of women include their right to have control over and decide freely and responsibly on matters related to their sexuality, including sexual and reproductive health, free of coercion, discrimination and violence,' reads paragraph 96 of the *Plan of Action*.

There is little question that feminist analysis has had significant influence on policy worldwide, principally through the actions of women's nongovernmental organizations. Feminist scholars are now pressing for a similar impact on the discipline of demography, where gender issues have remained marginal. While ideological resistance presents a considerable obstacle, 'intellectually, the incorporation of gender issues in demography promises to enhance the science by offering a deeper understanding of social process and the application of multilevel methodologies' (Presser 2000).

Feminists are now focusing on implementation of the ICPD. Even with the advances in international agreements, many observers have pointed out that change on the level of rhetoric is one thing, and change in the everyday lives of women is another. Studies in many countries show varying levels of success in making reality conform to aspirations. Feminists continue to point to reluctant donor nations, recalcitrant cultural conventions, and wayward practitioners as some of the many obstacles to realizing quality family planning programs that are based on the expressed needs and desires of individual women and men.

Family Planning Programs: Quality of Care

The term 'quality of care' was introduced into the family planning lexicon around 1990. Since then, the concept has been widely accepted as an important dimension of family planning programs by managers, donors, health activists, and researchers. However, the actual progress in improving quality of care rendered by these programs has been limited for various reasons: lack of demonstrated large-scale experience in improving quality in different settings; limited number of studies to document the effects of improved quality; misperception of high cost; and lack of indicators to measure and monitor quality on a regular basis. A number of field studies are currently underway which will remedy this situation. This article reviews the concept of quality of care and the progress made in the field of family planning over the past decade.

1. The Concept of 'Quality of Care'

The concept of quality has been difficult to pin down precisely. Bruce (1990) defined quality as an important but neglected 'dimension' that all family planning services have. Whether the quality of a given service is good or bad is a matter of judgment. Bruce identified six elements in the quality of care framework as 'critical' aspects of services from the perspective and experience of clients. These are: choice of methods; information given to users; technical competence of providers; interpersonal relations between providers and clients; follow-up or continuity mechanisms; and appropriate constellation of services. While the use of these elements will assess from client's perspectives, their actual articulation in the framework are not based on any systematic or random surveys of clients' attitudes toward and expectations from services. Furthermore, clients may not be able to assess the adequacy of elements such as the technical competence of providers or what information they should have received at the time of interaction. The main purpose of this framework has been to draw attention to a neglected dimension and to generate interest among managers and donors toward improving the quality of care.

One criticism of Bruce's framework has been that clients themselves may not necessarily define these

elements as critical in their decision to use family planning services. In this sense, quality needs to be distinguished from other concepts, such as availability, accessibility, and cost of services—all of which may also influence an individual's decision concerning the use of services. Sometimes there is a tendency to discuss all these factors together; but that is not useful for understanding and improving any particular dimension of services. While availability simply refers to the physical availability in an area, accessibility to a service delivery point (SDP) is usually defined and measured in terms of the available mode of transportation and the time taken in reaching that SDP. The cost of utilizing services is typically defined and measured by financial cost involved in getting services once the client reaches that SDP. At times, total cost also includes other costs that the client may bear—social, psychological, and the opportunity costs. Quality, on the other hand, reflects what happens to the client once they reach the SDP.

Often the two terms—'quality of services' and 'quality of care'—are used interchangeably. Nevertheless, a distinction must be made between them. The quality of services refers to attributes of the family planning services, e.g., the number and types of contraceptive methods, staff, and equipment available at an SDP. In comparison, quality of care refers to the way clients are treated by the system providing these services. For example, choice can be offered to clients only if the SDP stocks various methods; on the other hand, availability of methods at an SDP does not guarantee that a choice will be offered to a particular client. In this sense, quality of care places additional emphasis on the interpersonal interactions between providers and clients.

1.1 Improving Quality

A distinction must be made between determinants, indicators, and impact of quality. The determinants of quality include factors such as national population policies, resources allocated to services, and other social and cultural factors. The impact of quality, by contrast, can be considered in terms of improvements in clients' knowledge and behavior with respect to contraception, fertility, and health. As mentioned above, quality is a dimension that all programs have. In this sense, there is always room for improvement, irrespective of the current level of quality. There is no real maximum or upper limit. As far as the minimum level of quality is concerned, such standards should be set locally and explicitly through a process of discussion, which should seek to address the following four interrelated questions:

1. What quality of care does a program *intend* to offer?
2. What quality of care is a program *prepared* to offer?

3. What quality of care is *actually offered* to clients?

4. What quality of care is *received* by the clients?

The process of quality improvement can start with any question. The process is illustrated here by considering the element of choice. The first question deals with the explicit statement at the policy level about clients' right to choose among appropriate methods. The statement then has to be translated into practice through asking the second question, i.e., by considering the type and number of methods that are approved by the program in a country and by considering how appropriate the logistic system to deliver these methods to SDPs is. The next step in the process will be to ascertain whether the intended methods are actually available at an SDP and whether the providers are prepared to offer these methods, i.e., whether they have the requisite training and equipment. This type of assessment at the SDP level will inform the program managers about the extent to which the SDPs are prepared to offer a choice.

Next comes the assessment of the interactions between providers and clients, and this can be done from two perspectives, namely (a) whether the provider has actually offered a choice to clients, and (b) whether the client has received the choice. A particular program may, for example, decide to include three methods, improve the logistic system to get these methods and other required equipments to SDPs, and train providers to offer these methods, i.e., the program intends and is prepared to offer three methods. When a client walks into the SDP, the provider may even offer a choice between two methods; but the client's experience may be that she was not offered the third method of her choice even though all the procedures were in place and even though she had no medical contraindication.

Thus, it is important to think of quality at three levels—policy, SDP, and client. Quality at the policy level and quality of services at the SDP level can be considered as determinants of quality of care actually received by clients. What a particular client receives is the most important basis for assessing, monitoring, and improving quality of care. The identification of gaps between intention, preparedness, services offered, and care received through self-assessment and through systematic data collection is important for an eventual improvement of the quality of care received by clients over time.

The management literature suggests that the commitment of top management is critical in improving quality of care. But how one can generate commitment to quality of care among top management of family planning programs remains an unresolved issue. Unlike in the private sector, a commitment to improve quality in public sector programs with no competition cannot be generated by the motivation of maximizing profit or by the fear of going out of business if consumers do not like the product. Nevertheless, a

combination of various approaches can make it happen.

One way to generate commitment to quality of care is through an organized movement of consumers to demand services of good quality. Another way could be for international donors and institutions to lobby for good quality of care from the consumer's-right perspective. A third possibility is for the top management to realize that improvements in quality will help them to achieve their stated goals of providing services in the first place. A fourth way is for the research community to generate empirical evidence to demonstrate the effect of improved quality of clients' knowledge and their reproductive behavior and health.

1.2 Monitoring Quality

There is considerable interest in creating indicators to measure and monitor quality. This interest stems from the observation that what gets measured and monitored also gets improved. Various efforts have been made to create indicators of quality. A breakthrough came with the methodological invention—Situation Analyses—to collect data from SDPs by actually visiting them. The technique usually involves collection of data about services on the day of a team's visit to a SDP through four questionnaires. The inventory questionnaire collects data about equipment and commodities available at the SDP. Information about provider's background, training, experience, attitudes, and knowledge is collected by interviewing providers working at the SDP. Information about quality provided and received is collected by observing client-provider interactions and by interviewing clients after they finish receiving services. These surveys conducted throughout many developing countries, especially in Africa, have provided important and useful information about the service environments. Surveys conducted over time on a representative sample of SDPs are also useful in measuring, monitoring, and improving quality. However, there is no agreed and tested set of indicators of quality. Additional efforts continue to be made.

Regular monitoring of commodities, equipment, and staff is equivalent to monitoring quality of services, which is sometimes included in what is called 'quality assurance.' Quality assurance is, however, not the same as quality of care, and it may be more difficult to measure and monitor the latter regularly. The problem is created by the small number of clients who use the SDP on the day it is visited by the data collection team. In some surveys, many SDPs visited did not have a client, and quite a few had just one or two clients. Biases are also introduced simply by the presence of an 'observer' at the time of interaction. Finally, it is difficult to assess the effects of variations among SDPs and providers on the overall quality of

care indicators developed on the basis of only a few observations. Some of these issues are also being addressed by ongoing research.

2. Impact of Quality

Clients deserve services of good quality, and they deserve to be treated with dignity and respect while accessing these services. From this perspective, there is no need to demonstrate the effect of improving quality on the reproductive behavior and health of clients. However, since family planning programs in developing countries have also been justified and evaluated in terms of their contribution to fertility decline, an assessment of the effect of improved quality on some indicators of fertility becomes critical in the process of improving quality.

Women who are very motivated (or desperately want) to control their fertility would do so even without the public sector services or even if these services were of poor quality. At the other extreme, women who do not want to regulate their fertility would not use services provided even if they were of the best quality and were available next door at no cost. Improved quality is hypothesized to affect the behavior of women in between these two extremes—those who are ambivalent about their fertility intentions, and those who do not go to services or discontinue the use of contraception because they feel that they receive poor quality or bad treatment. Improvements in quality of care thus can be expected to contribute to the reduction of unintended (unplanned and unwanted) pregnancies and not so much to the reduction in intended pregnancies.

Empirical studies to demonstrate the effect of improved quality on women's reproductive behavior are limited. It has been suggested that a focus on decreasing discontinuation of contraceptives is a better strategy than a focus on attracting new users and not taking good care of their needs. There is also some indication that improved quality in terms of providing a choice among methods increases contraceptive use by attracting new users, as well as by improving continuity of use. Moreover, improving the contents of information exchange between clients and providers improves the initial selection of the method and also improves continuity of contraceptive use. Additional studies are underway in Pakistan, the Philippines, Senegal, Zambia, and other countries, and they will shed further light on the effect of improved quality on clients' knowledge and behavior.

3. Future Directions

Quality was a neglected dimension of family planning services until about a decade ago. Clients have the right to, and they deserve, services of good quality. Therefore, program managers need to pay attention to

improving quality of services. Empirical studies to demonstrate the effect of improved quality on clients' knowledge and behavior can only provide additional justification for improving quality; they cannot replace the main rationale of improving quality—clients' right to good quality.

The original framework of quality assessment was developed for contraceptive services provided through the public sector and through its fixed SDPs. Moreover, the framework is primarily applicable to first-time users of these services. This does not mean that services provided through the private sectors are of good quality or are monitored regularly. This also does not mean that repeat users of a SDP receive services of good quality. There are some efforts to extend the framework to other services and also to incorporate the experiences of repeat users. Such efforts need to be continued. Above all, there is a continued need to initiate processes in developing countries to improve quality of care received by clients.

It is possible to improve quality. It is true that improvements in certain elements (e.g., improving choice of contraceptives by adding new methods) will imply additional costs to the program. It is also true that poor quality resulting in the underutilization of services is costly. Moreover, an improvement in certain other elements is unlikely to cost much. This is especially true for items such as treating clients with respect and dignity and providing them with adequate and accurate information.

Providers often go through initial and refresher training programs. It should not be costly to modify the content and philosophy of these training programs so that providers learn how to solicit information from clients about their reproductive intentions, prior contraceptive experience, and to learn about other pertinent social factors which might influence the selection and use of a particular contraceptive method. It should also be possible to modify training programs so that providers learn how to offer clients adequate and accurate information about how to use the method selected and its adverse effects, how to manage those effects, when to come back for a checkup or a new supply, protection against transmission of disease, and the possibility of switching between methods or sources of supply whenever the method or source initially selected does not remain suitable for the client. Such a transformation, however, would require a shift from using family planning programs as a tool to reduce aggregate fertility and population growth to helping or empowering clients to achieve their own stated reproductive goals in a healthful manner.

A. K. Jain

Family Processes

Although there is no univocal or consensual definition of the meaning of family processes, it most often refers to the interactions by which families make up and maintain their unity, manage their conflicts, achieve their socioeconomic integration, and model the social and emotional personality of their members (Sussman et al. 1999). These processes have been analyzed from various theoretical perspectives: structurofunctionalism, symbolic interactionism, development framework, system theory, conflictualism, rational choice, ecological analysis, and so forth (Klein and White 1996). This article will briefly review some of the major results and issues raised by these analyses.

1. The Constitution of Couples and Family

Several trends characterize the process of constitution of couples and family in modern societies. First, there is the widespread custom of romantic marriage, where the partners themselves—rather than parents or tradition—choose their spouse and their civil status.

However, various authors have shown that this individualization of the process of mate selection is accompanied by strong homogamy: people often

choose their partner within their own social, cultural, ethnic, or religious background. The consequence of this homogamy—which is not so obvious in the middle of the social pyramid than in its extremes—is that love marriage does not disrupt social divisions, but conforms to and possibly reinforces them, as in the case of arranged marriages (Aldous 1996). It should, however, be noted that initial homogamy often alters during the family life course because of the disparity of social mobility between the spouses.

Former linear and standardized sequences of becoming part of a couple (i.e., courtship, engagement, marriage), punctuated by strong rites of passage, are often replaced by recursive and individualized paths, which are not culturally well-established. This is true for both the life course of one particular couple and the frequent succession of several marital stories: Family careers diversify and jostle together. Far from signifying an obsolescence of marital union, this individualization of the process seems to meet the couple's increasing concern for personal identity and stability within a mobile, polyreferential, anonymous, and segmented society. In the same way, different forms of today's family ties—cohabitation, one-parent families, step-families, and so forth—can be viewed simultaneously as much in terms of their appropriateness to a complex society as of a factor of stress or deficiency for the person (cf. Kaufmann 1993, Singly 1997).

Although it is individualized, the process of constitution of the couple is also shaped by omnipresent scientific and popular models of 'the' good marriage, models which partly replace the role of juridical norms and religious beliefs.

The transition from couple to family has formed the subject of more contradictory theoretical modeling. Economic theories, like Becker's (1981), model this transition as a balance between the important emotional meaning of the child for potential parents from all social backgrounds, and the cost it involves (loss of profit, restriction to autonomy, contribution and support to education, etc.). Therefore, the number of children born in a family, or their 'quality' (i.e., their social endowment), mostly depends on the parent's material resources. Without denying the growth—within secularized societies—of the importance of intentionality, of evaluation in terms of costs and profits, and concern for family planning, sociological theories are reluctant to limit the meaning of the child to its relational dimension. They add to it a statutory motivation for parents (the child as a resource of prestige, as a means to gain power, as a resource against the outside world) and a motivation regarding the child's needs (care, protection, attendance, etc.). According to the spouses' social assets, these different types of motivation can either be in competition with each other (the attraction for the relationship can be balanced by the fear of losing one's self-identity, professional power, and daily activities) or in con-

vergence. The situation of competition occurs more frequently as the cultural level of the wife increases. This often leads to a delay in producing a child, even when strongly desired, or even to this being renounced it completely by the couple (cf. Teachman et al. 1999).

2. Types of Functioning

Once the families are constituted, how do they work? Early analysis on this theme (e.g., Burgess et al. 1949) have contrasted traditional families (institution)—strongly institutionalized, with clear differentiation of roles between spouses, hierarchical organization of the relationships, and with instrumental goals (economic survival, social integration) prevailing within the couple—with modern families (companionship), marked by the predominance of expressive goals, of equality as the norm, where institutionalization and the differentiation of family member's social identities are softened.

But the growing variety of structural types of families has led several researchers to also emphasize the diversity of the types of functioning of contemporary families. Different typologies have been put forward.

First, focusing on primary goals, Farber contrasts the 'child-oriented families'—where emphasis is placed on children's social integration, on the differentiation of domestic tasks, and where constraint of socialization prevails on the couple's personal interests—with the 'home-oriented families,' where the emphasis is placed on comfort and mutual support in the family, and a flexibility of regulations, and to 'parent-oriented families,' more concerned with the parent's socioprofessional integration, who place parental constraints over those of children, and promote a certain lack of differentiation of roles.

Second, and more centered on modes of cohesion, the typologies of Roussel (1989) contrast 'association families' (strong emphasis on the autonomy of the spouses, a little differentiation of roles, essentially individualized goals) with 'enmeshed families' (emphasis on consensus and full sharing in the couple, predominance of emotional goals of the couple, relative flexibility of roles), and 'alliance families' (strong institutionalization, predominance of the family's social integration as a goal, strong differentiation of roles).

Lastly, other authors have focused on types of normative regulations. For Kantor and Lehr, 'open families' are characterized by organization standards (roles, behavior, etc.) that evolve with contextual changes, whereas 'random families' show almost no intersituational coherence in their norms of functioning, and 'closed families' are characterized by a rigidity of their rules and incapacity to adapt to the evolution of the context and to take into account external

information. A similar interpretation can be found by Reiss, who contrasts 'consensus-sensitive families' with 'environment-sensitive families.' Olson's circumplex model, crossing dimensions of cohesion and regulation, seeks to show that extreme types of functioning (i.e., too rigid or too enmeshed) are more at risk than balanced types. These types of functioning vary according to the social status of the spouses: an increase in economic and cultural assets is linked to a more distinct emphasis on individual autonomy, a flexibility of regulation, and wide receptiveness of the group towards relationships and external information (see Kellerhals et al. 1994 for a synthesis).

3. Distribution of Roles, Power, Justice

Within the study of these modes of functioning, the question of role and power distribution has obviously occupied a central position. In the 1950s, the dominant idea was that small groups—that is, the nuclear family—generally engender a differentiation between instrumental roles (contribution of external resources, choice of the group's orientation) and expressive roles (organization of the internal production and the management of relationships), that brings about a higher efficiency of effort and turns out to be essential to the success of the socialization process (Parsons and Bales 1955). However, under the triple influence of feminism, the diversification of lifestyles, and the revisiting of ethnological analysis, the universality of this model has been contested and its functional character challenged by research showing that within a romantic marriage, the sharing of the expressive function and the equality of involvement is a determining factor of relational and educational success (Aldous 1977).

This 'functionalist consensus' was then overtaken by a rational utilitarian perspective—the resource theory (Blood and Wolfe 1960)—that understands the exercise of power in the family as a reflection of the inequality of socioeconomic resources between the spouses. According to this theory, the actor with higher outside resources exercises—despite possible egalitarian norms—a greater internal decision-making power; moreover, the comparative significance of the spouses' resources dictates their respective contribution to educational and domestic tasks. Criticism of this theory has been mostly concerned with the fact that (a) resources, far from being only economic, can also be charismatic, can concern expert knowledge, or be normative; (b) the weight of the latter vary according to the cultural context; and (c) the power of the other depends on the ego's alternatives. This triple determination can explain the permanency of sexism or domestic violence, as much as the unequal distribution of tasks in contemporary families. However, contemporary formulations of the problem emphasize the fact that by increasing the wife's potential in-

dependence and economic power, professional integration of women also increases her motivation and ability to speak for herself and require some consideration, while these elements will in turn reinforce the actor's power in negotiations (cf. Szinovacz 1987, Gelles 1995). The mechanistic exchange model is thus taken over by a sociocognitive formulation, where processes by which identity is constituted play an important part.

This transition from one paradigm to another has had repercussions particularly on the theorization of feelings of justice (fairness) in the family. The extent of inequality suffered by couples on a long-term basis tends to show that the simple equity theory—according to which feelings of injustice (unfairness) appear when the balance between one actor's contributions and rewards is different from another—is not always appropriate here. In fact, criteria of fairness vary according to status (social rank, age, sex), to the primary goals of the group, and to its type of cohesion. Three very different concepts of justice can thus be drawn (Kellerhals et al. 1997). The 'voluntarist' concept considers that justice comes when all concerned parties have been duly referred to and have been able to make an explicit or implicit agreement concerning the distribution of tasks or rewards in the family. Agreement between each other's will creates fairness. The 'finalist' concept defines the occurrence of fairness when the distribution of rights and duties brings positive outcomes to the individual or the group, with no primary consideration for merit or agreement. Finally, the 'comparative' concept considers that fairness occurs when people with the same status are treated in a similar way.

As we can see, these concepts of justice enable individuals to allow or make sense of very strong objective inequalities. They result from a collective construction of meaning, rather than from a static comparison between debts and bonds. This collective construction varies according to the type of cohesion of the group (normative families with a strong sense of unity tend to favor the 'comparative' concept, whereas more associative and negotiator families prefer the 'voluntarist' concept), and to social status ('comparative' concepts are more common at the bottom of social hierarchy, whereas 'voluntarist' ideas prevail at the top). Lastly, the spouses' concepts are not necessarily identical, so much so that the fairness/unfairness debate often seems to refer more to the confrontation of ideals, rather than to the objective disparity between contribution and retribution.

4. *The Educational Relationship*

Every family has to comply with an educational task that usually aims at providing children with social competencies (cognitive skills, social skills, and sense of autonomy/belongingness) essential to their social

integration. However, in doing so, the parents' educational strategies vary greatly. They have often been characterized by their degree of permissiveness or control, on the one hand, and by their degree of warmth, commitment, and support (vs. lack of concern or hostility), on the other. It is on that basis that Baumrind, for instance, distinguishes between an authoritarian style (weak support and nurturance, quite strict and punitive authority, little rational communication), as opposed to a permissive style (high support and weak control, either rational or punitive), to a harmonious style where parents try to have influence on their children by egalitarian negotiation, and an authoritative style (high degree of support and control) which favors rational communication and the child's autonomy. Many researches show that an average degree of control and support are favorable to a good acquisition of social competencies and good self-esteem, whereas too much authority and punishment—or conversely too much protection—lead to blocks or rejections (cf. Rollins and Thomas 1979).

The parent's social status (education, occupation, income) affects educational strategies. Kohn (1977), for instance, shows that self-control, autonomy, and curiosity are given more value at the top of the hierarchy, whereas immediate conformity tends to be emphasized at the bottom. Concerning educational methods, it has been found that coercive methods are slightly more used in poorer backgrounds, with emphasis on motivation increasing along the social scale (Gecas 1979). According to Kohn (1977), these disparities reflect the occupational situation of the parents: The more their occupation necessitates initiatives, autonomy, and symbolization, the more their educational methods will value these elements, and vice versa.

Subsequent studies have improved the rather mechanistic aspect of these analyses by giving more importance to a mutual, joint, and socially constructed character of socialization. First, observation of infants has shown how their reaction can modify the mother's attitude. Moreover, the mutual ability of children and adults to establish synchronies, turn-taking, or behavior state matching proved to be an important factor of the attachment to, and the transmission of, norms (Peterson and Rollins 1987). Lastly, sociocognitive aspects, expectations relating to the 'good child,' and common knowledge relating to interpretations of deviant behavior model the adult's response to the child's actions and doings. This diversity of perspectives leads naturally to viewing the educational process as a site of interinfluence of the family microsystem, the institutional mesosystem, and the society macrosystem (Bronfenbrenner 1986). This 'ecological' perspective has notably shown how much the quality of the relationship between husband and wife affects the mother's relationship with her child (second-order effect). In the same way, it has also been proved that

educational style is an integral part of the family's type of cohesion: 'associative' families are likely to insist on autonomy and creativity, whereas merged families concentrate mostly on mimicry and conformity (Kellerhals et al. 1994). Then again, mechanistic models have been taken over by more symbolic interactionist perspectives.

5. Families and Kinship Network

Because families have so many tasks to accomplish, there is a question as to whether they generally face these problems on their own or not. In this regard, the idea of the modern family withdrawing into itself has not stood up to several studies on the theme of family solidarity which show that the kin group's support in the family management—purchase of property, child care, moral support, and so forth—is often essential, due to its flexibility, versatility, and speed (Pitrou 1992). However, these kinship ties are often characterized by a poor number of effective links, a clear primacy of vertical links (filiation) over horizontal links (sister/brother link), the predominance of the mother's kin, and by a much higher involvement of women. Kinship solidarity is, therefore, much affected by geographical distance, divorce, and professional occupations of both spouses, three points which limit availability.

Moreover, because kinship relationships often rely on affinity rather than on duty or status, and because the number of recomposed families following a divorce is multiplying, the kinship tie looks increasingly like a network (weak bond connections and absence of an important center point) rather than like a group concentrically focused on forebears and endowed with a strong collective consciousness (cf. Coenen-Huther et al. 1994).

6. Adjustment and Divorce

The study of family processes logically leads to research concerning reasons for the success or failure of the family faced with its tasks; in other words, concerning factors of adjustment. But what criteria of adjustment can be used?

Measuring marital and family adjustment in regard to the propensity for divorce creates confusion between the question of relational difficulties and economic or cultural obstacles preventing separation. Situations where marital stability coexist with disappointment often occur. However, it is important to try to define what are the factors of divorce. Before and during the 1960s, marital separation was usually interpreted with deficit models. Poor adjustment has therefore been viewed as a result of deficiency in the socialization to the other: couples getting married and having children very young, and also those whose

parents have failed to pass on stable or harmonious models of marital union, have a higher rate of divorce than others. It has also been shown (Cherlin and Furstenberg 1994) that probability of divorce is higher in second unions, where there is often a lack of clear cultural models to guide relationships between generations.

Poor adjustment has also been related to a deficiency of symbolic or economic resources. The emphasis on happiness, communication, and consumption often found in contemporary family's plans demands financial resources that are not always available. Consequently, it is understandable that couples with low income and poor education separate more often, the distance between objectives and means being so large.

Poor adjustment has finally been viewed as the result of pronounced cultural differences between spouses, which finds expression in a lack of shared codes and values. A higher rate of divorce has therefore been noticed among mixed religion or nationality couples, or among heterogamous couples in age or social level (cf. Faust and McKibben 1999). However, once again, we should be aware that the social meaning of difference is probably even more important than the difference itself: hypergamous couples (where the man occupies a higher position than the woman does), for instance, are far more stable than hypogamous couples (where the situation is reversed), who are not so well accepted socially. But these different deficit models fail to explain the majority of contemporary divorces. More global, but also less verifiable, interpretations have been suggested, like Berger's, for whom too much expectation regarding the couple and the family explains the extent of disillusion. Other analyses (Popenoe, Bellah, Roussel) insist on the incompatibility of individualistic concern for personal genuineness with constraints related to community commitment; others also have placed the accent on the existing hiatus between egalitarian models of marital relationship and very unequal marital practices. In all these approaches, divorce appears to be more like an intrinsic property of contemporary couples, rather than linked to clearly identifiable individual deficiencies (Roussel 1989).

Given the biases of the 'divorce' indicator, there have been attempts—since initial studies by Burgess and Cotrell—to measure marital adjustment with a great many multidimensional scales (implying, e.g., degree of satisfaction, cohesion, consensus, and emotional expression) and to examine factors that affect this marital quality. These are due to the marriage's previous history (homogamy, socialization to appropriate role models), to the spouses' current resources (integration and community support, economic level, educational level), and to the nature of their interaction (quality of communication, appropriateness to roles) (Gelles 1995). One can believe that these different 'resources' make it possible to avoid extreme

forms of cohesion (enmeshment or disengagement) and of normative regulation (rigid or chaotic) which themselves limit the family's ability to cope with stress, to adapt to external changes, and to manage disruptions (cf. Olson et al. 1983, Boss 1988).

Family Size Preferences

Preferred or desired family size is the number of children wanted in one's lifetime. Family size preferences are viewed as measures of the demand for children which, in combination with the supply of children and contraception determines the number of children born. Family size preferences may change over the life course, especially in response to child-bearing and childrearing experience.

Family size preferences or desires are conceptually and empirically distinct from family size ideals, norms, intentions, and expectations. Fertility ideals and norms represent what is desirable for a group of people or a typical group member, rather than what is desirable for every person in the group. Family size intentions or expectations reflect not only family size preferences but also constraints on one's ability to achieve desired or preferred goals.

1. Conceptualization and Measurement

1.1 Desired, Intended, Expected, and Ideal Family Size

McClelland assessed the construct desired family size as a measure of the demand for children, that is, 'the

number of children parents would have if there were no subjective or economic problems involved in regulating fertility' (1983, p. 288). He concluded that family size desires do, indeed, represent the theoretical construct, demand for children.

Family size intentions and expectations reflect not only family size preferences but also perceptions of the likelihood that preferences can be translated into outcomes. The gap between intended or expected family size and desired family size may reflect influence of partner's desires, perceived fecundity and fertility control, or other known constraints on fertility behavior or outcomes.

Questions about a general ideal family size produce responses that fit the character of a social norm rather than that of a personal preference. For some individuals—those who have internalized societal ideals or who believe their own situation is typical—ideals may be identical to desires (Mason 1983).

1.2 Measures of Family Size Preferences

Two types of questions are most commonly used to measure family size preferences. The first asks respondents how many children they would want to have in their lifetime, if they could choose the exact number. For childless respondents, this question measures desires prospectively; for parents, the question includes a retrospective assessment of previous births with a prospective assessment of potential future births. Retrospective assessments of birth wantedness are subject to social desirability bias or rationalization and therefore produce upwardly biased estimates of desired family size. Another version of this question attempts to give respondents permission to report previous births as unwanted by asking something like: 'If you could start life over again, how many children would you want to have?' Such questions may also place conditions on the question, specifying that the respondent's life would be in other respects about the same as it had been so far. It is not clear that these two forms of the lifetime question produce different responses.

The second type of question asks respondents how many more children they would like to have; for childless respondents, the answer would presumably be the same as for the first type of question, but for parents, retrospective assessments of previous births are excluded. To obtain an estimate of desired family size, some analysts simply add the respondent's current number of children to the additional number desired. This strategy assumes that all previous births were wanted, producing an even stronger upward bias than does the first type of measure. Several methods have been proposed for estimating the number of unwanted previous births from parity-specific values of additional desired children, and thereby to produce a more accurate measure of desired family size

(Bongaarts 1998). Unfortunately, these methods do not provide estimated family size preferences for individuals.

An alternative measure of family size preferences asks respondents to make choices between pairs of family sizes, producing a scale reflecting desires for large versus small families. Scales have also been developed to incorporate preferences for sex of children in family size preferences and vice-versa (Coombs 1979). The interdependent IN and IS scales reflect the fact that family size desires may incorporate desires for particular numbers of boys or for particular numbers of girls or some balance between the two.

1.3 Non-numerical Responses

In high-fertility societies, small but significant proportions of respondents do not provide a numerical response to questions about desired family size, reporting instead that the number of children they have is 'up to God' or that they will accept whatever number of children they have. These responses raise the question of whether individuals form preferences about things they believe they cannot or should not try to influence. Such respondents do respond to questions about family size ideals, preferences for one family size over another, and unwanted or mistimed previous births (McClelland 1983, Riley et al. 1993).

2. Her, His, and Their Family Size Desires and Intentions

Most data on family size desires or intentions come from interviews with women. The assumptions underlying women-only fertility surveys are that (a) women and men share the same conditions of life and will therefore want and intend the same number of children, (b) because women bear children and are primary childrearsers, their desires and intentions are those that determine fertility, and (c) women's desires and intentions will incorporate those of their partners, reflecting resolution of any initial disagreements. These assumptions appear to be tenable in the aggregate; when data are collected from women and men, their respective family size desires and intentions are more similar than different (Mason and Taj 1987). On the other hand, data collected from couples consistently show that substantial proportions of couples disagree about desires or intentions for further childbearing or completed family size (Becker 1996).

3. Family Size Preferences, Intentions, and Births

The relationship between family size desires and births depends on relationships between preferences and intentions, between intentions and behavior, and

between behavior and outcomes. Couple disagreement is a primary source of gaps between desires and intentions, that is, the gap between individual desires and intentions to have a child is explained in large part by a spouse's different preference (Thomson 1997). Another key source of gaps between desires and intentions is the perception of control over fertility. Those who believe themselves to be infecund may desire more children than they intend; those who do not perceive themselves to be able to control fertility may intend more children than they desire.

Family size preferences or intentions may also change over the life course and are particularly likely to be influenced by experiences with previous births (Namboodiri 1983). In spite of these expected gaps, measures of family size desires, particularly the desire for additional children, have moderately strong effects on fertility behavior and outcomes (McClelland 1983). Lee (1980) has demonstrated that a 'moving target' model of desired and achieved fertility produces even stronger correspondence between family size desires and period fertility.

Davidson and Jaccard (1979) identified many of the key conditions under which a strong effect of fertility desires or intentions on births should be expected. First, the strength of the effect depends on the extent to which the ultimate goal (birth or no birth) is achieved through a sequence of behaviors and events, including sexual intercourse, contraception, conception, and abortion. Fertility desires and intentions should have stronger effects on the behaviors at the beginning of the sequence than on the ultimate outcome. Second, the effect will be stronger over shorter versus longer periods of time because the opportunity for new experiences that change desires or intentions is reduced. Third, effects of desires or intentions on behavior and outcomes should be stronger for individuals who place a high value on cognitive consistency, who believe they have control over their actions, and who generally engage in planful behavior than for those who do not. Finally, desires and intentions and behaviors and outcomes should be measured at the same level of specificity in order to expect a strong relationship; desired or ideal family size should not, for example, be expected to have strong effects on contraceptive use or even the timing of a particular birth.

The relationship between childbearing desires or intentions and births depends to a considerable extent on couple agreement. Couple disagreement leads to birth rates between those for couples who both desire or intend a child and those who do not. This means that both partners' desires have at least some influence on births (e.g., Thomson 1997, Thomson and Hoem 1998, Dodoo 1998).

Estimated relationships between fertility desires and intentions or between intentions and behavior also depend on measurement quality. The IN-scale discussed above provides more accurate measures of

preferences and therefore has larger estimated effects on fertility behavior than does a single most preferred number of children (Coombs 1979). Measures of the desire for children that incorporate dimensions of attitude strength have stronger effects on childbearing intentions and behavior than do yes-no-don't know responses to direct questions about desire for children (e.g., Davidson and Jaccard 1979). Similarly, intentions measured with some degree of certainty or uncertainty are better predictors of outcomes than a simple dichotomy (Thomson 1997).

Family Systems and the Preferred Sex of Children

1. Introduction

Most human societies exhibit some degree of gender inequality, but there is enormous variation in its nature and manifestations. In some societies, women face only mild or moderate constraints on functioning as socially and economically autonomous persons in the public life of the community; in others, women are largely subordinate to males. This has implications for any old-age support parents can expect from daughters, which, in turn, affects the aspirations of couples regarding the sex of their children. In most regions of the world, parents express a preference for a gender-balanced family—with, perhaps, mild preferences for children of a particular gender. However, in some regions parents exhibit a significant degree of son preference. These preferences manifest themselves in decision making at the margin in many ways—ranging from investing more in educating sons to the extreme outcome of excess mortality among daughters.

To understand why some societies have strong son preference while others do not, we need to examine the gap between sons' and daughters' ability to contribute to the physical, emotional, and financial well-being of their parental household—as this is the unit primarily responsible for making and implementing decisions about childbearing and childrearing. This gap is determined largely by kinship systems, which specify clearly defined roles for different categories of family members. In most societies, it is possible for women to maintain mutually supportive relations with their parental household even after marriage, making for little difference in the value of girls and boys to their parents. However, in other societies women's links with their parental household are largely severed at marriage and sons are enjoined to care for their parents—making it clearly more attractive for parents to rear sons instead of daughters. Gender-appropriate roles are also decided, to a lesser extent, by other norms—such as religious beliefs and injunctions, which can, for example, discourage women from participating in the labor market and thus reduce their ability to help their parents financially.

In this entry we review the broad features of family systems in different cultural regions of the developing world to describe how far daughters are in a position to contribute to parental well-being—both in absolute

terms, and relative to what is expected from sons. We then explore how these sex preferences are reflected quantitatively in survey data on family-building desires and in measures of excess female child mortality.

2. Family Systems

The strongest son preference is evident in societies which are rigidly patrilineal and patrilocal. Patrilineality implies that group membership and productive assets are passed on through the male line. Patrilocality implies that it is normative for a woman to take up residence with her husband's family after marriage—often outside her parental village. In these societies, in which both inheritance and marriage rules are heavily weighted in favor of men, women have little economic independence or autonomy. Furthermore, since daughters move away from their birth homes after marriage, parents can have little expectation of subsequent physical or emotional sustenance from them since they are not living in close proximity. Even if women are educated and employed, the fruits of their labor are monopolized by their husband's family, and parents cannot claim a share of their daughters' earnings. On the other hand, a son is expected to provide his parents with economic security and insurance. He is also expected to bring in a daughter-in-law who will take care of his parents' physical needs in their old age. In these societies, women also gain in prestige and status if they bear sons to continue the family line, so both women and men have a strong interest in producing sons.

In some patrilineal societies, there are additional norms which increase the burden to parents of raising daughters. Religious beliefs and social customs such as dowry and 'purdah' serve as further instruments of patriarchal control, and reinforce son preference. Furthermore, family honor often depends on the purity of patriarchal descent, which requires ensuring women's sexual purity. This often entails secluding women from outside activities—which implies reduced income-earning opportunities—and marrying them off at young ages, before they have had a chance to develop into independent people.

In contrast, where kinship rules and norms make fewer distinctions between males and females, women have greater voice in the household and in public spaces, and face fewer constraints in becoming independent economic and social actors. In these societies, women are not constrained from providing old-age support to parents, and are valued accordingly.

2.1 South and East Asia

Much of South Asia displays the patterns of patrilineal and patrilocal kinship systems. This is especially

strong in the northern part of the subcontinent. The widespread practice of dowry payments constitutes a drain on family resources, further raising the relative cost of a daughter (Miller 1981). In Bangladesh, as in much of the rest of the subcontinent, daughters are perceived as burdens due to the custom of dowry and their limited income opportunities, while sons are preferred due to their higher earning potential (Muhuri and Preston 1991).

Much of East Asia is also characterized by rigidly patrilineal kinship organization, although in recent decades women have become educated along with men and have been active in the industrial labor force. Patrilineality is most pronounced in South Korea and amongst the majority Han population of China (Goodkind 1996). Moreover, it is believed that only sons can give their parents the crucial support they need in their afterlife, to prevent their being hungry spirits for eternity. This puts additional pressure on people to have sons even if pension plans and other mechanisms for providing for one's old age are in place, as they cannot provide for the afterlife—this can only be done by sons. (Japan is an exception to the East Asian pattern, practicing a very flexible form of patrilineal kinship organization which permits daughters under many circumstances effectively to substitute for sons; Nakane 1967.)

However, in Kerala and Sri Lanka, kinship systems allow women greater flexibility to interact with their parents after marriage than in the north (Dyson and Moore 1983). Village endogamy and cross-cousin marriages are favored, allowing women to live closer to their parents. Women sometimes transfer and inherit property as well. Thus there is considerable scope for mutually supportive relations between a married woman and her parental household.

2.2 Southeast Asia

Most Southeast Asian societies have bilateral kinship systems, which allow people to maintain strong links with both their family of birth and their family of marriage. Reciprocal obligations and expectations are more flexible than in strongly patrilineal societies. In much of Southeast Asia—as in Thailand, Indonesia, and the Philippines, for example—women have traditionally had considerable social and economic autonomy, playing a significant role in marketing and other independent income-generating activities. This makes it possible for them to provide old-age support for their parents should it be needed. In some cases, daughters are the main source of support—in Northern Thailand, for example, the norm is for newly married couples to live with the wife's parents for some years, and for the last daughter to stay on and inherit the land and house after the parents' death (Limanonda 1995). Although Islam has been actively

practiced in several of these societies for some centuries, this had relatively little impact on traditional kinship systems, as documented for Malaysia (Kling 1995).

On the other hand, the Chinese populations of Southeast Asia—including those in Malaysia and Singapore—display patrilineal and patriarchal kinship systems (Wongboonsin and Ruffolo 1994). Vietnam is an interesting amalgam of kinship systems, with strongly patrilineal values stemming from the incursion of Confucian ideologies from the north, superimposed on more bilateral Southeast Asian kinship systems, resulting in moderate levels of son preference (Goodkind 1994). As in China, sons alone can perform traditional rights of ancestor worship.

2.3 Middle East and North Africa

North Africa and the Middle East are characterized by patrilineal systems in that the family line is traced through males, but people are permitted to marry within their lineage, including cousins. This means that women often live in close proximity to their own parents, and can be a source of physical and emotional support to them. Economic reasons for son preference also do not appear to be strong—in Egypt, for example, parents value the labor of both sons and daughters, marriage expenses may actually be higher for males, and daughters can remain close to their parents after marriage (Makinson 1986). There are significant groups of educated and employed women in most of these countries, especially amongst the middle classes (Rostam-Kayali 1999).

However, the extent to which daughters can provide material support is constrained by the norms of Islam and the Arab family, whereby the husbands are the dominant decision makers in the household and most women are discouraged from active participation in the world outside the home (Obermeyer 1995). Normative pressures for bearing sons is strong, and women derive social status while men continue their name and lineage through sons. Overall, women are not as well placed as in Southeast Asia to contribute to their parental households, but not nearly as constrained from doing so as in East Asia and the northern parts of South Asia—making for moderate rather than strong son preference in the region.

2.4 Sub-Saharan Africa

Sub-Saharan Africa includes societies which are patrilineal, bilateral, and matrilineal. Despite these apparent differences, they have a great deal in common in terms of gender relations. Men tend to be dominant in the household—even in several of the matrilineal societies, property is passed through the female line,

but from men to men (Kevane and Gray 1996). However, conjugal bonds in sub-Saharan Africa are weaker than in South Asia, and women have a higher degree of economic independence (Cain 1984). They have freedom to remarry upon divorce or widowhood (Bledsoe 1990). Marriage often involves bride-price from the groom to the kin of the prospective bride, rather than dowry (Oppong 1987).

Women typically function easily as independent economic actors who can operate comfortably in public arenas—whether as self-employed market women, or as managers of their own farm plots. In several West African societies, women are very active traders and are completely accustomed to being the mainstay of the household, through marital union and dissolution. There is substantial flexibility in terms of those whom people can choose to live with and support, and parents have little reason to be desperate about old-age support if they do not have sons. Hence, one is unlikely to see strong preferences for children of a particular sex on the part of parents.

2.5 Latin America

Central and South American societies are formed from the confluence of many different ethnic groups, each with their own customs and social organization. For all their differences, however, these societies derive from cultures which are not heavily patrilineal or gender differentiated. The dominant culture is that of those of European origin, mixed with those of sub-Saharan African origin, neither of which place rigid constraints on women's participation in public life and interaction with their parental household. The Latin American family structure allows women a high degree of female autonomy. The conjugal bond is weaker than in countries of South Asia, the Middle East, and North Africa (Cain 1984). Childbearing outside formal marriage or stable unions is common, and women may spend much of their reproductive lives in consensual unions with men. Economic dependence of women on men is inconsistent with such family patterns. The result is that there is a strong tradition of male machismo, but there are few rigid rules constraining women from participating actively in social and economic life, or from helping their parents. Thus, there is little reason to expect strong gender preferences among parents—and whether or not they receive support from daughters is a matter of choice and circumstance, rather than one of custom and ability.

3. Quantitative Evidence of Son Preference

Son preference is manifested in quantitative data in various ways. In this section, we focus on two measures—survey data on desire for additional chil-

dren by number and sex of living children, and the sex ratios of children across developing countries—to examine the correspondence between family systems and these measures of revealed son preference.

As an indicator of sex preference among currently married nonpregnant women, the Demographic and Health Surveys (DHS) asked respondents whether or not they wanted another child, by sex distribution of their living children. The results from the latest available country studies are reproduced in Table 1, for women with two and three living children of the same sex. (This indicator is limited in that it focuses on a selected sample of women with a specific number of children rather than on the entire population of women of childbearing age, but is suggestive, nonetheless.) Son preference is indicated if, for a given number of children, a lower percentage of women wanted an additional child if all their children were sons, as compared with if they were all daughters. The number of children at which such preferences manifest themselves depends on the overall level of fertility in the country—it is only when people approach their desired family size that they are compelled to make decisions on additional childbearing to achieve their desired sex composition. Thus, where overall levels of fertility are high—as in some countries of South Asia, the Middle East, and North Africa, for example—gender preferences manifest themselves at higher numbers of children than where fertility levels are low.

Another way to measure sex preference is to examine the sex ratios of children aged below five years (Fig. 1). This reflects the extent to which the stated preference for sons actually translates into significant levels of excess female child mortality. Excess female child mortality can result from discrimination before birth (sex-selective abortion), at birth (female infanticide), and during early childhood (most commonly through neglect in providing timely health care). These are all motivated by the desire to rear more sons than daughters, and which method is used depends largely on the technological choices available.

There is no single 'expected' ratio of boys to girls, as this depends on the level of mortality. The observed sex ratio at birth is around 1.05 on average, and excess male mortality in early infancy is the biological norm (Waldron 1998). A recent study of 82 developing countries that had populations in excess of a million in 1990 confirms that mortality among male infants (aged below a year) is higher than that of females, the median sex ratio of infant mortality being 1.18—although actual figures vary around this median, with lower ratios in societies with higher life expectancy (United Nations Secretariat 1998). In the age-group one to four, the median sex ratio of child mortality is about 1. Based on this information, sex ratios among children aged zero to 4 can be expected to be below 1.05, *on average*. We have used a cut-off ratio of 1.045 (see Fig. 1), and sex ratios above this expected value

Table 1

Percentage of currently married nonpregnant women who want another child, by number and sex of living children

Figure 1
Juvenile sex ratios in Africa, Asia, and Latin America, 2000

can be viewed as indicative of excess female child mortality. The higher the observed sex ratio above this cut-off, the stronger the manifestation of son preference.

The data presented in Table 1 and Fig. 1 are consistent with the broad regional differences in family systems outlined above. In Latin America, sub-Saharan Africa, and Southeast Asia, where there is a higher degree of female autonomy, there is little consistent evidence of son preference in either juvenile sex ratios or desire for additional children. In Latin America, there are actually instances of a mild preference for daughters, in countries such as Colombia, Trinidad and Tobago, and Paraguay (Table 1).

On the other hand, in regions of the world where patrilineal and patrilocal family systems prevail, the data reveal a distinct preference for sons. Son preference in the desire for additional children is evident in all countries in the Middle East and North Africa, and even more strongly in South Asia, at a parity of 2 (Table 1). (Since the DHS surveys were not conducted in East Asia, these observations are missing from the table.) These preferences are strengthened at a parity of 3—reflecting that in high-fertility regions, son preferences are more evident at higher parities. (Only

Sri Lanka in South Asia displays a different pattern; see Table 1.) These regions, along with China and South Korea in East Asia, have distinctly higher juvenile sex ratios than average as well—suggesting excess female mortality (Fig. 1).

Estimates indicate that in China and South Korea, around 7 percent of girls were ‘missing’ in 1990 on account of excess prenatal or postnatal mortality (Das Gupta et al. 1997). Globally, estimates indicate that there are between 60 and 100 million fewer women than there would be in the absence of gender discrimination—mostly in South and East Asia (Coale 1991, Klasen 1994, Sen 1992). (These estimates are based on comparing the actual sex ratio of the population against the sex ratio that would theoretically exist in the absence of gender discrimination.)

Since China and India are large countries with considerable cultural heterogeneity, it is instructive to look at province-level data (Fig. 2). This shows patterns which accord further with the description of family systems above. In India, the northwest shows sex ratios as excessively masculine as South Korea and the mainstream Han-populated provinces of China. South India shows less discrimination against girls, as do the interior provinces of China, where minority

Figure 2
Juvenile sex ratios in provinces of China and states of India, 1990-1

ethnic groups are clustered. Thus the strongest evidence of excess female child mortality is from the regions of East and South Asia characterized by rigidly patrilineal kinship systems. Similar consistency between kinship systems and son preference is evident in the data from Malaysia, where the Malays with their Southeast Asian patterns of bilateral kinship show little sign of excess female child mortality, while the Chinese and Indians show it clearly (Goodkind 1996).

4. Other Factors Affecting Son Preference

Although son preference is culturally determined, the extent to which the preferences within a given society are translated into actual discrimination against

daughters is influenced by the pressures operating on parents at a given point in time. Such pressures can take many forms. For example, in times of adverse income shocks, investment in girls may suffer more than investment in boys. (See, for example, Behrman and Knowles 1998 for Vietnam, which suggests that the income elasticity of investment in daughters is higher than that of investing in sons. This implies that if household income falls, discrimination against daughters will rise.) It is not that parents are unwilling to invest in children, but that they would prefer to invest less in daughters who will be subsequently lost to them.

External crises, such as famine and war, increase the pressures on parents to discriminate against daughters, as the difficulties of nurturing all household members

Figure 3

Excess sex ratios at census time by five-year birth cohorts in China and South Korea, 1920–95

Note: The excess ratios peak amongst cohorts born just before a war or famine, because those who were young girls at the time of the crisis experienced the maximum excess mortality

Source: Das Gupta and Li 1999

rise and harsher choices have to be made. Fig. 3 shows how the extent of actual discrimination against girls was affected by wars and famines in China and South Korea during this century (Das Gupta and Li 1999). (China experienced many severe crises during the twentieth century—during the first half of the century, civil war and invasion in China led to an enormous amount of disruption, which was followed by the famine of 1959–61.) The South Korean data show a massive deficit of males associated with the loss of young men during the Korean War in the early 1950s, followed by a rise in sex ratios as fertility declined.

Fertility decline also adds to the pressures to discriminate against daughters. When parents desire a smaller number of children, this further limits the number of daughters they would like to rear. If, for example, they want to have no more than two children, and the first is a girl, they are under severe pressure to ensure that the next is *not* a girl. Thus child sex ratios

were observed to become more masculine when fertility declined significantly in India, China, and South Korea (Das Gupta et al. 1997).

5. Conclusions

This entry provides a broad overview of family systems in the developing world, and how they influence sex preference for children. In general, evidence for son preference is strongest where women are not in a position to contribute to the well-being of the family.

Family Systems in Europe

Contributing to a long tradition of scholarship on family life in Europe, a group of scholars in the 1960s redirected research by arguing that a unique system characterized the traditional European family. They criticized what they took to be the received wisdom on European family life in the past, which portrayed the nuclearization of the coresidential family as a recent product of industrialization and urbanization. The final decades of the twentieth century saw increasing criticism of this revisionist perspective, leading to a more nuanced and theoretically sophisticated understanding of the nature of coresidential processes in the European past.

1. A European Family System

The debate over the existence of a European family system has revolved around two related elements—a marriage system and a household system—emphasizing the demographic aspects of each. The former focuses on the age at which men and women marry, as well as the proportions who never marry. The latter concerns the principles by which coresidential units form and dissolve. The two are linked via the principles governing postmarital residence, that is, where newlyweds live following marriage.

These are only two aspects of what could be seen as the larger matrix of a family system. The anthropologist Goody (1983) has called attention to a variety of features that together historically differentiated European family dynamics from those found elsewhere in the world—including a prohibition on poly-

gamy and child adoption, and various restrictions on marriage to kin—differences which he attributes in good part to the influence of the Church. An understanding of family systems more generally would also include consideration of kin ties beyond the household; however, relatively little empirical attention has been focused on such issues historically.

1.1 From Le Play to Laslett

Most prominent among the nineteenth-century progenitors of the social scientific study of European family systems was the Frenchman, Le Play (1895), who combined a series of empirical studies of families across much of Europe with pronouncements about the evolution of family life in the west, warning of an alarming erosion in traditional family forms that was eating at the moral fabric of European society. He contrasted what he took to be the traditional family, consisting of a large, patrilineally extended group of kin under the senior male's autocratic control, with the unstable family that was rapidly spreading throughout the industrializing population of a rapidly changing Europe.

Between the two extremes was the household form that Le Play thought best, the stem family, which mixed a high degree of respect for authority and concern for other kin with an element of independence and room for innovation. The farmstead lay at the center of stem family life, and was passed on, intact, from generation to generation, to a single child, preventing land fragmentation.

Le Play believed that the large patriarchal family had already receded in Europe, remaining primarily among Eastern nomads, Russian peasants, and the Slavs of Central Europe. The epic struggle that gripped nineteenth-century Europe, in Le Play's view, pitted the stem family against the unstable family.

Such evolutionary perspectives as Le Play's were taken up by American sociologists in the middle decades of the twentieth century. Many assumed that large, complex family households had characterized the European past, and were being ineluctably replaced by small, nuclear family households as a result of modernization, however defined (Goode 1963). Challenging these assumptions, Laslett (1965), using British historical evidence, argued that the view of the large, complex household as typical of the European past was a 'myth.' According to Laslett, western Europe was long characterized by neolocality (i.e., couples established their own independent households at marriage) and it was rare for people in the past to live in large, complex family households. The Cambridge Group for the History of Population and Social Structure, which Laslett and Wrigley cofounded at this time, became an influential center for historical household studies, and the 1972 volume edited by Laslett and Wall, *Household and Family in Past Time*,

set the terms of the debate for years to come and spawned hundreds of local-level studies throughout Europe.

1.2 The European Marriage Pattern

Just as Laslett was attacking the myth of the European extended family, Hajnal (1965) advanced the claim that a unique marriage system had characterized the whole of Europe except for the east and southeast for at least two centuries preceding 1940. It had two key features: a high age of marriage and high proportions of people who never married. A line could be drawn, he argued, stretching from St. Petersburg (then Lenin-grad) southwest to Trieste. To its east the system was not found.

Two decades later, Hajnal (1983) partially retreated from his by then famous 'line,' portraying the European marriage pattern as characterizing northwestern Europe and excluding not only eastern Europe, but the south as well. In this reformulation, he emphasized a third characteristic of the European family system, in addition to high marriage age (men 26, women 23) and high proportions (10 per cent or more) never marrying: young people in large numbers left their parental home and spent the years before marriage circulating between houses of nonkin in the capacity of servants. It was this circulation of servants that gave flexibility to the nuclear family system, facilitating the redistribution of a household-based rural labor force in response to each household's labor needs.

1.3 Geographic Diversity

As Hajnal's retreat from his own 'line' suggests, the proponents of a traditional European family system soon found themselves under heavy criticism from scholars who determined that some form of a more complex household system had indeed been typical of the areas they were studying. Both Hajnal and Laslett attempted to salvage their model of the European family system by restricting its territorial reach. It is revealing that French family historians never participated in these efforts to find a single European family system, for they were all too aware of the fact that even within a single country—in this case, their own—more than one family system had existed. In northern France a system much like that described by Laslett and Hajnal appeared, but in the central and southern regions larger, complex family households were common in past centuries. Similarly, work on Spain (Reher 1997), Portugal (Kertzer and Brettell 1987), and Italy (Barbagli 1984) found clear internal divisions: in each country nuclear family systems predominated in the south but more complex household systems were found in parts of the north. Nuclear family systems and neolocality were linked to systems

of partible inheritance or contexts in which there was little of productive value to inherit (as in the case of the proletariat).

Laslett (1983) responded to this new evidence by proposing a new division of traditional Europe into four areas—the West, Middle, Mediterranean, and East—each having a distinctive family system. It turned out that the ‘myth’ that Laslett had punctured, if it was a myth at all, pertained only to one of the four areas of Europe, the West. In this new model, not only did Eastern Europe have low female marriage age and high proportions of joint-family households, but so did Mediterranean Europe.

Laslett continued to hold to Hajnal’s notion of a family system in which neolocality, high female age at marriage, and the prevalence of service as a life stage go together. Yet the Italian case, among others, shows that this is not necessarily true: in Italy in past centuries, it was the central and northern areas having high proportions of joint family households that had high proportions of servants, while in the south, where nuclear family residence prevailed, life-cycle service was rare (Da Molin 1990). Moreover, age of female marriage was typically higher in the center and north than in the south, again going against the Hajnal/Laslett model.

2. *Rethinking European Family Systems*

Laslett’s later work on European family systems rejected crude generalizations about ‘the’ European family. A more fully satisfactory approach should build on these insights, recognizing the role played by political economic, demographic, and cultural forces in local contexts. It should also abandon the notion that northwestern Europe is the kernel of Europe and the lingering attempts to rescue a quintessential European family system.

2.1 *Political Economy*

Family historians frequently have pointed to two major, related economic pressures shaping family systems: the household as production unit, and inheritance norms. The traditional model of rural life in preindustrial times depicts a peasant society in which the household was the unit of production. Where this is the case, the composition of the household, and the timing of marriages, are shaped by labor needs and relations between peasants and the land they farm (or ownership of other productive resources, such as livestock). A dramatic case comes from central Italy, where sharecroppers typically lived in large joint family households. Landowners sought to maximize the number of adult laborers on each plot of land, to maximize their income (classically one-half of the produce). In the Alpine area in the north of Italy,

likewise, Viazzo (1989) describes a system in which complex family households prevailed, allowing peasants to diversify their holdings and their risks, combining herding with farming scattered plots of land at different altitudes.

Political forces entered into these dynamics both indirectly, via political support for various land-holding systems, and directly, as when systems of household taxation or military conscription influenced peasants to live in more extended or more nuclear households. In the case of serf systems of Eastern Europe, controls on movement out of estates had a similar influence (Czap 1982).

Inheritance systems are tied closely to family systems. In Spain, France, and elsewhere, areas practicing impartible inheritance tended to have stem family systems. On the other hand, where peasants did not own their own land, the link did not operate in this way. Italian sharecropping households practiced partible inheritance, but the pressures to have large numbers of coresiding adults resulted in joint family households.

2.2 *Demographic Constraints*

A continuing theme in debates about European family systems concerns the constraints placed on family dynamics by the brute facts of demography. In 1965, Levy argued that the great majority of people in the past lived in relatively small nuclear family households regardless of family formation norms, because high mortality rates interfered with the formation of extended family households. In critiquing Laslett’s original thesis of the prevalence of the nuclear household system in Europe, Berkner (1972) took up this idea, arguing that census data showing that the great majority of households at any one time are nuclear does not in itself provide evidence of a nuclear family system. Rather, he argued, under preindustrial demographic conditions, people following extended family norms would spend most of their lives living in nuclear households.

Given the workings of such demographic constraints, inheritance was typically a much more messy process than a focus on norms would suggest. A study of a nineteenth-century Austrian community, in which impartible inheritance was the rule, for example, found that large numbers of households heads died before they had a son old enough to take over. When their widows remarried, tensions between stepfather and sons resulted (Sieder and Mitterauer 1983). Yet work in sharecropping Italy and on the Russian serf estates shows that such demographic constraints were much less evident in joint family systems: where all sons are supposed to bring their brides into the household at marriage a nuclear phase is much less common, as many other combinations of coresiding kin are possible (Kertzer 1989, 1991, Czap 1982). Indeed, there is

evidence that in the nineteenth century the proportion of people living in large, complex family households was growing in several areas as a result of a combination of demographic and economic factors (Ruggles 1987). In central Italy, with a largely fixed number of sharecropper farms available, a growing rural population, and the primary alternative—agricultural wage labor—providing a much poorer living, there was increasing pressure on the children of sharecropper families not to strike off on their own at marriage, and in this area the nineteenth century saw the historical zenith in the proportion of people living in joint family households (Barbagli 1984).

3. Culture

Understanding European family systems requires not only attention to historically changing political economic and demographic forces, but to cultural norms regarding proper family life as well. For example, each society has norms about the proper timing for a woman's marriage. While in some settings marriage age was affected by changing economic conditions (i.e., marriage being postponed during hard economic times) (Wrigley and Schofield 1981), there is also much evidence of the resistance of cultural norms to economic pressures. One manifestation of this is the number of studies showing a very similar female marriage age across different economic segments of local stratified populations (Knodel 1988, pp. 130–6).

The great bulk of the work on European household systems—following Laslett and Hajnal—focuses on the cultural norm of postmarital residence as the key (identifying neolocality with nuclear family household systems). However, it is becoming clear that another cultural norm must be entered into the model: the fate of older people as they become frail or widowed (Kertzer 1995). Even where newlyweds routinely establish their own household, a pure nuclear family system does not necessarily result. Recent studies show that in the very heartland of Hajnal and Laslett's northwestern European family system, large numbers of older people did live in extended family households. Wall (1995), for example, in a sample of English communities for 1599–1796, found that half of the men aged over 65 and over a third of the women lived with at least one child. While some of these adult children were not married, many of them were.

Finally, while most work on European family systems has focused on household units and on marriage, any satisfactory understanding of the role of family must consider relations that extend beyond single households. Reher (1997, p. 114), for example, found that in the Spanish community of Cuenca in the middle of the nineteenth century, while neolocality prevailed about three-quarters of the newlyweds set up their households in the same immediate vicinity of one of their parental households.

In short, no single family system—in the sense intended by Hajnal or Laslett—characterized 'traditional' Europe, nor even western Europe. While broad general differences among family systems in different parts of Europe can be distinguished, attempts to divide the continent into distinct family zones are misguided. In those areas where complex family households were commonly found, significant sections of the population lived in simpler households, while even in the heart of northwestern Europe, the epicenter of the presumed nuclear family system, more complex household dynamics were often at work.

D. I. Kertzer

Family Theory and the Realities of Childbearing Behavior

Childbearing takes place within the socially defined context of family life, but there have been substantial changes in family life in recent decades and it differs between societies and population subgroups. While childbearing patterns have also changed substantially in developed societies since the 1950s, there has been a tendency for trends to be broadly similar (Fig. 1(a)). The annual level of fertility in the post-1945 period rose to a peak around the late 1950 to mid-1960s, followed by a sharp decline in the 1970s and a slight rise and relative stabilization in the recent period, although some countries such as those in Southern Europe have continued to decline to levels of fertility just above one child per woman in the late 1990s (Coleman 1996). The average age at childbearing fell until the late 1960s or early 1980s and then rose substantially (Fig. 1(b)).

Annual levels and mean age at childbearing are closely related since a move towards earlier childbearing will increase the annual fertility rate even if the women having their children in that period do not ultimately have any more children by the end of their reproductive lifetime than other cohorts of women. Most of the large-scale movements in fertility in the postwar period are attributable to shifts in the age at childbearing rather than to changes in the overall propensity to have a given number of children: 'most of the baby boom would have occurred without any change in the numbers of births per woman, and most of the decline since the baby boom as well' (Ryder 1980, pp. 39–40). While the level of childbearing in a given year may reflect contemporary factors such as income or employment, some women may be having

children then because they have postponed births from an earlier period or wish to bring their births forward for particular reasons. The fact that married women are much more likely to have a child than those not in a partnership, with cohabiting women generally in an intermediate position, means that earlier experiences of entry into and exit out of partnerships also need to be taken into account.

The main alternative theories that have been put forward to explain childbearing patterns will be reviewed briefly, before considering the extent to which they can be empirically validated.

1. Explanations of Childbearing

1.1 Proximate Determinants of Fertility

Fertility is often usefully analyzed in terms of a proximate determinants framework (Bongaarts and Potter 1983) which for developed countries means concentrating on three main factors; the proportion of women in a sexual union, their use of contraception, and the level of induced abortion. These factors biologically determine childbearing, but women's choices about partnership and family limitation may also be consequences of their fertility decisions. One reason why women may enter a partnership is in order to have children, but it is unlikely to be the only one. On the other hand, use of contraception and abortion on 'social' grounds are determined by fertility preferences. Over time, there has been a change from a period when methods of family limitation were generally ineffective, difficult to obtain, and/or disapproved of, to one when methods are safe, easy to use, relatively inexpensive, reliable, and acceptable. This change occurred with the introduction of the contraceptive pill and IUD around 1960 in many developed countries, and the subsequent introduction of laws permitting abortion on wider grounds than previously. Studies in the US showed that the level of 'unwanted' fertility in the 1960s was about 0.5 of a child per woman (Westoff and Ryder 1977), similar to the difference in cohort fertility between women completing their childbearing at that time and today. The availability and acceptability of efficient contraceptive methods has had a major contribution to the change in timing which is the major determinant of overall period change. The effect of access to improved contraception not only affects childbearing, but permits couples to have a childless relationship (and, in particular, to facilitate the emergence of cohabiting relationships that have low rates of childbearing) and to decide on the pattern of childbearing with greater precision, since, for example, the possibility of an unwanted birth can be eliminated by contraceptive sterilisation. In turn, this has permitted the increase in mean age at childbearing and hence led to changing attitudes about women's roles since a full satisfying

sex life is now compatible with career progression by married women that would have been difficult in the past.

As improved access to methods of family limitation have increased across and within nations, variability in fertility has declined, so that the maximum difference in TFR levels between the OECD member countries in 1995 was 0.9 of a child, compared with a value of 1.9 in 1965 and 1.8 in 1980.

1.2 Economic Approaches

In the past, a positive relationship between fertility and income (in cross-section) and with the business cycle (in time trend) had been accepted. However, in the period since 1945, fertility and real incomes generally have been negatively rather than positively related in developed countries, since fertility is now at an all time low, whereas average real incomes have risen. The current widely used microeconomic model of fertility is the 'new home economics' one particularly associated with the work of Becker (1981) that has been extended to both marriage and marital breakdown.

The model brought together two features within the framework of microeconomic analysis to account for the postwar baby boom and bust: the first was the increasing importance of women's work outside the home and its competition with childrearing for the wife's time. Since women undertake the greater burden of childrearing, the costs of childbearing, especially in terms of earnings foregone while they are looking after children and future labor market prospects, fall most heavily on them. Therefore, the number of children is expected to be strongly negatively related to her earnings, but weakly positively related to her husband's earnings, and the opportunity costs of childbearing are greatest for women in highly paid jobs.

The second element, the demand for children, is determined in part by economic factors and in part by 'tastes' which may differ by religion, race, age, and time period, etc. Decisions concerning childbearing have two major components, those related to quantity and 'quality': 'quality' is simply measured by the amount spent on a child on items such as clothing, education, etc. ('higher quality' does not mean superior, just more expensive). Thus, parents can choose higher 'quality' of a lower quantity of children for a given level of overall expenditure. It is assumed that increased income will be diverted more towards

Figure 3
Total fertility rate vs. females as a percentage of the labor force

increases in quality rather than quantity, and it is possible that if the shift towards higher quality is so substantial, increased income may result in fewer

children. At present, the cross-national relationship between average income and fertility is positive but weak in developed countries (Fig. 2).

Figure 4
Total fertility rate vs. unemployment percentage, 1995

The relationship between female employment and fertility is expected to be more clearly negative since a basic incompatibility between work outside the home and childrearing is assumed as they are competing demands for the mother's fixed amount of available time. (This approach has been criticized on the grounds that it emphasises the differentiation of gender roles: however, since it reflects how things are, rather than how many think that things ought to be, such criticisms are unfair.) While in the 1960s, there was the expected negative relationship between female employment and fertility across countries, by the 1990s, the relationship had become positive (Fig. 3). In the 1990s, Scandinavian countries have relatively high fertility and female employment, while Mediterranean ones score low on both counts, whereas although the female employment rankings have remained relatively constant since the 1960s, the fertility ones have reversed. Of course, such simple correlations do not establish that the nature of the relationship has switched over time, but it is clear that the other factors that cause the correlation to be in the unexpected direction in the 1990s must also have a very substantial, if not dominant, effect on childbearing.

An alternative economic-demographic model is that of Easterlin (1980). In simplified form, it assumes that individuals' (or couples') expectations are set by the standard of living in the home that they had as children. Those born into large birth cohorts will have

many direct competitors for education, employment, housing, etc., and are likely to be relatively disadvantaged compared with those from smaller cohorts and they will react by marrying later and having fewer children. There is little empirical evidence that large cohorts are disadvantaged and earnings are more likely to be associated with other period and structural factors. This model emphasises men's as well as women's employment situations, but because it appeared to have little explanatory power, the role of male employment has tended to be neglected compared to that of women. However, the declining position of men relative to women in the labor market, and, in particular, the rise in unemployment that particularly affected young men is likely to inhibit leaving home and partnership formation, as well as making young men less attractive lifetime partners to young women (Oppenheimer 1994). Such considerations may be especially important among disadvantaged groups such as young black males in developed countries. Overall, there is a negative relationship between unemployment and fertility in the OECD countries (Fig. 4). Although the unemployed are disproportionately drawn from groups that would in any case be expected to start childbearing early and for this reason, among others, may have higher fertility than those in employment, a high level of unemployment is likely to have the effect of inhibiting partnership formation and childbearing of those in employment.

1.3 'Cultural' Explanations

In a study of the determinants of fertility decline in European historical and contemporary Third World countries, Cleland and Wilson (1987) concluded that 'economic' theories are much less successful than 'cultural' explanations. For example, fertility change was more closely associated with factors such as language and voting patterns than with income or employment (Coale and Watkins 1986).

Attitudes to increased sex role egalitarianism, and permissiveness to divorce and cohabitation have become more positive over time, whereas attitudes to religion, traditional family orientation, and deference to authority have declined. These changes are associated with a move towards greater individualism that has been associated with a range of emerging patterns of family formation and dissolution often referred to as a 'Second Demographic Transition,' based on individual autonomy, female emancipation, and increased consumerism (van de Kaa 1987, Lesthaeghe 1995). Such approaches integrate the interaction of different life events such as partnership, childbearing, and employment within the historical context, both national and individual, including cohort effects.

2. Assessing the Empirical Validity of Alternative Explanations

While swings in annual levels of childbearing have attracted much comment, especially the very sharp and largely unanticipated change between the late 1950s and 1970s, from a long-term perspective, it is the baby-boom period that stands out as the anomaly as fertility has shown a generally declining trend for over a century in many developed countries. In the 1950s the main alternative to remaining at home with one's parents was early marriage (sometimes precipitated by pregnancy), followed by a relatively quick start to childbearing, both because this was expected and the possibilities of delaying births were limited. The relatively high level of fertility at that period reflects the selection by women of a package of husband/home/children rather than solitude/parental residence/work. In addition, couples expected that the marriage would last and that employment would be permanent, so increasing the attractiveness of marriage. More recently, people have had the opportunity of childbearing without partnership and vice versa, and other options such as living alone have become more feasible. Therefore, the nature of the choices made with respect to childbearing have changed substantially over time, which complicates the specification of appropriate empirical models.

There are many levels at which analysis and interpretation may be undertaken: international comparisons; subpopulations within nations; families/households; individuals; and, most generally, combin-

ations of data from different levels. Childbearing is clearly sensitive to short-term factors such as pill scares, which may therefore provide good short-term explanations of fertility change (Murphy 1993). However, establishing the reasons for the long-term changes shown in Fig. 1(a) is more difficult. Some of the most widely cited studies for empirical underpinning of the theory have been based on the macrolevel time-series studies of the effects of income on fertility in developed societies. The problem in using aggregate-level data to draw conclusions about individual-level behavior is widely recognized.

A rational choice model underpins most discussion of childbearing, although this is often less helpful than might be thought since the number of factors that enter into the choice are very broad in both time and space. Childbearing is likely to have substantial effects on the emotional, lifestyle, and financial circumstance of the mother for at least two decades, and for most fathers too. Over time, the balance of advantage will have changed considerably. Some of these aspects may be much easier to measure than others. For example, higher social benefits for unmarried mothers which are relatively easy to measure, would be expected to lead to more births outside marriage, but a more important factor could be a reduction in public disapproval for such childbearing, and the availability of benefits a consequence of changing public attitudes, which may be difficult or impossible to quantify especially if no contemporary data exist.

It may be useful to make a distinction between those factors that have an unambiguous effect on childbearing and those for which the effect is likely to be context-specific. For example, it has been assumed that the effect of women's work outside the home is to reduce their fertility, as seen in the 1960s in Fig. 3(b). However, by the 1990s, the reverse was the case in that those countries with high rates of female employment had higher fertility also. The range of reasons for this could include:

- (a) formerly it was considered inappropriate for women with young children to be in paid employment, whereas now it is not considered harmful to the child (social influence);

- (b) to bring up a child, two incomes are now required whereas one would suffice in the past (reversed female income effect);

- (c) improved childcare facilities and technology makes it more feasible to combine childrearing and work than in the past (institutional and technological change);

- (d) withdrawal from the labor force for childrearing could have harmful long-term economic and career prospects for women, especially in societies with high rates of marital breakdown (external demographic effect);

- (e) societies that have low female employment have high unemployment and poor job security that inhibits family formation (historical macroeconomic factor);

(f) societies that have exhibited substantial fertility declines recently may reflect reduced fertility by older women who have sufficient children and postpone by younger women (transitory effect).

This list is not exhaustive but serves to emphasise the difficulty in establishing empirically the nature of the relationship between childbearing and the single variable of female employment. The statement that if increases in paid work outside them by women of childbearing age makes bringing up children less attractive as an option, with other things being constant, then childbearing will fall is uncontroversial. However, these other relevant factors that are not constant may be moving and be the dominant determinants of change. The dependent variable in the new home economics model is not number of children born, but it is the benefits obtained from their children, yet this cannot be clearly specified and so number of children is often used as the variable to be explained. The biological, cultural, institutional, economic, and historical factors that influence childbearing decisions are complex and it is impossible to obtain comparable data on these different domains, so in practice, it is almost impossible to specify a comprehensive formal model to 'explain' contemporary patterns. It is, therefore, unsurprising that after many decades of investigation, although a number of valuable insights have been made about the determinants of childbearing trends and differentials between subpopulations, full explanations remain elusive.

Family Theory: Competing Perspectives in Social Demography

Two competing perspectives on the effect of postwar changes in men and women's economic behavior on the family have characterized recent demographic research. Each primarily focuses on one of two fundamental theoretical pillars which underlay most demographic research on families in Western societies: (a) the economic implications for family behavior of an independent nuclear family system; and (b) the importance of sex-role specialization in marriage. This article will undertake an examination of each of these perspectives in terms of these theoretical underpinnings, how they are affected by changing economic behavior, and the implications of this for the emerging nature of the family.

1. Overview

A number of major changes in marriage and family behavior have occurred in the West since the early 1970s. Age at marriage and marital instability have risen considerably while fertility has declined substantially (Blossfeld 1995, Mason and Jensen 1995, Oppenheimer 1994). The magnitude of these changes has fostered considerable debate about their determinants and consequences and what these imply for the future of the family. However, in most cases, the debate is not so much about major theoretical differences on the nature of the family but differences in which aspects of two long and commonly accepted underpinnings should be emphasized the most. One is that marriage as an institution, as well as marriages as

functioning social forms, is based on sex-role specialization. Although there are variations in how this specialization argument is conceptualized, the general idea is that the husband's role is largely economic while the wife's lies in the care of the home and in the reproduction and socialization of the children.

The second theoretical underpinning to most discussions is that an independent nuclear family system is a long-standing feature of populations of Western European origin. Such a family system is characterized by husband-wife families which are economically independent and live separately in their own household, although a single aged parent might also have sometimes been included in the past. This is opposed to an extended family system which is usually characterized by joint family households consisting of several nuclear families. In general, historical demographic research has indicated that marriage and fertility behavior have often been quite different in populations with independent nuclear as opposed to joint family systems. In the former case marriage is contingent on the couple's ability to be self-supporting and able to set up a separate household; in the latter, the economic ability of the household as a whole to absorb new members has tended to be more important. Since young people's economic position is often precarious, the requirement of economic independence has historically led to somewhat later marriages and also to periodic fluctuations in marriage timing, depending on variations in economic circumstances. This has often resulted in substantial short- and long-term effects on fertility, especially in periods before the deliberate control of marital fertility became common.

This article focuses on two opposing positions regarding the effect of shifts in the economic behavior of men and women. One emphasizes sex-role specialization, arguing that the rising employment of women has been the major factor leading to the observed changes in marriage and family behavior because it has reduced specialization and hence permitted women to become economically independent of marriage, thereby reducing the gain to marriage. Assuming women's employment is unlikely to decrease, the result will be a major and irreversible transformation of the family in modern industrialized societies.

The opposing position is that the family has not been transformed as much as the women's independence argument maintains nor has women's rising employment had a negative effect on marriage formation, although it undoubtedly mitigates against high fertility. On the other hand, there is some evidence that a deterioration in young men's economic position has had an important effect on marriage and family behavior because it has seriously affected the ability of young couples to set up an independent household. If so, then the assumed irreversibility of present trends is open to question, although it is extremely unlikely that a return to postwar patterns of the 1950s to 1970s will occur.

These two alternatives do not exhaust the many possible reasons that have been proposed for changing family behavior, although they cover the major debates related to the effect of changes in economic behavior. Nevertheless, it is often the case that different explanations may be implicitly, if not explicitly, dependent on one or both of these positions. For example it has been argued that modernization and the rise of individualism is the major force behind the recent demographic changes (see *Demographic Transition, Second*). However, neither men nor women can be autonomous individualists if they are still economically dependent on traditional marital and kinship ties.

2. Independent Nuclear Family System

Given the assumption of sex-role specialization, demographic research on marriage and family behavior in independent nuclear family systems in preindustrial and early industrial populations has tended to focus primarily on the economic position of men, although there has long been a general recognition that women could help facilitate the formation of a marriage via earnings before marriage. In farming communities, marriage was often considerably delayed as the heirs had to wait for the father to die or retire before they inherited the property and with it the means of marrying. Even where leasing rather than owning land was the rule, as in England, there were often extensive delays until a man could save enough to lease a farm and set up a household. The effect of this pattern on marriage timing—and hence on fertility in historically noncontracepting populations—was often substantial with high proportions not marrying until their thirties and relatively substantial proportions never marrying (see *Family Systems in Europe*; Arensberg and Kimball 1968, Goldstone 1986).

With the growth of wage labor in the cities and on the farms as industrialization progressed, young men could much more easily become economically independent at a relatively young age. This promoted a reduction in the age at marriage, although offsetting factors were the need to save up to establish an independent household and prior obligations to contribute to the parental household, especially if one or both parents had died or were incapacitated in some way. In general, economic development also increased the sensitivity of young men's economic position to business cycles and structural changes in the economy. Recessions or depressions reduced marriage propensities, especially among the young, and recoveries led to sharp rises in rates. Moreover, the structural changes in the economy associated with economic development changed the skill levels and types of skills demanded of workers. This has placed an increasing premium on education and technical training in modern industrial

societies which has, in turn, postponed the full-time entry of young people into adult-level employment and, with it, entry into marriage and the achievement of the degree of economic stability usually considered necessary for starting to raise a family.

2.1 Role of Relative Cohort Size

Postwar analyses of the influence of men's economic position on marriage formation and fertility was initially dominated by the work of Richard Easterlin who hypothesized that fluctuations in relative cohort size had a major impact on young men's labor market position, thereby affecting marriage timing and marital fertility (see *Baby Booms and Baby Busts in the Twentieth Century*; Easterlin 1987). Thus, Easterlin argued that the postwar baby boom, such as the US experienced in the early postwar period, was largely caused by the favorable economic position of the small depression cohorts entering the labor market at that time. This encouraged them to marry earlier and have more children than previous cohorts. However, the relatively large cohorts they produced crowded the labor market, negatively affecting their lifetime earnings. This led to postponed marriage and childbearing, lower completed fertility, and greater marital instability. In addition, more wives would be working to compensate for their husband's poorer economic position. The result was smaller birth cohorts in the next generation—the baby bust cohorts—who would be in a much more favorable relative labor-market position. According to the theory, this, in turn, should lead once again to earlier marriage and childbearing, somewhat higher fertility, increasing marital stability, and the slowing of the growth in married women's employment. In short, the theory posited a self-perpetuating cycle.

The relative cohort size argument ran into empirical difficulties as research in the 1980s showed that postwar marriage and fertility fluctuations were largely *period* rather than *cohort* driven, i.e., fluctuations in demographic rates occurred simultaneously for numerous birth cohorts, regardless of cohort size. Moreover, the theory essentially accepted the premise that marriage is based on sex-role specialization. Women's labor-market behavior was considered to vary primarily in response to men's earnings position rather than in response to women's own employment opportunities, independent career goals, or family cycle variations in economic needs. However, women's employment continued to rise rapidly throughout the postwar period, regardless of variations in cohort size. As a result, the focus of research interest began to shift to the familial consequences of the transformation of women's economic roles. Moreover, since the concern with the economic position of young men had become so closely identified with the relative cohort size argument, interest in men's changing economic pos-

ition flagged for a number of years while the research focus shifted to analyzing the effect of women's rising employment.

3. Sex-role Specialization

At the same time that relative cohort size and hence male-oriented explanations of changes in marriage and family behavior began to lose favor, the continuing rapid rise of married women's employment has seemed to provide a ready explanation for the ongoing changes in marriage and family behavior. Hence, the theoretical emphasis shifted from a concern with the ability to set up and maintain an economically independent household to the critical importance of sex-role specialization for family formation and cohesion.

While it has only recently taken center stage as an explanation of changes in marriage and family behavior, a long-standing and influential tradition in the social science literature is the importance of differentiated sex roles for a stable marriage system. In the early postwar period this idea was emphasized by Talcott Parsons (1949) who argued that sex-role segregation was a functional necessity for marital stability and even for the viability of society itself. More recently, this same theme has been elaborated somewhat differently in the economic theory of marriage by Gary Becker (see *Family Theory: Economics of Marriage and Divorce*). In an argument very similar to one Durkheim made over a century ago, Becker maintains that the major gain to marriage lies in the mutual dependence of spouses, each of whom specializes in certain functions—the woman in domestic production (and reproduction), the man in market work. Marriage then involves trading the fruits of these different skills. However, in response to economic growth and the rising wages it produces, women's market work also rises. The result is that women become less specialized and, as their earnings approach those of potential mates, more economically independent, leading, in turn, to a decline in the desirability of marrying or of staying married as well as the desirability of high fertility.

Not all scholars necessarily agree with Becker's argument in its entirety. Nevertheless, an economic independence argument of one sort or another has had wide appeal among sociologists as well as economists and is currently one of the major contenders in trying to explain recent marriage and family trends in the United States (Cherlin 1992, Oppenheimer 1997). One reason is that the model seems to have tremendous face validity. Not only does the notion of specialized sex roles fit in with long-held views of how the traditional family historically functioned, but the rapid changes in marital behavior appeared to have followed very closely upon the rapid rise in married women's employment, especially that of young

women. Moreover, the theory has the elegance of simplicity, yet it can apparently explain a wide variety of complex changes and differentials in marriage and family behavior—from delayed marriage to non-marriage, marital instability, nonmarital cohabitation, female-headed households, declining fertility, and so forth. Nevertheless, the independence hypothesis has also run into a number of serious theoretical and empirical problems.

3.1 Mismatches

One problem the theory has encountered is that there are number of mismatches between the phenomena it claims to explain and the behavioral changes that are actually occurring. First, the independence hypothesis is essentially a theory of *nonmarriage* for it argues that if, by their own endeavors, women can achieve approximately the same income as a prospective spouse there is not much to gain by marrying and specializing in home production. However, so far, while there has been a considerable increase in *delayed* marriage, as yet there is little evidence of a substantial rise in *nonmarriage* (Oppenheimer 1994, Blossfeld 1995). For example, in the United States although white women reaching age 20–24 in 1980 were more likely to be single than earlier cohorts at that age, by the time they were 35–39 in 1995 just under 10 percent were still never married, below that for late nineteenth century cohorts who were presumably living in a ‘traditional’ family system. Hence one reason for the apparent support for the hypothesis is due to a serious confounding of *delayed* marriage with *nonmarriage* in the statistics. Moreover, to date, there has also been little effort to articulate how the independence argument could lead to *delayed* instead of *nonmarriage*.

A major difficulty in assessing the outcome of recent marriage trends lies in the recency of the trends and the necessity of waiting 20 years or more before one can accurately determine whether there actually will be a significant rise in nonmarriage. Efforts to estimate the future proportions never marrying are often misleading because they typically use the current behavior of older people as a guide. However, during a period of rapid timing shifts, the *current* behavior of somewhat older people, who are the relatively sparse and atypical remains of much earlier marrying cohorts, is often a particularly poor guide to the future behavior of the much larger and less select group of younger people who have been delaying marriage in more recent years.

A second kind of mismatch lies in using the family behavior of the 1950s and 1960s in the US (and somewhat later in Europe) as typifying the traditional family patterns when sex-role specialization prevailed; compared to this, the large subsequent changes in marriage and family behavior certainly appear to represent a major retreat from marriage and the family. However, this was the baby boom era when

fertility was unusually high compared to the previous 50 years; age at marriage was unusually low—far lower than at the turn of the century—and, in the US at least, even marital disruption was somewhat less likely than in previous years. In short, this benchmark was highly atypical historically and unrepresentative of the supposedly ‘traditional’ family. Hence using it as a benchmark has led to a considerable exaggeration of the extensiveness of the subsequent break with historically traditional patterns and of the historical origins of many recent trends.

There is still another type of mismatch characteristic of a theory which posits that the stability of the family is founded on women specializing in home production. The proposed model seems strangely out of tune with the needs and characteristics of modern societies. Much of the specialized home production of women in the past was devoted to bearing and rearing children who never survived to adulthood. For women to be equally occupied in contemporary low-mortality societies would result in large families. However, even moderate family sizes in a low-mortality society lead to rapid population growth. Moreover, couples do not just want to produce children *per se*, they want to produce children like themselves—that is, they are interested in social, not just biological reproduction. But the cost of social reproduction is high in a society where increasingly substantial and lengthy investments in human capital for each child are required. Hence, high fertility is usually not a realistic option for most people in modern industrial societies. With low fertility, however, the female specialist would not be doing anything highly productive for much of her life. In short, specialization in home production appears to be a rather anachronistic institutional role for women in industrial societies.

3.2 Empirical Status of the Independence Hypothesis

Much of the empirical work on the women’s independence hypothesis has not supported it. At any given time, empirical analyses show that indicators of women’s economic independence have not generally had a negative effect on marriage formation. For example, under an independence argument, better-educated women should be more economically independent of marriage; however, microlevel regression analyses show that, once school enrollment is taken into account, they have a *higher* rather than a *lower* propensity to marry.

The empirical work on marital dissolution is more mixed. Some studies have found evidence of an independence effect, whereas others have not. There are a number of possible reasons for these conflicting findings. A major one is that the measurement of women’s economic independence is difficult and inconsistent across studies. Some studies use absolute

income while others use some measure of relative income. While the hypothesis implies that the *relative* earnings of wives should be the important factor and hence should be directly modeled, using the ratio of wives' to husbands' income alone can lead to ambiguous results. The wife's earnings in some families may be higher than in others, reflecting a better labor-market position and, consequently, indicating a greater financial independence of her husband. However, the ratio could be higher because the husband's earnings are low compared to other couples, while the wife herself may also be in a very weak labor-market position.

A second problem that is more likely to occur in analyses of marital dissolution than marital formation is the greater difficulty of determining the appropriate causal direction. Wives who are more extensively employed in one year may be more likely to separate the following year—but not necessarily because they are more economically independent. Instead, their marriage may have already been in trouble, causing them to increase their labor-market involvement in anticipation of a marital breakup—the reverse causal direction than that hypothesized.

3.3 Coping with Risk and Change

Although rarely considered in explications of the theory, historical research on independent nuclear families indicates that extreme sex-role specialization in marriage is essentially a high-risk and inflexible family strategy unless accompanied by supplementary support mechanisms (Oppenheimer 1994). Even with such supports, specialization often entailed considerable individual and social costs. An inherent problem is that the temporary or permanent loss of one specialist in a family can mean that functions vital to the well-being of the complementary specialist and children are not being performed. Husbands/fathers can die or become ill or disabled; they can lose their jobs and have difficulty finding another one; they could desert the family for a variety of reasons or become an alcoholic; and so on. The result is that the family is left without its major source of income. Except for employment-related shifts, there are similar problems involving the wife-mother specialist. In that case, there could be no one to take care of the children or the home. Specialization may be a feasible strategy in a large extended family household where no particular individual is indispensable because of the redundancy in personnel that can characterize such a system. However, for independent nuclear families and their individual members, specialization entails considerable risks.

Extreme sex-role specialization is also not a very flexible way of dealing with the varying needs of nuclear families over their developmental cycle. Since individuals' consumption needs and productive capa-

bilities vary markedly by age, a basic feature of nuclear families is that the ratio of consumers to producers, and hence the family's level of living, can vary substantially over the family's developmental cycle. Hence, specialization involves a potentially serious inflexibility in dealing with changes in both a family's internal composition as well as the stresses posed by its environment.

The large literature on family history in Western societies indicates that a variety of strategies were developed to maintain economic stability over the family's developmental cycle and in the event of the temporary or permanent loss of specializing parents (Goldin 1981, Haines 1979, Rowntree 1922, see Oppenheimer 1994 for a review). In the nineteenth and early twentieth centuries these strategies usually involved utilizing the productive labor of children, daughters as well as sons. The evidence also indicates that utilizing the labor of one's children could exact substantial costs. A sufficient number of children old enough to make an economic difference was generally not available until the middle or later stages of the family cycle. Families who temporarily or permanently lost the contribution of the father early in the family cycle were not greatly helped by such a strategy. If the mother was lost when the children were young, the family might break up with children being parceled out among relatives or even going to orphanages. In general, this economic reliance on one's offspring often led to a pattern of 'life cycle poverty' where periods of poverty and comparative plenty alternated over the life cycle of workers. Another well-known disadvantage to the extensive employment of children to supplement their family's income was that it tended to discourage schooling and hence had a negative effect on children's adult socioeconomic status.

Even aside from the drawbacks of using children's work, the economic advantages of this strategy were eventually bound to decline during industrialization as the adult labor force became more skilled and hence the relative economic contribution unskilled children could make declined. This suggests that other equilibrating mechanisms were likely to develop. One mechanism may be governmental social support systems. At the family level, however, from a historical perspective, the rise in married women's employment might be viewed as a functional substitute for the work of their children, facilitating the more extensive schooling of the next generation and thereby fostering upward intergenerational social mobility. In addition, wives' employment is not limited to the later stages of the family's developmental cycle and wives, being adults, and usually having educational attainments roughly similar to their husbands, can command a much higher wage than unskilled children could. Moreover, recent research indicates that wives' earnings are currently playing an important role in offsetting the less favorable earning position of their husbands (Levy 1998). It seems likely, then, that wives'

employment could be a source of cohesion in marriages; in difficult times, a helpmate may be of much greater value than a complete economic dependent.

Even aside from wives employment during episodic periods of an increased need for additional income, wives who work regularly may also increase the interdependence of spouses. Two-earner families where the couple pool their resources are families whose level of living is based on their *combined* income. Even when the income contribution of each spouse is equal, given economies of scale, neither partner could live as well on his/her own or save and invest as much. Hence, instead of the asymmetric dependence of the wife which is characteristic of complete specialization, there is a symmetric dependence where each spouse depends on the other to maintain living standards. What this may also indicate is that the combined income of the two-earner family has come to form the social standard rather than the husband's income alone. To the extent this is the case, it becomes increasingly difficult for single earners and married couples with a more traditional division of labor to achieve the same level of living as the two-earner family. Hence, the mutual dependence of the two-earner family may not only contribute to their own gain to marriage but may also reduce the relative gain to being single and to marriages characterized by a specialized division of labor.

In sum, it is unclear that specialization is the only, or even the optimum, method of creating cohesion in marital relationships in modern industrial societies. The specialization model itself seems highly problematic and women's rising employment may actually be promoting a more collaborative model of marriage.

4. Rising Economic Inequality

Given the empirical and theoretical limitations of the specialization model of marriage, research attention has been returning once again to the role of economic difficulties in setting up and maintaining an independent nuclear family. While the effect of relative cohort size earlier dominated research in this area, the more recent focus is on such issues as changing economic structure, chronically high unemployment rates (particularly among young adults), and rising earnings inequality (again especially among the young but also among the moderately-to-less educated as well). These analyses have also returned to the question of men's changing economic position which had been neglected for quite some time. Research in this area is still in its early stages but some of the major questions to be addressed are: (a) whether, how, and why young men's labor-market position affects cohabitation and marriage and what difference socioeconomic differentials make; (b) and whether economic changes in a society are likely to have had an

important impact on young people's economic position and have thereby influenced changes in their marital behavior.

Virtually all recent research has shown that men who are more likely to be working full-time/year-round, had higher current earnings, and/or greater future career prospects were more likely to marry in any given short time interval (Clarkberg 1999, Huinink 1995, Oppenheimer 1997, Oppenheimer et al. 1997). Some research in this area has also started to look at the role of economic factors in the formation of cohabiting unions and this indicates that here too, some level of economic stability is important, although apparently not as much as for marriage formation (Bracher and Santow 1998, Clarkberg 1999). Oppenheimer (1988) has theoretically and empirically elaborated on these issues in a variety of ways. First, she has conceptualized the transition to work as a career-entry *process* rather than a *step*, which was more commonly the approach in previous life-course analyses. This change in approach emphasizes that embarking on a relatively stable occupational career takes time, during which a young man is in a relatively 'immature' career state. One aspect of career immaturity directly impeding the formation of an independent household is relatively low income; however, another is uncertainties regarding what kind of stable employment may eventually be achieved, when this may occur, what lifestyle the individual may ultimately expect or desire, and so forth. Such uncertainties can impede mate selection and affect the individual's own desirability as a prospective marriage partner. Hence, career immaturity is not only likely to foster delayed marriage for economic reasons but for social-psychological ones as well. Second, viewing the transition to work as a *process* expands the emphasis beyond the effect of career immaturity at any single point in time to the length of time it takes to achieve some career stability and the cumulative impact this will have on marriage timing. The delaying effect of only a modest effect of career instability in any given year, for example, may nevertheless have a large cumulative impact if the instability persists over many years. Moreover, this approach is well suited for examining how the length and difficulty of career development could vary substantially among different groups and over time as well, thereby facilitating analyses of socioeconomic differentials in marriage timing and trends in marriage behavior.

Using 12 years of an American longitudinal survey of young people, Oppenheimer and her colleagues (1997) found that not only did a variety of indicators of career immaturity have a substantial effect in any given year on marriage formation, but that the cumulative impact was substantial when the career-development process was followed over time. Moreover, there were large race-schooling differences in the length and difficulty of the career-entry process which, in turn, produced major differences in marriage timing.

Because the analysis was limited to the young adult life course of young men born between 1957 and 1964, how much of the rise in delayed marriage over the past 25 years can be accounted for by career-development problems has yet to be directly examined. However, there has been a substantial and well-documented rise in inequality in the US since the 1970s, and this has had a particularly severe effect on moderately-to-less educated younger workers, suggesting that career-entry difficulties may be playing an important role in these trends. In Western Europe there has been a substantial increase in persistent unemployment, especially among the young which also indicates that career-entry difficulties may be important in changing European marital behavior (Levy 1998).

Family Theory: Complementarity of Economic and Social Explanations

1. The Problem

With the growing specialization in the social sciences the various disciplines have often developed their own traditions and paradigms in explaining social phenomena. There is, however, a risk that this may lead to segregated 'communities of belief' that advance only 'positive proof' in support of their own positions. This has, on occasion, led to the presentation of methodologically flawed research that is supposed to enhance the supremacy of one discipline over the other (see Burch 1996).

As far as family and population research is concerned, contributions are made regularly from a wide variety of disciplinary backgrounds. The phenomena that needed to be explained, such as the fertility or mortality transitions or the change in demographic behavior and household structures, have drawn the attention of sociologists, historians, economists, anthropologists, geographers, biologists, epidemiologists, and statisticians alike. As a consequence, the field of population studies—or demography in a broad sense—has always had firm interdisciplinary roots. The leading journals, such as *Population Studies* (UK), *Demography* (US), *Population and Development Review* (US), and *Population* (France) have remained loyal to their interdisciplinary tradition, and they are still firmly in the lead over their more 'mono-disciplinary' competitors.

Yet, there have been skirmishes and frustrations. The former have often been similar to the nature–nurture debate in psychology. But in the field of family and population research, they emerge in the form of an economics vs. culture debate. The demand theory used by economists in explaining declining fertility or differential fertility between social groups is matched by a diffusion theory, advanced by economists and noneconomists alike. In the latter, the roles of social

learning and the worldwide spreading of new ideas and attitudes are being accentuated. Today, there is still a small cluster of neoclassic economists that hold the belief that nothing more is needed on the explanatory side than changing constraints and opportunity structures (see Becker 1991, Stigler and Becker 1977), but at the other extreme, there is also a hard core of diffusionists who claim that historical and contemporary fertility transitions are occurring under such highly contrasting economic conditions that only the cultural diffusion of new ideas—now also followed by family planning programs—can account for them (e.g., Cleland and Wilson 1987). Obviously such discussions have major policy implications, and the debate has had a lasting life (see the contrasting results on the effects of family planning in Schultz 1997 and in Bongaarts et al. 1990).

In contrast, the frustrations among the mainstream participants in family and population studies stem from the observation that the different explanations live side by side as distinct narratives, as separate 'good stories.' Van de Kaa (1996) describes an anchored narrative by the following two characteristics: (a) there must be an easily identifiable central action (such as a detailed statistical account of changing trends or of newly emerging differentials) and (b) there must be a setting or theory that allows for an easy interpretation of that action. A well-anchored narrative consists of subnarratives that can be ordered from the general to the highly detailed. The question is whether the various social science disciplines can achieve a sufficiently high degree of sophistication that lifts them beyond anchored, but still compartmentalized narratives.

A classic recipe for theory integration emerged from the great debate in philosophy of science on the evolution of scientific knowledge as it took place in the late 1960s and much of the 1970s with Karl Popper and Thomas Kuhn as major protagonists (see Lakatos and Musgrave 1970). The gist of Lakatos's (1970) strategy of progressive problem shift is that a scientific theory H_1 can be regarded as falsified only if another theory H_2 has been proposed such that:

(a) The counter-evidence to H_1 is corroborating evidence for H_2 ;

(b) H_2 satisfactorily explains all the empirical successes hitherto explained by H_1 (i.e., partial inclusion of H_1 into H_2); and

(c) H_2 is also capable of explaining or predicting new facts or facts that were unlikely or impossible according to H_1 (i.e. enlarged content of H_2).

If these three principles are applied to the theories and anchored narratives in the broader field of demography, one comes to the following observations (see Lesthaeghe 1998):

(a) Many theories, or substantial parts of them, are not mutually exclusive but merely complementary: H_1 and H_2 explain different aspects or account for different subnarratives;

(b) Mechanisms described in H_1 are often connected to mechanisms identified by H_2 . Theories escape from these connections through *ceteris paribus* clauses with respect to different but nonetheless highly relevant omitted variables. If put together, however, the respective mechanisms in H_1 and H_2 often produce mutually reinforcing (or neutralizing) consequences or lead to important interaction effects; and

(c) Nonoverlapping parts of H_1 and H_2 that produce opposite predictions have rarely been falsified. Rather, their respective predictions have often come true in different contexts. Hence, a substantial degree of historical path dependency or context specificity emerges. This points in the direction of conditionality on factors not specified in either H_1 or H_2 but to be identified in a broader theory H_3 .

These points will now be illustrated with respect to the changes in family formation and dissolution in industrialized countries since the 1950s.

2. A Comparison of Three Theories of the 'Second Demographic Transition'

The term 'second demographic transition' was introduced by Lesthaeghe and van de Kaa (1986) to describe the changes in family formation, union dissolution, and patterns of family reconstruction in Western nations during the latter part of the twentieth century. By now, these patterns are also emerging in the former Eastern bloc countries of Europe including Russia. The changes in family formation operate through the postponement of marriage, a rise in single living, prolonged residence in the parental household, increases in incidence and duration of cohabitation (both pre- and postmarital), a postponement of parenthood leading to overall subreplacement fertility, and an increase in procreation within consensual unions. Patterns of union dissolution are characterized by rising divorce rates occurring at shorter durations of marriage and by high separation rates among cohabitants. These phenomena lead to more single person households and to more female-headed single parent households. More children grow up in non-conventional families. Although countries differ with respect to incidence and timing (e.g. Lesthaeghe 1995), most changes have consistent international trends.

These features of the narrative have been explained in three ways:

(a) by the theory of increased female economic autonomy combined with other ingredients of the neoclassic demand theory in economics (Becker et al. 1977, Becker 1991, Hotz et al. 1997, Bergstrom 1997);

(b) by the theory of relative economic deprivation (Easterlin 1976, Easterlin et al. 1990);

(c) by the theory of ideational shift (Preston 1986, Lesthaeghe and Meekers 1986, Thornton and Camburn 1987, Lesthaeghe and Surkyn 1988, Bumpass 1990).

The neoclassic economic theory of the family posits that (a) increasing investment in the quality (e.g., education) of children rather than in their numbers is being made as individuals and societies become wealthier, and (b) that increased female education and the opening up of employment opportunities for women has led to increased female economic autonomy and to increased opportunity costs associated with household tasks and child rearing. Services provided by the market are substituted for such tasks. Economic autonomy also means that women are less dependent on husbands, so that entry costs into marriage have become higher and exit costs lower. From these core propositions one can easily derive the changing position of men in households (sharing of tasks and child rearing activities, the quest for gender symmetry, weakening of male authority, etc.). By the same token, the rules of the game are being altered, especially with respect to intrafamilial exchange: less trust from family members in the family head is exchanged for less altruism from the family head toward the members. All of this leads to an economic disinstitutionalization of the family, and the narrative of the 'second demographic transition' describes the demographic outcomes produced by these forces.

The theory of relative economic deprivation provides a number of other key ingredients. The outcomes of this narrative essentially are produced by the tension between the consumption aspirations and employment opportunities of successive male generations. Easterlin originally used the theory to account for the baby boom of the 1960s and the baby bust of the 1970s and thereafter. The generations that produced the marriage and baby boom were raised in periods of less economic growth and had not developed high consumption aspirations during their childhood. These cohorts, however, benefited from expanding economic opportunities during the 1960s, and as a result they could more easily satisfy both consumption aspirations and family formation desires. Subsequent cohorts experienced high levels of consumption in their families of origin and developed high consumption aspirations themselves, but could not as easily fulfill these as a result of less advantageous labor market conditions. All the crucial steps in family formation were, therefore, postponed and new arrangements with a more temporary character, such as prolonged residence in the parental household or cohabitation, emerged as a necessity while waiting for better times. Furthermore, high consumption aspirations in tandem with scarcer opportunities for males fostered the need for an additional partial or full income to be provided by the female partner. From there onwards, the story could easily be completed according to the lines provided by the 'female economic autonomy' version of the neoclassic school.

Yet, both the starting point and the mechanism of the narratives are different. Becker et al. (1977) start from the female side, whereas Easterlin et al. (1990)

start from the male point of view. Moreover, the Easterlin version has the built-in mechanism of cohort succession and a link to values (concerning consumption) fostered during childhood and adolescence. In the original version, a demographic factor was also given greater prominence: cohort size would exacerbate the consumption aspirations-income tension since larger cohorts would face more competition and hence also tougher employment conditions. Higher female education and a larger female labor force supply (see the neoclassic version) would of course result in similar effects.

From the above narratives it is clear that the two economic theories H_1 and H_2 are not mutually exclusive and that their respective mechanisms have, to put it metaphorically, several cog wheels that grip into each others.

The theory of ideational shifts links the features of the second demographic transition to long-term trends, often starting in the nineteenth century, toward greater individual autonomy in the ethical, religious, and political domains. Typical expressions of this trend are the steady rise of secularism in the West over the last two centuries, the growth of emancipation movements operating first in the domain of social stratification, and then in the area of gender relations, the steady rise of postmaterialist political aspirations (see Inglehart 1990) in each successive birth cohort since 1920, the historical alteration of priorities in child socialization values (see Alwin 1990); or more recently the growth of scepticism toward institutions and the weakening of civil morality. In this respect, the baby boom in the original six member countries of the EU corresponded with the arrival at childbearing age of a cohort of parents that had hardly progressed on the postmaterialism scale with respect to political aspirations, whereas the baby bust corresponds with the childbearing of the cohort that made the largest leap of all on the same scale (Lesthaeghe and Surkyn 1988). Very much the same result emerges with respect to the relative pace of secularization in Europe, and also among American youths, a significant shift away from community orientations and toward a self-centered preoccupation with material riches was observed (Easterlin and Crimmins 1991). On the whole, the rise of secular individualism and the concomitantly diminishing acceptability of institutional regulation in the sphere of the family are part of the same trend. This also implies that individuals are allowed more freedom to opt out of any arrangement if returns are judged to be inadequate and hence, that the cost-benefit calculus, which features so prominently in the neoclassic economic version, has gained legitimacy in most spheres of life.

A distinct feature of the ideational shifts theory is its preoccupation with intergenerational values transmission, the predictive power of value orientations on subsequent choices with respect to patterns of family formation and dissolution (selection effects), and the

feed-back effects in the form of value adjustments (affirmation or negation) in function of certain life cycle events. This line of research has made extensive use of panel data in assessing the strength of these effects net of other predictors commonly used in microeconomic empirical analyses (see Thornton and Camburn 1987, Axinn and Thornton 1993, Clarkberg et al. 1995, Barber 1999, Moors 1999). These meticulously designed studies all show that value orientations, even when measured at young ages (including those related to consumption aspirations and labor force commitment), have highly significant independent effects on future life course choices such as cohabitation vs. marriage, parenthood within and outside wedlock, timing and quantum of fertility, separation and divorce. While not refuting predictions derived from economic theory, these studies document the extra predictive power of ideational dimensions.

Finally, it is clear that several ingredients of the ideational theory can be linked directly to those featured by the economic views. For instance, the neoclassic central focus on female economic autonomy leads directly to the changes in gender relations, and these indeed matter in the unfolding of alternative forms of family formation. In addition, both the Easterlin version and the ideational theory pay ample attention to the role of socialization in successive generations and both are essentially cohort theories of social change. Ideational theory, however, traces the trends in causal factors much further back in time, and it does not of course restrict itself to consumption aspirations alone. But in doing so, the ideational shifts theory provides support for the neoclassic economic position by showing how increased legitimacy of individual economic rationality is taking the lead over the forces of institutional normative regulation.

3. Predictions and Contexts: The Example of Cohabitation

The three theories just discussed offer different mechanisms for explaining the rise of premarital cohabitation in the West since the 1960s. According to the neoclassic theory, the phenomenon results from increased economic independence of women, and expects, therefore, that better educated women with better employment opportunities and higher incomes take the lead. In the relative economic deprivation version, cohabitation is a preliminary stage typically emerging prior to the full establishment of economic self-sufficiency of a new household. Cohabitation is, therefore, more typical for lower income groups with less employment stability, or for subgroups that have not yet matched their incomes to their consumption aspirations. In the ideational version, cohabitation is not so much predicted on the basis of economic constraints or opportunities, but it stems from a set of value orientations already emerging during the 'for-

mative years.' As these values are often linked to more advanced education, a positive correlation between education and cohabitation is expected. Furthermore, antecedents in the family of origin (such as parental divorce) also contribute to earlier home leaving and cohabitation (see, for example, Cherlin et al. 1995, Kiernan and Hobcraft 1997), *inter alia*, via the accentuation of values of ethical autonomy.

The neoclassic economic theory and the ideational theory both draw support from the initial positive correlation between education and cohabitation in a number of countries. At the microlevel, attitudes associated with career commitment and gender symmetry, also tend to be positively related to premarital cohabitation. However, in several contexts (e.g., Scandinavia, Austria), historical patterns of premarital cohabitation had survived in specific subgroups, and the diffusion of premarital cohabitation did not originate from the college educated or in large urban areas, but rather in the working class and more remote areas (e.g., northern Sweden, Alpine valleys). In addition, in most other Western countries, younger generations from working-class backgrounds and with less education adopted the pattern of cohabitation very quickly, so that the initial positive correlation with education vanished or even reversed. The predictive power of specific value orientations is also weakening as cohabitation has ceased to be an expression of protest among the highly unconventional (for these trends see Villeneuve-Gokalp 1990, Oppenheimer and Lew 1995, Boulanger et al. 1997, Bracher and Santow 1998, Kravdal 1999).

To sum up, cohabitation has become widespread among very different socioeconomic strata, suggesting (a) the existence of particular diffusion patterns in various national contexts, and (b) a rapid differentiation of motivations behind the choice. This form of family formation can be initiated for reasons suggested by all three theories. As a result, a particular theory may have higher or lower predictive power depending on the phase of the process of diffusion and on national or historical contexts.

4. Conclusion

The scientific traditions in the different social science disciplines leave an important imprint on both the theoretical conceptualization and the research agenda. Neoclassical economists have a strongly deductive approach and typically start with theory construction and the specification of the corresponding equations. Often they stop short of adequate operationalizations of basic concepts or fail to incorporate noneconomic variables in tandem with economic proxies (Robinson 1997). Demographers, sociologists, and statisticians use both deductive and inductive strategies, and they are engaged continuously in concept operationalizations and statistical testing or exploration. The latter

group is, therefore, more likely to report 'mixed results' than the former. Empirical scrutiny of associations derived from theory invariably points in the direction of theoretical incompleteness. As shown by the example above, the separate narratives are seldom mutually exclusive, they complement each other in more than one way, and they produce predictions that are restricted to context, time, or social group. All three theories are, therefore, candidates for inclusion into a larger theoretical framework.

Finally, there are two particularly fruitful ways of advancing empirical research. First, the use of panel data, with measurements of both socioeconomic and attitudinal variables at each wave, is ideally suited to check predictions deduced from various theories. And second, much can be learned from comparisons across contexts if attempts are made to specify and to test the presumed contextual causes at work.

Family Theory: Economics of Childbearing

Economic theories of childbearing relate decisions about family size and the timing of births over people's lives to elements of the constraints on choice that people face, particularly prices and incomes. This article presents the basic concepts and approaches used in these theories, discusses their main lines of argument and summarizes some of their empirical implications. It first examines 'static' theories of completed family size and then discusses dynamic theories of the timing of childbearing. While mainly concerned with theories of marital fertility, it concludes with a discussion of nonmarital fertility.

1. 'Child Quality' and Fertility

Economic theories of fertility have been around for over 200 years. The ones advanced by Thomas Malthus are the best known. In a few words, Malthus' view was that fertility was determined by the age at

marriage and frequency of coition during marriage. He argued that an increase in people's income would encourage them to marry earlier and have sexual intercourse more often. Modern economic theories of fertility date from a paper by Becker (1960), which generalized and developed the Malthusian theory. Until Sect. 4, it is assumed that fertility decisions are made in a stable marriage.

Becker's point of departure is that children are usually a source of psychic satisfaction for parents. An important aspect of his seminal contribution was to point out that this satisfaction is likely to depend on the amount that parents spend on children as well as the number of children that they have. For instance, parents are likely to receive higher satisfaction if their children obtain a university degree than if they leave school as teenagers. For short, he calls children who have more spent on them 'higher quality' children, hastening to add 'that "higher quality" does not mean morally better' (Becker 1960, p. 211). The basic idea is that if parents voluntarily spend more on a child, it is because they obtain additional satisfaction from the additional expenditure. It is this additional satisfaction that is called 'higher quality.'

The concept of 'child quality' continues to be an important element in the economic analysis of fertility today. The characterization of 'child quality' has moved in the direction of identifying child quality with the lifetime well-being of the child, which can be increased by investing more in the child's 'human capital' (i.e., his or her ability to earn income as an adult) or by the direct transfer of wealth to the child. That is, the parents receive more satisfaction from having children who are better off throughout their lives, and they make monetary transfers and human capital investments to influence their child's lifetime standard of living. Thus, child quality could be thought of as the child's future 'quality of life.'

Having incorporated the quality dimension of reproduction decisions, the well-developed model of consumer choice is applied to them. Parents are assumed to choose the best combination of the number of children, their quality and the parents' own standard of living subject to parents' lifetime income and the prices that they face in markets. An increase in parents' income is expected to increase both the quantity and quality of children. In light of the tendency for people to increase the quality of most consumer durable goods proportionately much more than the quantity of such goods when their income increases, Becker argued that this is also likely to be the case for children. In economics, the 'income elasticity' of a good is defined as the percentage increase in the demand for that good in response to a 1 percent increase in income. Thus, using this terminology, Becker's contention is that the income elasticity of the number of children ('quantity') is small compared to the income elasticity of child quality. Put somewhat differently, an increase in parents' income

may increase the amount spent on children substantially, but this would mainly take the form of higher quality rather than more children. The introduction of the child quality concept generalizes the Malthusian theory, which only allows responses to income along the quantity dimension.

1.1 Quantity–Quality Interaction

A new twist to the quantity–quality model was added in the influential papers by Willis (1973) and Becker and Lewis (1973). They assumed that parents view child quantity and quality as substitutes and that parents treat all their children equally, in the sense that child quality is the same for each child. The parents' lifetime budget constraint is that the sum of expenditures on their own consumption, expenditures on their children's human capital acquisition, and monetary transfers to their children equals the parents' lifetime income. The latter two elements of spending represent expenditure on child quality, which is the product of the number of children, quality per child and the full cost per unit of child quality (which is discussed later). This model can be generalized to incorporate costs of the number of children that do not depend on child quality and costs of quality that do not depend on the number of children. As an example of the former, a decline in the cost of averting births, say because of the introduction of the oral contraceptive pill, would increase the marginal cost of a birth without affecting the marginal cost of child quality.

This product in the budget constraint implies that the cost (or 'shadow price') of an additional child is proportional to the level of child quality, and the cost ('shadow price') of raising child quality is proportional to the number of children the parents have. As a consequence, there is an important interaction between family size and child quality. Suppose, for example, that there is a *small* exogenous decrease in fertility, say because of lower contraception costs. This lowers the shadow price of child quality, which in turn raises child quality, which raises the shadow price of children, which lowers family size further, and so on. Thus, a cumulative process favoring child quality and reducing fertility ensues. Similarly, a *small* exogenous increase in desired child quality could produce a *large* decrease in family size and a much larger increase in child quality.

This interaction between child quality and fertility does not derive from assuming that child quality and quantity are *close* substitutes for one another. Indeed, just the opposite must be the case, because if both fertility and child quality are to be nonzero, then they cannot be close substitutes. Thus, family size can be highly responsive to changes in prices and incomes, even though children have no close substitutes.

Another consequence of this interaction is that it may appear that the income elasticity of fertility is

negative, even though children are 'normal goods,' in the sense that parents want more of them when parental income increases. The reason is that the true income elasticity is defined with prices constant, but, because of the interaction, it is not possible to hold the shadow prices of an additional child and of child quality constant when measuring the elasticity. The measured income elasticity of family size is more likely to be negative (even though the true elasticity is positive), the more responsive is child quality to changes in income relative to the responsiveness of fertility (i.e., the higher is the quality elasticity relative to the quantity elasticity), and the better substitute is family size for child quality or parental consumption.

1.2 Child Mortality and Fertility

The ultimate manifestation of low child quality is a child not surviving to adulthood. In light of the 'demographic transition' (i.e., the change from a high fertility–high child mortality environment to a low fertility–low mortality one), an interesting question is how fertility responds to changes in the 'risk' of child mortality. Because parents may know the risk, but not exactly how many of their children will die for any given number of births, this is a problem of choice under uncertainty. Sah (1991) assumed that parents choose the number of births to maximize their 'expected utility.' This is the weighted sum of the utilities of having particular numbers of surviving children (inclusive of all benefits and costs), with the weights being the probabilities of obtaining that number of surviving children from given numbers of births.

Suppose first that only surviving children bring costs and benefits. Sah (1991) showed that the number of births cannot increase with an increase in the probability that the child survives to adulthood. While the parents may wish to have more births when survival chances are low, because some may die before adulthood and they will not have enough time to replace them in their fecund period, their incentive to practice such 'hoarding' is less when survival chances are better. Thus, their fertility will not be higher when child survival is more likely.

A cost may, however, be incurred by a birth regardless of whether or not the child survives. In this case, a higher probability of child survival reduces the effective price of a surviving birth, thereby encouraging higher fertility. Sah finds that this effect will be smaller than the 'hoarding effect' above if parents are sufficiently 'risk averse,' or there is a 'target fertility level,' in the sense that the marginal utility of the last child is nonpositive if all the children from an optimally chosen number of births were to survive. If either of these conditions hold, better survival chances for children tend to reduce fertility.

In the analysis by Cigno (1998), parents can influence the chances that their child survives (an element

of 'child quality') by spending more on him/her. In his model, an exogenous reduction in child mortality may either raise or lower fertility. When the level of child mortality is high, reductions in it are likely to raise both fertility and survival-enhancing expenditures on children, because it lowers the price of a surviving child. When, however, the level of child mortality is already low, further reductions in it are likely to reduce both fertility and survival-enhancing expenditures on children.

2. The Cost of Children

Consumer theory tells us that, like any other price, a higher full cost of child quality per unit ought to reduce both fertility and child quality. Elucidation of the factors affecting this cost was another important contribution to the literature on the economics of fertility. In particular, it acknowledged the key role of parental time, especially the mother's, in the rearing of and investment in children. The foundations for this analysis were laid in a paper by Mincer (1963) and in Becker's (1965) theory of time allocation, and Willis (1973) built on them in his analysis.

The concept of 'household production' is important in understanding what influences the cost of child quality. Following Becker (1965), the parents' standard of living, the number of children and quality per child yield satisfaction to the parents, but these cannot be purchased directly in the market. Rather, the parents' standard of living and child quality are both produced within the household by combining parents' own time and purchased goods and services. It is the costs of these inputs that determine the cost of child quality relative to the cost of the parents' living standard. Parental time in the production of child quality is primarily the mother's time, and the rearing of children is assumed to be *time-intensive* relative to other home production activities. That is, the proportion of the total cost of producing children represented by the value of the mother's time input to children is larger than the proportion of the total cost of producing the parents' standard of living represented by the value of her time input to that production. Thus, the unit cost of child quality relative to the cost of the parents' living standard is directly related to the mother's cost of time. If she has ever been in paid employment, her cost of time is the wage she could earn in employment (i.e., her forgone earnings). The higher her wage, the higher the cost of an additional child and of additional quality per child.

This analysis suggests, therefore, that men's and women's wages should have different effects on fertility. Higher wages mean higher income for the parents, encouraging them to have more children and to invest more in the human capital of each child or to make larger monetary transfers to them (i.e., higher quality). But higher wages also mean more income lost by those caring for children and investing in their

human capital. Because most child-rearing is done by the mother, higher women's wages raise the opportunity cost of a child as well as increasing family income, while higher men's wages mainly affect childbearing through their effect on the couple's income. If the opportunity cost effect of women's wages is larger than their effect on fertility through higher family income, then higher women's wages reduce family size and child quality. It then follows that an increase in the ratio of women's to men's wages would reduce fertility.

In this model, the fraction of the woman's time supplied to the labor market is also a choice variable, which depends on the wage that the woman can earn and her partner's wage. Women who can earn high wages, or whose partners have low earnings, tend to devote a high proportion of their time to the labor market and remain childless. At the other extreme, women who could only earn low wages, or who have partners whose earnings are high, do not work in the labor market at all and have large families. For this latter group, women's wages have no impact on their fertility and higher men's wages increase the opportunity cost of children, because home production time is scarce for these women (they cannot increase it by reducing time in paid employment) and the production of child quality is assumed to be time-intensive relative to other household production activities. Thus, higher husband's wages have a smaller effect on fertility among this group of couples than among couples in which the woman spends some time in paid employment.

In between these two extremes are the bulk of the population of women, who combine childbearing with paid employment. Within this group, there would tend to be a negative correlation between family size and the fraction of their life they spend in paid employment. This is a correlation between two choice variables. Variations in each partner's wages and in tastes drive both variables.

Purchased childcare can weaken the link between a woman's wage and the cost of an additional child. In Ermisch (1989) it is treated as an increasingly imperfect substitute for the mother's time in child-rearing as the amount of it increases. Mothers with high wages tend to purchase a much larger proportion of childcare time. For them, higher wages have little effect on the cost of children, making it more likely that they increase fertility by raising family income. Similarly, in countries with heavily subsidized childcare, mothers contribute much less of childcare themselves, making it more likely that women earning higher pay have larger families. At low to moderate levels of wages, a higher mother's wage reduces fertility, but its negative impact attenuates as her wage rises, or the price of childcare falls, because mothers purchase a larger proportion of childcare time under these conditions. The impact of the price of childcare on fertility displays a similar interaction, becoming more negative as the mother's wage rises.

Nevertheless, when examining changes in fertility over time, the cost of purchased childcare and women's wages tend to move together, because women's labor is such an important input to the provision of childcare services. Thus, over time women's pay relative to men's and fertility should be negatively related, because higher women's pay raises the cost of children.

3. *Dynamic Fertility Models*

The theories discussed so far are 'static' in nature, the relevant time unit being the parents' lifetime. In order to consider decisions about the timing of births, imperfect fertility control, or the consequences of unexpected outcomes like birth-control failure or child mortality, a dynamic model is needed. First, some features of dynamic life-cycle theories are discussed, and then a model of fertility dynamics across generations is introduced.

3.1 *Life-cycle Dynamics*

Dynamic models incorporating a sequence of decisions and imperfect, costly fertility control are more realistic than the static theories discussed above. Their predictions often depend on what is assumed about parents' ability to borrow and save. One of two polar assumptions has been made in the literature: either parents can borrow and save as they choose ('perfect capital markets') or they cannot do so at all (i.e., they must consume all of their current income).

In one of the earliest dynamic fertility models (Heckman and Willis 1976), a couple's fertility is controllable by the contraceptive strategies they adopt, but control is not perfect. Because it is assumed that couples start obtaining satisfaction from children as soon as they are born, they wish to have their children early. Couples may, however, find it best to adopt a 'precautionary' contraceptive strategy early in their partnership in order to reduce the risk of having more children than they would have chosen to have if fertility control were perfect and free. Such a strategy would result in postponing the age at first birth. If people cannot borrow or save, and their incomes rise with age, they would also wish to practice contraception in order to try to postpone childbearing to a time when the marginal benefit of income for parental consumption is lower (when they can 'better afford' children). Subsequent spacing of births (rather than having children as quickly as possible) would also be a response to this tension between their desire to have children early and the economic incentive to have them later, when parents' income is higher. The more rapid the increase in income with age, the greater the incentive to postpone the start of childbearing and to space births. In other words, births are timed in order to 'smooth' parental consumption over time.

Another common (but not universal) feature of dynamic models is allowance for the possibility that a woman's current participation in paid employment improves her future earning capacity, and that absence from employment may reduce her pay when she returns to employment. Thus, a mother's absence from paid employment because of a birth has two costs: a loss of current earnings and a loss of future earning potential. An early example of such a model is that of Moffitt (1984).

Even when there are perfect capital markets, couples may choose to postpone childbearing because these opportunity costs of childbearing are high when the woman is younger and on the steep part of her career-earnings profile. Women in jobs in which work experience has little effect on earnings have less incentive to postpone. In addition, if the care of young children is particularly intensive in the mother's time, then a birth produces a temporary increase in the value of her time in the home to a level above the value of her time in the labor market, causing her to leave paid employment. It also increases the cost of an additional child, encouraging her to postpone the next birth until the value of her time declines sufficiently through the aging of the child. Thus, even with perfect capital markets, there is an economic incentive to space births. An unexpected birth, because of contraceptive failure, would generate similar incentives for the mother to leave paid employment temporarily and postpone having another child.

The death of a child encourages its replacement, because the marginal benefit of an additional child is likely to increase substantially when a child dies. Replacement makes a woman's number of births increase with the experience of child mortality. Unless child mortality is expected when the mother is older, replacement is a better response to child mortality risk than 'hoarding,' because the latter involves a larger deviation from what the parents would have done in the absence of child mortality. Wolpin (1984) was the first to incorporate uncertainty about child survival into a sequential, dynamic fertility model, which permits analysis of replacement in response to child deaths and of the effect of infant mortality risk on fertility.

Recent detailed surveys by Hotz et al. (1997) and Schultz (1997) discuss the empirical strategies for applying the theories discussed above and the results of many empirical studies.

3.2 *Easterlin's Relative Income Hypothesis*

In Easterlin's (1980) view, an important factor affecting a young couple's willingness to marry and have children is their outlook for supporting their material aspirations. If they expect their earning potential to be high relative to their aspirations, they will be more optimistic and will feel freer to marry and have children. If they expect that they will find it difficult to

achieve the standard of living to which they aspire, they will hesitate to marry and have children. The ratio of the couple's potential earning power to their material aspirations is called their 'relative income.'

A person's material aspirations are formed through experience; for a young person, the primary relevant experience is the standard of living experienced in his/her parents' home. Young people's expectations concerning their earning potential are largely shaped by their experience of working.

A person's relative income may be related to the size of his/her generation relative to the size of previous generations. There are important differences between the characteristics of new labor force entrants and experienced workers. The former have not yet acquired a high level of skills and are engaged in a considerable amount of job search with consequent high job turnover. Older workers are more skilled and occupy career jobs with relatively low job turnover. As a consequence of these differences, the ability to substitute between young and older workers is limited. Thus, when young workers are scarce relative to older workers, their wages are higher relative to older workers and their chances of upward mobility improve. When they are in relative abundance, their relative wage declines and their promotion chances deteriorate. If there is a steady growth in labor demand, the earnings of young people (say, aged 15–29) relative to older people (say, aged 30–64) tends to be inversely related to the number of young people relative to older people ('relative generation size'), which suggests that their relative income also moves inversely with relative generation size.

The relative income theory of fertility would then lead us to expect that people from smaller birth cohorts would have higher fertility than people from larger cohorts. If couples feel constrained to choose family size within certain limits, say two to four children, then 'scarce' generations, who start childbearing earlier because of their favorable economic prospects relative to their material aspirations, would cut back later as they reach their upper limits, and people from 'surplus' generations would catch up later to attain their lower limits. Such behavior tends to make the fertility rates of women of different ages (different generations) move together. The period total fertility rate would then also move inversely with relative generation size, and it would fluctuate much more than completed family size.

4. Non-marital Fertility

Since 1990 there has been a shift away from the paradigm of the married couple making fertility decisions as a single entity. This reflects in part the fact that births outside marriage now represent a substantial proportion of births in many countries, which suggests that men and women should be treated as

individual agents in fertility decisions. Higher divorce rates would reinforce such a treatment.

This is clearest considering births outside a live-in partnership, drawing on the analysis of Willis (1999). Child quality is a 'collective good' to the parents (i.e., both the mother's and father's satisfaction depend on child quality). As a consequence, men fathering children outside a live-in partnership may choose to make transfers to the mother. Assume that the amount of transfer is determined in a noncooperative way: the mother has custody and chooses child quality and her own consumption taking transfer payments from the father as given. Fathers choose transfers and their own consumption, taking into account how the mother reacts to such a transfer. Then a father would voluntarily make a transfer if his income is high relative to the mother's income and he cares sufficiently for the well-being of his child. The higher is his income relative to hers, the larger is the transfer. But the mother, father, and child could be even better off if the couple cooperated in their decisions. Because of difficulties in monitoring expenditures on children, cooperation is facilitated by the parents forming a live-in partnership. Thus, these relatively affluent fathers would usually not want to father children outside a live-in partnership.

In a frictionless 'marriage market,' the collective-good nature of child quality encourages the highest income man to live with and have a child with the highest income woman, the next highest income couple would live together and have a child, and so on. If there are more men than women, then the men with the lowest incomes remain without a partner and all childbearing would be within live-in partnerships. If the number of women exceeds the number of men and if women at the lower end of the income distribution have incomes which are sufficient for them to want to raise children with their own resources, then fatherhood outside a live-in partnership would be free. If low-income men can father children by more than one woman, out-of-partnership fatherhood may be more advantageous for them than forming a union with a low-income woman, even though the mother and child would be better off in the union. This is more likely if the man's income is not much higher than the woman's, in which case he would not want to make transfers to her. The single low-income mothers gain by becoming mothers rather than remaining childless.

Thus, there may be what Willis (1999) calls an 'out-of-wedlock equilibrium' in which men with low incomes seek to father children outside live-in partnerships and women oblige them in preference to remaining childless. This outcome is more likely when there is an excess of unmarried women relative to unmarried men, men's incomes are not much higher than women's in the lower portion of the income distribution, and the combination of women's earnings and government transfer programs are adequate to raise children without the father's help. Thus, this

theory explains fertility outside live-in partnerships as a rational choice by low-income men and women, while at the same time higher income couples choose to have children within live-in partnerships.

In the world described by this model, people either form live-in partnerships or remain single forever. A simple model of time-consuming search for a partner, in which a woman may have a birth before entering a live-in partnership but still partner subsequently, yields a few similar predictions. Pre-partnership childbearing is more likely when the incomes of single mothers are higher relative to the incomes of single women (perhaps because of welfare benefits to single mothers), both because more partnership offers are rejected and because the value of becoming a single mother increases relative to the value of remaining single and childless. It is also more likely when single motherhood does not substantially reduce the chances of subsequent live-in partnering. The fathers of these children, whose partnership offers have been rejected, tend to have low incomes.

There has been little economic analysis of childbearing within cohabiting unions, which has grown in importance in many countries. In unions that are expected to have a short life, it may be akin to the analysis of out-of-partnership childbearing discussed above. More generally, it shares some features of the analysis of marital fertility, but there are also unique attributes of cohabiting unions that are probably important for fertility decisions. One is their high risk of dissolution. In light of it, it is essential to treat the fertility decision as problem of choice under uncertainty in which each partner is an individual agent whose preferences, expectations, and resources influence the decision. This presents new and difficult analytical problems, which are also relevant to marital fertility in high-divorce countries. These are new challenges in the economic theory of fertility.

Family Theory: Economics of Intergenerational Relations

In economics, the term ‘transfer’ is used to refer to the delivery of money or other assets, without counterpart. We do not talk of transfers, therefore, in the context of a commercial transaction, where money is the counterpart of goods or services. Public transfers, by contrast, are the direct subsidies that governments pay to households and firms. Although such subsidies are financed out of tax receipts, there is in fact no direct link between what any particular firm or household pays in taxes, and what it gets back in subsidies. A gray area is represented by certain types of old-age pensions, where the size of the benefit is related in some way to contributions made, but the rules on the basis of which the calculation is made are subject to change by political decision.

Transfers between generations may be voluntary, or forced by the tax system. Here, we are concerned with

Figure 1
Help given/received by age group

voluntary transfers between different generations of the same family, but we are also interested in how these respond to public transfers. Typically, the latter redistribute income away from working-age cohorts, who pay more taxes and receive less subsidies than younger and older cohorts. A similar age pattern applies to voluntary *inter vivos* transfers: Fig. 1, drawn from Cigno and Rosati (2000), shows the distribution, by age of the household head, of monetary help to and from non-coresident 'friends or relatives' (overwhelmingly relatives) by Italian households during the late 1980s. It transpires that the probability of making a transfer is highest, and that of receiving one lowest, when the household head is in the 40–59 age range. Similar pictures can be constructed for other countries. What can be the reason for such a pattern?

Economic explanations fall into two broad categories. One follows what is called the altruistic approach, whereby individuals are assumed to derive direct utility (satisfaction) from the wellbeing of other family members. The other assumes that individuals are ultimately self-interested. Transfers are straight, no-strings-attached gifts according to the first of these explanations, part of a strategy that is expected to bring, directly or indirectly, benefits to the donor according to the second.

1. Altruistic Explanations

Simple altruistic explanations assume that sentiment is unidirectional: either from parents to children (*descending altruism*) or from children to parents (*ascending altruism*). More complicated versions allow for altruism in both directions.

Descending altruism underlies Richard Barro's and Gary Becker's theories of voluntary transfers. This assumption allows them to model transfers within the family as the outcome of a single optimization, whereby parents decide how much each family member will consume, subject to two constraints. One is that the sum of the consumption expenditures of all

family members cannot exceed the sum of their incomes. The other is that transfers received (the difference between consumption expenditure and income) by any family member other than the decision-maker(s) must be positive or zero, otherwise they would be rejected. Under standard conditions, the model predicts that transfers will not decrease (increase) as the income of the donor (beneficiary) increases. This is consistent with the observation (Fig. 1) that the probability of making a transfer is highest, and that of receiving one lowest, in middle age, when incomes are generally at their peak. It is difficult to reconcile, however, with the observation that people continue to receive *inter vivos* transfers after the age of 60 (or even 75), when few of them have living parents.

If it is assumed that parents make transfers in the form of bequests, rather than *inter vivos*, the descending-altruism model predicts that household saving is increased, dollar for dollar, by any current government deficit (Barro 1974). That is because, conscious of the government intertemporal budget constraint, altruistic taxpayers perceive any current deficit as a tax on their descendants (this is the so-called *Ricardian equivalence*, from the name of David Ricardo, who first detected it). According to the model, taxpayers thus respond to a government deficit by saving more, in order to be able to leave their descendants bequests large enough to pay the extra taxes. One of the mechanisms that might generate such a deficit is a pay-as-you-go public pension system, where current pensions are paid out of current contributions. Whichever the mechanism, however, any net public transfer will be matched by private transfers of opposite sign.

Ricardian equivalence does not hold if fertility is endogenous i.e., if parents can choose how many children to have (or, more realistically, condition the probability distribution of births), and parents derive satisfaction from the number of children, as well as from how much each of them consumes (Becker and Barro 1988). Suppose, then, that the government were to take a dollar off the social security contributions due by each of the present workers, without any corresponding reduction in their pension entitlements. Each member of the next generation would then have to pay (r/n) more dollars in taxes, where r is the intergenerational interest factor, and n the ratio of future to current taxpayers (roughly, the population growth factor). Knowing that, present workers would then want to compensate their own children by making larger bequests to each of them. But this would make it more expensive to have an extra child relative to increasing the wellbeing of existing children. Under standard conditions, the present generation would then choose to have fewer children, and to *more* than compensate each child for the heavier tax burden he or she will have to shoulder. Of course, the change in fertility behavior would result in a lower n , and thus raise the burden on each future taxpayer, but the effect

of each couple's actions on the aggregate fertility rate is infinitesimal. Couples, therefore, will not take this effect into account when they decide how many children to have. Hence, fertility would fall. Saving could rise or fall, depending on whether the rise in transfers per child is proportionally larger or smaller than the reduction in the number of children. By contrast, if the government were to promise higher benefits to current taxpayers already covered by old-age security, or extend coverage to new categories, and simultaneously raise taxes or contributions so as not to force a transfer in favor of present workers, there would be no effect on either saving or fertility behaviour. There is evidence (Cigno and Rosati 1996, among others) that old-age security *per se* (i.e., without intergenerational spillovers) encourages household saving and discourages fertility, while deficits discourage saving. This empirical finding is consistent with the Becker-Barro prediction that a deficit *could* result in lower savings, but contradicts that model's prediction that, in the absence of intergenerational transfers, saving and fertility would remain the same.

The implications of ascending altruism (Nishimura and Zhang 1992) are somewhat different. The direction of transfers is not from working-age parents to young children, as in the case of descending altruism, but from working-age children to retirement-age parents. This is consistent with the observation that old people receive *inter vivos* transfers, but difficult to reconcile with the one that they also make such transfers. As children are a source of income, parents treat them as an asset. If fertility is endogenous, working-age individuals (or couples) then choose the composition of their portfolios so as to equate the marginal return to having children to that of holding conventional assets (capital). According to this model, a gift to current tax payers at the expense of future ones would induce parents to save more, not in order to leave larger bequests, but in order to put some of the windfall aside for old age. By contrast, a fully funded expansion in pension coverage (a form of forced saving) would reduce voluntary saving. These predictions clash, however, with the empirical finding, already mentioned, that deficits discourage voluntary household saving, while social security coverage *per se* has the opposite effect.

Whichever the direction, unilateral altruism is thus an inadequate explanation of what we observe. Can bilateral altruism (parents love children, children love parents) do better? If family members are unanimous in their preferences, intrafamily transfers can again be described as the outcome of the maximization of a single preference function (this time agreed upon by all family members), subject only to the constraint that the sum of the expenditures cannot be greater than the sum of the incomes of all family members. There is now no restriction on the direction of money flows: depending on life-cycle patterns, transfers from middle-aged children to elderly parents may be positive in

some families and negative in others. This is consistent with evidence of two-way flows between generations, but the model also has a stronger behavioral implication: since the amount consumed by each family member depends on *total* family income, and not on his or her own individual income, changing the intrafamily distribution of income should not change the intrafamily distribution of consumption. Statistical tests based on this property of the model (Cox 1987, Altonji et al. 1992) reject the hypothesis of altruism. That property also has the strong implication that redistributive policies are ineffective: taking a dollar off the rich (the parents) and giving it to the poor (the children) would reduce the amount voluntarily transferred from the former to the latter by exactly one dollar.

In general, however, different family members are likely to have different ideas about the most desirable pattern of transfers. Even if all family members were altruistic towards one another, each of them might in fact appreciate his or her own consumption a little more (or, for that matter, a little less) than another family member. If that is the case, transfers cannot be viewed as the solution to a single optimization. They must rather be seen as the outcome of a game (in the sense of formal game theory) in which family members bargain with one another, or respond strategically to one another's moves, pretty much as if they were pursuing purely selfish aims (Manser and Brown 1980, Stark 1993). In such a situation, transfers depend on individual fall-back positions (what the player would get, if he or she dropped out of the game), as well as on preferences and characteristics. It is then difficult to distinguish empirically (McElroy 1990) bilateral altruism from self-interest, to which we now turn.

2. Non-altruistic Explanations

Non-altruistic explanations are based on the assumption that individuals are interested only in their own lifetime consumption stream. If a person voluntarily surrenders money to another, it will be for profit, or in order to improve the allocation of consumption over the life-cycle, or across states of the world. It must also be true that the person in question could not get a better deal from the market. There does not seem to be any difference of substance, therefore, between this and giving money to the grocer in exchange for a dozen eggs. Nonetheless, it is customary, maybe due to lack of information, to classify as transfers any moneys changing hands within the family whenever there is no explicit *quid pro quo* (not, however, in the case of a father paying his child to wash his car).

Mutual insurance ('I help you if things go well for me and badly for you, you help me if it is the other way round') is a typical form of intrafamily arrangement. But why should people want to enter into such informal, maybe even tacit, agreements, if it is possible to buy insurance from the market with all the safeguards

afforded by the law? The insurance market has the advantage over the family that individual risks are less likely to be correlated in a large heterogeneous population than in a small homogeneous group. Because of adverse selection and moral hazard problems, however, the market might not offer insurance, or offer it on very unfavorable terms, to certain individuals or for certain types of risk. Such problems are generally less acute within the family, the members of which have privileged information on one another's characteristics, and lower costs of monitoring one another's behavior. In some circumstances, it may thus turn out that intrafamily arrangements are more advantageous than market insurance, or that there is no alternative.

Mutual insurance may or may not result in intergenerational transfers (not if the agreement is among contemporaries). Intergenerational transfers, by contrast, are essentially another kind of insurance arrangement whereby a person (parent) transfers wealth or pre-commits to leave a bequest to a younger relative (child) in exchange for a promise of indefinite old-age support, effectively in exchange for an annuity (Kotlikoff and Spivak 1981). That way, the parent buys insurance from the child against the risk of running out of money after too long a period of retirement.

Another type of mutually advantageous intrafamily deal, also giving rise to intergenerational transfers, stems from life-cycle income variations and capital market imperfections. Standard microeconomic theory predicts that individuals smooth consumption over the life-cycle by borrowing from the market when they are young, and lending (buying assets) when they are middle-aged. In reality, however, minors cannot sign contracts, and young adults have difficulty in obtaining credit against future earnings. The very fact that people survive to adulthood is thus evidence that the young receive support in other ways, but from whom? We have just seen that nobody makes genuine presents. Self-interested relatives, on the other hand, will make loans, not presents, and only if the risk-adjusted return is at least as high as that offered by the formal capital market. And what is there to induce a selfish adult to honor an informal debt incurred 20 or so years earlier?

Imagine a set of family rules (family constitution) prescribing the amount that a parent must pay a young child, and the amount that a grown-up child must pay an elderly parent, subject to the clause that nothing is due to a parent who disobeyed the rules. Such a constitution is self-enforcing, in the sense that it is in everybody's interest to comply, if the rules are so designed that complying with them is at least as advantageous, for a middle-aged person, as the alternative strategy of having no children, giving nothing to parents, and providing for old age by buying capital (Cigno 1993). This line of reasoning explains transfers to the young as implicit loans, and transfers to the old as implicit loan repayments. In such a situation, paying

back one's own parents is a condition for getting the same treatment from one's own children. Now suppose that the level of old-age security is raised, or coverage extended to new categories. The present middle-aged affected by the policy will then want to shift less of their current spending capacity to old age. Since the amount they are supposed to pay to their elderly parents has not changed, however, some of these middle-aged persons will find it advantageous to disobey the constitution, and consequently give up the idea of being supported by their own children in old age. They will then default on their implicit debt towards their own parents, have no children, and possibly top up their expected pensions by buying assets. Conversely, if the government were to cut current taxes or social security contributions without reducing pension entitlements, some middle-aged individuals, who would otherwise have found it advantageous to buy assets, would have children instead. This is consistent with the already mentioned empirical evidence that aggregate household saving responds positively to old-age security, and negatively to deficits. It also explains why fertility responds negatively to old-age security.

Family Theory: Economics of Marriage and Divorce

From an economic point of view, marriage is a voluntary partnership for the purpose of joint production and joint consumption. As such, it is comparable to other economic organizations that aim to maximize some private gains, but are subject to market discipline. This article describes the working of the marriage market, as a feedback system in which the aggregate divorce and marriage rates influence and are influenced by individual choices, and explains the features of this market that have led to the sharp increase in marital turnover.

1. The Gains from Marriage

The economic analysis of the family naturally begins with the gains from marriage. These gains are a major determinant of the decision to form a new union or to break an existing relationship. The main economic advantages of being married, rather than being single, are as follows.

(a) *Children*. Although children can be produced and raised outside the family, the family has a substantial advantage in carrying out these activities. There are two inter-related factors that cause this advantage: by nature, parents care about their own children and, because of this mutual interest, it is more efficient that the parents themselves determine the expenditure on their children. Because children are viewed as a public good by their parents, an efficient allocation of family resources between public and private uses requires some coordination between the parents. If the parents live separately, as either single or remarried, the noncustodian parent loses control of child expenditures and is less likely to contribute. In addition, lack of contact may reduce the parent's benefits from the children's 'quality' (i.e., their well being and success).

(b) *Division of labor*. Family members coordinate their work activities to exploit comparative advantage and increasing returns. For instance, one partner works in the market while the other works at home.

This pattern is economically efficient if the partners have different market wages or different productivity at home. Such differences may be inherent or, more likely, acquired through investment in skills. Investment in human capital is more profitable the higher its rate of utilization. This type of increasing returns leads to specialization that can, in principle, create mutual gains through redistribution.

(c) *Sharing*. There are collective (nonrival) goods that can be jointly consumed by both partners: for example, child quality, common leisure activities, housing expenditures, and shared information. The share of such public goods in family expenditures can be substantial. Lazear and Michael 1980 estimate that two single individuals can almost double their purchasing power by forming a union.

(d) *Credit and investment*. Married partners often engage in implicit loans that facilitate investment activities. For example, one partner works when the other is in school, expecting to share in the future gains from the investment. Similarly, parents often finance the schooling of their children, in part in the anticipation of old-age support. Such internal transfers can support investments that are mutually beneficial and would not be carried out because of market imperfections.

(e) *Risk pooling*. A family can spread the risks of idiosyncratic shocks to individual members. For example, one partner can work when the other is sick or unemployed. The family jointly accumulates precautionary savings that can serve *either* member in case of need.

There is plenty of evidence for division of labor within families. Typically, husbands work more in the market than do their wives. In addition, married men work longer hours in the market and have substantially higher wages than unmarried men. Similarly, married women have lower wages and work more at home than unmarried women. This division of labor is influenced by the higher market wages of males, which are reinforced by their higher participation in the labor market. Somewhat surprisingly, the evidence for mutual insurance is not easy to come by. In particular, an employed person is generally *more* likely to have an employed spouse than an unemployed person, suggesting that common factors affect the unemployment of both spouses.

The family is not the only organization that fulfills these functions. Markets and government institutions compete with and complement the family in this regard. If all goods and work activities are marketable, there is no need to form marriages to enjoy increasing returns or to pool risks. Similarly, with good medical or unemployment insurance one does not need to rely on one's spouse. Generally, the role of the family varies depending on market conditions and government policies. In addition, human partnerships need not be confined to couples of opposite sexes. One also observes 'extended families' of varying structures that

coordinate the activities of their members and provide self-insurance. The prevalence of male–female partnerships has to do with sexual attraction, which triggers some initial amount of blind trust and the production of children. These emotional and biological considerations are sufficient to bring into the family domain some activities that could be purchased in the market. Then, the accumulation of specific ‘marital capital,’ such as children and shared experience, increases the costs of separation and creates incentives for a lasting relationship. In this sense, there is an accumulative effect in which economic considerations and investments reinforce the natural attachment.

The potential gains from marriage generally depend on the personal traits of the two partners. Some individual traits are complements, and the gains from marriage rise if the partners have similar endowments. For instance, similarity in tastes facilitates decision on collective goods, such as the education of the children. In other cases, the traits are substitutes, and gains from marriage rise if the partners have different traits. For instance, the gains from division of labor and from credit are higher when the wages or incomes of the partners differ.

2. Family Decision Making

The existence of potential gains from marriage is not sufficient to motivate marriage and to sustain it. Prospective mates need to form some notion as to whether families realize the potential gains and how they are divided. Because families consist of several members with potentially conflicting interests, there is a question as to how families reach decisions. The old notion that consensus leads to joint maximization of a common objective appears too narrow. However, because of their proximity and repeated interaction, it is plausible to assume that married partners reach some sort of agreement that specifies an *efficient* allocation of resources and a *stable division rule*. These two principles replace the principle of rationality in individual choices.

In a special case, referred to as *transferable utility*, it is possible to separate the issues of efficiency and distribution. This situation arises if there exists a commodity (say money) that, upon changing hands, shifts utilities between the partners at a fixed rate of exchange. In this case, the family decision process can be broken into two steps: first choose an action that maximizes a weighted sum of the individual utilities, then use money to divide the jointly maximal outcome. The basic idea is that the partners can agree on most aspects of their choice and restrict their bargaining to transfers of money, which do not detract from total resources. In general, the problems of efficiency and distribution are intertwined. The family can still be described as maximizing a weighted sum of

the individual utilities, but the weights depend on the individual bargaining powers and any shift in the weights will affect the family choice. The bargaining power may depend on individual attributes, such as earning capacity, subjective factors such as impatience and risk aversion, and on market conditions, such as the sex ratio and availability of alternative mates.

Realization of the potential gains from marriage requires coordination between the two partners and durable relationship. Durable relationships are motivated by the long-term investment in children and the accumulation of marital capital, which is lost or diminished in value if separation occurs. However, to induce the actions that generate the gains from marriage, it is necessary for the partners to exchange *commitments*. For instance, a young wife is unlikely to support her husband by working while he is in medical school, if she expects him to leave her and marry a young nurse when he gets his degree. To some extent, emotional factors such as love and guilt replace formal commitments and facilitate efficient investments and effort levels. As an example, consider the role of an altruistic family head. Suppose that the head is given control over family resources and can make transfers as the head sees fit. The only requirement for becoming a head is that they should care about *all* family members, willing to raise their income, whenever the total resources at the head’s disposal rise. Under these conditions, selfish family members voluntarily act in the interest of the group. The reason is that any productive (destructive) action which increases (decreases) total family resources is rewarded by an increased (decreased) transfer from the family head (Becker 1991).

It is empirically testable whether families maximize a joint utility function, whether they act efficiently, and it is also possible to recover the sharing rule from observed family choices. Recent evidence shows that, holding total family income constant, an increase in the income of one member shifts the allocation of consumption goods in their favor. These findings reject the hypotheses that the family maximizes a joint objective, which would imply that within family, allocations are invariant under such redistribution of total resources, but are consistent with both cooperation and noncooperation. However, only cooperation implies efficiency, which yields testable cross-equation restrictions on family demand. Based on data on consumption and work patterns within families, efficiency is not rejected, suggesting that cooperation is the relevant mode (Browning et al. 1994). In the context of uncertainty, however, efficiency has some further implications that are rejected. Efficient risk sharing among linked individuals implies that, holding aggregate consumption constant, the consumption of each family member is independent of idiosyncratic shocks such as fall into unemployment or bad health. Stated differently, all individuals in the household are affected by a random shock to any individual income

and their consumption levels move together. Because of lack of data on individual consumption, the tests of this hypothesis involve larger units, such as villages or extended families, and, at this level of aggregation, efficiency is rejected.

3. Divorce and its Economic Consequences

Divorce is motivated by two general considerations. First, because it takes time to find a suitable match, people may enter a relationship which they intend to break in the future if a better match is met. Second, because of changing economic and emotional circumstances, the gains from marriage may dissipate. As time passes, new information on match quality and outside options is accumulated, and each partner decides whether to dissolve the partnership or to continue the marriage. In making this choice, partners must consider the expected value of each alternative, where the value of remaining married includes the option of later divorce, and the value of divorcing includes the option of later remarriage. Divorce occurs endogenously whenever one partner has an alternative option that the current spouse cannot, or is unwilling to, match by a redistribution of the gains from marriage.

The model outlined above yields several testable implications:

(a) It is the *unanticipated* changes in the characteristics of the partners or the quality of match which trigger divorce. It is clear that falling out of love can destroy the gains from the current marriage and cause divorce. It is less obvious how unanticipated changes in personal attributes, such as earning capacity, influence divorce, because they affect both the gains from the current marriage and the outside options. However the partners were matched, based on their traits as observed at the time of marriage, any unanticipated change reduces the gains from interaction. Thus, if the husband is unexpectedly wealthy, he will seek a better wife, and if he becomes unexpectedly poor, she will seek a better husband. Note that both positive and negative 'surprises' can disrupt the marriage.

(b) If the gains from marriage are substantial, small shocks will not lead to divorce. Therefore, the probability of divorce will be lower amongst couples who are well matched. Anticipating that, couples sort into marriage according to characteristics that are likely to enhance the stability of the marriage. In this respect, the decisions to marry and divorce are linked.

(c) By the same logic, costs of divorce mitigate the impact of unanticipated shocks on marital dissolution. The costs arise from loss of specific capital, such as information about the current spouse, and loss of coordination, especially with regard to child expenditures. There are also emotional and legal costs associated with the break up.

(d) Somewhat more controversial is the role of divorce laws, in particular whether the legal possibility unilaterally to walk away from a marriage influences the divorce rate. With transferable utility, such a change should only affect the shares in the gains from marriage but not the decision to separate, because the partner who wishes to continue the marriage can compensate the one who wishes to leave by giving up part of the gains from the marriage. Conversely, the person who wants to leave can pay damages to the one left behind. In general, because the unexpected shock differs between partners and because the options for compensations are limited, divorce is less likely if mutual consent is required.

These implications have been tested empirically. There is evidence that surprises matter. Specifically, an unexpected increase in the husband's earnings capacity reduces the divorce hazard, while an unexpected increase in the wife's earning capacity raises the divorce hazard. The important roles of search and costs of divorce are indicated by the findings that higher age at marriage and the presence of children stabilize the marriage. There is only weak evidence that divorce rates are higher in states where 'fault' is not a prerequisite for divorce. There is clear evidence that individuals sort into marriage based on their anticipation of divorce. Thus, couples with similar schooling attainments at the time of marriage are less likely to divorce, and individuals are more likely to marry if they have a similar amount of schooling. The same patterns hold for religion and ethnicity (Weiss 1997).

The costs of divorce are influenced by the post-divorce transfer of resources in the form of alimony and child support. It has been observed that divorced husbands, even if relatively well to do, fail to support their ex-wives and their children at the standard to which they were accustomed during marriage. Consequently, divorced women and children in their custody suffer a large decline in income. The possible explanations for this phenomenon are: lack of binding marriage contracts, the inability of noncustodial parents to monitor expenditures by the custodian, and loss of interest in the child by the noncustodian parent. In most cases, the wife obtains custody and controls the expenditure on children. This situation creates an *agency problem*, because out of every dollar transferred to the custodial wife with the intention of raising the welfare of the child, part is used for her own consumption. Because of this 'tax,' noncustodial fathers reduce their transfer, and consequently child quality is reduced. The assignment of custody to the wife is usually motivated by her comparative advantage in child care, but the agency problem implies that such a practice has shortcomings that are not easy to overcome, because the courts cannot verify within-household allocations.

The adequacy of transfers must be judged not only on the basis of the efficiency of allocation of family

resources in the aftermath of divorce, but also on the basis of partners' options and expectations at the time of marriage. From the latter point of view, efficiency requires that the consumption levels during marriage and divorce are tied together. Courts do take into account these two broad considerations in awarding divorce settlements. These are usually based on post-divorce incomes and the accustomed consumption of the wife and children during marriage. However, the evidence suggests that actual transfers fall short of the efficient level from both the *ex post* and *ex ante* points of view (Weiss 1997).

With deficient transfer mechanisms, the partners must better prepare for the event of divorce. One important instrument is the allocation of time within marriage. By investing in human capital, each partner can be less dependent on transfers in the event of divorce. However, such investments may detract from marital output. For instance, a wife who works is better defended against divorce but has less time to spend with children. Indeed, there is evidence that women tend to increase their investment in market work in anticipation of divorce. Thus, if the risk of divorce rises, children may suffer even before the marriage breaks.

4. The Marriage Market

Individuals in society have many potential partners. This situation creates competition over the potential gains from marriage. In modern societies, explicit price mechanisms are not observed. Nevertheless, the assignment of partners and the sharing of the gains from marriage can be analyzed within a market framework, because an undesired marriage can be avoided or replaced by a better one.

Any market solution is a particular assignment of males to females. The major questions of interest are: what types of matches are likely to form in equilibrium; for instance, would a class structure emerge where the rich marry the rich? What determines the rates of marital turnover and the proportions of married and single individuals in society? Does the marriage market operate efficiently and, if not, what type of intervention is required?

Matching models provide a starting point for such analysis. These models investigate the mapping from preferences over prospective matches into a *stable assignment* (Roth and Sotomayor 1990). Reflecting the assumption that marriage is voluntary, an assignment is said to be stable if no married person would rather be single and no two (married or unmarried) persons prefer to form a new union. To illustrate, assume that each male is endowed with a single trait, m , and each female is endowed with a single trait, f , which positively affects the gains from marriage, denoted by $z = g(m, f)$. Suppose, first, that z is a public good that *both* partners can consume

jointly. Then, the only stable assignment is that in which males with high m marry females with high f , and, if there are more (less) eligible men than women, the men (women) with the lowest endowments remain unmarried, a positive *assortative mating*. However, if one assumes, instead, that z can be divided between the two partners, a positive (negative) assortative mating occurs only if the two traits are complements (substitutes). Matching models refer to these two situations as nontransferable and transferable utility, respectively. With transferable utility, a man with low m may obtain women with high f by giving up part of his private share in the gains from marriage. Complementarity (substitution) means that the two traits interact in such a way that the benefits from a woman with high f are higher (lower) for a male with high m than for a male with low m . The type of interaction in the gains from marriage determines the willingness to pay for the different attributes. An important lesson is that in a marriage market, with sufficient scope for compensation within marriage, the best man is not necessarily the one married to the best women, because, with negative interaction, either one of them can be bid away by the second best of the opposite sex (Becker 1991).

The process of matching in real life is characterized by scarcity of information about potential matches. The participants in the process must spend time and money to locate their best options. The realized distribution of matches and the division of the gains from each marriage are therefore determined in an equilibrium which is influenced by the costs of *search* and the search policies of other participants. The main ingredients of the search model are as follows. There is a random process that creates meetings between members of society of the opposite sex. When a meeting occurs, the partners adopt a reservation policy where the match is accepted only if it provides expected gains above some prespecified value. Otherwise, they depart and wait for the next meeting to occur (Mortensen 1988). Because meetings are random and sparse in time, those who actually meet and choose to marry enjoy a positive rent. An important issue is the division of these rents between the partners.

The literature mentions two considerations that determine the division of the gains from marriage: outside options, reflected in the value of continued search, and the self-enforcing allocation that would emerge if the marriage continued without agreement. Combining these two considerations, the sharing rule will be influenced by both the value of search as singles (outside the current match) and the value of continued search during the bargaining process, including the option of leaving when an outside offer (whose value exceeds the value of potential agreement) arrives. In this way, a link is created between the division of gains and the market conditions. For instance, if there is excess supply of women in a particular marriage market, the value of continued search by females is

reduced and consequently their share in the gains from marriage declines.

With friction, there is still a tendency to positive (negative) assortative mating, based on the type of the interaction in traits. If the traits are complements, individuals of either sex with higher endowment will adopt a more selective reservation policy and will be matched, on the average, with a highly endowed person of the opposite sex. However, with sufficient friction, it is possible also to have negative assortative mating under complementarity. The reason for this result is that, because of the low frequency of meetings, males with low m expect women with high f to accept them, and if the gains from such a match are large enough, they will reject all women with low f and wait until a high f arrives (Burdett and Coles 1999).

Generally, one would expect negative sorting on wages and positive sorting on nonwage income, because the gains from division of labor are larger when wages differ, while the gains from sharing goods are larger when incomes are similar (Becker 1991). Empirical findings suggest positive sorting on both wage and nonwage income. In particular, there is a substantial correlation in the schooling achievements of partners to marriage. Similarity in schooling has opposing effects on the gains in marriage; it reduces the gaps in wages and thus the gains from the division of labor, but it also induces similarity in tastes, which facilitates the allocation of public goods. It seems that the latter effect is empirically more important. We should further note that meetings are not really random, and that unattached individuals select jobs, schools, and leisure activities so as to affect the chances of meeting a qualified person of the opposite sex.

Frictions and search explain why, in any given moment in time, part of the population is single, even though there are positive gains from marriage. The aggregate stock of unattached individuals is determined by the rates of entry and exit into marriage implied by the arrival rates of offers and the optimal reservation policies chosen by individuals. These decisions, in turn, depend on the aggregate proportion of singles, because if one meets an unattached person it is more likely that a new union will be formed than upon meeting an attached person, who already has some positive rents. Therefore, the higher the proportion of singles, including divorcees, the higher the private expected gains from divorce. This type of reinforcement can lead to multiple equilibria, whereby both high and low aggregate divorce rates can be sustained through the induced change in the individual incentives to marry and divorce.

The time pattern of aggregate divorces is consistent with multiple equilibria. For instance, the divorce rate in the USA doubled during the decade between 1965 and 1975, standing at roughly 10 percent from 1940 to 1965 and at roughly 20 percent from 1975 to 1995, suggesting a switch from a low to a high equilibrium. Explanations for the timing of the change include the

appearance of the contraceptive pill, break up of norms, and legal changes (Michael 1988). The main conceptual point, however, is that any change in exogenous factors, even a small one, can have marked impact on the aggregate divorce rate, because of the inherent reinforcements in marriage markets.

The marriage market determines not only the assignment of partners but also the division of resources and activities within the family. As market conditions change, a shortage of suitable partners of a particular kind leads to an increase in their gains from marriage. For instance, there is evidence that an increase in the demand for men, created by faster population growth combined with the tendency of men to marry younger women (a marriage squeeze), has led to an increase of dowries in rural India. In modern societies, up-front payments are rare and market forces are mostly revealed by the division of labor within families. The trend of rising female participation in the labor force among married people is probably associated with a larger share that women can extract from marriage, following the rise in female wages. Additional information on the (expected) gains from marriage is contained in the decisions to enter marriage and to stay married. For instance, it has been observed that black women in the USA delay their marriage and have children out of wedlock, because of a shortage of eligible black men (Willis 1999).

5. Some Policy Issues

Despite its firm roots in nature and its antiquity in human society, the future of the family institution has been recently put into question. This was motivated by recent trends, common to all Western societies, of declining marriage rates, declining fertility, higher divorce rates, and a rise in alternative arrangements such as cohabitation, single-parent households, and single-mother families. Social observers view these trends with considerable alarm, especially because of the potential harm to children (more than one million children in the USA are involved in a divorce every year).

Although there is ample evidence that divorce reduces the welfare of single wives and of children with single or step-parents, this is only one part of the picture. Continuation of marriage under adverse conditions can have equally harmful results, although these are harder to identify. Broadly viewed, divorce is a corrective mechanism that enables the replacement of bad matches by better ones. There is a risk that a better match will not be found, in which case the person who has divorced and the children are worse off. But rational agents take this consideration into account and can make financial arrangements to ensure that separations occur only if they improve the welfare of all parties. The issue, though, is whether the courts can enforce such binding contracts and the extent to which they should intervene.

Because meetings are random and uncoordinated, the search behavior and the decision whether to marry or divorce of each individual influence the marriage (and remarriage) prospects of all other members of society who are potential matches. Therefore, legal intervention must take into consideration the impact of the law not only on particular families but also on the marriage market as a whole. These two considerations may be in conflict. As an illustration, consider an increase in the size, or the enforcement, of child-support payments. Holding the aggregate divorce and remarriage rates fixed, each family in isolation may be better off as a result of the additional insurance. However, the reduced propensity to divorce can have a negative effect on the remarriage prospects of those who have suffered a large negative shock to their quality of match and who wish to separate. Another externality that must be considered, and may operate in the opposite direction, is that the availability of alternative mates can reduce investments that are specific to the current match and detract from its quality. This is indeed the logic behind the laws and religious norms aimed at restricting divorce.

The observed changes in family arrangements are closely related to the dramatic changes in labor-market participation of women, and the associated technological advances in the workplace and in the home. Whatever the causal relationships, it is clear that these processes reinforce each other and generate complex dynamics. While the reduction in marriage has been fairly smooth, the changes in divorce appear discontinuous, suggesting search externalities and perhaps the breaking of norms in the processes governing divorce and remarriage. These abrupt changes cause a special adjustment problem that requires social and legal restructuring. However, the expected outcome for the early twenty-first century is that the marriage market will settle at a new equilibrium with higher marital turnover, reflecting the lower gains from marriage as the disparity in the market productivity of men and women gradually declines. Although reduced, the gains from marriage are unlikely to disappear and the family, in one form or another, will continue to have a major role.

Family Theory: Feminist–Economist Critique

1. Feminist Economics

The critique from feminist economics of economic family theory largely has been directed at the version developed in neoclassical economics, often referred to as the ‘new home economics,’ though Marxist economic approaches to the family have also come in for their share of the criticism. The latter approaches largely were explicated in the ‘domestic labor debates’ of the 1980s, with articles appearing on both sides of the Atlantic showing how Marxist concepts could be used to study household production. Both these bodies of family theory were developed mostly in the 1970s, though their origins go back to the nineteenth century and even earlier.

Feminist economics can also be traced back to earlier centuries, but it emerged as a discipline in its own right in the 1970s and has grown most strongly in the 1990s. It is the branch of economics that seeks to understand the economic aspects of the relations between women and men and the gendered aspects of economic activity. With this dual goal of inquiry, feminist economics substantially broadens the scope of human activity to which economics can be applied. While economics is most commonly defined as the study of the allocation of scarce resources to meet human needs, in practice that study has been limited to primarily market transactions. Scarcity implies choice and neoclassical economics generally posits that ‘economic man’ acts rationally to maximize his own well-being, choosing options subject to constraints. Feminist economics suggests broadening the scope to a comprehensive study of provisioning and distribution, or to how society meets all its needs for everyone (Nelson 1993).

This would include housework and home production as well as the labor of caring for others, much

of which is done by women within the family. Caring necessarily intertwines affection and work, and maximization of an individual's self-interest may not be the guiding principle of this type of production, requiring that, at a minimum, the simple neoclassical model be made more complex. Since a monetary measure is absent, it is difficult to determine precisely how much production occurs in the household sphere, but worldwide it has been estimated that one-third of all human production results from the unpaid work of women (UNDP 1995, p. 97). Feminist economists argue that if these aspects of economic activity are not considered, one has a very incomplete view of the economy.

As Peterson and Lewis point out in the introduction to their 800-page compendium on feminist economics (Peterson and Lewis 1999), this is a branch of economics that welcomes diversity and heterodoxy. Feminist economists borrow from many traditions of economic thought as well as insights from other social science disciplines (Kuiper et al. 1995). While some feminist economists work largely within the neoclassical tradition and seek to use its methods to answer feminist questions, others work more within the Marxist framework or institutional economic tradition, while yet others use philosophical, literary, or postmodern methods. Most agree, however, that traditional economics of all schools has failed to explicate the economic aspects of gender relations, specifically the differences in economic power between women and men or the subordination of women to men. Why do women earn less than men, on average, just about everywhere, why do women do most of the family care in virtually all human societies, why do men hold most of the positions of economic leadership as owners, top managers, financiers, and so on?

2. The Neoclassical Theory of the Family

Neoclassical economists did not turn their attention to the question of how economic factors affect decision-making within the family and the allocation of the time of family members among various pursuits until the market started to impinge on the family and to change family dynamics in an obvious way when labor force participation by married women began to grow in the United States in the 1960s. Before this period, the family was thought of mainly as a consumption unit spending income earned by the man of the family, who went outside the family to produce goods and services for the marketplace. As Albelda (1997) notes, this was the typical family arrangement of the white, middle-class men who founded the separate discipline of economics and increasingly professionalized it in the late nineteenth and early twentieth centuries in the United States and Europe.

Becker (1965, 1973) and Mincer (1962) developed a model of the family unit in which men who specialize in market work (at which they are assumed to be

relatively more efficient) and women who specialize in domestic production (at which they are assumed to be relatively more efficient) marry each other and maximize their joint satisfaction in a sort of trade exchange based on their comparative advantages. Each human needs both market goods and home-produced goods to survive (since the goods are substitutable but not perfectly so). If relative prices were to change, women and men would decide to trade different amounts with each other. The division of labor within the family (and the supply of family members' labor time to the market) can change with the male–female wage differential, changes in male–female productivity in housework, and the availability and quality of substitutes, all of which can be affected by technological change. Rising real wages, especially for women, would tend to lead women to work more outside the home, substituting market-based goods and services for their housework time. Fertility will decline as women will want to spend more time at market work and less at home production. Moreover, as technological change occurs and society becomes more complex, the quality of children (their education and socialization) becomes more important than their quantity. More market-based goods (more education and better food and clothing) can be combined with fewer children to yield higher quality output (children with more human capital). In this way the productivity of home production keeps pace with the growing productivity in market-based goods. In the several decades since its origins, the neoclassical theory of the family has been developed by the work of many economists carefully examining such issues as the allocation of time, the supply of labor, the development of human capital, population growth, and economic development.

The neoclassical approach views the household's role in the larger economy and society as the provision of labor to the market and the consumption of final products provided by the market. The household center (or factory) which performs these two functions combines market work, nonmarket work, and consumer products in an economically rational way: the mainspring of the system is the choice of individuals—who, faced with market options and given their own preferences and relative productivities, allocate their time and money accordingly. Thus, household production is the creation and maximization of utility to consumers in the household. It is assumed that the members of the household have harmonious interests which can be maximized by joint effort and decision-making (Hartmann 1974).

3. The Feminist Critique

Feminist economics challenges nearly every aspect of neoclassical economics. First, feminist economics challenges the limited role accorded the family or household, noting that caring labor is a large part of social reproduction and involves not only creating new

laborers by raising children and maintaining adult workers through daily care but also the care of those unable to work, not only the young, but also the sick, disabled, and elderly. Women's unpaid family work also includes maintaining kin networks and relationships, which provide a type of social insurance for the family. Women also contribute volunteer time to school, neighborhood, religious and community groups, which provide necessary services to family members, especially in countries without extensive welfare state services. Elson (1994) refers to all this crucial social reproductive work as the 'caring economy,' a term which brings its importance to the fore. The quantity and quality of the actual labor that takes place in the family is seldom examined carefully by neoclassical economists and thus the family portrait they paint is simplistic and incomplete. Too often women's caring labor is not seen as skilled work that must be learned but rather as an innate ability that women have, or as the manifestation of their natural affection.

Moreover, since in feminist economics caring labor combines affection and work, economic rationality and love, or its withering away, may dictate different 'choices.' A disabled child almost always requires more care and attention than an able-bodied one, yet investing more in such a child who most likely will be less productive hardly seems economically rational; such a 'choice' may be more a matter of affection and love than one of economic rationality. Economic rationality implies 'free' choice, choice that is not fundamentally coerced even though it is faced with constraints. If love or affection has waned, even otherwise enjoyable activities like sex could become oppressive. Women sometimes stay on even in violent relationships because their alternatives seem so limited to them—can such behavior be deemed a free or rational choice?

Second, the neoclassical economics model assumes choice by individuals of different relative productivities exercising their individual preferences, but it fails to explain why domestic labor is most often performed by women. It offers no convincing explanation of why this would be so (other than to assert that women's and men's abilities and preferences differ markedly on average, an assertion that has not been proved). Moreover, one cannot just assume that men's and women's preferences are determined individually. Instead, social roles may rather be collectively determined or politically enforced to such an extent that it is difficult for an individual to express a different preference. Even in the present-day United States, where it is common knowledge that there is increased flexibility and diversity in family structures, a typical married mother may seem to make an individual choice to stay home and care for the children because her wage rate is lower than her husband's, yet the wages women and men face in the labor market are affected by societal norms, including discrimination

against women. As much as she might like to work, given her wage and the cost of childcare, she may have no individual choice to make. Also, the neoclassical model assumes that on the margin men and women can make individual decisions about time allocation, and that an individual could choose to work 33 hours per week, or 17 hours, or 51. In practice, the 'choice' of the number of hours of work is also largely socially determined by the convention of the 40-hour work-week as full-time work. And in some countries, for the most part only full-time jobs come with all the fringe benefits (health insurance, unemployment insurance, and pensions) that families need. Such benefits are difficult to get elsewhere.

Third, it is hard to see whose utility is being maximized, since nothing in economic theory suggests that two adults often have identical utility functions. Sometimes neoclassical economics seems to assume a joint utility function; at other times the possibility of altruism enters, in which, for example, the male head makes altruistic decisions within the family but acts in a completely self-interested way in the market place. In reality it is most logical and quite common that men and women in families often have different interests, preferences, and utility functions, as do parents and children (Hartmann 1981, Folbre and Hartmann 1988, Woolley 1999). Neoclassical economics does not deal well with the possibility of serious conflict in the family.

Fundamentally, feminist economists challenge this model because it justifies the status quo of the gendered division of work, labor and care within the family. It assumes that women are disadvantaged socially, have less access to the economic resources of good wages and property, and are often oppressed by individual men. It, therefore, hides what feminists are most interested in explaining. As Galbraith (1973, p. 25) has put it, neoclassical economists have made the concept of the household 'a disguise for the exercise of male authority.' Albelda (1997, p. 119) writes: 'At the most fundamental level, neoclassical economics argues that women receive lower wages than men and perform more unpaid labor than men largely out of women's and men's own rational choices and desires.'

4. Marxist Domestic Labor Debates and the Feminist Critique

A debate about the unique aspects of production in the home took place within the Marxist economic school of thought in the 1970s, but it was never resolved. Does housework, like wage work, produce surplus value that is appropriated both by capitalists (who can pay workers a lower wage than they otherwise could) and/or by husbands (who appropriate personal services and who have a higher standard of living than they would otherwise)? Does home production constitute a separate mode of production, a feudal mode,

directly appropriated by the lord of the house, rather than a capitalist one based on wage labor?

As Himmelweit (1999) notes in a useful review, this debate was part of a feminist attempt to use Marxist economics to identify the material base of women's oppression. Since the Marxist framework gives prime attention to production, housework (i.e., the unique work of women) was scrutinized. Thus, earlier than in neoclassical economics, the actual content of housework was studied and theorized, but just as in the neoclassical domain, the role of housework had to be discovered by women. Just as the first neoclassical 'new home economics' treated the family as an unexamined black box with a unitary utility function, early Marxist analysis of the family generally suggested that the reproduction of the working class could safely be left to itself (i.e., to the invisible labor of women in the home). Since then the concept of housework as production has been firmly established and the importance of the changing nature of the boundaries between the spheres of domestic production and market production is understood everywhere. But the feminist critique also established that what is unique in women's work in the home to reproduce the next generation is 'its caring and relational aspects' (Himmelweit 1999, p. 133).

5. The Development of a Feminist Model

Using aspects from three major streams of economic thought, namely the neoclassical, institutional, and Marxist approaches, Table 1 describes the attributes of the 'traditional neoclassical; model of the family (or economic decision-making more generally) in column 1. The table also shows how they are modified when institutional perspectives and feminist critiques informed by Marxist and institutional economics are added. (The table has been adapted from Nancy Folbre's (1994) much cited *Who Cares for the Kids?*) In column 2 it shows that neoclassical institutionalists modify the simple model and emphasize that rules, norms, and preferences are not all exogenously given but are at least partially endogenous. As Folbre notes, it is often easier to act based on norms and on what everyone else is doing than to calculate each decision

anew. Individuals also sometimes act collectively. Folbre argues that these modifications come largely from institutional economics, which rejected both individual choice and Marxist class analysis and instead emphasized group behavior by voluntary interest groups, such as labor unions (Figart and Mutari 1999). This model notes that a transaction can involve bargaining and cooperation (based on love and affection) as well as simply buying and selling at fixed prices, particularly within the family, where there are no fixed prices at which a wife can sell her home-produced services to a new husband. Maximization of self-interest exists side by side with altruism in real life. One fruitful area of feminist research within this modified neoclassical framework is the use of game theory and models of cooperative and noncooperative bargaining to elucidate gendered outcomes in the family. (See Seiz 1999, for an overview, critique, and suggested extensions of this work.)

As the third column in Table 1 shows (the 'stylized feminist' description), not only are rules, norms, and preferences structural, but so are the assets with which the different parties begin the transaction. Using the concepts of material base and unequal ownership of assets from Marxist economics, feminist economists note that the genders do not come to the playing field as equals. Feminist economists also note that individuals do not choose all their group memberships, as the institutionalists often assume; many such memberships are assigned at birth. And, as in Marxist economics, important economic transactions are likely to involve coercion and production as well as cooperation and exchange. The relational aspect of caring is captured in the process of cooperation. Thus, in this example of a feminist model, the traditions of neoclassical, institutional, and Marxist economics are all challenged and incorporated in changed forms.

6. Impact of the Critique from Feminist Economics

The emergence of common elements of feminist approaches, from whichever economic framework they start, has contributed to a considerable policy impact of the feminist economic critique. The rec-

Table 1
Models of choice/action/collective identity

	Traditional neoclassical	Neoclassical institutionalist	Stylized feminist
Factors	Rules, norms, preferences (exogenously given)	Rules, norms, preferences (partially endogenous)	Assets, rules, norms, preferences (structural)
Agents	Individuals	Individuals, voluntary groups	Individuals, chosen groups, given groups
Processes	Exchange	Exchange, bargaining, coordination	Coercion, production, exchange, coordination
Sites	Markets	Markets, social institutions	Firms, states, markets, families

ognition of the different work, interests, and utilities of wives and husbands, mothers and fathers, and the durability of unequal gender relations within the family, has informed the policies of economic development and family planning around the world. The success of these policies requires an understanding of women's roles in the family and nonmarket production. Empirical research has shown that mothers use economic resources more for the welfare of children than do fathers both in more and less advanced countries.

Hence empowering women through education and employment is thought to be the surest way to improve the health and education of children and to raise a country's productive capacity in the long run. More economically conservative structural adjustment policies, often fostered by international financial institutions to curb inflation and public deficits, seek to shrink the public sector and lessen wage demands. These policies have been shown to have disproportionately negative impacts on women, who try to make up for the lack of market wages and government aid through more intensive unpaid work. The limits of women's ability to absorb the costs of adjustment necessarily limit the success of these and other macro-economic policies. Feminist economic analysis has led to the understanding that integrating women into paid work or into production for market exchange is not sufficient to overcome gender roles that remain unequal in the family, nor is it enough to call for more grassroots activism to allow affected women to participate in policy discussions (Bakker 1999). It calls instead for 'gender mainstreaming' or putting gender issues at the center of policy changes everywhere, including in international agencies such as the FAO, ILO, and UNDP.

National and international statistical efforts have also become informed by the feminist economic critique of the family model. For the first time, the UN Platform for Action from the Fourth World Conference on Women held in Beijing in 1995 endorses the measurement of all unpaid labor activities, including those for own consumption in the household (i.e., housework). It also endorses their inclusion as satellite accounts in the System of National Accounts for each country (Vanek 1996). In its 1995 *Human Development Report* the UNDP for the first time included measures of work-time, covering both paid and unpaid time, for women and men. Its data for 31 countries show that everywhere women work more hours than men. Beneria (1996) has called for the continuous collection and analysis of such data from all countries to better measure the effects of policy changes, such as structural adjustment policies. In the United States, the Bureau of Labor Statistics is considering a regular, periodic survey of time use (Committee on National Statistics 2000).

Feminist economists call for new measures of family poverty that challenge the assumption of income

pooling and equal sharing within the family (Shaw 1999). In the United States feminist analysis of poverty, single mothers, and welfare reform calls attention to the similarity of women's income packaging strategies across class—women package income from men or other family members, their own labor market participation, and government programs (such as welfare, unemployment compensation, or social security). Just as most middle-class married women now work both inside the home for no pay and outside the home for some pay, most mothers who receive welfare or welfare-state benefits do not rely on it alone but combine income from paid work and from other family members with their government benefits. But we still know too little about who controls income within the family and how resource allocation decisions are made (Spalter-Roth et al. 1995).

7. The Growth of Feminist Economics

The establishment of a list serve for feminist economists (Femecon-L) in 1991; the formation of the International Association for Feminist Economics (IAFFE) in 1992; its annual conferences held in diverse locations around the world; its regular presence as the sponsor and co-sponsor of sessions at the annual meetings of the Allied Social Science Association in the United States and in many other associations in many countries; and the founding of its journal, *Feminist Economics*, first published in 1995, have all contributed to the growing visibility of feminist economists and their ideas (Shackelford 1999). As is characteristic of so much other growth in social science in the past several decades, the development of feminist economics is distinctly diverse in method and approach, distinctly international in scholars, and distinctly global in its impact.

Family Theory: Role of Changing Values

1. Introducing the Issue

This article is about the significance of changing values in understanding demographic behavior. Questioning the significance of values may seem odd since in everyday life few people would doubt that values are important. Among social scientists, however, the issue of values still evokes feelings of ambivalence and controversy. Three issues that we think are pertinent to a sociological understanding of the significance of values in family research will be broached. First, the significance of values as such is dealt with, including a discussion of the concept of values. Second, we argue that if values theory is to play a role in family research, it should be able to complement other types of explanations as well as to have an intrinsic quality to explain demographic changes both at the individual and the societal level. Finally, two types of values theories, that is socialization and role theory are merged into one framework that highlights the dynamics of the values-behavior relationship.

A note on terminology: although logically one should write about 'value theory' (without the -s) the plural form 'values' is preferred because 'value' and 'values' are distinct concepts similar to 'medium' and 'media.' In writing about 'values' the totality of values is referred to as ideational factor, and not to 'value' in the sense of the worth of an object.

2. The Significance of Values

In general three types of attitudes toward the concept of values can be found among social scientists: denial, trivialization, and emphasis. Probably the most radical type of denial of the 'significance' of values is to refuse to give any role to 'values' altogether. In most economic theories for instance, 'value' (without the 's') enters the picture as a synonym of 'price.' 'Values' as a cultural factor are rarely considered. This is especially true for neo-classic economists (cf. G. Becker 1981). If ideational factors are allowed in economic models, it is often in terms of tastes, preferences, or needs, and not in terms of values in a sociological sense of the word (cf. infra). But even in sociology some approaches (e.g., structural theories) are notorious for denying the significance of culture (Thompson et al. 1990). Among approaches that explicitly give credit to

a cultural argument, several also raise doubt whether the concept of values is needed in the study of culture and social change (Adler 1956, Blake and Davis 1968; see also J. F. Scott's phenomenological approach (Cancian 1975). They question the usefulness of the concept of values in causal explanations because values can only be inferred from behavior itself or from specific norms and goals. Hence, in this view a direct explanation of human behavior by reference to values is a sociological tautology. Although these critics differ in opinion regarding the type of cultural factors that are significant, they all deny the significance of values.

Trivialization of values may manifest itself in several ways. Values may be trivialized by 'explaining it away,' that is by arguing that values are merely spuriously related to behavior. Such a view is congruent with the former critics regarding the tautological nature of any values explanation of behavior. Values may also be trivialized by making them a 'constant' or 'exogenous' factor in explaining behavior. Within rational choice theory the exogenous character of values is explicit: assuming that there is a rational actor is implying that 'rationality' is a natural characteristic rather than a cultural construct. Defining values as an exogenous factor or arguing that values are merely spuriously related to behavior is minimizing their role. However, maximizing their importance can also lead to trivialization. This is illustrated in the work of Parsons (1937) who—perhaps ironically enough—protested strongly against the aforementioned 'natural science' kind of attitude toward values. Parsons' own functionalist approach to values, however, can also be criticized for having an intrinsically trivial nature (Spates 1983). Part of the trivialization is due to the teleological conceptualization of values within the Parsonian tradition: 'a value is a conception...of the desirable which influences the selection from available modes, means and ends of action' (C. Kluckhohn, in: Parsons and Shils 1951, p. 395). Values determine behavior by definition. By consequence, the question whether they do so is irrelevant. Spates (1983) raises a second caveat, that is that Parsons' values theory faces the problem of deductive imposition by arguing that values can only be deduced by a careful theorist. Hence, observable reality is forced into accord with a preconceived model. Although theoretically values are emphasized, empirically they are trivialized. Dropping the element of action probably leads to a less trivial conceptualization.

The empirical tradition of studying values by definition emphasizes the significance of values. Conceptualization of values, however, has not proved to be its strongest point. Many researchers do not hesitate to use the concept of values implicitly in their work, assuming a mutually intuitive understanding of the concept. Others have claimed that the empirical tradition merely added to the conceptual confusion rather than anything else (Lautmann 1971). Although

there is a grain of truth in these claims, it is felt that they tend to exaggerate divergence. Within the ideational approaches of the concept of values, there is a tendency to fit in with two traditions. ('Fitting in' does not mean that scholars fully subscribe to the conceptualization within a tradition, but rather that they share its point of departure.) The Parsonian tradition has already been discussed in the preceding section. Researchers working within this framework seem to agree with Kluckhohn's idea that values are 'conceptions of the desirable.' The second tradition was initialized by the social psychologist Rokeach (1968, 1973), who explicitly opposed the Parsonian concept of values. Instead he argued that 'a value is an enduring belief that a specific mode of conduct or end-state of existence is personally or socially preferable to an opposite or converse mode of conduct or end-state of existence' (1973, p. 5). The major advantage of this definition is that it tries to avoid letting issues open to empirical questioning—such as reference to action—constitute elements of that definition. Presumably, this is one of the reasons why the two values theories that will be discussed in the last section adopt a similar concept of values. Nevertheless, one could interpret Rokeach's concept of values as being a conservative force since they are defined as enduring beliefs. Although socialization theories (cf. *infra*) tend to agree with the latter statement, Rokeach himself has pointed out that complete stability is not at issue. To avoid misinterpretation it is suggested the adjective 'enduring' is dropped from the nominal definition.

In spite of these arguments several researchers still reject Rokeach's definitions and prefer Kluckhohn's conceptualization (Mohler 1987 and Miceli and Castelfranchi 1989). This merely illustrates that both traditions are competing.

It is obviously important to distinguish 'values' from other ideational factors (Rokeach 1973, Cancian 1975, Fishbein and Ajzen 1975, and Miceli and Castelfranchi 1989). In family research, three such factors seem important, namely, norms, attitudes, and intentions. Especially the latter two concepts have received much more attention than values in studies of demographic behavior. Since there is little agreement on the meaning of these concepts a view is presented on the major differences. 'Values' and 'attitudes' differ because attitudes are more 'object' and 'situation specific' and because values are of a more general nature. Intentions are even more object-related. Consequently, an 'organization of attitudes' transcends the specificity of each attitude and may be interpreted as a 'values orientation.' Analyses of the European and World Values Studies often adopt such a strategy (Ester et al. 1993) by collapsing scores on different attitudes into one or several values dimensions. Hence, attitudes and values are strongly related. Intentions, on the other hand, are more closely related to behavior. For that reason measured intentions are often modeled as dependent variables as an alternative to indicators

of behavior in values research (Inglehart 1977, 1990). At least Fishbein and Ajzen's theory of reasoned action (1975) demurs at such a point of view. Instead they argue that the best predictor of behavior is the intention to do so. A second difference between values on the one hand and attitudes or intentions on the other is that the latter are individual predispositions, whereas values may also be characteristics of depersonalized entities, as in 'the values of the working class.' In such a connection values bridge the gap between attitudes and norms. Norms prevail at the society or macro level as products of cultural inheritance. They refer to prescriptions of how to behave. In fact they include sets of (normative) rules. Internalization of these rules may define values orientations.

3. The Role of Values in Family Theory and Research

The values argument belongs in a broader context concerned with the role of culture in social demography. As far as family research is concerned, one cannot 'neglect' noncultural types of explanation. One should not ignore the impact of G. Becker's New Home Economics (1981) and R. Easterlin's Social Deprivation Theory (1976, 1980) in explanations of demographic change in recent decades. Pollak and Watkins (1993) recently summarized the various perspectives on how cultural approaches relate to economic perspectives and argued that cultural and economic approaches are compatible when they are consistent or equivalent to one another or when cultural explanations attempt to specify the scope of economic rational choice explanations. Preston (1986) and Lesthaeghe and Surkyn (1998) are referred to in particular on this issue. Similarly, Lesthaeghe and Moors (1994) and Lesthaeghe (1998) have demonstrated the usefulness of a frame of reference that includes the complementarity of theoretical perspectives in studying family formation (see *Family Theory: Complementarity of Economic and Social Explanations*). They argue that our understanding of demographic transitions may improve if we avoid rigidly adopting a single grand theory or aiming at enhancing the supremacy of one particular paradigm. Treating theories as distinct but not mutually exclusive views gives rise to a multicausal theoretical framework that can be used to 'explain' historical and geographical variations (Preston 1986, Lesthaeghe 1995) as well as individual differences (Lesthaeghe and Meekers 1986, Lesthaeghe and Moors 1994). Irrespective of these notions, Oppenheimer (1994) remains skeptical of researchers who rely exclusively on the idea that values influence behavior. In her opinion, they face the problem that there is little empirical research that actually tests the presumed causal effect. However, the little evidence that does exist supports

the theory of ideational change. Using panel data, Moors (1997)—on values—and Thornton and co-workers (1992, see also Barber 1999)—on attitudes—clearly demonstrated that ideational factors influence demographic behavior autonomously. Hence, the ability of values theory to complement other types of explanations, its intrinsic quality in explaining demographic changes, and its empirical merits lead us to conclude that values have a role to play.

4. Values Theory?

In empirical research on values two theories developed in the 1970s drew much attention, namely, Inglehart's socialization theory (1977, 1990) and Kohn's role theory (1977, Kohn and Slomczynski 1993). They produced an independent body of research and stirred controversy, but have gained prominence in later decades. In demography Inglehart's theory has been used by the researchers focusing on values (cf. *infra*) because the theory is founded on the notion of ideational change. There have been some modifications of Inglehart's argument, but its core has remained intact. It is founded on two basic premises. First, Inglehart argues that an individual's values priorities reflect his or her socio-economic environment, people attach relatively more importance to relatively scarce objects. This scarcity argument is complemented by a socialization argument that stresses the importance of experiences in the so-called 'formative years.' Inglehart assumes that—in reaching adulthood—values tend to crystallize in the personality. By consequence he 'predicts' a generational pattern of change in values orientations toward increasing preference for autonomy and consequent behavior. The idea that a process of social metabolism (i.e., the succession of generations with distinctive profiles) may generate social change was nothing new to demographers familiar with the work of N. Ryder (1965). By consequence, it has been a small step to link a generational pattern of values change with changes in behavior, for example, rising levels of cohabitation, independent living and divorce, an increase in single parenthood, etc. Inglehart's values theory primarily emphasizes that values influence choices people make. The possibility of reverse causation is not explicitly discussed.

Whereas Inglehart focuses on historical conditions during the formative years, Kohn claims that values are directly influenced by 'here-and-now experiences' at the workplace. In Kohn's theory, values play a mediating role in relating social structure to behavior. As such he primarily focuses on 'contemporary conditions' rather than historical circumstances. The key argument of the Kohn thesis is that the normative requirements of a job generate values orientations which are appropriate to the actual circumstances of

the job. Hence, the relationship between social class and values can be explained by referring to occupational conditions, that is the level of occupational self-direction. Generalizing this point of view one could argue that people learn to value characteristics that are appropriate to their conditions of life. In contrast to Inglehart, Kohn highlights the adaptation of values to changing conditions. At first glance, the theories yield contradictory propositions. On consideration, however, these theories can be reconciled because they bring together different mechanisms that generate values orientations, that is, values may be socialized (Inglehart) as well as learned by taking up social roles (Kohn). Furthermore, even their difference in locus regarding the issue of values stability and values adaptation need not imply contradiction. To Inglehart values influence behavior because values are relatively enduring characteristics of individuals. Although Rokeach (1973) holds a highly similar position, he also demonstrated within experimental designs that values may change due to strong 'incentives,' for example, dramatic or intense experiences (Ball-Rokeach et al. 1984). Kohn's theory suggests that—given the centrality of work in the life of people—the everyday experience in the workplace may induce such change. Consequently, Inglehart's notion of relatively enduring values orientations after the formative years is compatible with Kohn's argument about the significance of temporal occupational conditions. After all, important changes in the life-course may re-affirm values rather than altering them. Young people who value traditional family life may decide to marry for that reason, and may find affirmation of their opinion by the very experience of marriage itself. Hence, even stability forms part of a dynamic process. As a consequence, the key question is no longer whether values change after the formative years, but when (e.g., under what conditions) they do so. By the same token the dynamics of the values-behavior relationship becomes manifest. Values influence the choices people make and the consequences of these choices—in turn—re-affirm or alter the values these people hold. It is important to reconcile both these theoretical perspectives in demography since there is little doubt that changes in family life can be intense experiences. As the research of Thornton et al. (1992, see also Axinn and Thornton 1993) has demonstrated, both historical and contemporary experiences affect demographic transitions. Hence, a life-course approach focusing on the sequential and recursive relationship of values and demographic transitions is most appropriate.

G. Moors

Family Therapy, Clinical Psychology of

The origins of family therapy can be traced to the 1950s, although its historical roots go back further. Several largely independent movements that deal with relationships among family members contributed to the development of family therapy. The oldest of these is the marriage counseling movement while, later, a separate movement toward conjoint marital therapy developed within the psychiatric community. Family therapy emerged from a union of several seminal thinkers from a variety of backgrounds. The main factors influencing its development were the expansion of psychoanalytic psychotherapy to include a broader range of emotional disorders and the application of

psychoanalytic principles to the entire family; the investigation of the role of the family in the development of schizophrenia and other mental and physical disorders; and the growth of the child guidance movement.

1. Historical Perspective of Family Therapy

1.1 Evolution of the Field

Social work, psychiatry, and psychoanalysis in both Great Britain and the United States all made enormous contributions to the development of family therapy. In her influential book *Social Diagnosis* (1917), Mary Richmond was one of the first proponents of studying the whole family and its needs. At the same time, the dominance of the psychoanalytic model in the mental health field focused on the mother–child dyad as the source of psychopathology. This model, with its linear–causal attributions, blamed maternal deficiencies for any childhood disturbance. Adler became the first of Freud's pupils to openly challenge such an explanation of human behavior. He offered an alternative and more socially rooted theory of psychodynamics, organized child guidance clinics in Vienna, and counseled children, parents, and teachers.

By the 1930s, a strong community of analysts had developed in the United States. Among the most influential to emerge was Harry Stack Sullivan. He focused on interpersonal relations in his research into family dynamics of schizophrenia. By the time family therapy pioneers began to experiment in the 1950s, there was a well-established bias toward social explanations among American analysts. This trend was underscored by a paradigm shift that occurred with the development of *General Systems Theory* (GST). GST implies that family therapy is grounded in a set of assumptions about the interchange between individual, family and social processes, which operate according to certain principles that apply to all human systems (Bateson 1971). Family members are inter-related such that every individual affects each other, while the group as a whole affects the first member in a circular chain of influence, making every action in a sequence also a reaction.

1.2 Pioneers of the Family Therapy Movement

John Bowlby's work at the Tavistock Child Guidance Clinic in London during the late 1940s exemplifies the transition from an individual to a family approach. These beginnings of family therapy were tentative in that Bowlby felt he had to 'reassure' readers that family interviews were 'rarely employed.' However, family interviews prior to the initiation of treatment

became routine, and served as a major stimulus to the development of this new approach in the United States. By the end of the 1950s family therapy emerged as a connected movement whose members exchanged correspondence and visits, and began to cite one another.

Nathan Ackerman came to family therapy from the field of child psychiatry. His involvement in a study of mental health problems among the unemployed, along with other experiences, convinced him that both the environment and the psyche could influence emotional problems. Although family interviews began as an experiment for Bowlby, Ackerman saw this as the major form of treatment in child guidance clinics. He saw the family as the unit of diagnosis and treatment, and began sending his staff on home visits to study families.

In 1958 Ackerman published the first book-length treatment of family relationships, *The Psychodynamics of Family Life*. By 1961 family therapists met to prepare the way for the first joint handbook and to found a common journal, *Family Process*. In addition, John Bell's respected monograph, *Family Group Therapy* (1961), constituted one of the founding documents of the profession. Carl Whitaker, who is noted as the most brazen of the founders, is generally credited with having called the first formal meeting in the family therapy movement in 1953. As family therapy developed, he played an integral role, as evident from his membership on the first board of editors for *Family Process*.

Among the pioneers, Lyman Wynne was particularly well prepared by formal training to become a family researcher and therapist. After his medical training in 1948, he embarked on doctoral studies in the Department of Social Relations. As a graduate student, he came into contact with many of the leaders in the field of sociology, social psychology, and social anthropology. Initially, he saw whole families only when individual treatment or joint interviews with the mother and patient were not effective. Gradually, however, he worked out his own theory of the family structure of schizophrenic patients. Murray Bowen, a psychiatrist who specialized in schizophrenia, felt that the parents—in particular, mothers, should be required to live in the hospital with their disturbed child. In 1954 he joined Lyman Wynne at the National Institute of Mental Health, where he established a program for treating families together.

The Palo Alto Group has probably one of the strongest claims to have been at the forefront of the development of family therapy. This group consisted of five richly individual persons, viz. Gregory Bateson, Jay Haley, John Weakland, Don Jackson and Virginia Satir. Bateson, an anthropologist and philosopher by training, and considered by many as the founder of family therapy, wrote important works such as *Steps to an Ecology of Mind* (1971) and *Mind and Nature* (1979). Bateson and his group hypothesized that

family stability is achieved by a feedback system, i.e., whenever the family system is disturbed, it will quickly move toward reestablishing balance/homeostasis. In 1956 this group generated one of the most discussed papers in the history of psychiatry. In *'Toward a Theory of Schizophrenia,'* they introduced the concept of double-bind as the crucial familial determinant of schizophrenia in children. Jackson published a seminal paper on conjoint family therapy, arguing that it was more effective than seeing family members individually (Jackson 1959). At the same time he founded the Mental Research Institute (MRI), and invited Satir to join him. The MRI, compared to the original Bateson group, was more focused on the treatment of families as opposed to research.

The influence of behavioral family therapy can also not be overlooked as it was launched as a specialist area in the late 1960s with the seminal work of Stuart (1969) and Liberman (1970). Behavioral approaches to family therapy can be characterized as goal oriented, a general reliance on principles of learning, directedness in interventions, and preference for short-term, problem-solving involvement.

While the pioneers dominated the 1960s and 1970s, they also saw new innovations. One innovator who has taken his place among the founders as one of the most influential of all family therapists is Salvador Minuchin. In the late 1960s he became the director of the Philadelphia Child Guidance Clinic and convinced Jay Haley, among others, to join him. The Minuchin-Haley team made substantial clinical and methodological contributions. 'Structural therapy' emerged from their interaction, and will be discussed below. In addition to carrying over the communications and systems elements developed at MRI, Minuchin and Haley gave added emphasis to the realignment of counterproductive family coalitions, and tied their theory to a family developmental framework.

2. The First Family Therapy Models

The field of family therapy encompasses many modalities, each with distinctly different ways of conceptualizing and treating families.

2.1 Psychodynamically Oriented Family Therapy

Nathan Ackerman was among the first to integrate psychoanalytic principles with systems theory. He viewed individual functioning as a reflection of constant interactions between the individual, the family, and society. For Ackerman, understanding a person requires an understanding of their intrapsychic processes and interpersonal interactions. Achievement of this goal involves helping family members adopt social roles that are flexible so as to permit role complementarity.

Murray Bowen's *Extended Family Systems Therapy* expands GST beyond the nuclear family. Behavioral disorders are the result of a multigenerational transmission process in which progressively lower levels of differentiation, i.e., independence of self from others, occur as the family's lack of differentiation is transmitted from one generation to the next. The primary goal of therapy is to increase the differentiation of family members. Bowen regards family relationships as involving 'triangles,' and therapy typically includes only two family members (usually the spouses) while the therapist becomes the third member in a 'therapeutic triangle.' As long as the therapist remains objective and neutral (does not become emotionally triangled), his/her presence helps family members resolve the fusion between them and achieve higher levels of differentiation.

Contemporary proponents of psychodynamically oriented family therapy include Christopher Dare, John Byng-Hall, and James Framo.

2.2 Problem-solving Approaches to Family Therapy

2.2.1 Communication interaction approach. This approach to family therapy grew primarily out of research conducted by Gregory Bateson and his colleagues. They recognized the importance of communication in family and individual dysfunction (e.g., the role of 'double-bind' communication in the development of schizophrenia), and developed a school of family therapy based on the principles of communication. This approach incorporates principles derived from information theory, cybernetics, and GST. Family therapists adopting this approach accept a circular model of causality that regards a symptom as both a cause and an effect of dysfunctional communication patterns. Although therapists do not deny that individual intrapsychic factors underlie family problems, the observable interactions between family members are viewed as appropriate targets of therapy. The primary goal of therapy is to alter interactional patterns that maintain the presenting symptom(s).

2.2.2 Structural family therapy. Salvador Minuchin (1974) originally developed structural family therapy through his work with poor, inner-city populations. In his seminal work, *Families and Family Therapy*, he argued that symptoms are the result of family structural imbalances. Structural family therapy focuses on concepts that describe space configurations: for example, malfunctioning hierarchy and boundaries, and maladaptive reactions to developmental and environmental changes. Structuralists use the key notion of 'complementarity' to denote a fit among matching parts of a whole. Symptomatic behavior is

seen as one such part that fits into a dysfunctional whole/organization. For instance, an adolescent's anorexia nervosa may be related to a mutual invasion of the patient's and their parents' territories. In a dysfunctional family, development has been replaced by inaction. When a family is stuck in a rigid arrangement, they cannot solve their problems and continue to grow.

Breaking away from such an organizational impasse requires the mobilization of resources that the family already latently possesses and which are often apparent in a different context. Systemic change, in the structural view, equals an increase in the complexity of the structure—an increment in the availability of alternative ways of transacting. The function of the therapist is to create a context for the family to experience these alternative patterns as accessible, possible, and necessary. What the structural therapist is trying to build through his or her restructuring efforts is more important than what he or she is trying to uncover. The therapist does not emphasize individual change or the prescription of specific solutions. Instead, he/she attempts to reorganize the family structure, or increase its flexibility. Through parental leadership and the creation of clear subsystems and boundaries, more adaptive coping is promoted.

2.2.3 Strategic or systemic family therapy. In addition to the strategic and systems models of the Palo Alto group, other innovative early approaches were Jay Haley (1976) and Cloe Madanas' (1981) problem-solving approach, and the Milan team approach (Selvini-Palazzoli et al. 1978). Haley and Madanas are now most associated with strategic family therapy, which combines the communication/interaction approach with Minuchin's structural family therapy. Haley coined the term 'strategic therapy' when describing the techniques used by the psychiatrist Milton Erickson. Like communication/interaction therapists, strategic therapists emphasize the role of communication in maladaptive behavior, but their focus is on how communication is used to increase one party's control in a relationship. Whereas struggles for control are inherent in any relationship, they become pathological when one or both parties denies his/her intent to control the other person, and when this results in symptomatic behavior. Symptoms are thus seen as interpersonal phenomena rather than intrapsychic events. The focus in strategic therapy is not on understanding the source of problems, but on alleviating current symptoms through altering family organization, hierarchy, and generational boundaries.

The Milan team consisted of Mara Selvini-Palazzoli, Luigi Boscolo, Gianfranco Cecchin, and Giuiana Prata. Their book, *Paradox and Counterparadox* (1978), presented the conceptual framework

and methodology of their systemic family therapy. Stimulated by Bateson's writings (Bateson 1971), the Milan group radically revised their analysis of systems. Until this point, they had seen the therapeutic process as one wherein the therapy team observed the family system in order to understand it. Working as a team, utilizing a one-way mirror, circular interviewing, and employing systemic analysis to describe the family's interactional map, interventions were designed to ensure that the therapist remains separate from the family. This analysis and approach was labeled 'first-order cybernetics.'

Through revisiting Bateson's work, the Milan clinicians began to take into account the context of observation itself, and hence the observational system as well. In first-order cybernetics a distinction is arbitrarily drawn between the family and the therapist, as though they were two distinct systems. The Milan clinicians began to see the family in the context of the therapist's interaction with them. This new awareness included a second level of observation that parallels the first. This second level of observation is that of the system created by the interaction between the therapist and family within the therapeutic encounter. This second level observation was termed 'second-order cybernetics.' Instead of only studying the interactional patterns of family members, the feedback loops that develop between interviewer and interviewees were also considered.

3. Recent Family Therapies

The 1980s ushered in a new stage in the development of family therapy, in part inspired by the Milan group. First, an era of skepticism and a reexamination of the old, under the banner of postmodernism, emerged. Postmodern psychologies concern themselves with how people make meaning in their lives; how they construct reality. Constructivism (how an individual creates his/her own reality) and social constructionism (how social interaction creates reality) took hold of family therapy in the early 1980s and have since exerted a powerful impact on the field (see *Constructivist Psychotherapies*). Second, a movement to deconstruct established knowledge expanded in the form of feminist critique. This exposed the patriarchal bias in the assumptions and practices of many family therapies (Hare-Mustin 1986). Third, postmodern family therapy became more collaborative, which led to a cross-fertilization among therapists, as well as between therapists and families. Fourth, the mechanistic aspects of systems thinking have become less popular. Instead the focus has shifted to the stories that govern a family's life rather than its structure or interactional sequences of behavior. Fifth, postmodernists have become less wedded to universal patterns, and emphasize diversity and pluralism.

The result of this review has been the realization that a favored therapeutic approach may only be one of many useful approaches. The field of family therapy has also shifted its view of the family as the source of symptoms to a biopsychosocial view. From this perspective, assessment and intervention attend to the impact of biologically based conditions as well as larger cultural influences, such as race, class, gender, ethnicity, religion, and sexual orientation on the family. Family therapy today is characterized as having a resource perspective as opposed to concentrating on deficits within the family. It has also shifted from a model of the therapist as expert to one of respectful collaboration with family members. Assessment and intervention have shifted their emphasis on problems and how they are maintained to the attainment of solutions (Walsh 1993).

3.1 Postmodern Approaches

Growing out of the strategic/systemic models, the post-Milan or 'second-order' family therapists invented techniques to engage families in 'conversation' about their problems; these are known as narrative (White and Epstein 1990) or conversational approaches (Anderson and Goolishian 1988). These therapies are based in constructivist and social constructionist views of reality. Normality is viewed as socially constructed. In narrative therapy, for instance, the therapeutic conversation and process of 'restorying' a problematic experience is emphasized. The goal is to envision optimistic life stories that are more empowering and satisfying. Another constructivist approach that has gained popularity is Steve de Shazer's solution-focused therapy (Berg and de Shazer 1993). This is similar to the narrative approach in that it uses leading questions to separate clients from their problem-focused stories. The therapist is affirmative in that he/she deconstructs the problem story by having clients focus on exceptions, i.e., times when their problem did not occur. No judgments are made about the solutions a family may discover. Goals in these therapies are achieved by externalizing problems, focusing on future-oriented potential, and the search for exceptions and unique outcomes.

3.2 Psychoeducational Approaches

The psychoeducational model was developed for family intervention with schizophrenia and other persistent mental and physical illnesses (Falloon et al. 1984). In schizophrenia, for instance, family management of the illness has been demonstrated as effective in reducing levels of 'Expressed Emotion' and lowering rates of relapse. Family therapy, combined with drug maintenance and social skills training, has produced the best results by reducing relapse rates and improving functioning. The process of change is

facilitated through information and management guidelines, social support, and a respectful collaboration between therapist and family.

4. Research in Family Therapy

The roots of family therapy are in research, as many founders came to this field through studying interactional patterns associated with problem families. Initially, no distinctions were drawn between researchers and therapists, as research had direct clinical relevance, and hypotheses were developed and tested in clinical settings. The growth in research depended disproportionately on intuitive appeal as opposed to evidence. This research was mainly qualitative and impressionistic in nature.

Since the early investigations, research in family therapy has grown dramatically and undergone at least two major transformations (Sprenkle and Moon 1996). First, the field has evolved from an impressionistic to a quantitative emphasis. This shift forced family therapists to operationalize less well-defined concepts, and to develop more reliable and valid measures. The early decades were characterized by a strong push for outcome research and, although the scientific rigor of some of the earlier studies may be questionable, it did give credence to an emerging discipline. Second and more recent, a transformation that is characterized by a shift from quantitative methods to the incorporation of qualitative methods can be discerned. This transformation was facilitated by the advent of the new epistemology constructivism, or social constructionism. Linear causality, assumed by traditional quantitative research, has been replaced by more systemic thinking. Proponents of the second transformation argued that family therapy concepts were operationalized before being truly understood and, consequently, seemed removed from clinical reality. Therefore, the second transformation emphasizes the 'context of discovery,' i.e., the intricate subtleties of the therapeutic process, as opposed to the 'context of verification.' The integration of outcome and process research that has characterized the first and second transformations, respectively, has gained the support of family therapy researchers. The Maudsley group in London exemplifies this integration with their family treatment studies for eating disorders (Eisler et al. 1997).

This 'third transformation' in family therapy research is called pluralism. A pluralistic research community values and appreciates different inquiry paradigms, methodologies and designs, and encourages an atmosphere of understanding, openness, and tolerance. Methodological pluralism encourages research from a wide variety of perspectives, and increases the tools at our disposal for understanding family therapy processes and outcomes (Gurman et al. 1986).

5. Future Directions

Family therapy is generally effective, and family treatments that focus on specific problem areas have been shown to have positive and enduring effects. If treated systemically, problems with clear family relations implications show a greater likelihood of a good outcome. The growing *diversity* of families poses new challenges for the family therapy field. Culture, class, race, ethnicity, sexual orientation, and religion contribute greatly to family beliefs and practices (Falicov 1995). A broader definition of normalcy has to be considered if family therapy is to remain responsive to this pluralism. Recent shifts from action to narrative, and from challenging to collaborating, have opened new possibilities for doing family therapy. Family therapy has developed greater humility about the influences of existing theoretical models, diminished the need to prescribe to and change people, and increased trust in a family's own resources.

Farmland Preservation

One might think that the escalation of the world's population and widespread famine would supply an ample reason for the preservation of agricultural land in the better-off countries where agricultural production is also the most know-how-intensive and efficient. But in fact, wherever conversion to urban development is more lucrative than the income from farming, agricultural land is in danger of losing out, unless special public policies are installed. This almost axiomatic conflict means that farmland preservation is a concern of every industrialized country. The relentless expansive energy of cities often affects precisely those areas that are most attractive to farming.

But despite the importance of preserving agricultural land from a worldwide perspective, the stimulus for farmland preservation in advanced economy countries is increasingly tilting away from concerns about agricultural production *per se*, towards environmental, landscape heritage, and quality of life concerns for the urban residents. Bruce (1998) shows how the interests and needs of the farmers themselves have receded almost to disappearance in the discourse about farmland preservation, while environmental and quality of life goals have risen. Moreover: the very goal of preserving farmland is not beyond dispute. It is sometimes challenged by competing goals, some stemming from the changing economics of particular types of agriculture, others from social equity policies or overriding national priorities, such as the supply to affordable housing. In the countries across the Atlantic, such goal conflicts are more intense than in North America.

Beyond the shared characteristics among advanced economy countries, there are significant differences in the specific goals and means for farmland preservation and in the degree of success achieved. While focusing mostly on the USA, this article takes a cross-national view of farmland preservation goals, means, and outcomes in selected advanced economy countries (see Table 1). The author bases this article on research about farmland preservation laws, policies, contexts, and degrees of success in the USA, Canada, the UK, France, The Netherlands, and Israel, and in more general terms, also Germany and Sweden. For a detailed exposition see Alterman (1997).

1. Comparing the Contexts

The conflict over land use has much to do with degree of urbanization, economic well-being, population

Table 1
Comparative background statistics of selected advanced-economy countries, 1999

Country	Population (in millions)	Average annual growth 1990–2000 (%)	Percent of population Urban	GNP per capita (US \$ current prices)	Fertility rate per woman	Surface area (sq. km)*	Density (residents per sq. km)
USA	272.0	0.91	76	29,080	2.0	9,363,520	29
Canada	30.3	1.14	77	19,640	1.6	9,970,610	3
France	58.5	0.41	75	26,300	2.2	551,500	105
UK	58.5	0.22	89	20,870	1.7	244,100	240
Germany	82.1	0.41	87	28,280	1.3	356,733	229
Netherlands	15.6	0.55	89	25,830	1.5	40,844	378
Sweden	8.9	0.41	83	26,210	1.6	449,964	20
Israel	6.0	2.88	91	16,180	2.7	21,056	286

growth, and population density. In the advanced economy countries, where the Gross Domestic Product per person is relatively high, growing food for subsistence is not a major problem because there is enough wealth to supplement what is locally grown with imported food. Local food self-sufficiency is not yet an item on the agenda of most local land-use planning agencies, though some have argued that it should be (see Pothukuchi and Kaufman 2000). As a group, these countries contrast sharply with less developed countries or East European countries, where the figures for annual GDP per person would typically run in the hundreds or very few thousands. The advanced economy countries also differ significantly among themselves (see Table 1).

The USA and Canada are large countries and less densely inhabited than most European countries. In view of their sophisticated farming technology and know-how, the USA and Canada not only supply most of their internal needs for food and fiber, they are major food exporters on which many other countries depend. While these two countries share some aspects of farmland policies, they differ on others. Canada has by far the lowest population density among the countries surveyed. The US population density of 27 per square km, and Canada's 3 (only Australia and Iceland are Western countries with similar densities), are low compared to most countries across the Atlantic. Although most of Canada's land area is quite inhospitable climatically and its 8 percent agricultural land is concentrated along a thin strip along the US border, the area of farmland per Canadian is considerably higher than in the US.

Crossing the Atlantic brings us to a different world of generally smaller farms than in the USA or Canada, much higher population densities, and distinctly more compact cities. France, with a lower population density than most continental European countries, has 105 persons per square km, while at the other extreme The Netherlands has 378 persons. Israel, though currently less densely inhabited than the Netherlands, is in the long term the densest because it has the highest population growth and fertility rates among advanced economy countries.

Even though it has less farmland per person than North America, Western Europe faces a reverse problem: agricultural surpluses endanger the maintenance of price levels and have led the European Union to adopt policies of compulsory 'set asides' of farmland. These pose a clear challenge to the very notions of farmland preservation.

There is no agreement cross-nationally about the size of farming units that should be the target for preservation. In the USA, hobby farming by wealthy ex-urbanites is regarded as a threat to commercial farming. Europeans, who are concerned more with preserving the visual and environmental character of the traditional countryside, tend to focus more on encouraging 'family farms.' Although there is also a

concern in the USA with supporting the family farm, the status of such farms is probably more secure there than across the Atlantic in view of the much-larger average size of American family farms.

2. *How Public Awareness and Planning Policies Emerged*

In both the USA and Canada, farmland preservation gained public support only in the 1980s; later than in most Western European countries. The landmark US National Agricultural Lands Study published in 1981 arose out of this growing concern and propelled it further. That study found that farmland conversion increased almost three-fold between the 1960 and the 1970s, rising from 1.1 million acres a year in the 1960s to 3 million acres a year in the 1970s. In Canada, policymakers' awareness about the depletion of farmland came approximately at the same time as the USA, and the major provincial programs, Ontario, British Columbia, and later Quebec, ensued (Reid and Yeates 1991).

In the USA and Canada, policies and methods for farmland preservation were a relative novice to the land-use planning and implementation kit of tools. No prescriptive formulae with proven results existed in the professional literature or in practice. Farmland preservation was not part of the routine work of local or state governments; someone had to 'invent' them. In the USA, the process whereby these tools emerged and tested (which, incidentally, is quite typical of other areas of land-use planning and implementation) may be called a 'survival of the fittest' process whereby more successful local policies survive and gain national recognition. While such policies were being developed and disseminated sporadically across local and state authorities in the 1980s, several 'how to' publications appeared that collated the emerging 'kit of tools' for planners and decision makers (for a listing of these see Alterman 1997). Scholarly evaluation of the degrees of success and impacts of alternative techniques has taken longer, and the jury is still out about some of them. In the Western European and Israeli context, where regional and national land-use planning is generally better entrenched in national legislation and tradition (for a comparative analysis of the broader land-use planning contexts in these countries see Alterman 2001), farmland preservation methods may therefore have been more 'natural.' That is not to say that they were more successful. Along with the general de-legitimization of direct government intervention, gradual changes occurred in the type of tools used for farmland preservation.

The other side of the coin of farmland preservation is containment of urban development and prevention of sprawl. This concern arrived in the USA and Canada much later than across the Atlantic where

compact cities are the tradition. American planners had to invent a special term, 'growth management' (and since the mid- 1990s, also 'smart growth') to discuss what is a routine part of land-use planning in much of Europe. 'Growth management' describes an open-ended set of policies and methods to phase and control the growth of cities and suburbs and to rationalize infrastructure investments. This approach often also prescribes a more coordinated institutional structure for land-use and fiscal planning (several of many titles on growth management include De Grove 1992, Stein 1993, Daniels 1999. A full review of growth management and 'smart growth' law and policy is presented by I Kushner 2000). However, only a minority of US states has seriously adopted growth management policies and tools.

3. Farmland Preservation Policies

With 50 states and innumerable localities, generalization about US policies is difficult. When compared with the other countries surveyed, American farmland preservation policies are characterized by a rich variety, innovativeness, and capacity for experimentation, but usually with only lukewarm effects.

A distinctive attribute of American farmland preservation policies is that planners and policymakers usually view them as a package of tools that cut across policy areas. By contrast, in some of the countries across the Atlantic, there is or was a dominant method of preservation usually based on top-down control that restricted the authority of lower-level governments to grant permits for conversion of farmland. The American-style package of tools offers not only land-use controls directly regulating the conversion of farmland to development, but also a variety of other tools such as taxation and developer exactions.

Direct control of land-use conversion from farming to non-farming use seems to be the most intuitively obvious tool. However, it does not hold center stage in the USA except in a few states, foremost Hawaii and Oregon. The most stringent version, called 'exclusive zoning,' restricts all uses of land except for farming or farming-related construction, but it is the least common of farmland preservation tool in the USA (Coughlin 1991, American Farmland Trust 1997). It is more prevalent in the countries cross the Atlantic, and ostensibly the most restrictive in Israel. In all the countries studied, exclusive zoning has been receding in importance and effectiveness. Yet in Oregon, where it is a major tool and is applied on a statewide level through a state institution, it has been found to be reasonably successful (Howe 1993, Nelson 1992). Much more common across the USA is a more flexible form of farmland conversion control, called 'non-exclusive zoning.' It permits many other land uses and puts few hurdles before conversion. Usually applied

on the local and county levels only, its effect is often quite lukewarm (Coughlin 1991).

Another direct control method that is so characteristics of British and some other Western European land-use policies is an effectively regulated 'greenbelt' around urban areas (an in-depth analysis of British greenbelt policies and their effectiveness is by Elson et al. This approach is not as common or effectively used in the USA. For example, the city of Madison, a mid-size Midwest city, discussed such a concept but interpreted it as the designation of several narrow one to three-mile buffers in a few spots along the circumference to be used as golf courses.

The dominant tools for farmland preservation in the USA are those that focus on the economics of conversion rather than seeking to limit the permission to build directly. These tools hope to defer the time when farming will no longer out-power real estate, but not to prevent it altogether. Among the most common are property or other tax relief programs such as existing use appraisal rules (where farming land is assessed for its value for agriculture, even if its real estate value has risen steeply). Also common are tax deferral programs, sometimes associated, as in Wisconsin, with agreements drawn with developers to continue farming for a preset number of years. Most widely used by all states are the so-called 'right to farm' laws that provide farmers immunity from lawsuits for causing a nuisance related to agricultural work. However, fiscal means are only mildly effective because once farmers feel that it is lucrative to sell, they do not deter conversions (see Nelson 1992).

Another economic tool, minimum lot size ordinances, aims to discourage suburban housing and thus defer conversion by making the land too costly for most population groups. However, research findings have shown that it is difficult to determine what is a viable cutoff line (Nelson 1992). Florida's infrastructure concurrency requirements are intended to render development in outlying areas less lucrative, but in fact at times work in the reverse.

Property-rights based tools (for which the USA is probably the world leader) are a promising set that attempt to prevent development by buying up the very right to develop, or in effect, by compensating for the farmer's willingness to forgo the opportunity for development. These include 'land trusts' by public agencies or, most commonly, voluntary sector organizations that purchase the development rights or easements from farmers while farmers retain the right to continue farming (Endicott 1993, American Farmland Trust 1997). Transfer of development rights is potentially a superb 'made in America' tool. In an area targeted for preservation, development rights are 'purchased' by landowners in another area, tagged a 'receiving area,' who wish to increase their development rights. However, research has shown that this tool can be used only in very particular market and land-use situations, otherwise, it is ineffective (see

Pruetz 1997). A simpler tool that can be effective in some situations is cluster zoning whereby development rights are concentrated in one part of a larger land area (see Daniels 1998). Significant in their absence from the typical USA package of tools (but used very selectively in the other countries studied) are those whereby governments directly intervene in land tenure. They do this either through expropriation ('condemnation') of land, consolidation of lots that are too small for viable agriculture (prevalent in France), redistribution of lots that are too large, or most ambitiously, 'land readjustment' that redistributes development rights more justly while preserving targeted land (used in Israel in spot cases). Also rare in the USA but prevalent in The Netherlands is land banking as an instrument for timing the conversion of farmland.

4. Levels of Government and Legal Constraints

An important variable in the effectiveness of farmland preservation efforts is the level of government involved. From an international point of view, the USA stands out in the extreme degree of freedom held by local governments in most US states. Despite the 'smart growth' movement that has called for greater state action on land management, in most states, especially those in the heartland, the fate of farmland is still largely in the hands of local government or local civic groups. An important factor is the extensive self-incorporation and annexation powers held by local residents and local governments in many states. A majority of landowners in a particular tract of land who wish to annex themselves to an urban jurisdiction can initiate such a procedure. Although an urban municipality is empowered to refrain from rezoning agricultural land, local interests often achieve both annexations and rezoning.

In a few states, often called the 'growth management' states, the state government does play a major role in farmland preservation. Oregon, recognized as the flagship state for preservation, has developed an especially rich package of policies. Compared with the national rate of farmland conversion, Oregon has been quite successful through a combination of exclusive agricultural zones implemented by a special state-level commission, alongside policies for containing urban growth. But even this comparative success is limited to only a few farm-size categories, not all (as shown by Nelson 1992, Howe 1993). Hawaii is a second flagship state. It is unique in that it has full statewide zoning, including agricultural, that covers approximately half the state. But Hawaii has been only mildly successful in preventing conversions to urban use and, indeed, the conversion rate has doubled as the farm economy faltered (Callies 1994 describes the Hawaiian system of land-use

controls. Empirical findings can be found in Ferguson and Khan 1992). Most states do not have state-level agricultural zoning. The Wisconsin tax relief and agreements program, while less illustrious than Oregon and Hawaii's, is a more typical degree of state involvement. Research into its implementation in Dane County shows little effectiveness and rampant circumvention.

What of the US federal level? National-level involvement in farmland conservation in the USA has been strikingly weak when compared with other environmental areas such as air, water, wildlife, coastlines, and other environmental areas. An attempt to enact a Federal Land Use Act was aborted in the 1970s and never reattempted (see Kayden 2001). The almost nonexistent federal role in farmland preservation (on the books is the US Farmland Protection Policy Act of 1981 oriented to minimizing the extent to which projects initiated by the federal government contribute to farmland conversion, but it has been called 'another case of benign neglect' because of its failure in implementation; see Ward 1991) contrasts with the UK, The Netherlands, and Israel (but interestingly, not France), where legislation has given central government a major role (however, the contents of the preservation goals themselves are changing across the Atlantic as well; see Alterman 1997).

A major legal impediment to farmland preservation would be if a designation of land for farming use were to be legal grounds to claim compensation from government. In none of the countries studied across the Atlantic would denial of an application to convert farmland currently designated as agriculture constitute a good ground for claiming compensation. The USA is a possible exception, but even there, the likelihood of a successful claim is very small. The inherent fear of all American planners is the 'taking issue': the constitutional limitation on excessive regulation that might be ruled by the courts to be tantamount to a taking of property without just compensation. Since the law on this issue in the USA is perpetually inconclusive and farmland preservation has not yet come up directly before the US Supreme Court (Myren 1993), there is still uncertainty about whether total denial of marketable development rights on farmland could be ruled a taking. In the past, several scholars have expressed optimism that restrictions on development would not likely be regarded as a 'taking' so long as some economically viable use is left. However, the 1992 US Supreme Court decision regarding 'Lucas' (1992) may have made the situation somewhat more uncertain; see Mandelker 1993, Lazarus 1992. The court applies a severe *per se* rule to any situation where no 'economically viable use' whatsoever is left, but leaves the law vague regarding situations of near total takings. So long as agriculture is economically lucrative, past optimism has no reason to recede. But it might prove to be less secure if farming economics were to render the 'beneficial use'

assumption tenuous, especially since farmland preservation often involves additional strata of regulations regarding runoff water, soil erosion, fertilizers, etc.

5. *The Relationships between Methods and Degrees of Success*

Achieving effective preservation is apparently much more complex and elusive than simply selecting from among the set of tools outlined above. Research shows that there is little direct relationship between the degree of success in preservation and the ostensible stringency of the tool applied (the research findings are presented in Alterman 1997). The two greatest success stories in farmland preservation among the countries studied—The Netherlands and Britain—do not primarily rely on direct control of farmland conversion. Furthermore, success in preservation does not depend on the characteristics of the broader planning system. The UK and The Netherlands have planning systems that, within the European vintage, are very different from each other (for a comparative analysis of national land-use planning in 10 advanced economy countries, including those analyzed in this article, see Alterman 2001), yet both are very successful. Nor is success intimately tied with the question of whether compensation for ‘taking’ is due. Most of the countries surveyed—indeed, all but possibly the USA—do not grant landowners compensation rights for denial of development permission on farmland, yet they exhibit widely varying degrees of success in preservation. In the USA there are significant variations between states in degrees of success in preservation, even though takings law in its constitutional aspects, is basically similar.

What, then, are the secrets of success in farmland preservation? First, the laudable achievements of the UK and The Netherlands could not have come about had the doctrine in these countries continued to focus on the preservation of agricultural land *per se*. In both The Netherlands and the UK, the concept of farmland preservation today draws much less attention than in the USA and Canada, despite the former countries’ higher population densities and smaller area of farmland per capita. Rather, in the UK and The Netherlands (and belatedly in Israel) there has been an overt redefinition of farmland preservation as countryside preservation. Second, both countries have achieved this outcome through national level policies that are planning driven, shared and applied effectively by local and regional planning authorities, and are less reactive to incremental developer initiatives than in the USA. Third, the UK and The Netherlands focus on the containment of growth of urban areas through infill and higher densities, many times higher than those prevalent in most US cities and suburbs, even where ‘smart growth’ is adopted. Fourth, and perhaps

most crucially, in both countries, preservation policies enjoy wide public support among electoral constituencies. Finally, planning policies in both countries are intolerant of sporadic exurban initiatives. They centrally determine the number and size of local governments, and notions such as ‘bottom up’ annexation initiatives are unthinkable. By contrast, since the 1980s, France, though relatively successful in the use of higher densities, is slack on local government management capacity and on national and regional planning. Now that the old tenure related preservation mechanisms are becoming economically obsolete, France is likely to achieve only lukewarm success in preservation.

Our most distinctive success story, The Netherlands, demonstrates that reliance on agricultural land conservation can no longer assure countryside conservation. The two are separate goals: economics may at times unite them, but will increasingly dissociate them, and may even place them at direct odds with each other by making industrialized farming in buildings lucrative. Countryside preservation must be considered in its own right.

Fashion, Sociology of

While the word 'fashion' in English comes originally from the Latin *facere*, to make, in many European languages it derives from *modus*, to measure. Fashion can be said to be that which is understood as being right in a specific time and context. Its underlying

principal is revealed in the link between the *modus*-derivatives and the term 'modern,' with its original meaning of 'now' or 'for today.'

1. The Scope of Fashion

Knowing what is 'right for today' appears to be fundamental to all periods and societies. It was only at the turn of the twentieth century, however, that fashion became the subject of serious sociological study. Its universal nature taken as read, much has been made of its growing importance. People's lives have been increasingly affected in new ways, while more of the general population has the chance to follow fashion. Sapir (1931) contrasts fashion's functional irrelevance with its tremendous symbolic significance. This explains in part why fashion can affect so much. While usually expressed outwardly in clothing and adornment, there is nothing to prevent modes of thought, morals, art, and the like from being the equivalent of clothing fashions.

More recently, attention has been drawn to fashion's growing importance to the general population. Fashion was once a limited phenomenon, with very few in a society able to participate. In modern societies, however, increasing numbers have become conscious followers of fashion. Economic well-being has made it possible for the vast majority to participate in the 'fashion race.' Wealth is not the only factor, however; people also enjoy far greater psychological mobility, and the new form of communication it generates makes fashion more important today. In *Psychologie économique* (1902), Tarde coined the term 'inter-psychologie.' Society is the sum of people's mental condition in constant interaction. Free time and consumption become increasingly significant vehicles for such communication. New needs are born out of this mental interaction.

2. Fashion in Different Societies

Fashion's universal nature does not preclude strong variations in its social significance from society to society. Thus, Tarde (1903) differentiated between customary and fashionable societies. In the former, people see *custom* as governing their lives; they are more passionate about their country than about their period because custom prizes the past above all. In periods where *fashion* predominates, people are instead prouder of their era than their country.

Variations between societies are thrown up by different conditions. In economically stagnant periods, conventional stratification variables such as class and income are more decisive in people's lifestyles. In economically expansive periods, increasing importance is laid on fashion instead. Modern society is often contrasted with earlier epochs, and it is argued that

fashion's role has markedly increased, although many reasons are given for the change. An influential argument is that the differences in lifestyle of different groups have increased in number and scope, making it possible for people to exhibit their group's distinctive nature.

Simmel sees the 'need for distinction' and the 'need for union' as preconditions for fashion. Certain societies therefore lack the necessary motivation. Simmel (1904) here mentions that in fourteenth-century Florence, male dress was devoid of fashion. The 'need for union,' the need to express how certain groups were distinct from others with the help of fashion, was absent, and everyone could dress according to personal preference. Another of Simmel's examples was Venice at the same time. Again we find that fashion is absent from upper-class dress. Venetian aristocrats were ordered to dress in black so that the lower classes would not know how few they were. They did *not* want to differentiate themselves, and thus the 'need for distinction' that fashion requires was missing.

Variations in fashion's importance have also been tied to women's standing in society. According to Veblen (1899), it was woman's role to be a vicarious consumer; her consumption symbolized the man's wealth, and thus she became the vehicle of fashion. In Simmel (1904), however, we find an early formulation of compensation theory. Fashion acts as a safety valve. Deny women self-expression in other areas, and the only thing left for them is fashion. In fourteenth- and fifteenth-century Germany, the chance of personal development had increased, which, however, was denied to women. Rarely have more 'hypertrophic' modes of female dress been seen than in this period.

Simmel (1904) further explains fashion differences between societies. Fashion has two fundamental, symbolic functions: an ability to mark difference and an ability to express community. In many non-industrialized societies, the need for union is acute, while the need for distinction is weak. Simmel mentions certain African tribes who lacked both class differentiation and the concomitant need to signal differences. Where people in these societies want to note differences, it is often a matter of open hostility, which in turn is sterile ground for fashion. Given that fashion functions best where the distance between groups is otherwise only vaguely established, in instances where open hostility already exists, fashion as a sociological form becomes meaningless.

A similar argument can be found in König (1974), who identifies three different stages in society, each with a different type of fashion. The first significant historical change was the emergence of a fixed class hierarchy; at this stage, fashion is the preserve of an exclusive, feudal nobility. In the second stage, rigid differences between upper and lower classes are weakened; lower classes adopt the fashion of the elite, ultimately forcing it to alter fashion constantly to

retain its individuality. The third stage sees the development of egalitarian democracies and industrial technology. This modern form of society brings with it the spread of fashion through mass consumption.

3. *Fashion as a Process of Change*

Fashion prescribes what is 'the right thing' for 'now.' The question of what drives fashion's continuous changes has kept researchers busy, and a series of different theories has been given in answer. In Simmel's analysis of fashion we find a foretaste of many of the theories that were to follow.

The theory of *social differentiation* argues that fashion is based on class, the upper classes abandoning a fashion as soon as it is adopted by the lower classes (see Sect. 3.1). The theory of fashion's *internal dynamic* contends that changes are powered by an *Eigen-dynamik* in fashion (see Sect. 3.2). The theory of fashion as a manifestation of the *expression for other social change* is a variant of *spirit of the age* theory (see Sect. 3.3). Additionally, different *system theories* of fashion have been proposed, pointing to various factors, for example fashion producers, that accelerate the speed with which fashion changes (see Sect. 3.4). Theories of fashion as a *violation of convention* argue that fashion always breaks with the past, for example with prevailing conventions and fashions (see Sect. 3.5). Finally, there are theories of fashion as a channel of psychological and social *needs for expression* (see Sect. 3.6).

3.1 *Social Differentiation*

Many have stressed fashion's origins in class. The analysis by Veblen (1899) of patterns of fashion dispersal has become a classic. A fashion begins with the 'leisure class,' the group with most money. It is attractive to this class because fashion items cost a great deal more. By degrees the fashion spreads to the upwardly aspiring middle classes. Simmel (1904) also describes how fashion must constantly be supplied with new content if it is to give social expression both to similarities within groups and differences between them. To describe fashion's downward spread through society, the *trickle-down* model was adopted by Barber and Lobel (1953), who dismissed the argument that fashion is irrational as obscuring its connections with the economic system. Meanwhile, named for the imitation of the elite that brings in turn an alteration in elite habits, we have the *chase and flight* model and the *paper chase* model.

Bell (1976) follows Veblen in seeing economic competition as a force behind changes in fashion. Dress for the middle and upper classes is an expression of wealth. This wealth can take the form of *conspicuous consumption*, *conspicuous leisure*, and *conspicuous*

waste. To these, Bell adds his own category of *conspicuous outrage* to convey the fashion-setting class' conscious choice of clothing that does *not* conform with prevailing notions of good taste.

The theory that fashion is the means of social distinction for the upper classes in a hierarchical society has had great influence. Mimicry of social superiors and an urge to be different from 'inferiors' are often noted as the reasons for fashion's changes, while an individual's choice of style is seen as a significant means of securing his or her position in society. Such choices often establish their distance from those below them in the social pecking order, and express subtle distinctions of degree within one and the same class. Researchers who present other models often start from the theory of social differentiation, even if they distance themselves from its application to today's society. Some reason that the idea that fashion was the distinguishing mark of the elite was probably valid in the eighteenth and nineteenth centuries, but not today. It has been argued that the traditional upper class has lost its fashion primacy to be replaced, for example, by today's powerless elite. This new elite, termed *Divi* by Alberoni (1967), uses the mass media to present new lifestyles and new consumption.

3.2 Fashion's Inner Dynamic

Simmel's analysis included a further suggestion of what drives fashion. Fashion is made up of internal, conflicting forces that necessarily lead to change; it is distinguished by both differentiation *and* union, superficiality *and* profundity, freedom *and* dependence, individuality *and* imitation, destruction *and* construction, leadership *and* submission. Antagonistic forces are united in fashion in a way that ensures continual change. Nedelmann (1990) develops the idea of the inherently contradictory nature of fashion, describing its *Eigendynamik*. Fashion, by its nature, contains a stimulus for change derived from polar opposites. People like to imitate, thus spreading a certain fashion, but are equally drawn to differentiation. Imitation leads to the spread of fashion, while innovation and differentiation lead to its contraction. Nedelmann invokes Simmel, writing that the greater the degree of concord within the upper classes, the more frantic the search for imitation from beneath, and the more constant the search for new fashions by the upper classes. On the other hand, the more the members of the lower classes use style to differentiate between themselves, the less the upper classes are inclined to come up with new fashions. Fashion in this society thus has less significance.

Davis (1992) has also noted the ambivalence of fashion, and identifies its source in sexuality. Davis writes of a continuous dialectic in clothing between the erotic and the modest. Sellaerberg (1994) similarly stresses the significance of antagonism as a driving

force of change. Fashion reduces *and* creates complexity. It is a continuous break with authority, but its break is authoritative: 'this is what matters, for now.' In this contradiction one finds the motor of change.

3.3 Fashion as an Expression of the Spirit of the Age

A given fashion draws a line between the present and the past, expressing what is right 'for the day': fashion represents the present. This view is the basis for theories that fashion is the spirit of the age. Fashion not only grows out of the designers' world view, but also simply reflects a time. Laver (1937), who worked mainly on dress, drew up a fashion timetable for when an item of clothing is ahead of, of, or after its time.

Indecent	10 years before its time
Shameless	5 years before its time
Daring	1 year before its time
Smart	
Dowdy	1 year after its time
Hideous	10 years after its time
Ridiculous	20 years after its time
Amusing	30 years after its time
Quaint	50 years after its time
Charming	70 years after its time
Romantic	100 years after its time
Beautiful	150 years after its time.

Blumer (1969) approached fashion as an expression of the present. In interviews with designers intended to identify the stimuli that they felt influenced their creations, they mentioned trying to 'feel' what was current within art, literature, and public debate. World events left their trace in fashion. It has to express what happened at the time, it must be a 'Zeitgeist.'

3.4 System Theories

Davis (1992) differentiates between two types of sociological model used to explain the dissemination of clothing styles. The first, the *populist* model, centers on the consumer's role and the laymen's innovations in dress. Researchers who use the populist model study general consumption, for example, how groups such as teenagers, surfers, gays, skateboarders, or feminists set their own stamp on fashion. The other model is a *system* model. Some system models are predicated on the existence of established social centers for innovation, for example Paris or Milan, with their fashion shows, designers, editors, wholesalers, stylists, and so on. The fashion system is here seen as a closed circle of producers, distributors, and consumers.

Trickle-down theory has been criticized by system theorists because it does not focus on the complex

structures of organizations and marketing that channel and mediate the fashion process. Those who use a system model aim to analyze the influence of the different elements of the fashion system. One subject of controversy has been whether designers are creative interpreters or merely passive intermediaries in the commercially vital process of heeding consumers' wishes and reconciling them with the producers' requirements.

3.5 Fashion as a Break with Convention

The destruction of what exists and the construction of something new in the process are the elements that unite in fashion, according to Simmel. Researchers who today see fashion as breaking current rules usually identify groups other than the socioeconomic upper class as leading fashion. Campbell (1992) has criticized the class differentiation theorist's explanations and identifies different types of 'new': the new, the innovative, and the novel. The novel—new as different—is central to fashion as it breaks with what already exists. The necessary conditions for creating novelty exist in peripheral groups such as bohemians and artists. It is these groups who set fashion in motion, *not* an upper class. To argue that fashion is unconventional, however, is also to argue that fashion continuously re-establishes social conventions and social order. Blumer (1969) sees both similarities and differences between fashion and custom. In both cases it is a question of social ordering. Custom, however, is static or changes only slowly, while fashion is a constant creator of social order. In Blumer's argument, every fashion emerges from an intensive process of 'collective selection.' The alternatives that are ultimately selected become fashion in different areas. Fashion conjures order out of the vast jumble of possible styles where no objective norm can determine 'right' or 'wrong.'

3.6 Fashion as a Psychological and Social Expression

Psychologically oriented theories of fashion frequently center on general human needs such as the wish to be appreciated. It is often pointed out that people's need to display and strengthen their ego is particularly strong. Fashion has great shock value in the hunt for self-expression; it provides a tangible 'look at me.'

In a discussion of fashion as an expression of personality we can return to Simmel. Fashion makes it possible to express opposites. While conveying personality (paradoxically in the extreme imitation of the modern), it also offers the chance to *avoid* conveying individuality, and thus functions as the ego's 'iron mask.'

Fashion offers a means of psychological expression, but also a social expression of protest. People express

in fashion the impulses and wishes that are *not* sanctioned by normal social conventions. There is thus a constant tension between the more established 'domain of culture' and the marginal 'domain of fashion.' In fashion, young people express their stance through wearing what König (1973) calls a 'Gegen-uniform.'

The idea of fashion as a vehicle of social protest has been criticized, however. Protest styles are usually incorporated into fashion and exploited economically (Emberley 1987). Others argue that fashion's break with convention is actually a pseudodeviation. Although certainly defying convention, each break loses its original edge as soon as it is expressed in fashion (Wilson 1985).

Fashion has been interpreted as an expression of the search for a personal identity in an insecure world, and 'fads and fashions' as an expression of the worry that typifies our time. This has sometimes been interpreted as a negative phenomenon. Blumer (1969) thinks that the operation of fashion becomes natural in a changing world where people must continuously cut their ties with the past. Individuals are liberated from earlier models, and orient themselves towards the future.

4. Fashion's Cycles

Some researchers have been less interested in fashion's social dynamic than in an in-depth descriptive study of its cycles. Richardson and Kroeber (1940) use empirical data to identify six different formal aspects in women's dress taking, for example, the changes in length and width of skirts over 300 years. A number of researchers have followed Kroeber's empirical tradition, in which specific changes in fashion are seen to occur within a continuous cycle of longer periods. For example, Robinson studied beard fashions between 1842 and 1972 as time series analyses. To understand the elapse between the reappearance of the same fashion, Robinson argues that certain ground rules apply for fashion's cyclical changes, one being that as long as a number of people still follow a certain fashion, it prevents younger people from adopting it.

Fashion in this perspective is not born, but is rediscovered. Cross-cyclical changes receive particular attention as demonstrating sharp reactions to extreme styles. For example, the streamlined form's soft curves are contrasted with the ensuing period's particularly angular design.

5. Ambivalence Towards Fashion: The Vitality Unimportant

Fashion's symbolic significance has been contrasted with its lack of practicality. This has led many today to express ambivalence towards fashion, and there is a

tendency to legitimize it using functional arguments; the rational and practical is acceptable where the impractical is not. Function and symbolism can sometimes be reconciled in fashion, however. Aerodynamics has been described as a discovery of great significance for industrial design, and for a time all household appliances were streamlined. 'Streamlining' symbolized America's enlightened practice of throwing over old conventions to create a new and dynamic civilization. Those who chose, for example, a streamlined kettle, demonstrated that they also chose the rational, the future, the practical.

6. Fashion as Unpredictable

Increasingly, fashion's analysts have come to emphasize the inner dynamic in fashion. Individual theories are run together to reflect fashion's inherent contradictions: it is coercion *and* individual choice; it is social order *and* a break with social order; it is union *and* differentiation. The nature of fashion is seen as ever more complex.

There is a more simplistic perspective, however, common to those who base their interpretation of fashion on industrial products. Here one finds phrases such as 'the most thorough logic of planned aging,' and 'industry is based on extolling a perpetual neology.' Fashion, however, is to be found everywhere, not only in areas that are subject to commercial planning, while the aging of fashion is impossible to predict precisely, however much industry demands precise guidelines. The problems stem from fashion's most central characteristic: because it symbolizes 'now,' it can never be foreseen with any certainty. Fashion pinpoints what is right in the present, but the moment it can be predicted accurately, it is no longer a matter of fashion. The transient symbols of what is right for now can never be nailed down in advance.

A.-M. Sellerberg

Fast Food Enterprises

Fast food enterprises are companies that supply catering services on a fast turnover basis. The fast food sector comprises hamburger, chicken, pizza and other food outlets, coffee, pastry and icecream shops, ethnic food outlets as well as home delivery services for some of these. Many are franchised to international food chains. The rapid growth of this sector across cultural, national, and geographical frontiers has been taken, first, to signify fundamental changes in consumer

tastes and lifestyles, associated with changing family structures and employment patterns. Second, it is viewed as one of the most tangible features of cultural and economic globalization, marking the colonization by transnational organizations of one of the most important cultural terrains, namely what, how, when, and where people eat. Third, fast food enterprises seem to offer a prototype of the transition of the service industries from skill-based and people-based technologies to Taylorist and Fordist approaches which revolutionized manufacturing in the earlier part of the century. It is further argued that the fast food industry has become a paradigm for profound changes in the nature of contemporary societies. The term McDonaldization (Ritzer 1993–6) has been used to indicate the increasing dominance of the core principles embodied by the fast food restaurant in virtually every sector of society. Fourth, employment in fast food has become the first ‘real’ work exposure for increasing numbers of young people, affecting subsequent work attitudes and experiences. Lying at the meeting point of work and leisure, fast food enterprises represent a vital area on which to develop and test theories regarding the formation of contemporary identities as well as the interface between customer and employee.

1. Rationalization

Numerous factors account for the spectacular growth of this sector since the late 1950s. These include new franchising systems, pioneered by McDonald’s Ray Kroc, as well as broader social changes such as increasing participation of married women in the workforce, devaluation of housework, decreasing size of households, ever more hectic lifestyles, the greater importance of children as consumers, increasingly personalized and differentiated tastes in food, and ever greater consumer exposure to advertising images. All of these factors can all be seen as contributing to the success of ‘convenience eating.’ Above all, however, the success of fast food enterprises is often seen as the outcome of the belated rationalization of production, delivery, and marketing of a consistent, reliable, and inexpensive product. Writing in 1972, Levitt argued that fast food marked the industrialization of service, the application in catering of ‘technocratic thinking which ... replace[s] the high-cost and erratic elegance of the artisan with the low-cost, predictable munificence of the manufacturer’ (Levitt 1972, pp. 43–4). Taylorist and Fordist principles of management are clearly observable in the organization of the fast food service. These include a highly standardized and uniform product, routinized and fragmented food preparation procedures, highly rationalized technologies, and the employment of staff with virtually no catering skills and minimal training. Thus, Levitt views a McDonald’s retail outlet as ‘a machine that

produces, with the help of totally unskilled machine tenders, a highly polished product. Through painstaking attention to total design and facilities planning, everything is built integrally into the machines itself, into the technology of the system. The only choice available to the attendant is to operate it exactly as the designers intended’ (Levitt 1972, p. 46).

Rationalization in fast food enterprises extends into several other areas—the glamorization of their brands through relentless advertising, the systematic control of the customer through numerous discursive and nondiscursive practices (the location of outlets, menus, products, pricing, queuing, seating and waiting arrangements, background music, lighting, and outlet décor), and the organized attempt to control the emotional displays of the employees through the emblematic ‘service smile’ (Sturdy 1998). In all of these respects, fast food enterprises have moved rationalization far beyond Fordist and Taylorist regimes. Ritzer (1999) has argued along Weberian lines that excessive rationalization brings about the dissolution of magic and disenchantment. This leads to attempts on the part of producers to re-enchant consumption, by transforming their outlets into ‘cathedrals’ where fantasies are enacted—thus museums, cruise-ships, holiday resorts, theme parks, shopping malls, and even solid utilitarian institutions, like hospitals and universities, are gradually becoming arenas where consumers can fantasize, explore, experiment, and spend, after the model of fast food outlets. In a paradoxical way, then, attempts to re-enchant consumption are organized around the same rationalizing principles which account for disenchantment.

2. McJobs

Employment in fast food enterprises (‘McJobs’ in Ritzer’s expression) is characterized by extensive use of young workers, part-time employment, casualization, and high levels of staff turnover. Very few employees, including managers, view their work in fast food as anything other than short-term. Levels of remuneration are generally poor, as many employees live with parents or other relatives. Union representation is low, partly due to the casual nature of employment and partly because well-organized resistance of unions by employers. Job satisfaction is generally low, even by the low standards common in catering (Gabriel 1988). Discretion and individuality at work are very limited. While there is evidence that employees frequently break the rules even with the collusion of managers, this is most often in the interest of meeting demands from customers rather than in the form of resistance or self-expression. Gossip, joking, story-telling, day-dreaming, and some game-playing are all used as survival mechanisms.

Deskilling and control in fast food industries go beyond their counterparts in the manufacturing sector.

On the basis of fieldwork, Leidner (1993) and Reiter (1996) have argued that counter work entails extensive emotional labor (Hochschild 1983, Fineman 1993), a systematic attempt to control the employees' total emotional outlook towards the customers rather than simply their displays of emotion. While this argument has been contested, there is little doubt that much of the work performed in fast food enterprises combines low levels of skill with constant exposure to the demanding and critical gaze of the customer. Regular visits incognito by company inspectors add to the sense of constant surveillance. Interactions with the customers may not be scripted, but they are constantly monitored and assessed.

3. *The Consumers*

The high visibility of fast food enterprises, their restaurants occupying conspicuous positions in virtually every city and town, their logos, signs, and advertisements instantly recognizable, has made them an almost archetypal symbol of globalization. Some have argued that Americanization is a more appropriate term than globalization. Virtually all major fast food chains (including those associated with ethnic cuisine, like Mexican or Italian) originated in the United States, their products firmly developed on American food tastes. More importantly, fast food is symbolically linked to an American lifestyle, recognizable the world over, fast, informal, cool, fun, strong, reliable, open, modern, and democratic. The democratic quality of fast food is embodied in the orderly queues, the equal treatment of all customers, as well as well-publicized visits to outlets by celebrities, such as Prime Ministers, film stars, and tycoons, including Mr. Bill Gates, the world's richest man. The fun quality is highlighted by the ambience, the music, the smiling faces. The lifestyle symbolized by fast food outlets is especially attractive to children, who in many countries have been the consumer vanguard adopting fast food restaurants as their preferred venues for family entertainment. Fast food restaurants are not merely children-friendly places; they are places where the authority of the paying parent is diminished and replaced by an informal atmosphere of egalitarianism. The food has been prepaid, the tables have no heads to be occupied by the head of the family, the décor and music devised to mark the space as a space for children, where adults are welcome as long as they relinquish any claim to authority and discipline.

Based on a series of ethnographic studies of the growth of McDonald's in five East Asian countries, Watson claims that 'more than any other factor, ..., McDonald's success is attributable to the revolution in family values that has transformed East Asia' (Watson 1997, p. 19). The decline in family size, the weakening of extended kinship systems, and the erosion of

parental authority have all contributed to the considerable success of fast food in many developing countries. This has given rise to criticism of fast food as a type of American cultural imperialism, contributing, among other things, to the corruption of local traditions, the increasing uniformity of tastes, and the unstoppable growth of commercialization and consumerism. Watson and his colleagues observe unmistakable signs of cultural change brought about by the growth of transnational enterprises. An interesting example is the adoption of Western birthday parties in countries which neither celebrated birthdays nor even viewed them as significant dates. Moreover, they document evidence of direct resistance to the expansion of fast food restaurants ranging from rumor-mongering in Japan ('hamburgers contain cat-meat') to overt charges of antipatriotism leveled against fast food patrons in Korea. They conclude, however, that the impact of fast food on local cultures is neither wholly negative nor wholly one way. They observe that many local traditional restaurants have been forced to improve the standards of cleanliness, hygiene, and service in order to remain competitive against Western fast food chains. They also point at evidence of 'localization,' arguing that when an international institution is adopted by a new culture it is modified (occasionally as a token gesture) to suit local cultural and social conditions. While initially accepted as an exotic import, such an institution eventually becomes acclimatized to local culture. Some elements of fast food, like queuing, self-provisioning and self-seating, have been accepted, others have been modified. In Asian countries, McDonald's outlets are often turned into *de facto* leisure centers, coffee houses, and after-school clubs.

The charges leveled against the fast food business, however, go well beyond those of cultural imperialism. Some of these charges surfaced in 1994 during a well-publicized case in which McDonald's sued for libel two British activists who had published a pamphlet strongly critical of the company. This accused McDonald's of (a) causing widespread environmental damage, (b) exploiting young consumers through invasive advertising, (c) mistreating their employees, (d) causing unnecessary cruelty to animals, (e) promoting unhealthy eating habits, and (f) causing hunger in the Third World. The 'McLibel' trial became the longest trial in English history and was a public relations disaster for the company, spawning a much visited Website and becoming a focal point for antifast food activism. The verdict, handed down in 1997, amounted to a Pyrrhic victory for the company—the judge ruled that while some of the activists' allegations had been excessive, many were based on fact (Vidal 1998). In addition to giving the original pamphlet unprecedented publicity, the trial also had the effect of revealing the extent to which McDonald's resorted to litigation to silence its critics, resulting in further negative publicity for the company.

In spite of such incidents which indicate resistance to the fast food business on political, environmental, and cultural grounds, their growth appears unstoppable. The demographic, cultural, and employment factors which account for their early successes, if anything, appear to accelerate and spread to the newly industrialized countries. It appears that the major challenges to fast food enterprises in the future will come, first, from an increasing difficulty in recruiting casual, low-paid, young workers, and, second, from customer fatigue and the transience of fashions. It is quite possible that already some of the major fast food chains are losing customers to more up-market, fashionable, and at least temporarily alluring competitors.

Fatherhood

Fatherhood defines a biological and social relationship between a male parent and his offspring. In common usage, 'to father' means to impregnate a woman and beget a child, thus describing a kinship connection and allowing for the intergenerational transfer of wealth

and authority in a patrilineal descent system. Fatherhood also refers to a patterned set of parenting behaviors and reflects a society's ideals about the rights and obligations of men in families. In general, fathers (including biological fathers, step-fathers, divorced fathers, and father-figures) are expected to love, support, protect, nurture, teach, discipline, and control their children, though many men do not fulfill all aspects of this idealized role. The concept of fatherhood also generalizes to other social and symbolic relationships, as when Christians refer to 'God The Father,' Catholics call priests 'Father,' Germans speak of their native country as 'The Fatherland,' and Americans label George Washington 'the father' of their country. Fatherhood thus reflects a normative set of social practices and expectations that become institutionalized within the family, religion, law, and culture.

1. Cross-cultural Variation in Fathering

Although folk beliefs suggest that fathering and mothering entail behaviors that are fixed by reproductive biology, humans must learn how to parent much like they learn other social behaviors. In every culture and historical period, men's family roles are shaped by social, economic, and cultural pressures, resulting in unique fatherhood ideals and practices. Although women have been the primary caretakers of young children in all cultures, the father role has varied from virtually no direct involvement to active participation in all aspects of children's routine care, feeding, and protection.

Anthropologists have identified two general patterns of male involvement in domestic life across the world's societies—one intimate and the other aloof. In the intimate pattern, men eat and sleep with their wives and children, talk with them during evening meals, attend births, and participate actively in infant care. In the contrasting aloof pattern, men often eat and sleep apart from women, spend their leisure time with men, stay away during births, and seldom help with child care (Whiting and Whiting 1975).

Cross-cultural research shows that about half of the world's known societies have exhibited close father-child relationships, with contact typically increasing as children grow older. Compared to societies with distant father-child relationships, those with involved fathers are more likely to be peaceful and include nurturing deities of both sexes in their creation stories (Sanday 1981). Distant-father societies are more likely to have stern male gods, with groups of men routinely excluding women from community decision-making, demanding deference from wives, and engaging in competitive displays of manliness (Coltrane 1996). Higher levels of father involvement with children are thus associated with more intimate husband-wife relationships and more gender equality

in the society, whereas lower levels of father involvement are associated with more distant husband–wife relationships and more overt male dominance.

2. Theories of Fatherhood and Families

To understand cross-cultural variation in fatherhood and identify the essence of family, Malinowski (1929) developed a theory based on the ‘principle of legitimacy.’ Malinowski observed that in Western societies, families were organized around the authority of fathers, with patrilineal descent and patrilocal residence assuring the position of the male household head. In matrilineal Trobriand Island society, in contrast, Malinowski observed that fathers were virtual strangers living among their wives’ relatives, making few contributions to the family household and exercising little power. The important link was not between husband and wife as in Western societies, but between sister and brother, with the latter being the symbolic and actual head of the household. These observations led Malinowski to question the universality of the father-centered household pattern and the importance of biological fatherhood, suggesting an alternative focus on the legitimacy of children. To be legitimate, a child must be socially approved through a formal marriage that has taken place between his or her parents. Malinowski thus argued that the important focus was social fatherhood, (not biological fatherhood). The purpose of social fatherhood was attaching a child to a particular man (whether father or uncle), thereby securing a place for that child in the social structure.

Subsequent theories of family and fatherhood suggest that Malinowski’s formulation may have been too narrow, as well as containing some gender-biased assumptions (Coltrane and Collins 2001). Societies have existed where the majority of children are not born to mothers married to husbands (e.g., in the Caribbean Islands), and similar patterns are becoming increasingly common in urban centers of modern industrial societies. Malinowski’s theory focuses on connecting children to social fathers because this brings them legal and social status, but it ignores the possibility that children could gain that status from mothers. Since males usually control more wealth and exercise more political power than females, it has been more important for a child’s economic fate to be connected to a man than to a woman, but it is important to see how this pattern can vary under different social and economic conditions.

According to Collins’ (1975) conflict theory, a strong emphasis on legitimacy is most common in societies with high levels of male dominance. Non-marital birth (‘illegitimacy’) is punished most severely in societies where men have the most extreme monopoly on power. In medieval Arab societies, for example, if a woman of the harem had an illegitimate

child, she was punished by death, with the sentence carried out by the woman’s husband, father, or brother. On the other hand, if the father of the illegitimate child was powerful enough, the mother could have a reasonably honorable status as a concubine or mistress, and the child could grow up with a recognized social position. This pattern has been repeated in male-dominated societies throughout the world. In medieval France, for instance, one duke’s son was known as William the Bastard; later, after he founded the English throne, he was called William the Conqueror. Considering variations in male dominance, Collins (1975) argues that illegitimacy rules do not so much say *no child without an official father* as they say there should be *no childbearing woman who does not officially belong to a man*. Collins extends Malinowski’s legitimacy theory by conceiving of the family as a property system regulating three kinds of property: rights of sexual possession, economic property rights, and intergenerational property rights. Such approaches help explain how fatherhood ideals and practices maintain men’s dominance over women in both premodern and modern societies.

3. Historical Development of Fatherhood

Fatherhood has been linked to the exercise of family authority at least since Ancient Greece and Rome, but it has been fathers’ public lives—their work, political exploits, and heroic battles—that have been chronicled in most histories. Fathers have also been care providers and teachers in different cultures and eras, and recent scholarship documents such practices. Before the modern era, childrearing was a collective enterprise and most family matters, including father–child relationships, were ruled primarily by duty and obligation (Shorter 1975). Because men’s work as farmers, artisans, and tradesmen occurred in the family household, most fathers were a visible presence in their children’s lives. Men introduced sons to farming or craft work within the household economy, oversaw the work of others, and were responsible for maintaining harmonious household relations. The family home was thus a system of control, as well as a center of production, and both functions tended to reinforce the father’s authority (Griswold 1993). Though mothers provided most direct care for infants and young children, men tended to be very active in the training and tutoring of children, and most parental advice was addressed to fathers. Because they were moral teachers and family heads, fathers were thought to have far greater responsibility for, and influence on, their children than mothers (Pleck 1987).

As market economies took over from home-based production, the father’s position as head and master of the household and moral instructor of his children was transformed. Men were increasingly called upon to seek employment outside the home and their direct

contact with family members declined. Although men's physical presence in the home was diminished, most did not stop participating in family activities. In fact, the first 'new' fatherhood movement emerged in the nineteenth century as middle-class fathers helped their wives through childbirth, romped with their offspring, forged close emotional bonds with daughters, and worried about sons' vocations and education (Griswold 1993). As the wage labor economy developed, however, men's occupational achievement outside the household took on stronger moral overtones and men came to be seen as fulfilling their family and civic duty not by teaching and interacting with their children as before, but by supporting the family financially (i.e., being a 'good provider'). The middle-class home, which was previously the normal site of production, consumption, and virtually everything else in life, was transformed slowly into a nurturant child-centered haven set apart from the impersonal world of work, politics, and other public pursuits. The ideal of separate spheres for men and women—work for him and home for her—became one of the defining features of the late nineteenth and early twentieth centuries.

4. Recent Trends

By the middle of the twentieth century, mothers had become almost solely responsible for home and children. Separate spheres ideology and the popularity of Freud's ideas about mother-infant bonding led to widespread acceptance of concepts like 'maternal deprivation.' Though few researchers bothered to ask who besides mothers took care of children, some researchers focused on 'father absence,' worrying that single-mother families could not set firm limits nor provide adequate masculine role models for sons. These studies have been criticized for confusing father absence with poverty, and for adopting the narrow view that aggressive and unemotional masculinity was both normative and desirable.

Starting in the 1970s, psychologists and sociologists began to report that a new fatherhood ideal was gaining in popularity. Films and television shows celebrated men's love for children, even if the men they pictured were initially shown as comically inept. Most social scientists had assumed that men were not capable of, nor interested in, actual hands-on parenting, but research showed that, at least in laboratory settings, fathers could care for infants and young children (Parke 1996). Following an individual differences research tradition in psychology, studies tended to focus on 'sex differences' in parenting style. Fathers typically were found to be more likely than mothers to engage in rough and tumble play, to be more directive, to give more attention to sons, and to treat boys and girls in sex-stereotyped fashion. Fathers' unique play styles were found to enhance children's emotional and

social competence, in part because they forced children to self-regulate (Parke 1996). Other studies by sociologists and psychologists showed that men and women performed child-care in different settings and in conjunction with different activities. Women most often did child-care in the home and frequently were engaged in multiple household tasks while simultaneously attending to children's needs. Fathers, in contrast, were more likely to watch children in public settings (e.g., parks and playgrounds) and to take care of them as a sole activity. The conventional pattern was thus for child care to be an ongoing and taken-for-granted task for mothers, but a novel and fun distraction for fathers (Coltrane 1998).

In response to the women's movement and maternal labor force participation, many observers predicted that fathers would begin assuming responsibility for a larger share of parenting and other family work. Several decades of research, however, have shown that while men are doing more, women continue to do most of the housework, remain the child care experts, and serve as emotional managers for their families. In general, family divisions of labor become more gender-segregated upon having children, with men increasing, and women decreasing, their paid work hours, even though both tend to increase their hourly contributions to family labor after a birth. Mothers are still more likely than fathers to take time off from their jobs to provide continuous child-care, spending significantly more time than fathers feeding, dressing, cleaning, and watching young children. Studies find that mothers spend double the time of fathers in these activities, even though many men did increase the time they spent with preschool and school-aged children during the 1980s and 1990s (Parke 1996, Pleck 1997). Two-parent, dual-earner families tend to share the most, with increasing numbers working different shifts and alternating routine child care between them. Research shows that couples share more family work when they are both employed full time, their incomes are similar, they believe in gender equality, and there are fewer, older, and male children (Coltrane 2000).

5. Measuring Father Involvement

Most researchers now agree that what fathers do with and for children is more important than simple co-residence or frequency of father-child contact (Parke 1996). The most influential approach distinguishing among various types of father involvement was offered by Lamb and his colleagues (Lamb et al. 1985) who suggested three principal components of fathering: interaction, availability, and responsibility. Interaction refers to the father's direct contact with his child through care giving and shared activities. Recent measurement strategies in this domain pay attention to the form and content of interaction, distinguishing between play, instruction, and care-taking, and at-

tempting to assess the quality of interaction, as well as the time spent interacting. Availability is a related concept focusing on the father's potential availability for interaction, by virtue of being present or accessible to the child. Responsibility refers to the role the father takes in ascertaining that the child is taken care of and arranging for resources to be available for the child both inside and outside the home. This type of parental management is one of the least studied aspects of fathering, but is one of the most important (Parke 1996). Mothers remain child-care managers in the vast majority of households, but evidence indicates that at least some fathers are taking a more active role in this domain (Coltrane 1996, Pleck 1997).

6. What Difference Do Fathers Make?

As scholars pay more attention to fathers, we are beginning to understand what influence their involvement might have on child development and gender relations. We know that fathers' resources improve children's life chances. When fathers also share child care and housework with their wives, employed women escape total responsibility for family work, evaluate the division of labor as more fair, are less depressed, and enjoy higher levels of marital satisfaction (Coltrane 2000). When men care for young children on a regular basis, they emphasize verbal interaction, notice and use more subtle cues, and treat sons and daughters similarly (rather than focusing on play, giving orders, and sex-typing children). These differences between everyday and occasional fathering deserve further study, for they portend differential social impacts. Most studies show that children with actively involved fathers demonstrate enhanced intellectual and socio-emotional adjustment, as well as developing more balanced ego structures and gender expectations (Coltrane 1996, Parke 1996).

At the same time that many fathers are spending an increasing amount of time with their children, high levels of divorce and increasing rates of nonmarital childbirth are keeping other men away from children. In many industrialized countries, growing numbers of men rarely see their children and do not support them financially. In the US, for example, single-parent households are increasing rapidly, but only about half of children eligible for child support from nonresident parents obtain court orders for it, and only about half of those receive full payments. Both trends in fatherhood—toward more direct involvement and toward less contact and financial support—are responses to the same underlying social developments, including women's rising labor force participation and the increasingly optional nature of marriage.

Longitudinal research shows that children from one-parent households (usually mother-headed) are at greater risk for negative adult outcomes (e.g., lower educational and occupational achievement, earlier

childbirth, relationship problems) than those from two-parent families (Cherlin et al. 1995, McLanahan and Sandefur 1994). Debates continue over whether these outcomes are specifically attributable to the actions or inactions of fathers, and whether state support and community programs might ameliorate negative effects. Some commentators call for a return to tougher fault-based divorce laws and gender-segregated models of fatherhood, but others label such responses a reactionary backlash against women's increasing autonomy. Reinstating fathers as household heads and expecting only minimal direct domestic contributions from them is likely to maintain hierarchical structures both inside and outside families. Whether absent or physically present and doing little, the ability of fathers to stay aloof from daily family life is linked to patriarchal family authority and the reproduction of systemic male dominance. Fathers' performance of everyday family work, in contrast, is associated with more intimate husband-wife relationships, more democratic family decision-making, and more gender equality in the society. The twenty-first century will undoubtedly see a continuing struggle between various intimate and aloof styles of fatherhood, with profound implications for men, women, and children.

Fear Conditioning

1. Basic Terms

The pairing of an initially neutral stimulus (the conditioned stimulus—CS) with a biologically relevant stimulus (the unconditioned stimulus—US) comes to elicit a response (conditioned response—CR) that is usually but not always similar to the response previously associated with the unconditioned stimulus (the unconditioned response—UR). In fear conditioning, the US is an aversive fear-eliciting stimulus such as painful electric shock or loud noise, the CS is a neutral tone or light stimulus. The unconditioned and the conditioned response consist of changes on the subjective, the behavioral and the physiological level and include (in humans) enhanced subjective fear and responses such as freezing, changes in heart rate and skin conductance, the release of stress hormones, reduced pain sensitivity and startle reflex potentiation.

The development of the CR is based on the formation of an association between a neutral stimulus and a stimulus with innate biological significance (Rescorla 1988). Most studies involving fear conditioning have used cue rather than context conditioning, i.e., discrete CSs were presented rather than using the environment of the animal (e.g., the cage) as CS. In addition, delay conditioning where the CS terminates with the US rather than trace conditioning where the CS and US are separated in time were used in most studies. Fear can be viewed as a specific reaction to threatening stimuli. It can turn into an anxiety disorder when the fear becomes disproportionate to the stimulus that elicits it or when fear is experienced in inappropriate situations.

2. Mechanisms of Fear Conditioning in Animals

The psychobiological basis of fear conditioning in animals, especially rodents, has been well established (LeDoux 2000, Davis 1992, Maren and Fanselow 1993). When a tone is used as CS and electric shock as US, the auditory CS reaches the lateral nucleus of the amygdala from the thalamus or the cortex, probably depending on the complexity of the CS. When contextual stimuli are employed as CS, the hippocampus is also involved and transmits the signal to the basolateral and the accessory basolateral nucleus of the amygdala. The nociceptive US also reaches the

Figure 1

Fear stimuli proceed from sense receptor systems to the sensory cortex and/or sensory thalamus and then to the amygdala. There are three important connections efferent to the amygdala: (a) a projection from the central amygdala to the lateral hypothalamic area that mediates the autonomic components of the emotional response; (b) projections to the midbrain central gray region mediates defensive freezing and escape behavior and (d) a direct projection to the nucleus reticularis pontis caudalis modulates the startle reflex. (Based on Bradley Lang 2000 with kind permission)

lateral nucleus of the amygdala via thalamic and cortical pathways. Conditioning seems to require an intact lateral nucleus of the amygdala when cue conditioning and an intact basolateral and accessory basolateral nucleus when context conditioning is involved. The central nucleus of the amygdala receives input from the lateral and the basolateral nuclei and it projects to brainstem nuclei that initiate the expression of peripheral fear responses. Whereas the lateral or basolateral nucleus are thus important for the acquisition of the CR, the central nucleus is essential for the expression of the CR (see Figure 1).

The initial site of plasticity seems to be the lateral nucleus of the amygdala; however, thalamic and cortical reorganization have also been shown during fear conditioning (cf. Weinberger 1998). It is to date not clear if the memory trace is stored in the amygdala or if the amygdala only modulates memories that are stored elsewhere, e.g., in the cerebral cortex. If the

amygdala is inactivated during fear conditioning, no CR is formed. If the inactivation occurs after conditioning, then the memory trace is not abolished (LeDoux 2000). In addition, cognitive aspects of fear may involve other pathways.

3. Fear Conditioning in Humans

In humans, the role of the amygdala is less clear. In contrast to rodents, humans possess a much larger frontal cortex and it is likely that it takes over some of the functions that are related to the amygdala in rodents. Damage to the amygdala in humans, has, however, also been related to deficits in fear conditioning whereas lesions in the hippocampus have been shown to interfere with declarative learning and contextual fear conditioning (cf. Bechara et al. 1995). Most studies using positron emission tomography (PET) were unable to replicate the findings from animal experiments that assigned an important role to the amygdala in fear conditioning (for a review see Büchel and Dolan 2000). They instead reported activations in areas such as the hypothalamus, the thalamus, the cingulate gyrus, the premotor and the parietal cortex and, recently, also in the cerebellum (Fischer et al. 2000). Later studies, using differential conditioning paradigms, found some amygdala activation that was positively correlated with activations in the auditory cortex, the frontal cortex and the thalamus. An additional PET study used masked CSs and found significant amygdala activation with the right amygdala showing more activation with unaware (masked) and the left amygdala showing more activation with aware (unmasked) CS presentation. The notion that a direct pathway from the thalamus to the amygdala also exists in humans was recently supported by Morris et al. (1999) who showed that activation of the right amygdala in a masked conditioning paradigm was associated with activity in the superior colliculus and pulvinar but not with activity at cortical sites.

Several recent studies used functional magnetic resonance imaging (fMRI) to study fear conditioning in humans (for a review see Büchel and Dolan 2000). Probably due to the higher spatial and temporal resolution of this method compared to PET, amygdala activation was reported in all studies. In addition to the amygdala, the acquisition of a fear response created activation in the cingulate gyrus and the premotor cortex. Activation of the insulae has also been reported when painful stimuli were used as US. When trace conditioning was employed, activation in the hippocampus in addition to activation in the amygdala and cortical areas was noted.

Based on the observation that not all stimuli are equally easy to condition Seligman (1971) suggested that phylogenetically relevant stimuli such as snakes or spiders might serve as 'prepared stimuli' and be more conditionable than others. Subsequently,

Öhman (for a summary see Öhman et al. 2000) has shown that conditioned skin conductance responses to a prepared CS such as an angry face or a picture of a snake persist for a longer time (even when the presentation is masked) than when a neutral stimulus such as a picture of a mushroom is used as CS and combined with electric shock as US. Moreover, masked presentations of these stimuli also lead to the acquisition of conditioned responses suggesting that unconscious learning of these stimulus associations is possible.

More recent accounts of fear conditioning have emphasized the role of cognitive variables as well as genetic predisposition in the acquisition of fear (e.g., Davey 1995, Kendler et al. 1992). Part of this may be a cognitive bias termed covariation bias that suggests that aversive outcomes are overestimated in the face of fear-relevant stimuli (e.g., Tomarken et al. 1989). However, although these cognitive variables have recently been discussed extensively as important mediators of the acquisition of fear, the biases themselves can be acquired through conditioning processes and it is not clear to what extent altered cognitive processing precedes or follows the acquisition of fear.

4. Genetic Factors

Genetic factors seem to play a role in the development in anxiety disorders in humans. In familial studies, twin studies and adoption studies show genetic variances of 20 to 40 percent. The same was found for questionnaire variables such as neuroticism. Fear conditioning ability and predisposition to learn fear responses were extensively studied in animals. In rodents, fear processes or anxiety measured in the open field test or avoidance conditioning have revealed a strong genetic basis explaining most of the inter-individual variance. However, the genes responsible for that trait have not yet been identified.

The situation is different for antisocial personality disorder and criminal behavior. Assuming that a deficit in anticipatory fear conditioning is the central symptom from which all consequent social problems follow, all evidence ranging from twin to adoption studies and gene sequencing suggests a moderate to strong genetic influence. If sensitivity to alcoholism and novelty-seeking are included as comorbidity factors the genetic variance increases further. Whether this is related to genetic fear conditioning remains to be seen (Plomin et al. 2001).

5. Significance of Fear Conditioning for the Understanding of Anxiety Disorders

Although classical fear conditioning has been implicated as an important mechanism in the development of most anxiety disorders, studies that support

the etiological significance of fear conditioning have been rare. Retrospective data from either adult or child patients or the parents of children with specific phobias revealed that about 40–75 percent of the subjects or the parents could recall a traumatic event (e.g., Menzies and Clarke 1993), a substantial number of the remaining subjects experienced vicarious conditioning or had been verbally informed about potential dangers related to the feared object. In evaluating these data it must be kept in mind that all these reports are retrospective and that fear conditioning may be nondeclarative and therefore not be accessible to conscious recollection. Of greater relevance are therefore studies that examine fear conditioning in clinical groups or analogue samples.

In social phobias, several studies used differential conditioning with faces as CS and aversive odor or shock as US. In two studies, a conditioned response was already present prior to the acquisition phase with the social phobics showing enhanced amygdala and (in one study) orbitofrontal responses to the face CS suggesting that they displayed a fear response to neutral faces that never elicits amygdala activation in healthy humans (e.g., Birbaumer et al. 2000). In another study stronger amygdala activation was present to the CS+ than the CS– only in social phobics whereas the healthy controls showed deactivation. However, the scanning was performed late in the acquisition phase and it has been shown that the amygdala is only responsive early in the acquisition process. Additional studies that used conditioning paradigms or phobia-relevant cues during imaging also found activation increases in the anterior cingulate and the insulae in accordance with the findings of fear conditioning in healthy subjects.

In persons with psychopathy and antisocial personality disorder disturbed fear conditioning seems to be present with a concomitant complete absence of orbitofrontal, insular and cingulate activation during fear conditioning (Birbaumer et al. 2000). This absence of associative learning with respect to the aversive consequences of a stimulus might be the basis of the antisocial and often criminal behavior of these persons.

In posttraumatic stress disorder, higher conditionability as evident in enhanced and more difficult to extinguish fear responses has been observed. It is, however, not clear to what extent this conditionality predated the disorder or if it must be viewed as a consequence of the disorder and to what extent conditioning of trauma-related stimuli actually occurred because none of the studies involved trauma-relevant cues (e.g., Orr et al. 2000).

6. Future Perspectives

Future research must focus on the elucidation of the neuronal correlates of fear conditioning in healthy humans and patients. It is not clear to what extent the

amygdala plays the same role in fear conditioning in humans as it does in rodents. Furthermore, the role of awareness of the CS and the CS–US relationship has not been determined by neuroimaging methods. The importance of fear conditioning for the understanding of anxiety disorders needs to be explored using paradigms that involve fear-relevant and prepared stimuli as well as longitudinal measurements. Finally, the role of cognitive and genetic variables and their relationship to fear conditioning needs to be further explored.

Fear: Potentiation of Startle

When people are afraid they tend to show a bigger startle response to a loud sound. Rats show a similar effect. This phenomenon, called 'fear-potentiated startle,' has been used to study the neural mechanisms involved in fear and anxiety in both rats and humans.

1. Fear-potentiated Startle in Rats

Capitalizing on anecdotal evidence that people startle more when they are afraid, Brown et al. (1951) demonstrated that the amplitude of the acoustic startle reflex in the rat can be augmented by presenting the eliciting auditory startle stimulus shortly after onset (e.g., 3s) of a cue (e.g., a light) previously paired with a footshock. This fear-potentiated startle occurs with an auditory, visual, or tactile conditioned stimulus (CS), and when startle is elicited by either a loud sound or an airpuff in rats (Davis et al. 1993). In this test a central state of fear is considered to be the conditioned response. Conditioned fear is defined operationally by elevated startle amplitude in the presence of a cue previously paired with a shock. Thus, the CS does not elicit startle. Furthermore, the startle-eliciting stimulus is never paired with a shock. Instead, the CS is paired with a shock, and startle is elicited by another stimulus in the presence or absence of the CS. Fear-potentiated startle only occurs following paired rather than unpaired or random presentations of the CS and the shock, indicating that it is a measure of conditioned fear. Discriminations between visual and auditory conditioned stimuli, and between auditory cues and visual cues that differ in duration, have also been demonstrated with potentiated startle. Pairing one cue with shock does not lead to generalization of fear-potentiated startle in testing with other cues. Fear-potentiated startle still occurs reliably at least

one month after original training, making it appropriate for the study of long-term memory as well.

It has been suggested, however, that potentiated startle may not reflect increased fear in the presence of a CS, but instead results from the animal making a postural adjustment (e.g., crouching) which is especially conducive to startle, in anticipation of the impending footshock. However, spinally transected rats that were held rigidly in a modified stereotaxic instrument, which prevented obvious postural adjustments, still showed fear-potentiated startle, measured with the pinna component of startle. Potentiation of startle measured electromyographically in neck muscles also occurs in the absence of any obvious postural adjustment. In addition, the magnitude of potentiated startle correlates highly with the degree of freezing, a very common measure of fear.

1.1 Effects of Different Drugs

Drugs that reduce fear or anxiety in humans decrease potentiated startle in rats (Davis et al. 1993). Benzodiazepines, opiates, β -noradrenergic antagonists, drugs that decrease norepinephrine release, certain serotonin agonists, nicotine, and perhaps alcohol decrease or fully block fear-potentiated startle. In many cases these treatments do not depress startle levels in noise-alone trials, although this is not always the case. Conversely, drugs that increase norepinephrine release or decrease GABA (γ -aminobutyric acid) mediated neurotransmission and exaggerate anxiety in anxious people increase the magnitude of potentiated startle in rats.

1.2 Neural Systems Involved in Fear-potentiated Startle

A major advantage of the fear-potentiated startle paradigm is that fear is measured by a change in a simple reflex. Hence, fear is expressed through some neural circuit that is activated by the CS and ultimately impinges on the startle circuit. Figure 1 shows a schematic summary diagram of the neural pathways we believe are required for both the acquisition and expression of fear-potentiated startle in rats using a visual CS. These pathways involve convergence of the CS and the unconditioned shock stimulus at the lateral and basolateral amygdala nuclei, which project to the central nucleus of the amygdala, and this in turn projects directly to the startle pathway.

1.2.1 The primary acoustic startle pathway. Because the acoustic startle reflex has such a short latency (e.g., 8 ms measured electromyographically in the hindlegs), it must be mediated by a simple neural pathway. Using a variety of techniques, we have de-

Figure 1
Schematic summary of the pathways believed to be involved in fear-potentiated startle in rats using schematic drawings of coronal brain slides in the rat (reproduced by permission of the Society for Neuroscience from *Journal of Neuroscience* 1996, **16**: 3775–89)

terminated that the primary acoustic startle reflex in rats is probably mediated by three central synapses (Lee et al. 1996). The first involves terminals of the auditory nerve that synapse with large neurons embedded in the auditory nerve, called cochlear root neurons. These send exceedingly thick axons (sometimes as large as 7 μm in diameter) to neurons in the nucleus reticularis pontis caudalis (PnC). These cells project directly to motoneurons in the facial motor nucleus (pinna reflex and perhaps the eyeblink component of startle) and spinal cord (whole-body startle). Chemical lesions of these neurons or local

infusion of glutamate antagonists in the vicinity of these synapses eliminated acoustic startle. Although other investigators have proposed that additional connections between the cochlear nucleus and the PnC may be important for startle (Koch and Schnitzler 1997), we believe that this simple, three-synapse pathway is the main acoustic startle pathway. For example, although the dorsal cochlear nucleus also projects directly to the PnC, lesions of the dorsal cochlear nucleus only decreased startle amplitude when high-intensity startle stimuli were used.

1.2.2 The role of the thalamus. Visual information uses parallel pathways that involve either (a) direct retinal inputs to the lateral posterior nucleus of the thalamus, which projects directly to the perirhinal cortex, or (b) retinal inputs to the dorsal lateral geniculate nucleus, which projects indirectly to the perirhinal cortex via the visual cortex. Lesions of both of these areas of the visual thalamus together, but not either one alone, blocked fear-potentiated startle using a visual CS (Shi and Davis 1996).

If an auditory CS is used, this involves parallel inputs from the auditory thalamus to the perirhinal cortex, either directly or indirectly via the auditory cortex (Campeau and Davis 1995a). Pre- or post-training lesions of the entire auditory thalamus completely blocked fear-potentiated startle to an auditory CS but not to a visual CS. Post-training lesions restricted to the main body of the medial geniculate, which projects to the perirhinal cortex via the auditory cortex, also specifically blocked fear-potentiated startle to the auditory CS.

Pain information reaches the amygdala via parallel pathways that include the caudal granular/dysgranular insular cortex and the posterior intralaminar nuclei of the thalamus. Pretraining lesions of both the insular cortex and the posterior intralaminar nuclei of the thalamus, but not lesions of either structure alone, blocked the acquisition of fear-potentiated startle (Campeau and Davis 1995a, Shi and Davis 1999). However, post-training lesions of both of these areas together did not prevent expression of conditioned fear. These results suggest that parallel cortical and subcortical pathways are involved in relaying shock information during fear conditioning.

1.2.3 The role of the anterior perirhinal and insular cortex. The perirhinal cortex, which receives either visual or auditory CS information, projects directly to the lateral and basolateral amygdala. Post-training lesions of the anterior perirhinal cortex completely blocked the expression of fear-potentiated startle using a visual CS (Rosen et al. 1992), provided the lesion destroyed both the dysgranular and agranular

portions of the perirhinal cortex. Post-training lesions of the perirhinal area (including secondary auditory cortices) blocked fear-potentiated startle to both auditory and visual CS (Campeau and Davis 1995a). However, reliable potentiated startle was observed after retraining in animals that had sustained main geniculate body lesions (which would destroy cortical connections between the thalamus and perirhinal cortex), or following pretraining lesions of the perirhinal area. These data suggest that cortical areas are normally used for the expression of fear conditioning, but that subcortical areas can take over if the cortex is damaged. Finally, as mentioned before, shock information seems to require the insular cortex, which in turn projects directly to the lateral nucleus of the amygdala.

1.2.4 The role of the amygdala. The perirhinal cortex projects directly to the lateral and basolateral amygdala. Selective destruction of cell bodies in the lateral and basolateral nuclei by local infusion of neurotoxins caused a complete blockade of fear-potentiated startle when the lesions were made, whether before or after training (Sananes and Davis 1992). This blockade did not seem to result from a disruption of vision, and other studies found that neurotoxic lesions of these amygdaloid nuclei also blocked fear-potentiated startle using an auditory CS. In contrast, lesions of a variety of other subcortical areas, such as the hippocampus, the septal area, the cerebellum, or the bed nucleus of the stria terminalis, had no consistent effect. The lateral, and especially the basolateral, nuclei of the amygdala project directly to the central nucleus of the amygdala, lesions of which blocked the expression of fear-potentiated startle using either a visual (Hitchcock and Davis 1986) or an auditory CS (Campeau and Davis 1995b).

Because CS and shock information converge neurally at the lateral and basolateral amygdala nuclei, this could be the site of plasticity for fear-potentiated startle. In fact, local infusion of NMDA (*N*-methyl-D-aspartate) antagonists into the amygdala blocked the acquisition, but not the expression, of fear-potentiated startle using either a visual or an auditory CS (Davis et al. 1993). This was probably not a result of shock information failing to reach the amygdala, because this treatment also blocked the acquisition of second-order fear-potentiated startle, which does not involve shock during second-order training.

By eliciting startle-like responses electrically from various points along the startle pathway before and after presentation of a light previously paired with a shock, we concluded that fear ultimately alters transmission at the PnC. Consistent with this, local infusion into the PnC of several compounds, such as glutamate antagonists and corticotropin-releasing hormone an-

tagonists, blocked fear-potentiated startle at doses that have no effect on baseline startle (Koch and Schnitzler 1997).

The central nucleus of the amygdala projects directly to the PnC, and lesions at several points along this pathway blocked the expression of fear-potentiated startle. Low-level electrical stimulation of the amygdala markedly increased the acoustic startle amplitude (Rosen and Davis 1988) at currents and durations that did not produce any other signs of behavioral activation. Transit times from the amygdala to the startle circuit appear to be about 4–5 ms or even less. Electrical stimulation of the amygdala in anesthetized rats facilitated tone-evoked activation of cells in the PnC (Koch and Ebert 1993).

However, it is now clear that there is at least one critical synapse between the amygdala and the startle pathway, located in an area in or very close to the mesencephalic reticular formation, dorsal periaqueductal gray or deep white layers of the superior colliculus (Koch and Schnitzler 1997). Neurotoxic lesions of this area or local infusion of muscimol blocked the expression, but not the acquisition, of fear-potentiated startle.

2. Fear-potentiated Startle in Humans

Fear-potentiated startle can also be measured in humans by using the eyeblink component of the startle reflex. In one test, people are told that when a certain colored light comes on they might get a shock on the wrist, whereas they will not get a shock when a different colored light comes on. Startle is elicited with bursts of noise through earphones, and the eyeblink component of startle is measured electromyographically from the orbicularis oculi muscles. Startle amplitude was consistently higher in the presence of the light that signaled shock (Grillon et al. 1991). The size of this increase depended on the time when the subject expected the shock on the basis of verbal instructions, and also occurred when conditioning procedures were used.

Thus far, there is a close correspondence between results gathered in rats and humans. Brain imaging studies show that the amygdala is activated during this verbally mediated fear-potentiated startle test, and that patients with lesions of the amygdala fail to display fear-potentiated startle. People also show an increase in startle when they see scary pictures—for example, of a gun in their face, a dog about to bite them, or mutilated bodies (Lang et al. 1990). The size of the increase in startle was related directly to how the subjects rated the pictures in terms of negative valence and arousal.

Fear: Psychological and Neural Aspects

Fear is an innate behavioral–cognitive–emotional system that evolved because of its evolutionary success in protecting animals (including humans) from danger. While fear to certain kinds of stimuli is unlearned, fear can also be acquired rapidly and lastingly to other kinds of stimuli, allowing animals to respond adaptively to new environmental threats. This entry will present some of the behavioral and physiological aspects of fear that make it a useful model system for understanding the psychological and neurobiological mechanisms of emotion, learning, and memory, as well as the development of a variety of human fear-related disorders.

1. Fear—Definition and Background

All organisms are subject to threats and dangers from their environments, such as predation, dominance, and territoriality. Through the process of natural selection, evolution has endowed all organisms with defensive mechanisms (e.g., chemical toxins in plants; fight-flight responses in animals) for self-preservation. Fear serves this same purpose. In humans and other higher functioning animals, ‘fear’ as a scientific term describes a behavioral–cognitive–emotional state in which a set of adaptive responses is activated in the presence of danger. As the term is more commonly used, ‘fear’ refers to a sensation (or feeling) of strong unpleasant emotion aroused by stimuli or events that are perceived as threatening or dangerous.

While this more anthropomorphic (psychological) sense of the word ‘fear’ may be useful in describing a person who is experiencing an environmental threat (e.g., electric shock) and exhibiting certain stereotyped behaviors (such as a fearful facial expression, autonomic arousal, behavioral readiness, and other defensive responses), it is probably inaccurate to use the term to describe a goldfish (or any other lower-functioning animal) that is exhibiting similarly stereotyped behaviors in response to electric shock (such as avoidance or escape). In this entry, fear will be defined as a by-product (or an emergent property) of a coordinated pattern of brain activities and bodily changes that appear in response to threats and dangers. Thus, fear serves an adaptive function, but evolved relatively recently among the continuum (or phylogeny) of defensive mechanisms.

Fear as an emotion has been a topic of interest to many subdisciplines of psychology, including psychoanalysis, behaviorism, cognitive psychology, and

Figure 1

Two influential theories of emotion propose different sequences by which threats and danger trigger fear. The main tenet of the James–Lange theory is that the animal feels fear after its body reacts (emphasizing bodily feedback in the brain representation of fear). In contrast, the Cannon–Bard theory states that threats and danger simultaneously activate the brain representation of fear and the bodily responses (bodily feedback is not a precursor of the brain representation of fear)

biological psychology (for detailed treatment and further references, see LeDoux 1996). Historically, two opposing theories of emotion, the James–Lange theory and the Cannon–Bard theory, have been especially influential (Fig. 1). According to the James–Lange theory, threatening or dangerous stimuli trigger physiological arousal and behavioral responses (via the autonomic nervous system), which are perceived and then processed as fearful by the brain (emphasizing the importance of bodily feedback to the brain). In contrast, the Cannon–Bard theory posits that threats and dangers simultaneously trigger brain activities representing fear and initiate physiological arousal and behavioral readiness (emphasizing the importance of the brain activity). Thus, the critical distinction between the two theories is whether the appearance of immediate danger (e.g., a bear) is postulated to activate the central fear system in parallel with fleeing and autonomic responses (Cannon–Bard theory), or to first trigger fleeing and autonomic responses, which are then detected and interpreted as fear by the brain (James–Lange theory). There is evidence in support of both theories, suggesting that central processes and bodily feedback (as well as other, cognitive processes) both contribute to the emergence of fear as an emotion.

2. Neuronal Substrates of Fear

Because humans share many biological and behavioral features with other animals, experimental studies with nonhuman animals provide valuable information

Figure 2

Simple models of fear system and fear conditioning. A. Innate fear: presence of danger triggers a coordinated set of programmed behavioral physiological and cognitive responses, which rapidly prepares the animal to contend with the immediate threat. B. Fear conditioning: fear of novel stimuli can be acquired through the process of classical conditioning. By virtue of association with the US, the CS comes to activate fear

* The putative locus of neural plasticity involved in fear conditioning

toward understanding the physiological as well as the psychological aspects of fear. Darwin postulated in *The Expression of Emotions in Man and Animals* (1872) that emotions such as fear are innate, highly specific to situations, and the product of coordinated brain activities, and that different animal species with diverse environmental demands (or histories) have evolved dissimilar specialized sets of fear (or defensive) responses to maximize survival. It follows from this line of reasoning that more related species will exhibit more similar fear responses than will less related species, whose nervous systems share fewer characteristics. Thus, it is highly likely that the neuronal substrates underlying fear (or other defensive mechanisms) in humans are more similar to those of other mammals (e.g., chimpanzees and rats) than those of nonmammalian animals (e.g., fish and birds).

A repertoire of innate fear responses that is characteristic of a particular animal species is often referred to as species-specific defensive reactions (SSDRs) (Bolles 1970) (Fig. 2, A). For instance, the universal expressions of fear in humans include particular facial expressions (seen in members of all cultures), changes in autonomic nervous system activities (e.g., increased heart rate, increased blood pressure, rapid respiration, perspiration, elevated pain threshold, pupil enlargement, and decreased digestive activity) and beha-

vioral readiness (e.g., freezing, increased propensity to startle, and sharpening of cognition) (see LeDoux 1996). These fear responses in humans are 'hardwired' (innate) as indicated by the observation that newborn infants, when exposed to aversive stimuli (e.g., a loud noise) for the very first time, exhibit responses, such as sudden eye closure, rapid breathing, clutching of hands, and crying, which are indicative of a general state of fear (e.g., Watson 1924). The innateness of the fear response is also demonstrated in animals; for example, laboratory-reared rats confronted with danger (e.g., a cat) for the very first time exhibit changes in autonomic nervous system activities and behavioral readiness (responses that are remarkably similar to those seen in humans), and ultrasonic (22kHz) distress vocalization (a response that is an example of an SSDR) (e.g., Blanchard and Blanchard 1971, Blanchard et al. 1991, Bolles 1970).

Several lines of evidence point to temporal lobe structures (specifically the amygdala, an almond-shaped group of nuclei buried deep within the temporal lobes) as the key neural system underlying the central state of fear (see LeDoux 1996). The classic studies of Klüver and Bucy (e.g., 1937), who examined the effect of temporal lobe ablations in rhesus monkeys, were pioneering in this respect. Klüver and Bucy noted dramatic postlesion behavioral changes, including hyperactivity, hypersexuality, and a so-called 'psychic blindness' that was manifested as an apparent indifference to the significance of previously frightening and/or arousing stimuli. While the monkeys were wild and aggressive prior to surgery, they were remarkably tame and agreeable to human contact afterwards, suggesting that a crucial emotive brain center had been removed or significantly affected by the lesions. Subsequent work, such as that of MacLean and Delgado (1953) using focal stimulation of temporal lobe structures in awake, behaving monkeys, pointed to the amygdala as the critical site. The importance of the amygdala in fear has been reconfirmed in numerous studies employing diverse species of animals (e.g., rats, mice, cats, rabbits, monkeys) and various experimental techniques (e.g., lesions, stimulation, drug infusions, recordings), and most current theories of amygdalar function reflect the importance of the structure in the processing of emotional stimuli (see LeDoux 1996). Consistent with this view, recent human neuropsychological and brain-imaging studies have found that patients with amygdalar damage are selectively impaired in the recognition of facial expressions of fear (Adolphs et al. 1994), and that there is a significantly increased blood flow to the amygdala (as measured by functional magnetic resonance imaging, fMRI) when normal subjects are presented with pictures of fearful faces (Morris et al. 1996).

The amygdala, as one of the principal structures of the limbic system, has access to sensory input from diverse areas of the brain (e.g., olfactory cortex,

hippocampus, thalamus, hypothalamus, neocortex), and projects to various autonomic and somatomotor structures that mediate specific fear responses (e.g., bed nucleus of stria terminalis for activating stress hormones, periaqueductal gray matter for defensive behavior, lateral hypothalamus for sympathetic activation) (see LeDoux 1996).

Given this pattern of connectivity, it is not surprising that damage to the amygdala eliminates stereotypical fear responses, such as defensive freezing (characterized as a motionless, crouching posture that functions to reduce the probability of detection by predators) exhibited by rodents in the presence of predators (Blanchard and Blanchard 1971). Nevertheless, while the amygdala is apparently an important component of the central fear-processing system, it does not necessarily follow that the amygdala is the seat of fear as an emotion (or a feeling). Given its intricate reciprocal connections with the neocortex, a structure implicated in higher cognitive functioning, it is very likely that the interactions between amygdala and neocortex (particularly sensory and limbic association cortices) are responsible for the emotion of fear. Thus, although the amygdala is essential in activating various fear responses (or SSDRs) in both humans and rats, the fact that there are great differences in the neocortices of humans and rats suggest that perhaps there might be important differences in fear as experienced by the two species.

3. Acquired Fear

While humans and other animals are genetically predisposed to fear certain stimuli/events, it is also adaptive for animals to have the capacity to learn about new dangers in their environments. For instance, although newborn infants innately exhibit fear to certain stimuli (e.g., loud noises), they do not show innate fear to flame or height (two stimuli that most children learn and adults remember to avoid). Thus, fear responses to many stimuli and events in the environment appear to be acquired.

Classical or Pavlovian fear conditioning has been widely employed for studying the mechanism(s) by which fear is acquired. Fear conditioning occurs when initially neutral conditioned stimuli (CSs) such as tones, lights, or distinctive environmental settings, are contingently paired with aversive unconditioned stimuli (USs) such as electric shocks, which reflexively activate unconditioned fear responses (URs). Through CS-US association formation, the CS comes to elicit various conditioned fear responses (CRs) that are similar to innate fear responses (Fig. 2, B). Perhaps the best known example of fear conditioning is the Little Albert experiment by Watson and Rayner (1920). Little Albert was an 11-month-old infant who initially exhibited curiosity (no fear) to a white rat by touching and playing with it. Watson and Rayner attempted to

Figure 3

A simplified putative fear-conditioning circuit. Conditioned stimuli (e.g., tones) are processed via two separate pathways to the amygdala (where fear conditioning is thought to take place). One pathway is via the direct (1) thalamo-amygdalar projections. The second pathway is via the indirect (2) cortico-amygdalar projections

Source: Adapted from Armony and LeDoux 1997

condition Albert to fear the rat by striking a steel bar with a hammer behind his head (US) as his hand touched the rat, causing him to startle, fall forward, and cry (UR). A week later, when the rat (CS) was placed near Little Albert's hand, he withdrew his hand and began to cry (CR). This fear of the rat was also said to be observed in the presence of other white furry animals and objects (e.g., rabbits, dogs, fur muffs).

Modern investigations of fear conditioning typically employ rats as subjects and use a tone as a CS and a mild footshock as an US. Under these circumstances a single CS-US pairing results in robust (rapid and enduring) fear learning, as evidenced by a variety of conditioned fear responses exhibited upon subsequent presentations of the tone. Thus, the biological significance of fear conditioning is reflected by the quick and permanent nature of changes in the behavior toward the initially neutral stimulus that has been paired with an aversive experience.

Fear can also be rapidly acquired through instrumental or operant conditioning, in which the presentation of an aversive stimulus is contingent upon the behavior of the animal. A widely employed procedure with rodents is the passive (or inhibitory) avoidance task (see McGaugh et al. 1996). In this paradigm, the animal's response (e.g., entering a dark compartment

of a box when placed in an adjacent lighted compartment, or stepping down from a platform onto a grid floor) is paired with an aversive experience (e.g., a footshock). As a function of this response-stimulus pairing, the animal learns to avoid making the response that was followed by the aversive experience.

Similar to innate fear, evidence from lesion, pharmacological, recording, and stimulation studies indicates that the amygdala is essential not only to innate fear, but also to the acquisition of fear, as with fear conditioning (see Lavond et al. 1993, LeDoux 1996). Thus, amygdalar lesions (particularly lesions of the central nucleus) impair the acquisition (learning) and retention (performance) of various fear-related behaviors in rats, rabbits, and cats; neurons in the central nucleus of the amygdala are responsive to both conditioned and innate fear stimuli and undergo plastic changes during fear conditioning; and restricted stimulation of the amygdala elicits specific fear responses (e.g., freezing). Recent findings from human studies that patients with amygdalar damage are impaired in fear conditioning, and that blood flow to the amygdala is increased during fear conditioning in normal subjects, further add to the evidence that the amygdala is crucially involved in fear learning.

One hypothesis of amygdalar function in fear conditioning is presented schematically in Fig. 3. In this model, an emotional stimulus (such as a tone that has been paired with a footshock) is presented, and its sensory characteristics are processed by way of two parallel pathways that ultimately converge in the amygdala. One of these pathways is 'direct' and provides relatively 'raw,' unprocessed information about the stimulus, but does so very quickly. If the neocortex is the seat of consciousness, this thalamic pathway to the amygdala can be considered the subconscious (nondeclarative or implicit) fear route. The second pathway is 'indirect' and provides highly processed information about the stimulus, but does so at the cost of an increased processing time (LeDoux 1996).

This cortical (conscious, declarative, or explicit) pathway consists of projections through primary auditory cortex to higher-order auditory association areas and the hippocampal formation, which then project to the amygdala. Upon reaching the amygdala (specifically the lateral/basolateral nuclei), these two converging representations of the stimulus are subjected to additional processing within the amygdala itself. Most current theories assume that the essential plasticity underlying this form of learning occurs in the amygdala and corresponds to a neural instantiation of the association between the CS (the tone) and the US (the footshock) long assumed by psychologists to lie at the heart of classically conditioned behavior. The precise functions of the inputs to and outputs from the amygdala, as well as the intraamygdaloid processing of CS- and US-related information, remain a topic of intensive research.

4. Fear Conditioning and Clinical Implications

Fear conditioning serves as a model system for understanding not only the neural basis of acquired fear in nonhuman animals, but also the etiology of a variety of fear-related disorders in humans (e.g., anxiety, phobias, post-traumatic stress disorder, and panic disorder). Since the characteristic behavioral and physiological symptoms of human anxiety disorders closely resemble many of the fear responses observed in fear conditioning paradigms, it is possible that anxiety and fear are closely related (Table 1). (It is important to note, however, that the fact that the symptomatic manifestation of anxiety disorders is similar to the fear responses observed in fear conditioning does not necessarily mean that the underlying neuronal substrates of fear and anxiety are the same (*post hoc, ergo propter hoc*).) While anxiety disorders can arise unpredictably, it is known that most patients experience their first symptoms in early adult life, indicating that maladaptive anxiety may be at least partly acquired. Indeed, clinicians from the time of Freud have speculated that anxiety patients have acquired their disorder as a result of traumatic learning experiences. Since the paradigm *par excellence* of traumatic learning is fear conditioning, fear conditioning appears to be useful in understanding the genesis of anxiety disorders (Fig. 3).

The question of whether anxiety is analogous to fear conditioning might be one of semantics; the difference is between normal, adaptive fear and abnormal, maladaptive fear (anxiety, phobias). However, there is an important distinction between anxiety disorders and fear conditioning (e.g., Seligman 1971) that might be taken to suggest that the two have very different bases. That is, while conditioned fear responses may be extinguished by, for example, actively preventing an animal from making escape or avoidance responses to a danger-signaling stimulus, fear-related disorders in humans (e.g., phobias) are quite resistant to extinction. In fact, anxiety disorders are characterized by fears that the patients recognize to be irrational but are unable to control.

Based on Fig. 3, it is interesting to speculate that fear-related disorders (irrational fears) might be due to

Figure 4

A simple model of normal and abnormal fear based on the putative circuitry of cortical and subcortical fear-conditioning pathways. The subcortical fear route provides a quick but imprecise representation of sensory information for activating fear (a nonconscious pathway), whereas the cortical fear route provides relatively slower but more detailed information for activating fear (a conscious pathway). In normal fear expression there is a balance between the cortical fear and subcortical fear pathways, such that the cortical component is stronger than or equal to the subcortical component. Abnormal fear might arise when this balance is disrupted such that the activity of the subcortical fear system overwhelms the activity of the cortical fear system

Table 1

Behavioral and physiological responses associated with anxiety disorders and fear conditioning

Anxiety disorders	Fear conditioning
Palpitations; pounding heart, or accelerated heart rate	Increased blood pressure, tachycardia
Sweating	Increase in Galvanic skin response measures
Sensations of shortness of breath or smothering	Increase in respiration, quick, shallow breathing
Nausea or abdominal distress	Ulcer
Paresthesia (numbness or tingling sensations)	Hypoalgesia or analgesia
Exaggerated startle responses	Potentiated startle

unbalanced activities in the cortical and thalamic pathways to the amygdala. For example, in most people a snake seen behind a glass window will elicit a different response than will a snake encountered in the woods. Both cortical and subcortical routes will process information about the snake, but the cortical (conscious) route will integrate the contextual information of the glass window and assess the safety of the situation (possibly acting as a gate). However, if the cortical pathway is somehow disrupted, the subcortical activity will be left unchecked to activate fear, even in the inappropriate context. It is possible that this type of unregulated subconscious activation of fear contributes to the etiology of fear-related disorders.

Figure 4 illustrates a hypothetical model of normal, adaptive fear and abnormal maladaptive fear. It is conceivable that genetic predisposition and environmental factors (e.g., stress) interact in such a way as to disrupt the normal balance between cortically activated fear and subcortically activated fear, leading to fear-related disorders. If it is then supposed, as some have suggested (LeDoux 1996), that the direct thalamic inputs to the amygdala are relatively resistant to extinction, whereas the cortical inputs are not, it follows that fear disorders based on overactivity in the subcortical pathway should be 'irrational,' in the sense that they do not subside even when the patient recognizes them as such. A more comprehensive understanding of the neuronal substrates and, subsequently, the molecular mechanisms of the fear system will be useful in understanding and developing treatments for fear-related disorders.

5. Conclusion

The study of fear, a form of emotion that evolved relatively recently among the phylogeny of successful defensive mechanisms, is but one means of understanding emotion, but it is the most fruitful one to have been employed to date. This is likely due to the primacy of fear: unlike other emotions, fear is apparently shared by a wide variety of species. This ubiquity speaks to its importance as a mechanism for self-preservation.

Feature Representations in Cognitive Psychology

One of the most basic assumptions of cognitive psychology is that entities in the world can be described in terms of simpler components called features. For example, when asked to list the features that tend to characterize a bird, the typical undergraduate would mention that a bird has wings, flies, lays eggs, builds nests, has a beak, has feathers, and so on. This article discusses psychological research on how people represent features, and examines a number of challenges to developing a theory of feature representation.

1. Introduction

Cognitive psychologists have often attempted to characterize the entities of a domain in terms of a

relatively small set of such features, with different entities having different combinations of these features. To take a simple example, consider capital letters. Each capital letter can be described uniquely by some combination of seven basic features: vertical, horizontal, or oblique lines; continuous or discontinuous curves; and right or acute angles between the junctions of lines. For instance, the letter R has a vertical line, two horizontal lines, an oblique line, a discontinuous curve, and three right angles. In contrast, the letter O has a single feature—a continuous curve.

Being able to characterize the entities of a domain in this manner would be an important step in specifying how entities are identified. For example, suppose that in a person's long-term memory, capital letters were represented as combinations of basic features like those described above. Then by using processes that identified such features and matched them to ones represented in long-term memory, a person could identify a letter. For example, upon detecting an oblique line and a continuous curve, a person would determine that these features matched those of the representation of Q and identify the letter as a Q. Evidence suggests that the human visual system has feature detectors (i.e., neurons). For example, some neurons respond to lines of different orientations and to junctions of lines (i.e., corners) (Hubel and Wiesel 1965).

Identifying entities is the starting point for many important, everyday cognitive tasks. In this example, identifying the letter would be an important step in identifying a word, which in turn would be an important step in reading. As another example, by identifying an object, we gain access to a large amount of stored information that is useful in interacting with that object. For instance, by recognizing something as a bear you can then access stored knowledge which lets you anticipate things about the bear that may not be immediately present (e.g., that the bear may approach and attack you).

In many domains, the representation (and subsequent processing) of features is considerably more complex than implied by the example of capital letters. In contrast to capital letters, it is not always clear what features characterize an entity. In addition, multiple factors often determine how a feature is identified. Further, relations between features can be important for identifying entities. Finally, people not only identify features but must also learn new ones. In the remainder of this article, I discuss these and other issues related to feature representation and processing.

2. Context-dependent Feature Representations

The features that we use to represent entities in the world are often influenced by the surrounding context (what other information is present at encoding, our expectations, etc.). A classic example is illustrated by a

Figure 1

The rat-man figure used by Bugelski and Alampay (1961)

study involving the rat-man figure (see Fig. 1). Bugelski and Alampay (1961) found that when preceded by several pictures of human faces people tend to see the rat-man figure as a man, but when preceded by several pictures of animals they tend to see the rat-man figure as a rat. In these cases, people represent the same perceptual input in terms of different features. For example, the small circles in the figure are seen as ears or as eyeglasses depending on the preceding pictures. As another example, whether a white area on an X-ray indicates a lung tumor, a bone, or an artifact of the procedure can depend on a variety of contextual factors, including the radiologist's knowledge of the patient's case history, the location of bones, whether the X-ray is a chest X-ray, and the likelihood that the X-ray was underexposed. These and many other examples suggest that the representation of a feature is not just based on perceptual input but also on what is in the head of the perceiver. As result, the features associated with a perceptual input can vary depending on the perceiver's prior knowledge.

3. Relations between Features

Feature representations often capture relations between other features. These relations are necessary in order to identify an entity accurately. For example, a bucket and a coffee cup can both be described by the same two basic features (an open cylinder and a handle). Thus, it would not be possible to distinguish these objects if they were only represented by such features. Note, though, that the spatial relationship between the two features differs in the two objects. That is, the handle of the bucket is attached to the rim of the open cylinder, whereas the handle of the coffee cup is attached to the side of the open cylinder. Thus, people could distinguish these objects if their featural representations included such spatial relationships. Biederman (1987) describes a model of object recognition that represents objects in terms of part-like features (called *geons*), and the relations between them. As another example, the words 'team' and 'meat' are made up of the same basic features, called

phonemes (i.e., the smallest significant sound units in a language). However, the temporal relationship between these phonemes is different. For example, the 't' sound is pronounced first in 'team,' but last in 'meat.' Thus, people could distinguish these spoken words if their featural representations included such temporal relationships.

4. Construction of New Features

In a number of areas of cognitive psychology, the researcher and subject agree implicitly on the features which characterize the cognitive task being investigated. For example, in studying how people learn about new categories of entities, researchers often present subjects with stimuli whose features are well-specified, familiar, and unambiguous. The question of interest is how people determine which features are important for distinguishing one category from another. However, learning does not just involve selecting relevant features. In any domain, people must sometimes figure out the features themselves (i.e., acquire new features; see Biederman and Shiffrar 1987, Lesgold et al. 1988, Schyns et al. 1998, Wisniewski and Medin 1994, for examples).

To illustrate this point, consider a study by Schyns and Rodet (1997) in which subjects learned about categories of novel stimuli called 'Martian cells' (see Fig. 2). One group of subjects first learned a category whose members had x blobs followed by a category

with y blobs, and then a category with xy blobs (a fusion of the separate x and y blobs; see Fig. 2a). A second group learned the categories in the reverse order (see Fig. 2b). These different orders affected how subjects determined the features of the category with xy blobs. The first group perceived the xy blob as a conjunction of the x and y features. They had previously learned that x was diagnostic of the x blobs category, and that y was diagnostic of the y blobs category. Thus, previously learning the x and y features biased the first group to segment the xy blob into these two features. In contrast, the second group perceived the xy blob as a single, unitary feature xy . Because the initial category that they learned was the one with xy blobs, their perception of the xy blob was not influenced by having learned features x and y .

5. Local vs. Global Feature Representations

In many areas of cognitive psychology, researchers use symbols to represent features that correspond closely to language, and which tend to bottom out at the level at which the language bottoms out (Solomon and Barsalou in press). For example, in the English language, people typically use the word 'stripes' to refer to the stripes of zebras, barber poles, the American flag, and so on, rather than a more detailed term. In turn, researchers represent features using similar, language-like terms. Often, these representations take the form of attribute-value pairs. For

Figure 2

Schematic drawing of two different orders of novel categories learned by subjects in a study by Schyns and Rodet (1997)

example, stripes could be represented as the attribute texture. Do researchers believe that such representations have no further specification of meaning? They probably do not, as intuition strongly suggests that there is something more to such representations. Instead, such a feature representation may be a shorthand term for the commonalities shared by its referents (which researchers usually leave unspecified). For example, one possible commonality among the stripes of entities is that they have a color which contrasts with the background color of the entity. Thus, researchers generally assume that a feature has a similar representation across the entities to which it applies (i.e., a global representation).

However, evidence suggests that feature representations are also more fine-grained and specific or local to their associated entities. For example, Solomon and Barsalou (in press) tested the local representation view in a series of property verification tasks. Subjects saw an object (e.g., a bus) followed a property name (e.g., seat) and had to verify whether the property was true of the object. On a subsequent trial, verifying that property for a different object was facilitated if the property had the same form in the second object. For example, having previously verified that seat is true of bus, subjects more quickly verified that seat was true of truck. However, this benefit was not obtained when verifying that seat was true of bicycle. This finding implies that the representation of seat in truck and bus is similar, but differs from that in bicycle. As another example, many properties are relative. For instance, a large mouse and a large house are not very similar in size. A large mouse is large compared to other mice, but a large house is large compared to other houses. Thus, relative properties also have local representations.

6. Determining the Appropriate Features

As much of the discussion above implies, a central issue in feature representation is determining the appropriate features of an entity. In principle, one can describe any entity by an infinite number of features (e.g., a German shepherd dog has 4 legs, but it also has fewer than 6 legs; it has a tail, but also a tail of a particular length; it is found on the planet Earth, but not at the bottom of the ocean; it has a nose, but it also has a nose of a particular color and shape, and so on). Clearly, there must be constraints on what counts as a feature (Murphy and Medin 1985). Many of these constraints are provided by the perceptual system (see Barsalou 1999, Schyns et al. 1998, for discussion of perceptual mechanisms that extract features). For example, the perception of an object part is influenced by discontinuities and points of maximum curvature on its surface (e.g., Hoffman and Richards 1984).

Other constraints are related to the categories to which an entity belongs. For example, a small, umbrella-shaped entity growing in a forest might be

categorized as a mushroom. The representation of mushroom might contain the features stem and umbrella-shaped cap so as to distinguish it from other plants. On the other hand, a mushroom belongs to a more specific category such as Death Cap—the most poisonous mushroom. Its representation might contain the features green-tinged cap and thick stem, so as to distinguish it from other mushrooms. Thus, the features associated with a category may be partially constrained by its contrasting categories. Further, the same aspect of an entity may have multiple feature representations (e.g., cap, green-tinged cap).

7. Final Comment

Ultimately, any theory of how features are represented must address the symbol grounding problem (Harnad 1990). That is, the representations of features that are in our heads must make contact with what they represent—what is out in the world. Much of the utility of representations is in allowing us to interact successfully with the world. For example, the representation of the green-tinged cap must allow mushroom pickers to identify actual green-tinged caps of mushrooms so that they can avoid eating them. As another example, a relatively abstract feature such as ‘plays music’ for a CD player is not particularly useful unless it indicates more specifically how one can use a CD player to play music.

Fechnerian Psychophysics

Fechnerian psychophysics is based on the idea that an appropriately chosen measure of local discriminability in a continuous stimulus space (the degree with which an observer can discriminate a stimulus from its very close neighbors) can be used to compute ‘subjective’ distances between very close stimuli; and that by integrating these small distances appropriately along paths connecting different stimuli one can compute ‘subjective’ (Fechnerian) distances among all stimuli comprising the space. This idea, together with experimental procedures for measuring local discriminability, was originally proposed by Fechner (1860, 1877) for unidimensional stimulus continua (such as the space of fixed-frequency tones varying in intensity, or visually presented line segments varying in length). Historians often date the beginning of scientific psychology from Fechner’s work.

1. Classical Theory (Refined)

If a stimulus x changes along a single physical dimension (an interval of reals), and $F(x)$ is the *local discriminability measure* at x (positive and continuous), then the *Fechnerian distance* between any two stimuli a, b is defined as

$$G(a, b) = \left| \int_a^b F(x) dx \right| \quad (1)$$

The Fechnerian distance clearly satisfies the defining properties of a metric: $G(a, a) = 0$, $G(a, b) > 0$ for $a \neq b$, $G(a, b) = G(b, a)$, and $G(a, b) \leq G(a, x) + G(x, b)$.

Assuming that x is much greater than the *lower absolute threshold* x_{inf} of the stimulus continuum, so that the random variability in x_{inf} can be ignored, the distance $G(x, x_{\text{inf}})$ can be called the ‘Fechnerian magnitude’ of x (traditionally, ‘sensation magnitude’).

Let $\xi_x(y)$ be the probability with which y is perceived to be greater than x , and assume that $\xi_x(x) = 1/2$ (the

latter can be ensured by an appropriate recalibration of the reference stimuli x). Then the *local discriminability measure* $F(x)$ is defined as

$$F(x) = C \frac{d\xi_x(y)}{dy} \Big|_{y=x+} \quad (2)$$

where certain regularity assumptions ensure that the derivative exists and continuously changes with x ; $C > 0$ is a proportionality coefficient allowed to be different for different stimulus continua.

For $1/2 \leq p < 1$, let $W_p(x)$ denote the value of y at which $\xi_x(y) = p$; then $W_{1/2}(x) = x$. The difference $W_p(x) - x$ is called the ‘just noticeable difference’ (JND) at x on level p , or p -JND, for short. Putting $y = W_p(x)$ and using the identity $\xi_x[W_p(x)] = p$, Eqn. (2) can be written as

$$F(x) = C \frac{dp}{dW_p(x)} \Big|_{p=1/2+} = C \lim_{p \rightarrow 1/2+} \frac{p - (1/2)}{W_p(x) - x} \quad (3)$$

Since, by Eqn. (1)

$$\begin{aligned} \lim_{p \rightarrow 1/2+} \frac{G[a, W_p(a)]}{p - (1/2)} &= \frac{dG[a, W_p(a)]}{dp} \Big|_{p=1/2+} \\ &= \frac{d \int_a^{W_p(a)} F(x) dx}{dp} \Big|_{p=1/2+} \end{aligned}$$

one can use the chain rule and apply Eqn. (3) to $F[W_p(a)]|_{p=1/2+} = F(a)$ to show that

$$\lim_{p \rightarrow 1/2+} \frac{G[a, W_p(a)]}{p - (1/2)} = C \quad (4)$$

By fixing p at a value sufficiently close to $1/2$ one concludes that $G[a, W_p(a)]$ is approximately constant for all a , because of which $G(a, b)$ in Eqn. (1) is roughly proportional to the number of chained p -JNDs, $W_p(a) - a$, $W_p[W_p(a)] - W_p(a)$, etc., that fit between a and b (see Dzhafarov and Colonius 1999 for details). The p -JNDs can be estimated from empirical data by a variety of techniques (see, e. g., Falmagne 1985). The use of the methods of *limits* and *adjustments* in Fechnerian psychophysics, as these provide JNDs on unknown probability levels, is predicated on the assumption that these JNDs are roughly proportional to p -JNDs on a constant level p sufficiently close to $1/2$.

2. Psychophysical Laws

If, with some choice of the physical measure for x , $d\xi_x(y)/dy$ at $y = x$ is proportional to $1/x$ (Weber’s law), then Eqns. (1) and (2) yield $G(a, b) = C \log(a/b)$

(Fechner's psychophysical law). In spite of the enormous importance attached to Weber's and Fechner's laws in the history of psychology, the logic of Fechnerian psychophysics by no means implies them and is not contingent on their validity. Fechnerian psychophysics is equally consistent, for example, with such often found empirical approximations as $F(x) \propto 1/(x + \delta)$ (modified Weber's law) or $F(x) \propto 1/x^\alpha$ (called the near miss to Weber's law if α is just below 1, and the Fullerton-Cattell law if $\alpha \approx 0.5$). These two forms of $F(x)$ imply, respectively, $G(a, b) = C \log[(a + \delta)/(b + \delta)]$ and $G(a, b) = C'(b^{1-\alpha} - a^{1-\alpha})$ as substitutes for Fechner's law.

3. Criticisms of Classical Theory

3.1 Infinitesimals vs. Finite Differences

The account in Sect. 1 is a refined interpretation of Fechner's original theory. It is supported by Fechner's writings, but being voluminous and rather lacking in mathematical rigor, these writings lend themselves to alternative interpretations. According to one of them, Fechner believed in 'true' irreducible JNDs, $W_*(x) - x$, and simultaneously maintained that $G[x, W_*(x)] = \text{const}$ ('Fechner's postulate'), and that Eqn. (1) holds with $F(x) = C/[W_*(x) - x]$ compare with Eqn. (3). These propositions, however, are mutually inconsistent (Luce and Edwards 1958). Fechner knew of this criticism, and his 1877 rejoinder indicates that the interpretation it is based on is not correct. Whatever the historical truth, it is a sound scientific strategy to reserve the term 'Fechnerian psychophysics' for the interpretation that preserves the essence of Fechner's approach while freeing it from logical contradictions.

3.2 Fechnerian Distances and Subjective Matching

Consider four stimuli, say, tones with amplitudes and frequencies (A_1, f) , (A_2, f) , (A_1, f') , (A_2, f') , and let (A_1, f) and (A_1, f') be matched in loudness, and the same be true for (A_2, f) and (A_2, f') . Then the 'loudness-wise' Fechnerian distance between (A_1, f) and (A_2, f) should equal that between (A_1, f') and (A_2, f') , and one could expect that the numbers of chained amplitude JNDs fitting between the first two and the last two tones are roughly equal (under the assumption stipulated in Sect. 1). Riesz (1933) found this prediction wrong: for instance, the number of amplitude JNDs between two 4000-Hz tones may exceed that between the corresponding 200-Hz tones by a factor of four. This may be thought to invalidate the Fechnerian theory, as the difference seems too large to be attributed to the approximation error associated with counting finite JNDs (on unknown probability levels). The counter-argument is as follows. If the amplitudes coupled with frequency f and

those coupled with frequency f' can be treated as separate stimulus continua, then the values of C in Eqn. (3) (and hence the approximate proportionality coefficients between Fechnerian distances and JND counts) may be different for f and f' . If, on the other hand, the amplitude-frequency combinations should be treated as comprising a single two-dimensional stimulus space (see Sect. 5), then it is no longer justifiable to measure the Fechnerian distance between (A_1, f) and (A_2, f) along the straight line connecting them. For a detailed treatment of subjectively unidimensional (e.g., 'loudness-wise') discriminations among multidimensional stimuli see Dzharfarov and Colonius (1999).

3.3 Fechnerian Magnitudes vs. 'Directly' Estimated Magnitudes

For certain stimulus continua, called *prothetic* (intensity, length, duration, etc.), the Fechnerian magnitudes $G(x, x_{\text{inf}})$ computed from discrimination data typically are found nonlinearly related to magnitudes obtained by 'direct scaling' methods (Stevens 1975). For instance, if Weber's law holds on a continuum of x , implying $G(x, x_{\text{inf}}) = C \log(x, x_{\text{inf}})$, the observer's numerical estimates of x are often found closely adhering to $S(x) = Kx^\alpha = \exp[\lambda G(x, x_{\text{inf}})]$ (Stevens' psychophysical law). Many have agreed with Stevens that $S(x)$, and not $G(x, x_{\text{inf}})$, is the 'true' measure of the 'sensory magnitude' of x . As no independent definition of sensory magnitude is available, however, the argument is largely semantic. The classical Fechnerian theory does not predict that all judgments of stimuli interpretable in terms of 'how large,' 'how high,' etc., must be proportional to Fechnerian magnitudes (although this happens to be the case for some *metathetic* continua, such as frequencies of constant-amplitude tones). A meaningful question to ask within the framework of Fechnerian psychophysics is whether one can propose a plausible mechanism, process, or computation by which an observer arrives at the $S(x)$ -measures of prothetic stimuli based on their Fechnerian magnitudes $G(x, x_{\text{inf}})$. A naive but refinable example of such a proposal can be found in Ekman (1964).

4. Probability-distance Hypothesis

According to Eqns. (1) and (2), Fechnerian distances $G(a, b)$ are computed from discrimination probabilities $\xi_x(y)$ taken in arbitrarily small vicinities of $y = x$. A natural question to ask, therefore, is whether $\xi_a(b)$ (provided it is not zero or one) is determined uniquely by $G(a, b)$ for all stimulus pairs a, b . More generally: can one find a continuous internal metric $D(a, b)$ and a continuous function f such that

$$\xi_a(b) = f[D(a, b)] \quad (5)$$

and if so, what is the relationship between $D(a, b)$ and the Fechnerian metric $G(a, b)$? Metric $D(a, b)$ is called *internal* (also, *inner* or *intrinsic*) to the given unidimensional continuum if $D(a, b) + D(b, c) = D(a, c)$ for any $a < b < c$ on this continuum. Thus, the Fechnerian metric G is internal. The assumption that Eqn. (5) holds true can be called the *probability-distance hypothesis*, and the problem of finding D and f satisfying this hypothesis is referred to traditionally as ‘Fechner’s problem’ (Luce and Galanter 1963).

Primarily due to the criticism mentioned in Sect. 3.1, Fechnerian psychophysics since the 1960s has been reduced essentially to the probability-distance hypothesis. One should note, however, that the classical theory presented in Sect. 1 does not imply the truth of this hypothesis. At the same time, the implication holds in the reverse direction: Pfanzagl (1962) proved that (subject to some regularity conditions) Eqn. (5) may hold for an internal metric D only if $D(a, b) = G(a, b)$. That is, discrimination probabilities may not depend on any internal metric other than the Fechnerian one.

Falmagne (1985) proved that Eqn. (5) is equivalent to either of the following two conditions: (weak bicancellation) $\xi_a(c)$ is determined uniquely by $\xi_a(b)$ and $\xi_a(c)$, for any a, b, c ; (weak quadruple condition) $\xi_a(b) = \xi_a(b')$ if and only if $\xi_a(a') = \xi_b(b')$.

5. Multidimensional Fechnerian Psychophysics

A generalization of Fechnerian psychophysics to continuous stimulus spaces of arbitrary dimensionality (such as the CIE color space, or space of tones varying in both frequency and amplitude) was proposed by Dzhamalov and Colonius (1999). A special form of this generalization, however, can be traced back to the tradition, originated by Helmholtz and Schrödinger, of computing colors metrics from color-discrimination data (Wysocki and Stiles 1982). The discrimination of multidimensional stimuli $\mathbf{x} = (x_1, \dots, x_n)$ cannot be defined in terms of ‘greater-less,’ and the function $\xi_a(y)$ of the classical theory should be replaced with $\psi_x(y)$, the probability of y being perceived as *different* from x . Let $\psi_x(y)$ attains its minimum at $y = x$ (if necessary, after an appropriate recalibration of reference stimuli x). The local discriminability measure $F(\mathbf{x}, \mathbf{u})$ at stimulus $\mathbf{x} = (x_1, \dots, x_n)$ in direction $\mathbf{u} = (u_1, \dots, u_n)$ is defined as

$$F(\mathbf{x}, \mathbf{u}) = C \lim_{s \rightarrow 0+} \frac{\Phi[\Psi_x(\mathbf{x} + \mathbf{u}s) - \Psi_x(\mathbf{x})]}{s} \quad (6)$$

where the transformation Φ is one and the same for all $\mathbf{x}$ and $\mathbf{u}$. The assumptions about $\psi_x(y)$ underlying the theory guarantee that $F(\mathbf{x}, \mathbf{u})$ is determined by $\psi_x(y)$ uniquely, and is continuous and positive, while Φ is determined asymptotically uniquely (put roughly,

uniquely in a small vicinity of zero). The local discriminability $F(\mathbf{x}, \mathbf{u})$ can be used to compute the *psychometric length* L of any path $\mathbf{x}(t)|_a^b$, $a \leq t \leq b$, lying within the stimulus space and connecting stimuli $\mathbf{a} = \mathbf{x}(a)$ and $\mathbf{b} = \mathbf{x}(b)$:

$$L[\mathbf{x}(t)|_a^b] = \int_a^b F[\mathbf{x}(t), \dot{\mathbf{x}}(t)] dt \quad (7)$$

The Fechnerian distance between $\mathbf{a}$ and $\mathbf{b}$ is defined as

$$G(\mathbf{a}, \mathbf{b}) = \inf L[\mathbf{x}(t)|_a^b] \quad (8)$$

where the infimum is taken over all paths connecting $\mathbf{a}$ with $\mathbf{b}$. Under certain conditions, this infimum may equal the psychometric length of a certain (‘shortest’) curve connecting $\mathbf{a}$ with $\mathbf{b}$, a *Fechnerian geodesic*. Fechnerian distances are determined uniquely and are invariant with respect to all smooth one-to-one physical reparametrizations of the stimulus space. If $\psi_x(\mathbf{x}) = \text{const}$ (*constant self-similarity condition*), then Fechnerian distances are also invariant with respect to smooth monotone transformations $T[\psi_x(y)]$ (e.g., due to *response bias* changes).

The construction just described identifies the Fechnerian metric as *internal to the stimulus space*. (In general, a distance function is internal to a space if the distance between any two points in the space is the infimum of the lengths of all paths connecting these points and lying entirely within the space.) A multidimensional generalization of Pfanzagl’s theorem on the probability-distance hypothesis holds: $\psi_a(\mathbf{b})$ (different from zero and one) may be determined uniquely by an internal metric $D(\mathbf{a}, \mathbf{b})$ only if $D(\mathbf{a}, \mathbf{b}) = G(\mathbf{a}, \mathbf{b})$.

The multidimensional Fechnerian theory, when specialized to unidimensional continua, sheds additional light on some aspects of the classical theory. While the concept of a unidimensional Fechnerian distance readily generalizes to spaces of arbitrary dimensionality, no natural generalizations exist for the notions of a Fechnerian (‘sensation’) magnitude and psychophysical law, such as Fechner’s or Stevens’. This suggests that the importance traditionally attached to these notions may be unwarranted. By the same criterion (multidimensional generalizability), it is desirable to reformulate the classical theory in terms of the ‘same-different’ discrimination probabilities $\psi_x(y)$, instead of the traditional ‘greater-less’ probabilities $\xi_x(y)$, and accordingly to revise the empirical procedures for computing the local discriminability measure $F(x)$.

6. Concluding Remark

With discrimination among stimuli being arguably the most basic cognitive function, Fechnerian psychophysics is motivated by an expectation that distances

computed from discrimination probabilities should have a fundamental status among behavioral measurements, and that in the final analysis various kinds of perceptual judgments could be shown to depend prominently on Fechnerian distances among stimuli involved. The eventual status of Fechnerian psychophysics will depend on the extent to which this expectation will be confirmed by future experimental and theoretical developments.

Federalism

'Federalism' refers to both an arrangement of political institutions and a philosophy of government. Federalism as a set of institutional arrangements denotes a political system in which power is shared between a central government and regional governments. Federalism as a philosophy of government holds that such federal structures are a desirable governmental form.

1. Federalism and Related Terms

The distinction between 'federalism' and related terms should be clarified. A government displaying the institutional characteristics of federalism is referred to as a 'federal system,' and the institutional structures themselves are described with the adjective 'federal.' A federal system is contrasted with a 'unitary system' of government in which all major decisions are made by the central government; some degree of administrative decentralization, however, may be present in a unitary system (see *Unitary State*). The terms 'federalism' and 'federal system' have been used as overarching terms which encompass a variety of more specific types of political arrangements, including federations, confederacies, and leagues (Riker 1975). The origins of the word 'federal' can be traced to the Latin *foedus*, denoting a league, treaty, or covenant. The term 'intergovernmental relations' refers to interactions between different governmental units within a political system. This term includes but is not limited to the study of interactions between central and regional governments within federal systems.

2. The Normative Study of Federalism

The study of federalism can be usefully divided into normative and empirical branches. The normative branch, which dates back centuries and remains very important today, includes the arguments in favor of the US constitution put forth in *The Federalist*. This normative literature consists of systematic consideration of federalism as a philosophy of government, including the enumeration of possible advantages and disadvantages of federal systems.

Proponents of federalism argue that federal systems are desirable because they may produce a number of advantageous consequences. In particular, advocates of federalism suggest that federal systems protect citizens against tyranny by dividing power among central and regional governments; expand possibilities for political participation by increasing the number of governments within a political system; allow for regional variations in public policy that are reflective of geographic differences in citizen preferences; and provide multiple governmental 'laboratories' in which innovative policy responses to public problems can be tested (Shapiro 1995).

Other scholars have argued that federal systems may produce a variety of negative consequences. For example, federal systems may encourage regional inequalities in the distribution of the costs and benefits of public policies; allow for the oppression of local minorities by local majorities within the subnational jurisdictions; and produce an undesirable 'race to the bottom,' in which regional governments attempt to attract economic enterprises by lowering regulatory standards and reducing governmental taxation and expenditure (Shapiro 1995).

3. *The Empirical Study of Federalism*

The empirical branch of the study of federalism has focused on the description and measurement of federal systems, and also on the establishment of relevant causal relationships.

3.1 *Descriptive Approaches*

In the descriptive realm, scholars have been concerned above all with identifying the core characteristics of federalism, characterizing variation in federal systems, and describing the mechanisms through which federal systems operate. At the heart of the federal idea is the division of powers and responsibilities between an overarching central government exercising authority over a broad territory, on the one hand, and a number of constituent governments each exercising authority over a particular subset of that territory, on the other. This division of power is generally enshrined in a constitution that guarantees the existence of all of the governments and provides at least a rough outline of the division of power among them.

Within these broad parameters, scholars have offered a range of more specific definitions of federalism, and no universal agreement about the term's precise definition has been reached. Different definitions produce somewhat differing classifications of political systems into federal and nonfederal categories. The result is that the term 'federal' can be applied to a variety of political systems in which power is shared between general and constituent governments. The political institutions of ancient Israel and the Greek city-states displayed federal characteristics. The US federal system, established in 1789, has served as the prototype of modern federalism (Elazar 1968). At the turn of the twenty-first century, significant federal elements existed in political systems across the globe, including Argentina, Australia, Austria, Belgium, Brazil, Canada, the European Union, Germany, India, Malaysia, Mexico, Nigeria, Pakistan, the Russian Federation, South Africa, Spain, Switzerland, the USA, and Venezuela (Elazar 1994).

Among federal systems, there is variation in the degree and character of the distribution of power between national and regional governments. This variation can be observed both in formal constitutional arrangements and in the working relationships among different levels of government within a political system. One component of the variation between federal systems, and within individual systems over time, is the extent to which powers and responsibilities rest with the central government or with the regional governments. Federal systems also vary in the extent to which these powers are either strictly divided between levels of government or shared between those levels of government.

With respect to the first of these dimensions, scholars have not yet reached a consensus about a

precise way to measure the relative centralization and decentralization of federal systems (Watts 1998). The formal distribution of powers set forth in constitutions may provide some insight into the comparative degree of centralization between systems. Such a constitutional focus has limitations, however, and is unlikely to be as useful in measuring changes over time within a federal system. Here, close attention must be paid to legislative and judicial decisions altering the balance of power between the central government and the constituent governments. One summary measure that is commonly examined is the proportion of governmental expenditures undertaken by the central government, either in total or in particular policy areas (Peterson 1995). Efforts to characterize variation in the distribution of powers between general and constituent governments in federal systems have also led to the development of a wide range of metaphors and conceptual models (e.g., 'dual federalism,' 'co-operative federalism'). These metaphors and models attempt to characterize either the degree of centralization in a federal system or the extent to which powers are strictly divided or cooperatively shared between levels of government, or both. In all, Stewart (1982) found more than 300 such models and metaphors that had been proposed in the literature.

Descriptive studies have also examined, both statically and dynamically, the mechanisms through which federal systems operate. Core areas of concern here include the constitutional, legislative, and judicial processes through which powers are allocated between levels of government, and the fiscal (e.g., grants-in-aid), regulatory, and political instruments through which governments within a federal system influence each other's actions (Wright 1988).

3.2 *Causal Approaches*

The causal branch of the empirical study of federalism addresses two major areas of concern: the causes and consequences of the establishment and dissolution of federal systems, and the causes and consequences of changes in how powers are divided between governments within federal systems.

Federal systems can be established either by joining together previously independent governments, or by decentralizing power in a previously unitary state. The formation of federal systems involves somewhat different processes and conditions in each of these two cases. In all cases, however, federal systems emerge under political conditions that contain strong pressures for both political unity (in the form of a national government) and political autonomy (in the form of regional governments with meaningful powers).

The pressures for unity most commonly result from a desire for military or economic advantage that constituent governments feel cannot be achieved independently. When federal systems are formed from previously independent governments, the reluctance

of these governments to cede too much power to a newly formed central government creates pressure for regional autonomy. More generally, pressures for autonomy most commonly involve protecting constituent governments' diverse interests, whether based on nationality, language, ethnicity, religion, economy, or other variables. Against the backdrop of these general dynamics, scholars have debated what conditions are necessary and sufficient to produce a federal system, with particular discussion of cultural, economic, political, social, and historical variables (Riker 1975).

Scholars have sought to understand not only why federal systems are formed, but also what the consequences of federal systems are. For example, federal systems can have important consequences for the management of ethnic conflict, either mitigating or exacerbating ethnic tensions, depending on the particular institutional arrangements in place.

The late twentieth century witnessed the disintegration of some political systems that were federal in principle or practice, including the Soviet Union, Yugoslavia, and Czechoslovakia. The survival of federal systems is imperiled when institutional arrangements reinforce rather than crosscut existing lines of division within the system, or when one group or constituent government representing a supermajority dominates the overall system (Watts 1998, Elazar 1968).

At a less macroscopic level, the causal study of federalism focuses to a significant extent on the evolution of federal systems: why the distribution of powers changes in federal systems, and with what consequences. There are numerous studies of the proximate impact of legislative, judicial, and executive decisions on the distribution of powers in federal systems. Other analysts have focused on the role of underlying forces such as changes in technology, culture, ideology, society, and economy (Anton 1984).

In all, there is significant dissatisfaction among scholars with the current state of our ability to construct robust theories of why federal systems evolve in the ways that they do (Beam et al. 1983). Explanations focusing on proximate causes have been criticized for being atheoretical and for too often relying on single case studies. Analyses focusing on underlying causes have not produced a clear consensus (Anton 1984). Understanding the causes of centralization and decentralization in federal systems will remain an important area of investigation in the decades ahead. Scholars may increasingly attempt to link explanations focusing on proximate and underlying causes, constructing theories that specify how underlying forces such as culture or economy might in turn produce centralizing or decentralizing actions by proximate institutions such as legislatures or courts.

Scholars have also discussed the consequences of centralization and decentralization within federal systems. For example, there is evidence that decentral-

ized systems make decentralized political party structures more likely (Riker 1975). In another realm, some scholars have argued that decentralization of redistributive and regulatory functions may lead to a competitive spiral in which subnational governments reduce their interventions in these areas (Peterson 1995).

4. Future Directions

Several areas of the study of federalism will likely be of particular importance in the first decades of the twenty-first century, as the literature continues to respond to important political developments. Scholars will be particularly interested in: the interaction between economic globalization and federal structures (see *Globalization: Political Aspects*); the emergence and evolution of supranational federal arrangements, including the European Union (see *European Integration; Regional Integration*); and the relationship between federal structures and the management of conflict in multiethnic political systems.

Female Excision: Cultural Concerns

1. Overview

Female excision, also known as female circumcision, is a euphemism for a variety of genital surgical procedures. It is a time-honored cultural tradition that has recently come under intense international scrutiny. Practices of genital alteration have existed in recent times in Australia, Asia, Latin America, America, and Europe. In fact, some Western surgeons claimed to have invented similar procedures as treatment for sexual dysfunction. Presently, excision is most common in Africa. Thus, this article focuses on African experiences. Given the discrepancies in existing studies, it is difficult to obtain accurate information about the exact prevalence of the practice. However, it is roughly estimated that about 80 to 110 million African women and children are affected.

There are at least four major forms of excision. In the mildest form, the clitoris is barely nicked or pricked to shed a few drops of blood. The second kind which is often called *sunna* involves the removal of the clitoral prepuce, hood, or outer skin. The third gradation, clitoridectomy, more accurately describes the process of excision. Here, the clitoral glans and some of the *nympha* or *labia minora*—the narrow lip-like enclosures of the genital anatomy, are severed. Infibulation is the least popular and most extreme procedure; it entails scraping the *labia majora*—the two rounded folds of tissue that contour the external boundaries of the vulva, and stitching the remaining raw edges together in a manner that reduces the vulva opening after the surgery heals. Different forms of the operation affect the genitalia differently.

2. Rationales

Nobody can unequivocally identify where, when, or why excision originated. The practice can mean different things to different actors in different milieus. Embedded in an intricate web of habits, attitudes, and values, excision has both functional and symbolic connotations. It is validated and undergirded by a spectrum of temporal and spiritual beliefs. While some of the justifications are at odds with ample medical knowledge, efforts to counter the practice by illuminating the medical contradictions have not been very successful in eroding commitment to it. This is mainly because, for adherents, the attraction and imperative of the practice has little to do with medical science. Recurring themes such as sexuality and fertility signify and affirm paramount indigenous values like solidarity, public recognition of lifecycle change, and procreation for social continuity. That it deals with the genitalia and is suffused with gender constructs does not denote unequivocally exclusive or primary concern with gender and sexuality.

Among the Sande for example, it has been reported that initiates spend months in seclusion being instructed on topics as broad as the cultural secrets of successful living and traditional medicine. With the Chagga, excision is said to test courage by simulating birth labor pains. To the Mende and Sherbro, it fosters cooperation among women. The Bambara and Mossi assume it reduces mortality and morbidity. Some Bantu and Sudanese use it for purification. In other areas, excision is employed as a means of self-definition, self-assertion, and expression of personhood and identity; it has also been characterized as the equivalent of an ornamental tattoo, or a kind of cosmetic surgery akin to ear-piercing. On a continuum with these worldviews are a competing set of beliefs which tend to emphasize the dimensions of sexuality and gender. But even these beliefs are tempered and nuanced in the manner in which they inform everyday realities.

The Mandingo, Massai, and Swahili believe that excision renders the body fertile and fit for the social order. Among some Yoruba it is considered a contraceptive device. In some other groups, excision reflects a fear of a primal hermaphroditic human nature and an attempt to differentiate the sexes. Still others justify it on grounds of aesthetics; to these, unaltered female genitalia are unsightly, and occluded or attenuated body orifices are more preferable. Some communities subscribe to the belief that a girl is ripe for sexual relations only after being ushered into womanhood by circumcision. Finally, there are communities that, to enforce moral values and ethical standards, discourage premarital sex. These groups believe that circumcision attenuates sexual desire and this mindset underscores its incorporation as a rite of passage. Regardless of the prevalence of this mindset in select groups, excision does not necessarily encode absolute prenuptial chastity nor does it *prima facie* signal a distortion of women's sexual experiences. From all indications, the practice is not homogenous; it has divergent contexts, meanings, and consequences. However, some opponents of the practice insistently explain it monolithically to privilege connotations of sexual politics and patriarchal control.

3. Emerging Trends

For various reasons, many communities where excision was once an aspect of elaborate rites of passage celebrations with minimum age requirements now excise children who are too young to comprehend the ritual implications of the experience. A corollary of this development is that some persons undergo the operation independent of accompanying ceremonies. In contradistinction to the evolving tendency to cut the genitalia without performing complementary ritual ceremonies, a few communities are embracing alternative rites that replace physical cutting with

symbolic enactments. Here initiation modules only entail health education, transmission of traditional knowledge, and festivity.

Patterns of change are also manifesting in more decidedly oppositional guises. Often, fierce opposition is a catalyst for other forms of transformation. Accordingly, it is not unusual to find the circumcision of the under-age and/or unceremonious cutting as forms of resistance to intense expressions of anti-circumcision impulses. These conflicts mutually reinforce each other.

An abiding bone of contention in the controversy about excision is the question of its health effects. Increasingly, the veracity of extant claims about health hazards and the premium that is placed on it as an arsenal for the anti-circumcision campaign, are being attacked. Searching analyses of available research suggest that advocates of abolition are quicker abstractly to chronicle an array of hazards than they are to produce objective evidence to back up their claims about the severity and frequency of health complications. Where these claims cannot be substantiated empirically, they operate as mere propaganda that remain unrepresentative of the lived experiences of circumcised persons. Although existing data are deficient, there is sufficient evidence to demonstrate that the health complications that are attributable to excision vary with the extent and circumstances of the surgery. The health hazards of the operation typically are compounded by the crude circumstances under which it usually occurs, including the lack of anesthesia and the use of unsterile instruments.

Drastic forms of excision such as clitoridectomy are associated with an increased risk of bleeding and infection; the complications of infibulation include serious bleeding, infections, urinary problems, infertility, labor and delivery difficulties, and adhesions and obstructions. There is no objective evidence that directly links excision with mortality. The World Health Organization categorizes a range of possible negative health consequences as follows: short-term complications which include pain, injury to adjacent tissues, potentially fatal hemorrhage and shock, urinary retention, and acute and chronic infections; long-term complications that range from difficulty in passing urine, urinary tract infections, pelvic infections, infertility, keloid scars, abscesses and cysts, to menstrual difficulties, dyspareunia and sexual dysfunctions, and problems in pregnancy and childbirth as well as sexual, mental, and social consequences.

This list is more concise and less exaggerated than the inventories of deleterious sequelae in other literature; nevertheless, it is subject to caution as it derives from cross-sectional studies that are not always able to establish direct causation between the operation and the putative complication. This list is also comparable to other studies in the sense that it offers little guidance for inferring the rates of complications. Recent systematic reviews of relevant materials show that

consistent and conclusive evidence of far-reaching complications are rare. These observations call for the qualification of the claims at the heart of the anti-circumcision campaign strategy. Notwithstanding the observations, the anti-circumcision alliance has done a remarkable job of mobilizing international consensus against the practice by emphasizing its harmful effects.

3.1 Eradication

Systematic efforts to abolish excision date back to the colonial era. In 1946, the British colonial administration in Sudan amended its Penal Code to make illegal all forms of genital surgeries, except *sunna*. In Kenya, interference by missionaries condemned the practice to secrecy; as a clandestine custom, it was particularly difficult to assess the incidence of casualties. In material respects, the intervention also politicized the significance of the operation as some began to appropriate it as a symbol of nationalism. According to Kenyatta (1938), the controversy came to a head in 1929–30 when families who interpreted the colonist measures as an affront to their freedom, social customs, and cultural beliefs hastened to circumcise their daughters, even at the hands of unskilled persons with inevitable tragic consequences.

The backlash recurred in 1989 when the incumbent President of Kenya, Arap Moi, denounced the custom and scores of women and girls volunteered for the procedure in protest of the official sanction. More recently, some grassroots communities are reinforcing, instead of resisting heightening global pressure against circumcision. To this end, several villages have adopted renunciation oaths and declarations that they complement with active learning and socioeconomic empowerment programs. Some eradication strategies train former excisors in grassroots management skills and facilitate their involvement in business enterprises. In lieu of material benefits, certain competing models—especially those that reconfigure the rite to eliminate the ritual of cutting—incorporate creative ways of enlisting the support of traditional excisors.

Several sovereign powers have prescribed an assortment of steps to stem excision. These range from economic sanctions and extradition to prosecution and punishment. In 1991, France became the first country to establish that the threat of ‘genital mutilation’ is sufficient grounds to grant women refugee status. Subsequently, Canada pioneered guidelines expanding the basis of refugee claims to include gender-related persecution which was construed to encompass circumcision. More recently in the United States, a few African women have succeeded in obtaining political asylum or staying deportation by conceptualizing circumcision as persecution.

A series of human rights instruments and provisions can also be read as prohibiting excision. These range

from regulations concerning equal protection and nondiscrimination to those pertaining to the rights of children, the right of sexual and corporal integrity, the right against torture, the right to life, and the right to health. The World Health Organization officially condemned surgical alterations of female genitalia in 1982. The World Medical Association, the International Federation of Gynaecology and Obstetrics, and the Population Fund issued warnings about the risks of the practice and oppose the participation of health professionals in it. In 1990, the Committee responsible for the implementation of the Convention for the Elimination of Discrimination against Women recommended the eradication of the practice.

Although a few African countries have instituted various initiatives to address excision, it appears that the force of culture and the poverty of resources inhibit meaningful implementation of these initiatives. A wide range of official declarations against excision have been made in Benin, Nigeria, Ghana, Burkina Faso, and Senegal. Some European countries have also promulgated relevant laws and policies. Several interventions promote prevention through information, education, and communication campaigns. However, the predominant trend proscribes the practice as a crime that is subject to prosecution. As of the summer of 1994, France was the only country in which the practice of circumcision has actually resulted in criminal trials. In 1982, the Royal College of Obstetricians and Gynecologists found that excision was a very infrequent occurrence in Britain. By 1985 however, a scare of waves of occurrences prompted the promulgation of the British Prohibition of Circumcision Act. Section 1 of the Act makes it an 'offense for any person (a) to excise, infibulate or otherwise mutilate the whole or any part of the labia majora or labia minora or clitoris of another person; or (b) to aid, abet, counsel or procure the performance by another person of any of those acts on that other person's own body.' Section 2 of the Act indicates that genital surgeries are not absolutely prohibited; its precise wording seems to accommodate exceptions under certain circumstances. This section provides that 'Subsection 1(a) of Section 1 shall not render unlawful the performance of a surgical operation if that operation (a) is necessary for the physical or mental health of the person on whom it is performed and is performed by a registered medical practitioner.' This provision allows the continuation of 'trimming' surgeries that typically are performed on women who are dissatisfied and psychologically disturbed by the shape or size of their external genitalia. Plausibly, the mental health exemption can be construed to support psychologically-grounded claims for circumcision. However, section 2 (2) of the Act precludes the consideration of psychological effects induced by any belief 'that the operation is required as a matter of custom or ritual.'

In 1996, the US Congress made the excision of a

person who has not attained the age of 18 a felony punishable by up to five years imprisonment. This statute equally exempts a surgical procedure performed by a licensed medical practitioner, which is either necessary for the health of the woman on whom it is performed, or is performed prenatally or postnatally on a woman. The US Congress further authorized the imposition of economic sanctions against any countries that have a cultural custom of female circumcision and have not implemented educational programs to counteract the practice. Resorting to this course of action as an antidote to circumcision is not without limitations. Withholding or conditioning aid as a mechanism for controlling the practice subordinates humanitarian considerations to political expedience. While there obviously are no simple solutions, it is important to recognize that when deeply embedded cultural attitudes are reinforced by complex economic, social, and political variables, a more nuanced strategy may be more effective than essentially top-down or carrot-and-stick approaches.

3.2 Medicalization

Empirical evidence of the range and frequency of adverse health outcomes posit a strong correlation between the probability of harm and the degree of cutting, the nonhygienic and anesthetic conditions under which it is performed, and the limited skills of the excisor. Drawing on these findings, some authorities recommend a spectrum of medical interventions as a way of containing potential harm. In one initiative, nurses dispense prophylactic antibiotics, anti-tetanus injections, and sterile razors to girls who are later cut by traditional circumcisors. In another model, traditional birth attendants are trained in septic and precautionary procedures for genital cutting. In urban parts of Sudan and in Egypt, the governments have attempted to curtail the adverse health consequences that can be traced to excision by clinicalizing mild forms of the procedure. In the Netherlands, a Welfare, Health and Cultural Ministry report and officials at the Harborview Medical Center in Seattle in the US recommended a similar course of action.

Apparently some African immigrants in Holland circumcised themselves under circumstances that compound the potential harms of the procedure. Their dilemma arose partly because, while they could not afford to be alienated for failure to comply with the cultural mandate for circumcision, the Dutch medical and social workers denied them assistance in executing the operation. To address the needs of these women, the Ministry, on the basis of the findings of a study it sponsored among 500 Somali refugee women, recommended a distinction between mutilating or tissue-impairing circumcision and nonmutilating ritual incisions. The report further argued for official stipulation of conditions under which doctors might

be allowed to perform simple incisions or ritual perforations of the clitoral covering as an alternative to infibulation. The report drew a storm of protests and eventually was superseded in 1992.

In 1996, a similar controversy erupted in Seattle, Washington, when in the interest of some Somalian immigrants, pediatricians at Harborview Medical Center took under advisement the possibility of performing 'symbolic blood-letting' procedures on girls. The proposed procedure would only involve a negligible nicking of the prepuce far less invasive than what is allowed in the circumcision of infant males. Beseiged by outraged opponents, Harborview decided to abandon the prospective accommodation.

The Dutch and Seattle experiences illustrate the extent to which sworn opponents of the practice favor prohibition and are vehemently opposed to medicalizing any variant of the practice—even as an interim measure to arrest potentially dire consequences.

One reason proffered for this position is that the surgical compromise ultimately signals complicity in patriarchal control and diminution of the right of women to sexual and bodily integrity. Some ridicule operations performed under medical conditions and/or supervision as an empty caricature devoid of traditional connotations. Others who envisage a scenario where traditional midwives are displaced by forum change seek to enhance their fundamental opposition to the practice by coupling it with an ancillary aversion to the implicit loss of income for the midwives. Another concern is that medicalization may unduly burden and deplete public funds which could be deployed for less controversial purposes. It is also contended that the compromise creates a slippery slope that can be abused to camouflage severe forms of the operation.

Whatever the validity of these concerns, it is worth ruminating over the merits of changing the forum and form of the practice. The options may be problematic, but as already suggested, there are no exact solutions. Criminalization, which is overwhelmingly championed by the anticircumcision coalition, is not a panacea. Indeed, where not being excized is perceived as a transgression of social mores, attempting an undifferentiated assault may jeopardize the prospects for enduring reform. The rhetoric of the opposition is premised largely on claims about the health hazards of excision. However, a recent examination of how much available research supports widely publicized allegations about the prevalence and harmful effects of female genital surgeries found that most of what are purported to be universal 'facts' vis-à-vis the deleterious consequences are drawn from studies of the Sudan where most women are infibulated. The review confirmed that obtaining irrefutable epidemiological data is limited by logistical and ethical constraints involved in monitoring over time the experience of individuals who undergo the surgeries.

The fact that adverse complications are exacerbated

by the poor skills, anatomical knowledge, sanitary conditions, and surgical equipment that characterize excision in traditional settings reinforces arguments for medicalization. By the same token, instituting a change of form such as symbolic pricking is inconsequential from a health standpoint. Without a probable risk of harm, it is difficult to make a compelling case against the accommodation of consensual genital marking. In this light, medicalization reconciles the need to protect women with a respect for embodied sociocultural identities. Some would even argue that the virtue of tolerance and the principle of self-determination allow accommodation of more extensive genital alterations, as long as the procedure is demonstrably benign. Given the current wave of anticircumcision sentiments, this view is subject to dispute and far from endorsement. Nevertheless, it raises issues that deserve serious attention.

3.3 Education

Several authorities hail education as the single most important factor in combating the practice. For one, law alone seldom changes behavior. Effective legal engineering can hardly occur without favorable public disposition, which in turn can be stimulated by fostering meaningful interactions between legal and educational strategies. In this vein, it is noteworthy that gains achieved through the medium of education are often contingent and enhanced by concurrent poverty alleviation. The emphasis on education and connection with poverty, however, can only go so far. The substantial prevalence rate of the genital operations among very educated and privileged women in many ethnic groups suggests that advances in literacy and socioeconomic status do not necessarily decrease allegiance to circumcision. Undoubtedly, good education is an effective antidote for challenging erroneous beliefs. However, many women undergo circumcision on the bases of rationales that cannot be readily refuted by objective evidence. Ritual thought and action belong to specific symbolic frames of reference and are best understood within the totality of their natural context. Attempting to falsify indigenous explanations of circumcision by regarding them as assertions of facts that can be disconfirmed through formally logical discursive categories obscure valid psychosocial processes.

Female Genital Mutilation

Female genital mutilation is a collective term for various surgeries performed on young girls, often done as part of initiation rituals into adulthood. Other terms commonly used are female genital cutting,

female circumcision, clitoridectomy, infibulation or Pharaonic circumcision, excision, and *sunna*. Except for female genital cutting and female circumcision which also are general terms and used interchangeably with female genital mutilation, the other terms are more specific, indicating the particular type of operations being performed.

1. Extent and Distribution

Sources estimate that perhaps as many as 130 million women in the world today have been mutilated genitally (Toubia 1995). Since relatively little extensive statistical research has been conducted on the topic, prevailing figures quoted tend to vary. Figures usually are derived from approximate population censuses from areas where mutilation is known to be practiced.

As a cultural practice, female genital surgeries are particularly widespread on the African continent and to some extent on the Saudi Arabian peninsula, but are only sporadically documented from the rest of the world. Instances of genital mutilation are reported from selected communities in the Middle East and from Muslim Malaysia. In Europe and the USA, clitoridectomy was until the 1930s medically administered in diagnosis of excessive masturbation, nymphomania, and hysteria (cf., e.g., Roheim 1932, Bonaparte 1953). Cosmetic surgery of enlarged clitorises and labia minora has been reported recently both from the USA and Europe (cf. Walley 1997). In Europe and the USA, female genital mutilation was primarily a single instance phenomenon and not a social convention. During the last few decades of the twentieth century, however, large-scale immigration to Europe, the USA, and elsewhere from African countries where genital operations are mandatory, has extended the geographical location of female genital mutilation (cf. Lionnet 1992).

In Africa, the practice of genital surgeries is contained to certain regions only, most notably to the northeastern and eastern parts of the continent, from Egypt in the north to Tanzania in the south and across the continent along the Sahelian countries from Ethiopia to Senegal. It is practiced in some 28 countries and by a wide variety and number of ethnic groups. The extent and type of surgical intervention as well as its cultural meaning and social context vary considerably making it difficult to generalize across the societies in which female genital surgeries are the norm. Female genital mutilation occurs among Muslims, Christians (particularly among Copts), as well as adherents of traditional systems of belief, among agricultural and nomadic peoples alike and in rural as well as urban communities. The highest regional concentration, that is, where a majority of women in a particular area are mutilated, is in Northeast Africa; in the Horn (Somalia, Djibouti, and Eritrea), across Ethiopia, and into northern Sudan

and Egypt. In Somalia and northern Sudan female genital mutilation is almost universal (Gruenbaum 1996). Elsewhere in Africa, genital surgeries as a cultural practice are scattered and alternate with ethnic affiliation, religious faith, economic class, and level of education. Within the same community, practices may even vary between subgroups and individual families, causing a situation where mutilated women live side by side with nonmutilated females.

As a general rule, where female genital mutilation is performed, male circumcision is also the norm. People themselves often draw a symbolic and social parallel between boys' and girls' circumcision. This is, among other things, reflected in a common term for the interventions in the local vernacular. While a number of societies in Africa and beyond practice male circumcision without cutting their women, the opposite, however, is never the case.

2. Operation Practices

Mutilation practices vary greatly. In some areas, such as Amharic Ethiopia, girls are operated upon within 40 days after birth, while in neighboring Somalia the operation usually is performed when the girls are between 6 and 8 years old (Hicks 1993, Talle 1993). In Kenya and Tanzania the girls are cut routinely just before puberty and often in association with elaborate initiation ceremonies (cf. Murray 1974). In a few, relatively exceptional cases reported among others from West Africa, the surgery is performed after puberty. It also has been reported that married women who have defied traditions and remained unmutilated, in cases of barrenness have undergone the surgery after being married in order to promote fertility. Not only the girl's age, but also the surgical intervention, the performance context, and ritual elaboration exhibit substantial variations. In places in Egypt and among devoted Muslims in towns in the Sudan, for instance, only the prepuce or the tip of the clitoris is excised. This operation is referred to as *sunna* ('duty' in Arabic, i.e., to follow tradition). Surgically, *sunna* is the mildest form of mutilation and physiologically comparable to the removal of the foreskin at male circumcision. Although encouraged by religious leaders, health personnel, and opinion makers as a commendable mutilation form, it is still uncommon. What people label *sunna*, however, in practice is often really a clitoridectomy.

The most widespread form of female genital mutilation in fact is clitoridectomy, an intervention that implies removal of the whole or part of the clitoris, sometimes together with the *labia minora*. In the latter case the operation is also referred to as excision. Various forms of clitoridectomy-cum-excision are practiced from Senegal and Mauritania in West Africa, across Sahel to Egypt in the northeast, and southwards to Tanzania in East Africa. It is carried

out across the whole area where female genital surgeries occur.

The surgically most severe form of operation is called infibulation (from Latin *fibulae*, clip) or Pharaonic circumcision. This is a form of surgery where the *labia minora* and parts of *labia majora* are excised wholly or partly, and often the clitoris; the sides of the vulva are then stitched together. A tiny orifice is left open serving as an outlet for urine and menstrual blood. The surgery transforms the genitals of a woman into a flattened, smoothed, and closed vulva with an oblong scar and a miniscule opening at the lower part. The practice of infibulation is particularly prevalent in the Horn of Africa, in the Sudan (Northern), and in southern (Nubian) parts of Egypt. It also occurs widely in Mali, in northern Nigeria, and among ethnic Somalis in other East African countries. The infibulated women are opened (defibulated) at marriage, either surgically—often by the practitioner who did the closing—or by the husband at penetration.

In medical and anthropological literature it is common to differentiate between four types of genital surgeries: *sunna*, clitoridectomy, excision, and infibulation. The types are classified by a gradient of surgical severity. Variations and modifications of the different types may occur over time as well in individual cases within the same geographical location. In the Sudan, for instance, an intermediate type, a compromise between excision and infibulation, sprung up during the colonial area as a local response to legislation against the practice imposed from outside (El Dareer 1982). The skills and techniques of the practitioners as well as the preferences of individual families may contribute to variation and differences in mutilation styles.

Genital operations usually are performed in the home of the girl and, as a rule, undertaken by an elderly woman skilled in the task. Often these women are local birth attendants as well. In Somalia, the practitioners belonged traditionally to a ritually ambiguous and despised subclan within the community. In other places, and these days even in Somalia, any adult woman with the necessary courage and skills may engage in the practice.

The operation normally is performed without any extensive form of anaesthetic or antiseptic precautions. Different herbs, animal fat, dung, or other substances believed to have homeostatic and cicatrizing properties are applied to the wound after the operation to prevent excessive bleeding and infection. Depending upon the routine, skills, and preference of the practitioner, the instruments used for the surgery are either a small knife prepared for that kind of work, or a razorblade. In the case of infibulation, the severed parts are stitched with thorns of the acacia species, or recently, with catgut. In urban areas, medically trained personnel or paramedics commonly perform 'circumcision' on both boys and girls. In addition to giving prophylactic antibiotics and tetanus injections, the

urban practitioners normally apply local anesthetics when operating. Many parents prefer these modern operations as they tend to reduce the pain and minimize adverse effects, such as hemorrhaging or infection from the operation. With the medicalization of the genital surgeries, men have also become involved in operating on girls. Traditionally, men operated only on boys, while women operated on girls. The same-sex pair of circumcizer and circumcized reflected the thinking of male circumcision as an analogy of female circumcision.

Among peoples in Kenya and Tanzania and in large parts of West Africa, the surgical intervention is associated with elaborate rituals of initiation into adulthood (e.g., Murray 1974). In northeastern Africa, where infibulation is widespread, the operation, however, is not normally followed by any extensive ceremonial celebration. The operated girl is usually given a few presents and the family mark the day with some extra food and drinks, but the event is not a ceremony of great societal worth. In cases of physical cutting being part of some more significant rites of passage into adulthood, the waning of such traditions has not necessarily led to a decrease in the surgery itself. Instead of being part of a larger event, genital mutilation is now often a single act performed on girls at almost any age.

3. *Historical Roots*

The existence of female genital mutilation dates back to pre-Islamic and pre-Christian time. Although the practice as such does not stem from religious affiliation, many people make an association between circumcision and religious faith. This is particularly the case in West Africa where genital surgeries both in men and women are more common in Muslim than Christian communities (Koso-Thomas 1987).

The term Pharaonic circumcision originates from the folk legend that the pharaohs of ancient Egypt performed similar operations on their women. Whether the pharaohs actually infibulated their women or not will probably never be substantiated, but the term nonetheless indicates that we are dealing with a cultural phenomenon of great antiquity.

Greek merchants and travelers who crossed the Mediterranean in classical time mention that female genital mutilation occurred among Egyptians as well as among the peoples along the Red Sea. The sparse descriptions emanating from these travelers, however, do not allow us to ascertain whether it was infibulation or clitoridectomy, or both, people practiced in earlier times.

European travelers visiting Egypt much later reported on the occurrence of clitoridectomy (Browne 1799, Seligmann 1913). However, female slaves from the south (perhaps Nubians from the Sudan or southern Egypt), whom the wealthy Egyptians favored

as mistresses, were infibulated (Widstrand 1964). Some authors held that these girls were mutilated upon arriving in the north by the slave merchants or by their masters to avoid loose living or unwanted pregnancies. This explanation is disputed as early reports suggest that infibulation occurred for some time among the peoples of the upper Nile in northern Sudan. Burckhardt who visited these areas early in the nineteenth century claimed that infibulated girls ('virgins') received a higher price on the Egyptian slave market than noninfibulated ones (Burckhardt 1819).

The beginning of female genital mutilation remains obscure. It has not been possible to determine whether mutilation originated in one area and from there spread to other areas or whether it originated independently in various places. With reference to the African continent, however, it is not unlikely that the practice arose in a culturally, commercially, central area and from there reached and influenced other parts of the continent. This assumption is based upon the fact that the practice of female genital mutilation appears to have had varying historical origins depending when people came into contact with each other (cf., e.g., Murray 1974). Historical and linguistic sources point to the Chusitic and Semitic-speaking peoples living along the Red Sea Coast as a core area of female genital mutilation (Seligmann 1913, Hicks 1993).

Recently, the practice of female genital mutilation is reported to have spread from one ethnic group to another in countries such as Chad, the Sudan, and Tanzania (cf. Leonard 2000, Gruenbaum 1996). In the Sudan, lower hierarchy groups often assimilate the practice of mutilation in order to be able to marry those of higher rank. Young girls in Chad are reported to perform clitoridectomy as a mark of modernity; since around 1980 the operation has become a kind of fashion in at least one reported area (Leonard 2000). Studies from places in West Africa suggest that the expansion of Islam is conducive to the spread of female genital mutilation. Among the ethnic Meru in Northern Tanzania, clitoridectomy has been revitalized as a sign of cultural pride and resistance against rapid modernization. These sketchy, contemporary examples show that the meaning of female genital surgeries may assume various values following shifts in social reality. To know its origin does not explain its present existence (Gruenbaum 1996). One distinguishable trait in the spread of female genital mutilation, however, appears to be the copying of cultural practices of higher status groups by people of lower rank (cf. Mackie 1995).

4. *The Cultural Explanation*

The practice of female genital mutilation is embedded deeply in cultural and moral preferences, gender identity and person forming, perceptions of body

aesthetics, and ethnic marking. The unsuccessful attempts made by the British colonial administration during the 1930s and 1940s to abolish or modify the most severe types of female genital mutilation in the Sudan and in Kenya testify to the social importance of the practice (cf. Murray 1974, El Dareer 1982). Anthropologists and others often associate the tradition of female genital mutilation with a patriarchal social structure, practically and symbolically privileging female reproductive powers over female sexuality. (cf. Boddy 1982, Talle 1994).

People themselves give many explanations to defend the practice. For instance, the pastoral Maasai of Kenya and Tanzania claim that a girl can neither be married nor give birth to healthy children if she is not clitoridectomized. Should she deliver before she is operated upon, the child will die or be born disabled (Talle 1994). In the Sudan and Egypt, uncut female genitals are considered ugly and dirty. Men are reluctant to marry such girls because by not being 'purified' by genital excision, they are held to be immoral in the widest sense. For the Bantu-speaking Kikuyu in Kenya a girl must have her clitoris removed to be considered an adult and responsible person. And so on. People present a plethora of meanings and motives for upholding the practice. Although seldom elaborated on explicitly, the control of female sexuality is at stake. References to moral looseness, unmarriagability, and fertility failures speak strongly to the societal value of female chastity and of male control of female fertility and sexuality (cf., e.g., El Sadaawi 1980, Gordon 1991, Talle 1993).

In Somalia, where the practice of infibulation is particularly widespread, the operation is performed in two stages: the excision and the stitching. First, the clitoris is excised. This is considered an act of purification (*xalaalays*; from the Arabic *xalaal*, allowed by religion). The clitoris (*kintir*) is a part of the body which is associated with dirt and childhood. A girl who has not been operated on is referred to as *kintirleey* (childish, i.e., having clitoris) and teased by peers. To adult Somali women the word *kintirleey* has a very negative and somewhat embarrassing ring. Another Somali synonym for *kintir* is *awle* which means approximately 'with (or having) father.' This term suggests that the Somalis, as a number of other peoples performing genital surgeries, see the clitoris as a male part in the female body and thus held to be unclean. When excised, women become more feminine (Talle 1993).

Where infibulation is practiced, virginity is not held to be a natural condition in women but has to be forcibly implanted in girls while they are still young. The hymen of a woman, which attracts so much interest and attention in many other Muslim societies and evokes strong sanctions if broken before marriage, has little social or cultural significance among infibulation practicing people. To them a chaste girl means a 'sewn' girl. A tight infibulation is a sign of

distinction and moral excellence. Symbolically, the closing is more important than the excision as the cutting of the flesh is irrevocable while the closing of the vulva can, in principle, be executed over and over again. Although never as tight as the first time, later surgeries (after childbirth and at divorce) return the woman's body to its previous state by remaking her virginity (El Dareer 1987). Virginity under such circumstances is not an anatomical facticity but a social category (Hayes 1975).

The closing of her vulva is looked upon as a protection for the girl against indecency and immorality. A reason often given, for instance by Somalis, as to why originally they began to infibulate their girls was to prevent sexual assault of young girls while out herding alone. The infibulation, or the creation of the artificial virginity, is seen as a safeguard against unwanted pregnancies and unidentified paternity. Both in northern Sudan and in Somalia a nubile, 'virgin' daughter upholds and marks the moral standing of the patrilineal group (Hayes 1975, Kennedy 1980, Talle 1993). To leave a daughter or sister 'uncut' is held to be unnatural; the vision of such a woman is beyond comprehension, something which cannot even be expressed in words.

5. A Global Concern

During the feminist wave of the 1970s in Europe and the USA, female genital surgeries became a politicized issue. At the Copenhagen conference in 1980 during the United Nations Decade of Women (1975–85) the issue was brought to widespread international attention. Opponents of the practice asserted that female genital mutilation was a severe abuse of women's and children's rights and demanded legislation against it. The term 'female circumcision' was substituted by 'female genital mutilation' (Hosken 1982). This change of name from circumcision which is used for genital operations on men, was meant to draw attention to the severity of intervention, primarily in terms of health risks, on girls and women as compared with that of men (cf., e.g., Toubia 1995).

Legislation against female genital mutilation is on the agenda of international organizations such as Save the Children, Amnesty International, WHO, UNICEF, and other UN agencies. To prevent the spread of such surgeries into their countries, European governments are passing laws criminalizing all forms of genital mutilation (cf. Lionnet 1992). African countries, Egypt, the Sudan, and Kenya among others, have also passed legislation against female genital surgeries.

The global discourse on female genital mutilation has often been moralizing, racially prejudiced, and without sufficient understanding of the social and cultural context of the practice. Many African women have reacted to the paternalistic attitude that often

permeates the global debate. The term female genital mutilation, which has received widespread acclaim, but which holds the implicit assumption that parents and kin deliberately intend to harm children, is contested (cf. Walley 1997). A more neutral term proposed recently is 'female genital cutting' (Shell-Duncan and Hernlund 2000). African women—themselves frequently victimized by genital surgery—have, however, also been among the strongest opponents to the practice (e.g., Abdalla 1982). The latest voice in a string of personal testimonies of an excruciatingly painful intervention with lifelong suffering comes from an internationally celebrated Somali model, now a UN ambassador against female genital mutilation (Dirie and Miller 1998).

Although opposition is growing everywhere, women continue to favor the practice. They do it not necessarily because they like it, but because they see no other alternative. Africans in exile, exposed to a majority society where mutilation is neither a norm nor an ideal and, additionally, relieved of the social pressure to perform it, may spearhead the eventual eradication of female genital mutilation.

A. Talle

Feminist Economics

This article analyzes the consequences of the underrepresentation of women in the foundation, developments, and applications of economic science.

The use of the term 'feminist economics' appeared in the 1990s with the emergence of a new, extensive, and evolving literature challenging economic theory and research by applying a feminist perspective in all fields of economics. This research, focusing on the relationship between gender and economics, and exploring the extent to which gender bias has influenced economics in all its fields, is based on the idea

that conventional economics is neither universal nor impartial, but that its concepts are built on masculine concerns.

Pluralism and diversity are the key characteristics of feminist economics and they appear in every aspect of the subject. The three main approaches to research in feminist economics are as follows:

(a) one group of studies is devoted to the analysis of the under-representation of women in the economics profession and applies discrimination theories to the profession of economics, stressing the consequences of the absence of women;

(b) a second approach, sometimes described as the 'add women and stir' approach, consists of studies in which a gender component is simply added into classical economics in order to make it more realistic, but without calling into question the fundamental hypothesis and the tools of analysis; and

(c) a third approach comprises studies that fundamentally re-examine the bases and hypotheses of so-called 'universal' and 'gender neutral' mainstream economic theories.

1. Feminism in Economics

The contemporary literature on women in economics developed during the course of the 1960s. Its development was linked to a reassessment of the micro-economic analysis of the behavior of households to adapt to the considerable change in family structures that took place and was due partly to the sustained and continued growth of female labor supply. Within couples, two-earner households have in many countries become the majority. An increase in the number of lone-parent families, mainly women raising their children by themselves, has also been noted.

The use of the label 'feminist economics' appeared more recently with the emergence of a new school of economic thought still marginal within the traditional discipline of economics.

Over the last decade, there has been an increase in research focusing on the relation between gender and economics, which is due largely to the dynamism of the International Association for Feminist Economics (IAFFE), established in 1992 in the USA to provide a feminist perspective in the economics profession. IAFFE annual summer conferences, held since 1992, and the publication of a scholarly journal, *Feminist Economics*, first published in 1995, have contributed considerably to the development of a fruitful challenge of economic theory and research, applying a feminist perspective in all areas of economics. The Association now has over 600 members based in 38 countries.

At the same time, and in a similar vein, the first international conference on feminist economics, entitled 'Out of the margin: Feminist perspectives on economic theory,' was held in Amsterdam in 1993 with over 300 participants from more than 20 nations.

This proved to be a major event, bringing together a series of groundbreaking papers focusing on the relation of gender to economic science. In 1995, a research network working on issues pertaining to gender and work, called 'MAGE,' was created in France, fostering comparative work and cross-disciplinary discussions.

The 1990s also saw the publication of the first anthologies of feminist economics, by Ferber and Nelson (1993), Humphries (1995), Kuiper and Sap (1995), Hewiston (1999) and Peterson and Lewis (1999).

The establishment of the IAFFE in the USA and of MAGE in France and their success testify to the inability of gender-neutral associations to reflect the questions and interests of feminist economists: in these associations, the feminist perspective is anything but mainstream; its sessions generally have a limited audience. The scant interest shown by economists in gender aspects is reflected in the findings of Randy Albelda's (1995) survey of 400 US-based members of the American Economic Association. The salient results (reported by Hewiston (1999, p. 29)) showed that the surveyed economists believed that feminism had made virtually no impact on the methodology of economics or on economic theory (exceptions: labor market analysis 12.3 percent, and household behavior and family economics 11.1 percent); less than one-fifth believed that more space should be devoted in economic journals to 'feminist perspectives on economic analysis'; more than 70 percent either strongly disagreed with or had no opinion on the statement that 'mainstream economics would be enriched if it incorporated more feminist analysis.'

Practitioners of the male sex heavily dominate economic science, and this dominance has heavily influenced the working hypotheses, theories, and methods developed and used. Whereas the discourse associated with research of a high standard is that of objectivity and universalism, the choice of themes covered and methods of analysis would appear to derive inevitably from social constructs which, in the case of economics, are a reflection of tradition: 'Victorian ideology is at the root of the treatment of women in the neoclassical paradigm' (Pujol 1995, p. 17). Economic science is not neutral, it is not a universal science, and it is permeated with sexist hypotheses. The pivotal hypothesis of the rational economic man is not an abstract, sexless concept: the rational economic man appeared to be a male, white, and Western person.

The androcentrism typical of theoretical and applied economic research has engendered bias, particularly in the analysis and design of economic policies, by ignoring the fact that assumptions about gender influence virtually all aspects of economic reasoning. It is this bias, evident in all fields of economic science, which is nowadays being highlighted in publications by feminist economists.

2. Under-representation of Women in Economics

The founding fathers of economics generally regarded women as separate beings, confined to household tasks and devoid of rational behavior. By the same token, the contributions of female economists to the history of economic thought have often been played down or ignored. Even today, female economists are under-represented in positions of responsibility, despite the sizeable growth in the number of female economics students, whose examination results often surpass those of their male peers.

2.1 Women in Economic History

In a forceful book, Pujol (1992) conducted an extensive historical study of the treatment of women by the founding fathers of classical and early neoclassical economics. In a later essay (Pujol 1995, p. 18) she analyzed five elements that characterize early neo-classical views of women based on the writings of the founding fathers, Marshall, Pigou, Edgeworth and Jevons:

- (a) All women are married, or if not yet, they will be. Similarly, all women have or will have children.
- (b) All women are (and ought to be) economically dependent on a male relative: father or husband.
- (c) Women are (and ought to be) housewives; their reproductive capacities specialize for that function.
- (d) Women are unproductive (whether absolutely or relative to men is not always clear) in the industrial workforce.
- (e) Women are irrational, they are unfit as economic agents, and they cannot be trusted to make the right economic decisions.

These elements, which fell within the unstated and undiscussed assumptions, justified the poor position of women in the labor market or their exclusion from it. Pujol (1995, p. 29) argued that 'approaches to women in the neoclassical paradigm have not changed much since the founding of the paradigm in the last decade of the nineteenth century.'

Pujol (1992) also underlined another important aspect of the under-representation of women in economics, namely the underestimation of the contribution by female economists to the history of economic thought. She showed the influence of Harriet Taylor on the work of John Stuart Mill as well as her personal contribution, and presented various works on the condition of women by Bodichon, Millicent Garret Fawcett, Adair Heather-Bigg, Eleanor Rathbone and Beatrice Potter Webb that were ignored by historians of economics.

One example, among many others, of the underestimation of women's contributions to economics is the scant attention paid to the writings of Margaret Reid (1896–1991), who worked on households, and of Charlotte Perkins Gilman (1860–1935), who focused specifically on gender in economic relationships.

'Reid's colleagues at the University of Chicago, Theodore Schultz and Gary Becker, incorporated Reid's idea of household production into their 'new home economics' (Woolley 1999, p. 335). 'Reid's contribution has been largely ignored in the histories of the 'new home economics,' which Becker is credited with "fathering"' (Lewis 1999, p. 437).

2.2 Women in the Profession

As in most professions in Europe and the USA, there is vertical segregation among economists: women are under-represented in positions of responsibility, in all sectors of activity.

In academic circles they do not occupy the most senior positions and are under-represented in the most prestigious institutions. They do not win prizes: not one woman has so far received the Nobel Prize for Economics; only exceptionally do they chair associations of economists, both in the USA and in Europe; likewise, their representation on the boards of journals is poor.

In the publicity leaflet for *Who is Who in Economics* (Blaug 1999), only two out of 19 photographs are of women: Joan Robinson and the newcomer Deirdre McCloskey.

This segregation is also to be found in the field of public administration as well as private companies. The glass ceiling, that invisible barrier hindering women's access to top jobs, is operating efficiently in economics.

Whereas there is everywhere a growing number of female students and graduates (first degrees) in economics, whose examination results are in no way inferior to those of their male peers, fewer women proceed to Ph.D.s and pursue academic careers. The factors put forward in an attempt to explain these behavioral differences include the following:

(a) The absence of women in the classical economics textbooks and the choice of male-oriented or even phallographic examples to illustrate theories: the white Western male is the norm in economics textbooks, but he is concealed behind a gender-neutral, universal façade. Similarly, few pages deal with gender and inequality: women are excluded as objects of investigation.

(b) A classroom environment unfriendly to women, the shortage of female lecturers to act as role models, the examination process, the intensive use of mathematical tools and abstract modeling have also been mentioned; however, the superior examination results of young women in mathematics do not corroborate this last explanation.

Moreover, in the same way as women occupy a traditional role in civil society, if female economists are to be acknowledged and valued by their male colleagues they must confine themselves to narrowly circumscribed fields: home production, voluntary

work, discrimination. Women economists have often written about so-called 'women's issues' such as women's labor force activity and wages, which seemed of little interest to male economists and benefit from a lower level of reward than other fields.'

The Massachusetts Institute of Technology established a committee on women faculty to understand and ameliorate the long-term effects of discrimination in academia: their key conclusion is that (Massachusetts Institute of Technology 1999, p. 3) 'gender discrimination is subtle but pervasive and stems largely from unconscious ways of thinking that have been socialized into all of us, men and women alike. ... Our first instinct is to deny that a problem exists, or to blame it on the pipeline or the circumstances and choices of individual women.' These conclusions could probably be extended to most faculties and universities in the world.

3. Consequences of Women's Under-representation in Economics

Women's under-representation engenders bias and error in the foundations, development and applications of economic science. The androcentric bias in basic neoclassical hypotheses is substantial: historically the entire theory of utility is based on the rational behavior of a *Homo economicus* who may choose to allocate his time to paid work or leisure. Only in recent economic research have male economists realized that life does not boil down to only a choice between paid work and leisure.

Women and the family are invisible in the economic analysis of human behavior: even when gender is central to the subject under investigation it is often ignored, as evidenced by studies of poverty.

3.1 Sex Discrimination

The question of inequality between the sexes has not been the subject of any key works of normative economics; instead, discrimination between men and women is either included in the broader issue of social inequality or ignored.

Discrimination has mainly been the subject of writings in applied and comparative economics, which have quantified it and measured its development but have left extensive shady areas in respect of its causes and dynamic. Two approaches have been followed in formulating the models appraised: human capital theory, which explains the differences evident between men and women on the labor market through differences in the investment in human capital—education, training, experience, health—and discrimination theories, which analyze the differences between individuals whose production capacity is identical—discrimination exists when persons of equal capacity

and with the same skills are treated differently because of their sex (Blau and Ferber 1992).

The factors explaining the segregation of men and women are to be found in the theories of labor supply and demand, institutional theories, and transaction cost theories (Jonung 1998, pp. 36–71). Labor-supply theories highlight the differences between the preferences and aptitudes of men and women, the socialization of roles and the domestic division of labor, all of which affect decision making; demand theories explain segregation in terms of the differing investment in human capital and the notion of discrimination that colors the attitude of employers towards women. Transaction-cost theories point to the incomplete information available to employers, which leads them to adopt discriminatory attitudes based on observations of average behavior; and finally, institutional theories stress the legal and social constraints, the traditions that influence individual decision making.

3.2 Household Economics

For feminist economists, existing economic theory and analysis are unsatisfactory when it comes to studying intrafamily relationships and the distribution of resources within the family unit. According to the neoclassicists, the household or family is a black box: it matters little who produces or who consumes resources; this share-out is a technical matter or one of preference, something of no concern to economic analysis.

The situation of households is characterized by global earnings or global consumption managed by an altruistic head of household who looks after the interests of his loved ones and behaves as a rational economic agent.

This simplistic view can be found in most European-level comparative studies on poverty or earnings inequality. The hypothesis is that resources are shared equally among the members of a household: poor individuals belong to poor households. Households are classified according to the age, occupation, and sector of activity and educational level of the head of the household. Rarely does the composition of the household feature, other than through the simplistic application of a scale of equivalence.

However, certain studies have underlined the importance of power in the distribution of earnings and consumption within households, not merely of preferences and abilities, the sole elements to impinge on the reasoning of economists. Recent empirical research has confirmed that the allocation of resources among family members depends on age and gender. Studies conducted in Asia and Africa have emphasized the high rates of female mortality due to the systematic deprivation of resources suffered by women within households (not necessarily poor ones; see Sen (1989)).

In one of the few studies on distribution within American households, Lazear and Michael (1988) reveal that the division of consumption between parents and children alters radically with the number of adults in the household: as the number of adults rises, the children's share declines proportionately. Furthermore, access to paid work considerably changes the share-out of power within the household. On average, women earning an income have more decision-making power within the family, and this share of the power increases in step with their earnings (England and Kilbourne 1990).

Findlay and Wright (1996, pp. 335–351) have assessed, for Italy and the USA, the way in which an unequal distribution of resources within households affected the measurement of poverty. They conclude that the conventional methods of gauging poverty within households lead to a systematic underestimation of female poverty and an overestimation of male poverty.

The criticisms of feminist economists have addressed the lack of analysis of the household as an economic entity, but they have also addressed the problematic analysis of the household in the new home economics: 'For feminists, the minimum requirement is a model of the household that allows for the conflict of interests and patriarchal power relations within and outside the family' (MacDonald 1995, p. 185). New home economics, an example of the 'add women and stir' type of studies, is based on an implicit hypothesis of women's natural superiority in nursing and housekeeping which justifies, from the point of view of efficiency, the division of labor within the family. It used to treat the sexual division of labor in the family as if the differences were biologically predetermined and not socially constructed. The neoclassical model or child support model disadvantages women by obscuring and justifying men's neglect of their parental responsibilities.

Bargaining theories and game theory are also becoming increasingly popular in dealing with intra-household allocations: the game theory model of household decision making is an interesting approach to overcome the restrictive assumptions of household intrafamily consent and formally develop a more realistic family behavior pattern. One application is the treatment of 'fertility as a prisoner's dilemma' (Ott 1995, p. 89). However, formal modeling limits the reality of analysis and the 'cooperative conflict' approach developed by Sen (1990) and Agarwal (1994) which incorporate qualitative, historical, and cultural variables provides an interesting alternative to game-theoretic models.

3.3 Labor Economics

Labor economics, along with the new home economics, is the first field to incorporate gender into the neoclassical framework. Gender has been included in

the models without challenging the theoretical foundations; it was merely a matter of arriving at a more accurate analysis of observable reality.

The mainstream understanding of women's employment in labor economics is 'men as breadwinners and women as second earners.' The concentration of women in low-wage occupations and atypical employment appears to be a result of their own choice.

In fact, there is circular reasoning at work here: women choose less well-paid posts which enable them to take on the domestic chores for which they have a preference and are made in the knowledge that the performance of domestic chores reduces the earnings which they could command from employers.

Numerous econometric studies (Silvera and Sonnac 1996) have attempted to explain the persisting wage gap between women and men: even when controlling for differences in working time, educational attainment, training, tenure, occupations, sectors, etc., an unexplained gap amounting to 11–14 percent of women's wages remains. This gap, a measure of pure discrimination, exists even in the countries where protective laws concerning wage equality are in application. However, and contrary to neoclassical principles, women's lower wages are not associated with lower unemployment rates: in nearly all European Union countries women's unemployment rates are considerably higher than men's.

3.4 Data and Methods in Empirical Economics

The same bias is evident in the development of statistical tools: to include a feminist perspective in empirical economic analysis, new kinds of data and indicators have to be constructed, and there is a need for more qualitative data and for panel data sets.

The available data concerning the labor market, for example, are constructed around standard male practice: full-time paid work without interruptions. In most cases these are individual data with no information as to the individuals' household or lifestyle.

The data available from national statistical agencies to study women on the labor market are inadequate in many ways (MacDonald 1995, p. 188):

(a) there is a preponderance of cross-sectional data, and very few panel data;

(b) the level of aggregation makes it impossible to study issues of segmentation within occupations;

(c) labor force data are collected on the individual, with information on the family context either missing or inadequate;

(d) the use of categories such as 'personal or family reasons' versus 'economic reasons' in labor force surveys, to classify reasons for not looking for work or for working part-time, embed gender biases in the data;

(e) skill measures have been shown to be gender biased (Boyd 1990); and

(f) it is difficult to measure changes in the quality of jobs.

National accounting ignores all non-monetary aspects: women's traditional contribution to growth—domestic work and child rearing—are never quantified. To develop alternative indicators of economic and social welfare is an important component of feminist economic research.

Bias in measuring economic growth, ignoring domestic work, leads to wrong political decisions insofar as no account is taken of cost when policies negatively affect home production. The fact that no value is attributed to home production, and that it is statistically overlooked, leads to an inferior allocation of public expenditure.

3.5 Policies

One example of the adverse effects of mainstream economics on economic policy is the structure of social protection systems. These often refer back to the neoclassical patriarchal model: a single main income provider per household. This reference engenders discriminatory practices, which can adversely affect the female supply of labor and can keep women in a situation of dependence. The existence of discriminatory measures, the trend in family structures, and the contradictions between the labor market and social security systems are three elements that lie behind the issue of individualizing social security entitlements.

As they operate at present, Europe's social security systems exert a discriminatory effect on women by two means. First, these systems do not ensure adequate protection for workers in atypical circumstances, among whom women are over-represented: such persons are often deprived of proper protection, mainly with respect to unemployment and pensions. Second, the absence of individual entitlements and the proliferation of derived rights forces women into relationships of dependence tinged with insecurity, which discourage them from entering the official labor market and results in inequalities between the benefits received according to family circumstances. Europe's taxation and social security systems contain various 'inactivity traps' which were deliberately set and still exist: derived rights in social protection systems are an incentive for women to remain at home or to engage in undeclared work, since marriage automatically confers on a spouse the healthcare and pension benefits enjoyed by the partner. The advantages granted to the home-based spouse by the tax system, namely due to dependents' allowances, as well as all the allowances linked to inactivity, such as career breaks, constitute inactivity traps that affect a far larger number of persons of working age than the unintentional traps that are currently being singled out for corrective action (Jepsen et al. 1997, pp. 81–98).

Whereas the Welfare State gave men their inde-

pendence in the market, it also reinforced the economic dependence of women on men by ignoring the sexual division of labor.

4. The Future: a Reconstruction of Concepts

Ferber and Nelson (1993, p. 8) identified five, not necessarily mutually exclusive, responses to perceived inadequacies in the academic discipline:

(a) Affirmative action: based on the idea that the central problem is the under-representation of women and acting to correct this by monitoring but not criticizing the discipline itself.

(b) Feminist empiricism: not calling into question the tools but rather the way in which they are used and the manner in which the issues are addressed: 'It is not the theory that is patriarchal, but the questions male economists have asked and the conclusions they have drawn and particularly the policy implications based on the research' Gustafsson (1990, p. 6); Ferber and Nelson (1993, p. 8) noted that 'Casual conversation suggests that most feminist economists currently adhere to this view.'

(c) Feminist difference: the replacement of male bias by a feminist bias, not a quest for objectivity but subjectivity, emotion, holistic approach (less well represented).

(d) Feminist postmodernism: to deconstruct traditional conceptions, the key point: is gender a meaningful categorization?

(e) Feminist constructionism: analyzing the social production of gender identity.

Whatever the classification, the reconstruction of economic concepts underpins the work of feminist economists: the concepts used for analysis and the way concepts are linked together in the theory may be better suited to explain the activities of some groups than others: they are culturally biased and show a tendency to treat male values and practices as universal. A gendered view applied to all parts of economics questions the hypothesis, methods, and data used.

The aim is also to take greater account of complex social constructs that have been ignored or inadequately incorporated into economic modeling. This means taking account of societal variables often neglected by economists, and implies a reconstruction of traditional databases that are unsatisfactory for gender mainstreaming.

Feminist economics also considers gender as a central category for analysis: a feminist reconstruction of economic theory can improve all the different fields; this new economics will not just address feminist issues, but will be better economics.

D. Meulders

Feminist Epistemology

Reflecting on feminist epistemology, namely the claim that there are distinctively feminist perspectives on the theory of knowledge, initially proposed at the end of the 1970s, is a little like recalling the English Chartist movement with its utopian program of radical political reform. Within what historians would regard as rather little time, what was seen as an absurd and impossible political project, not least the demand for universal suffrage, was to become an everyday reality. The utopian dreamers turned out to be more practical than the dismissive establishment. The equally utopian proposal for a distinctively feminist epistemology was placed firmly on the theoretical agenda of the second wave of feminism by the end of the 1970s. Within just two further decades, substantial aspects of the feminist epistemology debate began to find acceptance, not just among the diversity of feminists, but much more widely within culture and society.

That hot debate among the scholars and activists of the women's movement, which gave birth to the claims for feminist epistemology, took rather little notice of disciplinary boundaries. The new field they were in the process of creating, 'Women's Studies,' was self-consciously not only highly innovative but was also transgressive. Having found that the academic gaze was blind to the bodies and lives of women, to say nothing of sex–gender relations, there seemed little purpose in deferring to the canon of the old exclusionary disciplines. Thus the new epistemology drew in theorists whose disciplinary formation lay in philosophy, psychoanalysis, biology, history, physics, and sociology, but whose cultural products often showed little trace of their formation. These feminist epistemology debates, without quite ever settling down and forging an unequivocal consensus, have entered

and helped foster profound changes in many academic disciplines, particularly where the mode of production of knowledge requires rather modest capitalization. The so-called 'Little Sciences' have proved much more susceptible to change than the 'Big Sciences.' Thus the most power charged techno-sciences of molecular biology and informatics are proving to be remarkably resistant to the kinds of internal changes that primatology or sociology have experienced.

1. *The Birth of Academic Feminism*

Despite the power of late twentieth century feminism to touch women worldwide, the development of academic feminist theorizing required financial support. During this key early period support given to Women's Studies by both the Ford and Rockefeller foundations enabled US academic feminism to develop more strongly than its counterpart within Europe, not least in the development of feminist approaches to the theory of knowledge. By contrast, although Scandinavian research policy was swift to support Women's Studies, it did so as part of policy-oriented, rather than as basic research, while in Western Europe, with the exception of The Netherlands, support from either the state or from foundations was slow to arrive. Thus, while there was a rich outpouring of articles and books published by feminists from many countries criticizing existing theories of knowledge and proposing alternatives, the confident assertion that there were distinctively feminist perspectives on epistemology had to wait until the publication of *Discovering Reality* (Harding and Hintikka 1983). The editors, the US philosophers of science, Sandra Harding and Merrill Hintikka, described their theoretical project.

During the 1990s, feminist thinkers provided brilliant critiques of the political and social beliefs and practices of patriarchal cultures. But less attention has been given to the underlying theories of knowledge, and to the metaphysics which mirror and support patriarchal belief and practice. Are there—can there be 'distinctive feminist perspectives on epistemology, metaphysics, methodology, and philosophy of science' (p. 9)?

The US contributors, divided between deconstructionist accounts of the values embedded within organized knowledge or scientia, and those which try to set out the conditions for rebuilding these as feminist knowledges. A key target was the natural sciences, which had, with immense success, claimed to be above culture. In setting the natural sciences as their target, the feminist critics of science shared more than a little in common with the new, post-Mertonian, sociology of science, although there was little visible connection between the two. However, the very title of the book indicates that these were daughters, albeit dissident daughters, of the enlightenment. As feminist critics of

science, they sought to replace what they saw as flawed accounts of reality with more reliable accounts free from ideologies and relations of domination. For this generation of theorists, the fact that reality was both real and knowable was not significantly at issue; the nominalism which was to sweep the 1980s and 1990s, was not, at that moment, a powerful current. Recognizing the power of foundationalist thought, the authors set out to analyze the patriarchal constructions of those cultural giants who had deeply shaped Western culture from antiquity, to the early theorists of modernity to the late modern figures of Darwin, Marx, and Freud. Within the natural sciences it was not by chance that the focus was Darwin and the life sciences, and not, say Einstein and physics, for biology was the discourse which claimed cultural authority to define women's nature.

The definition of women's nature was an old battleground, with pioneer nineteenth century feminists arguing that in Darwinian theory, only men evolved. Unquestionably, scientific sexism along with scientific racism demanded critical attention; clearing away the culture of biology-as-destiny would help create a political space in which new human subjects could claim agency. Where in the past such detailed critiques had been mounted predominantly by progressive men biologists, as women entered the laboratories, their consciousness raised by the second women's movement, they too had the skills to enter the lists in their own right. The pioneers among these feminist biologists include Ruth Hubbard, Marian Lowe, Ethel Tobach, Betty Roscoff, Anne Fausto Stirling, Ruth Bleier, and Lynda Birke. These insisted that the androcentricity which produced and reflected a patriarchal culture also produced poor biology, and that a more faithful, more reliable account of women's nature could only be produced through feminist science resisting the relations of domination. It was the pioneering work of Carolyn Merchant (1980) as a historian of science that linked the problem of gender domination with the domination of nature. While this link by the feminist historians opened a continuing connection with the burgeoning environmentalist movement, the feminist life scientists made a powerful connection with the women's health movement. Both had, and have, epistemological and political implications.

Their deconstructionist critiques (without Derrida) constituted an immense methodological challenge to contemporary biomedical research. They charged successfully that biomedicine had taken the body of the male of European bio-geographic ancestry, or 'race,' and fetishized it as the universal human body. They demonstrated forcefully the ways through which women's bodies, apart from their problematic reproductive systems and their troublesome psyches, along with the bodies and minds of other Others, were subsumed within a demonstrably false universalism. Under the impact of this epistemological questioning,

together with the increasing presence of historically excluded groups within the laboratories, the discourse of biomedical research has gradually but dramatically changed, above all in the study of the pre-eminent lethal diseases of the West. Thus, heart research now routinely explores difference without hierarchy, where previously the study of the heart of the pale male was equated with some universal human organ. Researching cancer also underwent a sea change. It was not simply the immense pressure to address breast cancer seriously but, almost ironically, this attention to sex–gender difference has led to greater attention being paid to the specific problems of men, not least prostate cancer. Even mental health began to address gender and ‘race’ difference without automatic notions of domination. This was feminist epistemology in action.

2. *The New Feminist Epistemology*

This successful critique of biomedical science as skewed and inadequate, bad for women and bad for science, fostered an initial comfortable solidarity between the pioneer feminist science critics, embracing both the feminist biologists and those, typically from the social sciences and humanities, engaged in setting out the theoretical project of a distinctively feminist epistemology. One of the most influential theorists of the new feminist epistemology was political scientist Nancy Hartsock (1983), who formulated and named feminist standpoint theory. Her socialist feminist project revisioned Marx’s theory of knowledge. Taking the project of a proletarian science, she runs it through the sieve of feminist analyses of the specificities of women’s reproductive labor. She argues that it is a feminist consciousness that gives rise to the distinctively feminist standpoint. This approach was shared by Harding in the same volume, and by sociologist Hilary Rose in her *Signs* article (1978). In the important earlier natural science issue of *Signs*, the historian Donna Haraway (1978) had already spelled out the need to rebuild the life sciences outside the relations of dominance. In this project of a successor science these feminists reflected the strong Hegelian and Marxist influences in their work. The heretical claim that nature and not just society could be more reliably ‘seen from below’ challenged the hegemony of the claims of the natural sciences to be a culture of no culture.

Feminist standpoint theory, particularly when it was directed to the study of nature, represented a theoretical development from the ‘two sciences thesis,’ articulated initially as the struggle between proletarian and bourgeois science by the social relations of the science movement of the 1930s and 1940s, lost in the Stalinist period, but subsequently re-articulated as a rainbow politics of ‘science for the people’ by the radical science movement of the 1960s and 1970s. Other influential feminist science theorists came at the

epistemology question from very different theoretical and political trajectories. Thus, philosopher Helen Longino, while concerned to define a feminist science, did so by specifically repudiating the Hegelian master/slave argument; for her the view from below carried no epistemic privilege. Evelyn Fox Keller, by contrast, took a psycho-historical approach, focusing on the gendered origin stories of science. She saw masculinity as embedded in that mechanical philosophy which had triumphed in those founding years of both modern science and capitalism.

Not only did early feminist epistemology theorizing show little deference to the existing canon, initially it paid little formal attention to the paradigm-breakers emerging from the crisis of French social thought in the wake of the defeat of 1968. Few of these early feminist epistemological texts paid attention to the theorists of post-structuralism and post-modernism. As noted above, self-proclaimed feminist deconstructionists paid little attention to Derrida or to the discourse analysis of Foucault, or to Lyotard’s post-modernistic project, even though debates were raging around these in the mainstream disciplinary discourses. Despite the parallels which have led to some over facile assertions such as ‘feminism is part of post-modernism,’ these new currents were relatively slowly taken into feminist theoretical production. They first entered the humanities and then, with continuing resistance, the social sciences.

3. *Disciplining Feminism?*

Feminism’s successful arrival within the academy by the end of the 1980s brought with it substantial epistemological implications, not least the restoration of disciplinarity within feminist discourse. Feminists began to address the specific canon and current debates of their own disciplines; the ethical and political commitment to address the feminist movement both in and out of the academy increasingly weakened. The language of feminist theorizing soon changed. The early commitment to transparency and accessibility ceded to a new complexity, even obscurantism. There was a sudden interest in post-modern theorists, whom an early, more politicized, generation of feminists had set aside for their anti-feminism; earlier theorists such as Nietzsche became widely discussed despite an evident anti-semitism and misogyny. While disciplinary boundaries appeared, the claims of theorists became grandiose. Feminists in the humanities often spoke of ‘feminist theory,’ by which they meant more precisely feminist humanities theory, but tacitly let the term carry with it the aggrandizing claim that this had universal power over the diversity of fields. Even feminist sociology, something of a bastion of critical realism, entered a period of self-questioning. When the differences between women, whether of class, ethnicity, and bio-

geographic ancestry were so very visible, how did it make sense to speak of a single feminist standpoint? Theoretical developments responding to these challenges by feminist sociologists such as Canadian Dorothy Smith, German Frigga Haug, and African American Patricia Hill Collins gave standpoint theory a new and enriched life.

4. Feminist Science Wars?

Among feminist science studies scholars it was the historian Donna Haraway who embraced post-structuralism decisively, simultaneously throwing into question the possibility of universal reliable knowledge. In a key paper (which echoed silently philosopher David Bloor's methodological stance of refusing to privilege the truth claims of the natural sciences), Haraway, despite her respect for Hubbard as a pioneering feminist biologist, pointed to her uneven treatment of truth claims. She argues that for Hubbard, good science remained privileged; only bad science was to be deconstructed. This epistemological difference between the feminist scientist and the feminist historian foreshadowed, with some strained courtesy, the divisions among the feminist approaches to science theory which were to develop.

However, the tensions between feminists science theorists were never characterized by the savagery of those within mainstream epistemological fights, above all those of the Science Wars. Science theory feminists, despite their theoretical differences, frequently shared a desire to build solidarity between those in science studies and those in science. Thus it was matter of common recognition that natural scientists, particularly biologists, had to be realists. It was equally clear that, for science theorists, more relativistic positions were entirely possible, whether they were historicized as by materialism or full-blown as by nominalism. Feminist science theorists routinely drew back from stark 'either/or' choices, not least those dichotomously opposing relativism to realism. Thus, where the early Harding had shared Rose's concern at the hyper-reflexivity of the strong program of science, and the reduction of science just to social relations proposed by Robert Young and the *Radical Science Journal*, her subsequent publication suggested a new theoretical ambiguity. Certainly reviewers who were outside science theory of *The Science Question in Feminism* (Harding 1986) diversely claimed the book both for standpoint theory and as support for the more relativistic approach of post-structuralism. The ambiguity was not accidental but typical of the feminist science theorists as they fought to avoid an unwelcome dichotomy.

Later, Haraway made a sophisticated attempt to spring the 'either/or' trap: unwilling to lose all claim to objectivity she proposes a feminist objectivity built from 'partial critical knowledge located in multiple

embodied sites sharing a web of connections called solidarity in politics.' Harding too made an attempt to go beyond the 'either/or' dichotomy in her advocacy of 'strong objectivity,' an argument which has much in common with the earlier externalist analysis of Marxism.

5. Global Technoscience and Global Feminisms

In a quite extraordinary way, the feminist epistemology debates have paralleled and offered an entirely different face to the widespread demands for equal opportunities within the labor market, including that of science. This, whether claimed for reasons of justice or for economic efficiency, has become subtly linked to arguments about changing the character of cultural production, typically side-stepping whether the claim entails an appeal to social, cultural, or essentialist difference. Today, innovative corporations concerned for their global markets sound remarkably like dedicated multiculturalists in their arguments that products aimed at a socially diverse market are better if designed and produced by a matching diversity of producers. That the former tend to equate better with 'sells more' and the latter equate better with 'is more democratic' and 'will produce a more sustainable science and technology' is almost incidental. Both are responding to the feminist epistemological challenge that who gets to produce knowledge, and who is excluded, matters.

But it has been the advent of what social theorists have termed the risk society, that is, where the development of science and technology have become associated intrinsically with major environmental risks, which has also fostered an immense turn towards democratic control to protect the entire socio-ecosystem. This immense cultural and political move has paralleled the struggle within the sciences. Working from outside science, a mixture of NGOs and mass popular movements from both the North and the South have confronted the technosciences and the corporations. As we have seen with the fate of the Kyoto agreement, individual governments and global corporations continue to mobilize the old constructions of science as outside culture and capable of producing certainty, in order defend themselves against the need to take socio-ecological risk seriously. Nonetheless, although it would be a mistake to announce the environmentalist cause won, it has become less and less easy for the corporations and supportive governments to pursue their commercial and technological objectives without any sense of global responsibility and concern for either human or green nature. Where they display such indifference they find themselves confronted by new alliances capable of mobilizing immense popular criticism. The more sophisticated recognize the need for sustainable development and are more open to new more socially

inclusive forms of governance. How far these are serious or tokenistic is too soon to judge.

It is only possible in a brief article to do little other than hint at the links between the feminist epistemology debates and these huge cultural and political developments. Sometimes, as with the mass people's science movement in India and the work of the feminist science theorist and activist Vandana Shiva, the links are more evident. But it will be historians looking back at this extraordinary shift in the cultural status of science and technology at the cusp of the twentieth and twenty-first centuries, who will have the pleasure of disentangling the cultural and political contribution of the feminist epistemology debate to these sea changes.

Feminist Ethics

Feminist ethics has its roots in the more general feminist theory and politics, going back to Mary Wollstonecraft's Declaration of the Rights of

Women, and on through the work of Jane Addams and Charlotte Perkins Gilman early in the twentieth century, work that took women's moral visions seriously. As an intellectual discipline in Anglophone nations, it was born in the 'second wave' of the Women's movement in the mid- to late-1960s, taking a few clues from de Beauvoir (1948). The early feminist theories in this 'wave' were written by activists in the movement as position papers to provide conceptual and theoretical bases for charting strategy. The basic concerns and projects of feminist ethics today have grown from the political roots.

As time passed, the feminist activists entered professions across the disciplines. They established journals and courses and eventually the discipline of women's studies itself was legitimized and institutionalized, with its own subspecialties that include feminist ethics. Although feminist intellectual work has always been multidisciplinary, its institutionalization has taken place in the traditional context of departments, course assignments, disciplinary specialties, etc. One outcome has been that feminist ethics, like traditional ethics, has tended to fall within the territory of the humanities, despite the fact that the social sciences also have essential contributions to make.

Intellectually, feminist ethics was shaped by criticisms of the traditional moral theories that were developed to suit life in secular, Western capitalist democracies. Moral subjects and agents were defined as autonomous individuals who were equal under morality and the law—a stereotypically male subject. The traditional theories incorporate, for the most part, a variety of dualisms in which one side is valued over the other, underwriting an ethics that supports dominance and subordination of many sorts. The dualisms fundamentally value reason over emotion, with men identified with reason and mind and women (and the racially subordinated) identified with emotion, body, and nature. Out of this soil a variety of feminist moral theories have grown, ranging from modified, liberal theories of equal opportunity and rights; to theories of mothering, care, and relationship; to lesbian ethics; liberatory ethics; standpoint approaches; third world and minority approaches; and the feminist ecological ethics that is now being developed.

From the beginning, feminists worked in 'applied ethics,' for example, on moral issues of abortion, violence, prostitution, AIDS, clitoral cutting, the environment, peace, immigration, and many others. All of these theorists insist on taking women's experience seriously. In addition, some feminists focus on issues of power and dominance, insisting that feminist ethics must be 'liberatory' and provide guides for action. The liberatory focus can be seen as asking, 'What would an ethics be like that takes patriarchy, or racism, or anthropocentrism seriously as a social and political structure?'

The dominant public ethics in the Western democracies is an abstract moral theory of impartial reasoning, under which autonomous individuals freely chose principles of rights and justice and make their decisions accordingly. It has been used to good effect in some places as women argue for equal opportunity and rights. The impartial ethics is implicitly radical because it is supposed to apply to all individuals regardless of gender, race, age, ethnicity, relationship, etc. In practice, the radical extension to all individuals was politically won during nineteenth and twentieth century struggles to extend the suffrage, change property laws, and so on. In the process, the ethics itself was modified so as to include women (and others) among the autonomous individuals—leading to the intellectual discovery that the original moral agents of the theory were conceived to suit a stereotypically Western, white, higher class, male model. A family of feminist moral theories sprang up to remedy the problem.

The dominant Western ethics of justice, rights, and autonomy relies heavily on the reason–emotion dualism. One feminist alternative has been to remedy the imbalance by emphasizing women’s experience of care and responsibility. Long ago, Addams (1907) called for a ‘social ethic’ that would offer a guide to women’s action by expanding women’s morality in home and family into the public sphere—the Settlement House movement and the women’s peace movement were outcomes. This alternative puts the focus on care and relationship rather than on autonomous agents acting individually according to their interests, self-chosen principles, etc., and it has provided an important direction for feminist ethics. Diana T. Meyers, for example, developed an account of moral autonomy in terms of competency that could be exercised either under an ethics of impartial reason or under an ethics of responsibility and care—using studies in social psychology to support her work. Gilligan (1982) distinguished two ‘voices’ in moral reasoning, and two developmental modes, one of them charted by Lawrence Kohlberg’s scale, the other by a scale she developed through interviewing women about their abortion decisions.

Any moral theory presupposes a social theory and a theory of human nature—often implicitly. Kohlberg (1981) was explicit: his view on human rationality relied on Kant, and so did his social theory, traced back to Kant through Piaget and Durkheim. Like the latter, Kohlberg supposed there is an intimate connection between social organization and development of moral reasoning. Differences in the rate of moral development, he said, are due to differences in opportunities for social role taking—and for the highest stage of development, opportunities in the ‘public sphere’ institutions of government, law, and economy are required (historically ‘men’s sphere’), in contrast to the ‘domestic or personal sphere’ of family, etc. Women in general tested

out at the lower stages, and they were diagnosed as confusing moral problems with issues of interpersonal relations.

Kohlberg measured development in terms of subject responses to abstract moral dilemmas. Gilligan developed a different scale for measuring development by asking women about their actual abortion decisions. The basic concepts of her theory were those of care and responsibility in relationships—in contrast to individual rights and justice. She constructed the ethics in the mid-1970s, using interviews with women, but her later work indicates that both men and women use care and responsibility reasoning and develop along her scale.

Gilligan was one of the early theorists of the care and relationship approach, but there were many others, particularly those who focused on mothering as an alternative paradigm to the ‘public man’ that operated in a society of autonomous moral equals. These ‘maternal ethics’ concern care and responsibility among those who are not equal in power or ability—those who are cared for and those who give care, those who are dependent and those on whom they depend. Ruddick’s (1980) work on mothering was widely influential.

To a degree, these ‘care’ ethics accept the dualisms of reason/emotion and public/personal, but they argue for the distinctive importance of women’s experience in developing an ethics for both men and women. However, there are political implications of accepting the dualisms. Tronto (1993) connects the traditional separation of ethics and politics with the division into public and domestic (or personal) spheres, marking it as a boundary that has excluded women from power. She develops a positive alternative of an ‘ethico-politics’ of care.

The ethics of care and responsibility makes a major contribution to philosophical ethics by analyzing moral relations among persons who are not equals. For example, Baier’s (1995) work on trust considers relations among unequals in a way that is applicable in the ‘public sphere’—investigating trust between the governed and the governors. Baier also mined the history of philosophy to find alternatives to the ‘rights and justice’ approach, taking David Hume as a candidate for ‘the women’s theorist’ because he took sentiment and relationship as basic. Other feminists have broadened the ethics to other personal relationships, such as friendship or love, while some have developed an ethics of relationship within lesbian communities (Hoagland 1988, Mohin 1996).

The ‘care and responsibility’ approach has sometimes been labeled ‘feminine,’ rather than ‘feminist,’ because it emphasized women’s traditional place and feminine virtues. Proponents of what is labeled ‘feminist ethics’ claim that any feminist theory must be liberatory, or at least must provide a basis for arguing issues of injustice and domination in the public sphere. For this reason, many feminists have worked to inte-

grate the care and justice approaches (see Held 1995). They insist not only that women's experience be taken seriously, but that patriarchy, racism, class, and other oppressive social structures be taken seriously. Jaggar (1995) has offered an agenda for any ethics that is called feminist: the ethics must underwrite critiques of actions and practices that perpetuate women's subordination; it should prescribe morally justified ways of resisting those practices; and it should envision morally desirable alternative promises of women's emancipation. Feminist ethics should offer a guide to feminist action.

Traditional ethics was criticized because the ideal of a moral agent was modeled on certain men's experience, excluding the experience of women. Both feminine and feminist ethics have themselves been criticized for using an ideal of Western white, middle-class women's experience as the experience of all women—excluding the experiences of many women worldwide. They have been accused of 'essentialism'—assuming women everywhere share certain essential experiences of reproduction and of subordination under patriarchy. This is a very serious accusation, because it questions whether women share a common experience across race and class, in rich and poor nations, in radically different personal and public relations. Because feminists claim to take women's experience seriously, a 'common experience' is needed to make a general 'ethico-politics' that works for all women—whether it is classified as feminine or feminist.

Many critics argue that 'women's experience' is heterogeneous, and it varies along the significant lines of dominance that mark racial, economic, and political oppression. Women of color, lesbians, and working-class women have raised objections—with the result that the varieties of women's experience have been brought into the light. Collins's (1991) work on black feminist thought has offered both criticism and positive alternatives. Narayan (1995) has written on colonialism and the ethics of rights and care, and the place of 'the other' in feminist theory. The early and influential feminist theorist, Flax (1993), now calls for 'an ethics of multiplicity.' Those working in both feminine and feminist ethics agree to the need, but it is by no means clear how the ethics might offer either a general theory of care and responsibility or a general guide to feminist action. As Sandoval (2000) writes, 'US third-world women' have their own strategies of action which suit their own needs in their own situations.

Feminists are committed to respecting the experiences of all women—and avoiding the imperialism of traditional Western approaches. This commitment may be impossible to fulfill, given the multiplicity of ways of life in all the many places of the earth. Globally, women's situations and their moral and political agency differ radically. It is not clear how a secular, Western feminist ethics would apply in a

situation where Islam is important to the lives, identities, and politics of women, for example. In other communities, women have objected to the ethics of women's individual autonomy that is grounded in the ethics. Western feminists have themselves been accused of using Western standards and meanings to define third-world subjects (Ong 1988). 'Postmodern' feminists have argued that feminist ethico-politics presupposes women as the subject of action, and as moral agents, when in fact gender and agency are not givens but are political constructs, enacted in particular times and places (Butler 1990).

Other interesting developments in feminist ethics have been made by the 'ecological feminists.' These feminists offer general criticisms of hierarchies involved in dominance and subordination. They insist that the dualisms of the traditional ethics are incorporated into the social order so as to support dominance in many forms—with domination by men over women and man over nature being central. Ecological feminists share some of their ethics with nonfeminists in the environmental movement, but they insist that understanding patriarchy is fundamental to understanding the hierarchies involved in domination of nature (Warren 1995). One of the earlier books that had an impact was Merchant's *The Death of Nature* (1980), that presents a history of the change in the relation of man and nature from one of respect for a living being (Mother Earth) to a resource to be exploited. Feminist spirituality and 'third world' women have also been important influences in ecological feminism (Ruether 1996).

Within feminist ethics proper, there is criticism of the androcentrism or male centeredness of traditional ethics, but ecological feminists also criticize its anthropocentrism—putting humans at the center of the value universe in a way that permits exploitation of nonhumans. Human interests and human life are the sole moral issues, not only for traditional ethics but for most feminist ethics as well—adding women's interest to men's interest doesn't change that fact. The most interesting of the ecological feminist theories require respect for nonhumans, and they insist on including them within the range of ethics.

Over the years, feminist ethics has come to have a wide influence in other fields. It has made major contributions to biomedical ethics, to business, engineering, and other professional ethics (Leidka 1996, Tong 1997, Whitbeck 1997). The work on care in relationship and the discussions of trust have been particularly important. In this way, feminist ethics has offered practical, new 'guides to action' in some significant arenas of the public world.

Feminist Legal Theory

1. Background

Although it was only as recently as the 1970s that feminist legal theory or feminist jurisprudence were first heard as names for the diversity of gender-focused currents in legal scholarship and argumentation, these strands of contemporary thought have their roots in the 'rights revolution' that took place in the political thought of seventeenth and eighteenth century Europe and the Americas. The foundations of early feminist thought can be traced to explicit efforts to appropriate the emancipatory liberal ideals for women.

The extension of the right to vote was central to the nineteenth century feminist legal agenda. Informed by the social contract theory, early feminists believed that women's political enfranchisement would facilitate their emancipation from historical oppression. The women's rights movement was closely linked to the struggle for the abolition of slavery. In the United States, the campaign for women's vote is associated with the 1848 Seneca Falls convention and the Declaration of Sentiments that emerged from the meeting. It was at Seneca Falls that the former slave, Sojourner Truth, gave her celebrated 'Ain't I a woman?' speech, which questioned the parallel that is often drawn between the legal status of white women and that of slaves in the rhetoric of early nineteenth century feminism.

Despite the significance of voting as the emblematic act of citizenship and of full participation in the *polis*, gender-based discrimination was no less pervasive in other spheres of life. Under the common law doctrine of coverture, a woman lived under the tutelage of her father or other male guardian, until through the sacramental covenant of marriage, her civil legal identity was subsumed by that of her husband under whose cover she derived protection. A woman was typically incapable of making contracts or testamentary dispositions, owning and alienating real property, testifying as a witness in court against her husband, suing or being sued in her own name, or controlling her earnings. She could not even protect her own physical integrity—her husband had the right to chastise her, although only with a switch no thicker than his thumb (see *Gender and the Law*).

The legal fiction of the unity of spouses as well as the rise of separate spheres ideology exempted the private

sphere of the family from state intervention, and rendered women vulnerable to an array of abuses, including rape by their husbands. Beginning in the middle of the nineteenth century, a series of statutes—generically called the Married Women's Property Acts—removed some of the most severe civil disabilities pertaining to women, and acknowledged their personhood for the purposes of the law. Ultimately, struggles for the right to vote, for property rights, for protective labor legislation, for access to education and professional careers, and for related entitlements helped transform the legal landscape. Over the past few decades, feminist strategies have continued to effect change in consciousness and in laws. Legal efforts have focused, *inter alia*, on expanding reproductive freedom, deterring sexual violence, and eliminating sex-based discrimination in employment, education, family, welfare, and related contexts.

2. Definitions

Feminist legal theory is a legacy both of the nineteenth century campaigns for women's emancipation and of the renaissance of feminist activism in the United States and elsewhere since the 1960s. Although there is much debate about its definition, feminist legal theory can be understood as the manifestation in the legal academy of a range of efforts to understand the nature of women's subordination—especially the ways in which it is rationalized and naturalized—and to propose remedies for this subordinate condition. Drawing upon cross-cutting academic and activist traditions, feminist inquiry approaches law both as an ensemble of potential tactics for reform and, more generally, as a site of struggle for a more general political transformation. Most strands of contemporary feminist legal theory have conceptualized law as a historically and socially constructed artifact embedded in particular social relations. Feminist legal theory elucidates the ways in which law facilitates patriarchal dominance and control. Explicating how the doctrines, discourses, institutions, and culture of law perpetuate gender hierarchy, feminist legal theory has provided the impetus for reconceptualizing tightly bonded concepts and premises of legal thought.

Distinctions are often made among various strands of contemporary feminist legal theories. Liberal feminists emphasize the similarities between men and women as rights-bearing autonomous human beings (see e.g., Williams 1982, Kay, 1985, Littleton 1987). Radical feminists argue that society is premised on relations of male domination and female subordination, and that the very epistemological preconditions of law and politics are profoundly gendered (MacKinnon 1982). Postmodern legal feminists show how identities are constituted through multiple structures and discourses that in various ways overlap,

intersect, and contradict each other (Frug 1992, Williams 1991). Cultural feminists emphasize the differences in experience and perspective between men and women, challenging the reification of instrumental capacities of men and denigration of the affective capacities of women which prefer the connection of the individual self to others (see e.g., Menkel-Meadow 1985, West 1987).

The various strands identified above are not an exhaustive inventory of the competing perspectives in feminist legal thoughts, and each has been criticized for its limitation. For example, the cultural feminist perspective is sharply countered by critics who view it as simply an atavistic, throwback to nineteenth century stereotypes, which reified and naturalized the separate-spheres moralizing that entrenched gender asymmetry (Dubois et al. 1985). By the same token, the radical view is criticized for presupposing a unique female point-of-view that does not allow for social differentiation (Cornell 1990). Whatever their drawbacks, it is important to note that these strands are not at all mutually exclusive; their overlap is particularly evident in their commitment to make the world better for women by reconstituting legal practices that have excluded, devalued, or undermined women's concerns.

3. Legal Education

The emergence of the feminist legal theory critique is no doubt linked to the unprecedented entry of women into the legal academy over the past few decades. It was not until 1972 that all bar-accredited law schools in the United States admitted female students. In other countries, the participation of women in legal education has also not been without resistance (see e.g., Dahl 1987, Sachs and Wilson 1978). Feminist theorists have argued that legal education is a microcosm that reflects, reinforces, and reproduces the asymmetric gender relations of the society at large (Obiora 1996). The entire structure of law—its hierarchical organization, its adversarial orientation, and its privileging of formal logic—is considered evidence of its gendered historical and ideological foundations. Studies suggest that the standard law school curriculum marginalizes, distorts, and omits issues of particular concern and interest to women (see e.g., Charlesworth et al. 1991). A recurrent criticism is that the behavioral norms elicited and rewarded by dominant pedagogy are at fundamental variance with socio-cultural norms of female behavior and cause high levels of alienation and role conflict for women in law school (O'Brien and McIntyre 1986).

The idea that gender differences matter is by no means new in the legal terrain. Western philosophical and legal thought is informed and characterized by dichotomous paradigms that may be traced to ancient assumptions of male superiority. Such assumptions found particular expression in systematic sex-role

constraints that allocated public power and authority to men and increasingly relegated the activities of women to the private sphere. One of the theories justifying the exclusion of women from the public sphere posited that there was a discrepancy between womanhood and adulthood; the qualities deemed necessary for adulthood—the capacity for autonomous thinking, rational decision making, and logical action are associated with masculinity, but considered undesirable attributes of the feminine self. The opinion of Justice Bradley in the 1873 United States Supreme Court decision in *Bradwell vs. Illinois* (83 U.S. 130), which affirmed the Illinois bar's refusal to admit a woman, epitomized the operation of the ideological generalization about women's intellectual deficiency and providential ordination for domestic concerns. As he put it, '[t]he paramount destiny and nature of woman is to fulfill the noble and benign offices of wife and mother.'

4. Reform Initiatives

Feminist legal theory has had diverse targets of inquiry, and has sought to answer many difficult, sometimes intractable, questions about law and society. At the methodological level, it has foregrounded gender as an analytic category. Consonant with techniques of consciousness raising which made visible the personal consequences of gender inequities and the commonalities amongst women's life stories, feminist legal method draws and builds upon analyses of women's experiences. Through the critical scrutiny that it has brought to bear on the form and content of orthodox legal theory and practice, feminist methodology has exposed the ambiguities, contradictions, deficiencies, and politics of law. Interrogating the assumptions, arguments, and conclusions which underlie the patterns of constraint that pervade and define the everyday lives of women, it has illuminated how gender hierarchies have been constructed and legitimated in the legal arena.

Contemporary feminist legal theory has provided a framework for the questioning of numerous gendered social practices, such as prostitution and pornography, and made possible the recognition of sexual harassment and various forms of rape as legal categories (see e.g., MacKinnon 1989, Estrich 1986, Smart 1995, Strossen 1993, Shrage 1994). Feminist theorizing has also shown how the private sphere, as exemplified by the family, which had been treated in law as an autonomous realm deserving of protection from state intervention, incorporates myriad forms of gender subordination. Insisting that the 'personal is political,' feminist scholars have exposed the gendered consequences of domestic violence and of the allocation and valuation of 'invisible' domestic labor, such as child care and housekeeping (see e.g., Schneider 1991, Pateman 1988, Olsen 1983). They have also reinvig-

orated debates concerning family law issues, ranging from the consequences for women of traditional marriage, divorce, custody, and child support to issues relating to the control of reproduction (see e.g., Fineman 1991). Exposing how women's unpaid domestic labor and socialization patterns determine the extent to which they can enter the marketplace of paid employment and the terms on which they do so, feminist inquiry has illuminated the connection between domestic arrangements and the structure of the workplace, the regulation of motherhood, the availability of welfare, etc. (Finley 1986, Rose 1992, Radin 1987, Roberts 1991, Abrams 1995, Nedelsky 1990).

Just as beliefs about differences between men and women have rationalized gender inequality, other notions of sexual difference have inspired feminist theorizing. Given the centrality of the principle of equality from the Declaration of Independence to present day political discourse, it is not surprising that feminist legal theory began with an attack on discrimination. Criticisms of restrictive governmental categories were framed in terms of equality of treatment and opportunity. Within this framework, feminists have successfully challenged the assumptions and policies underlying many laws, such as those of female dependency and unsuitability for certain jobs, both in courts and in legislatures. Condemning policies or practices whereby women are denied opportunities simply because of their gender, the liberal feminist enterprise has stressed the similarities between men and women and sought to minimize their differences. Especially during the 1960s and 1970s, feminist jurists relied on a formal equality model which required sameness of treatment for similarly-situated persons and disparate treatments for persons who are not alike as a strategy to trigger the judicial invalidation of many sex-based discriminatory classifications and practices (see e.g., Franke 1995).

To survive judicial scrutiny in the United States, sex-based classifications must bear a substantial relationship to an important governmental purpose. Employing this standard of review, the Supreme Court has insisted on gender-neutral military, social security, welfare, and workers compensation benefits. Under the rule of gender neutrality, in many jurisdictions, the law of custody and divorce has been transformed, giving men (in principle) equal rights to the custody of their children and to spousal support. By and large, the objective of challenging unequal opportunities and the ideology that legitimated them has resulted in a certain undeniable progress. Women have increasingly attained equality in formal rights, but they still experience substantial inequity in social, economic, and political status. The persistence of such disparities is in part attributable to the continuing devaluation of women's capabilities and women's work. The ultimate defeat of the proposed Constitutional Equal Rights Amendment (ERA) in the

USA during the 1980s underscored the extent to which 'traditional' views of gender roles have continued to frame debates. Even in places such as Nigeria, where the mechanism for challenging gender-based discrimination is enshrined in the Constitution, efforts to implement the law remain constrained by deeply embedded customs and tradition.

Faith in formal legal equality obscured its political and practical implications (see *Discrimination*). Equality-based arguments were necessarily value-laden to the extent that they affirmed the status quo in general and accepted of the view of law as rational, objective, neutral, and apolitical. Such equality for women came to mean equality with men—in the United States, with white, middle-class men. In this fashion, the social attributes of men set the norm against which women often appeared deficient. Where there was no man to set the norm (as in pregnancy), it was assumed that there was no discrimination and differential treatment was not condemned. Discourse regarding pregnancy discrimination, for example, ignored women's reproductive health needs. The achievement of formal equality in some settings has aggravated the real world inequality of women in others.

The substantive approach to equality modifies the formalist argument by focusing on the outcome of actual differences between men and women. Proponents of substantive equality demand that rules address disparate outcomes resulting from sex differences. A variant of this model attempts to remedy past discrimination through measures such as affirmative action and comparable worth schemes. An alternative model of substantive equality invokes sex-based biological differences as a rationale for sex-specific protections. A more comprehensive strategy advocates special accommodations to counteract the costs of social norms and practices that disadvantage women (see *Affirmative Action, Sociology of*).

The debate over differential treatment strategies caused a rift in the women's movement. For some, emphasizing women's unique characteristics has exacerbated their economic disadvantage and magnified underlying stereotypes of their frailty. With time, equality has been reconceptualized as an anti-subordination principle to counter discrimination, not just because the classical focus on formal equality implied unfair treatment of specific individuals, but also because it perpetuated gender hierarchy. This perspective, also known as dominance theory, focuses attention on the imbalance of power between men and women (MacKinnon 1989). Increasingly, feminist legal theory has been influenced by a view of the individual as being constituted of multiple, intersecting, and contradictory institutional and ideological forces. This emerging view has been directed not only outward, against conventional legal principles and values, but also inward against feminist legal theory itself (see e.g., Minow 1988).

5. Critique of Identity

Feminist legal theory has been faulted for its failure to condemn the other dimensions of injustice that also mediate gender identity. The preoccupation with differences between men and women has obscured the differences among women and the way that other factors such as race, class, age, disability and sexuality mediate these differences (see *Critical Race Theory; Sexual Orientation and the Law; Law and People with Disabilities*). At the same time that women's choices have been limited, the role of some women—white women of the privileged classes—has been idealized and unreflectively generalized to the situations of other less fortunate women. Consistent with the recognition that the perspective from which one speaks affects the meaning of what is said, some feminists have criticized the liberal mainstream tendency to homogenize and universalize a tacitly normative concept of 'woman'—typically a white, heterosexual, bourgeois, able-bodied, female citizen of an advanced industrial democracy (see e.g., Harris 1990, Crenshaw 1989, Kline 1989, Williams 1991).

Influenced by the post-modern acknowledgment of the plurality of situated realities, these feminists have insisted that the analytic focus of the feminist paradigm take account of social context, structure, and history. Arguing that the category 'woman' has no universal explanatory force, they reject any foundationalist view of identity based on gender distinction alone. They challenge the very notion that there could exist a prototypical woman who can be described in ways that reflect and have meaning for the lives of many different women living in very different geographical, economic, political, and social settings (see e.g., Obiora 1996).

6. Global Dimensions

Gender relations in many non-Western societies are complicated by an intermingling of custom and religion in the law of personal status that governs gender relations. In nineteenth century British debates around numerous gendered practices in colonized regions, the agenda of rescuing non-white women from the barbarity of the culture into which they had the misfortune of being born played an important role in justifying the imperial project. With the intensification of global cosmopolitanism from the 1980s onward, local gender relations have increasingly been required to justify themselves in dialog with alternative modes of being. Gender equity norms symbolize the advance of the human rights agenda.

The most eloquent expression of the prohibition of gender discrimination is codified in the United Nations Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW). The imperatives that it articulates have been consolidated in subsequent documents and conferences such as

the 1993 Vienna Conference on Human Rights. Notwithstanding the force of the appeal of a global norm of gender parity, there is reason to question how well it has traveled across radically different histories, cultures, and socioeconomic structures. Amid the enthusiasm for spreading human rights ideas across the globe, it is easy to lose sight of the fact that abstract formal rights are seldom a panacea. Gender reform initiatives, laudable as they may be, show clearly that meaningful sociolegal acts of transformation must be sensitive to context and culture.

Feminist Movements

Feminist movements are, in the broadest sense, collective efforts to improve the situation of women. Yet much scholarly debate has focused on the question of what movements qualify as 'feminist.' The problem is one of both time and place. 'Feminism' is a term of relatively recent origin, and it was first used in the countries of Europe and the 'neo-Europes,' places such as the United States, Canada, and Australia where European settler colonies flourished. Furthermore, the meaning of feminism has changed over time. Scholars have proposed different definitions of feminism and different ways of categorizing feminist movements. This article considers these various approaches, explores the origins and development of feminist movements in different times and places, and ends with the coming together of women in international feminist movements.

1. Defining Feminism

The term feminism originated as the French word *féminisme* at the end of the nineteenth century and then spread to other languages and parts of the world (Offen 1988). It referred in general to women's emancipation but quickly developed multiple and even conflicting meanings. In the international women's movement in the years before World War I, the term feminism had come to connote, quite specifically, support for legal equality and equal opportunity in the labor market for women and men, particularly opposition to special—what was known as 'protective'—

labor legislation for women (Wikander 1992). Since then a raft of definitions and associations have developed, along with a multitude of qualifying adjectives preceding the word feminism. For some scholars, a feminist movement must specifically embrace that identity, while for others, any activism by women can qualify as part of a feminist movement. The former position means that there can be no feminist movements before the late nineteenth century, while the latter can claim such actions as food riots as feminist. Lerner (1993) locates the origins of the creation of feminist consciousness in medieval Europe, defining feminist consciousness as:

the awareness of women that they belong to a subordinate group; that they have suffered wrongs as a group; that their condition of subordination is not natural, but is societally determined; that they must join with other women to remedy these wrongs; and finally, that they must and can provide an alternate vision of societal organization in which women as well as men will enjoy autonomy and self-determination.

Cott (1989) comes down on the opposite side of the question, arguing that 'not even all activities undertaken by women who claim to have "women's interests" or "women's needs" at heart' are feminist. She proposes, instead, that we distinguish feminist consciousness from 'female consciousness,' that stems from women's shared sense of obligation to preserve and nurture life, and 'communal consciousness,' a sense of solidarity between women and men of any class, ethnic, racial, or other group.

One way scholars have attempted to deal with the complexity of feminism is by distinguishing among different varieties.

2. Categorizing Feminist Movements

The most influential scheme for categorizing feminism and feminist movements has been Offen's (1988) distinction between individualist and relational feminism. Arguing that the anomalous Anglo-American brand of individualist feminism that emphasizes human rights and personal autonomy has been taken as the yardstick to determine what was and was not feminist, Offen asserts that relational feminism, which advocates equity for women in their traditional familial roles as wives and mothers, has been more characteristic throughout time and in different locations. Critics have questioned whether relational feminism is really feminist.

Other schemes for categorizing feminist movements in the past include 'social feminism' and 'hard-core feminism' (Cott 1989) or 'social feminism' and 'equity feminism' (Black 1989). These pairs essentially mirror Offen's distinction. At bottom, the basic divide in these categories is between those who emphasize the sameness of women and men (individualist, hard-core, and equity feminism) and those who emphasize dif-

ference (relational and social, as well as 'domestic,' 'maternal,' and 'cultural' feminism). This ideological distinction has its counterpart in the goals of movements, some of which work to win identical treatment for women and men and some of which advocate different treatment as the right route to equality. In fact, there is no neat fit between an ideological tendency to sameness and the goal of identical treatment, since some feminists have believed that women and men should have identical rights precisely so that women can bring their different (and better) qualities into public life.

For more contemporary movements, scholars have distinguished among liberal, socialist, and radical feminism. Liberal feminism seeks equality for women within the existing social structure, holding that women lack power because as a group they are denied equal opportunity to compete and succeed in the male-dominated economic and political arenas. Thus, liberal feminist movements advocate equal access and equal opportunity. Socialist feminism identifies both class and gender as equally important in creating inequality and calls for a transformation of both capitalism and patriarchy. Radical feminism, in contrast, sees women as a 'sex class and views gender as the primary foundation for the unequal distribution of rewards and privileges. Radical feminist movements, which arose in the industrialized West in the late 1960s and 1970s, like socialist feminist movements seek more than access to existing privileges. Radical feminists call for a fundamental transformation of society based on the superiority of the 'female values' of caring, nurturing, egalitarianism, pacifism, and cooperation.

The categories of feminism have proliferated as research on different kinds of feminist activism has expanded. Scholars have identified Nazi feminists, Islamic feminists, lesbian feminists, and imperial feminists, to name just a few. Increasingly the plural, 'feminisms,' is used to capture the diversity of these varieties of feminism. From a social movement perspective, Rupp and Taylor (1999) have proposed to shift focus away from the ideology of feminist movements to the collective identities that are created and sustained within movements. Such identities exist at three levels: organizational, movement, and solidary. Women develop a sense of themselves as members of discrete organizations, as part of a movement, and, at the broadest level, as women. By exploring the construction of these overlapping identities within specific contexts, it is possible to see how women with very different understandings and strategies and goals might all claim the label 'feminist.'

3. The Origins of Feminist Movements

Social movement scholars point out that everywhere and at every time, women have had sufficient grievances to stimulate the rise of feminist movements. Yet

collective activity on the part of women aimed at improving their own status in society has blossomed primarily during times of generalized social upheaval. In addition, scholars have identified structural conditions that underlie the emergence of feminist protest, at least in the West: changes in patterns of female labor force participation, increased access to education, and shifts in fertility rates and reproductive roles. Chafetz and Dworkin (1986) argue that industrialization and urbanization play a critical role in the emergence of women's movements. In industrializing and urbanizing societies, a large middle class develops, women gain access to education, married women enter the labor force in larger numbers, and the resulting role expansion and conflict results in the development of gender-based and ultimately feminist consciousness. The levels of industrialization and urbanization, the size of the middle class, the extent of women's access to education, and the numbers of married women in the labor force, in combination with the attitude of governments to women's demands, will determine the size of women's movements and whether they qualify as feminist. Despite Chafetz's and Dworkin's attention to movements throughout the globe, their model privileges the western pattern of movement emergence. Feminist movements, scholars have argued, have emerged in other parts of the world in conjunction with nationalist movements, not industrialization and urbanization (Jayawardena 1986).

Although the conditions that lead to the emergence of feminist movements may vary in different parts of the world, there do seem to be broad commonalities in the ways such movements originate and develop. A first stage often begins with the writings of elite women (and men) and demands for greater access to education. In Egypt, e.g., educated, elite women in urban harems began to call for educational opportunity in the context of Islamic modernism at the end of the nineteenth century (Badran 1995). In Argentina, Uruguay, Chile, Brazil, Mexico, and Cuba, women schoolteachers took the lead in the late nineteenth century in calling for expanded education for women (Miller 1991). Chinese women, many educated in Japan, began in the early twentieth century to relate China's weakness to the lack of education for women (Beahan 1975). Typically, women who have gained some educational advantage begin to spread their ideas, often through their own publications. Throughout the Middle East, Asia, and Latin America, women's journals played a central role in introducing feminist ideas.

A next stage was often the formation of organizations devoted to various kinds of social reform. In the United States in the mid-nineteenth century, these included radical projects such as abolitionist groups as well as more societally acceptable activities such as literary societies and church groups. In many cases, demands that originally sprang from women's interest in other causes—that women be allowed to speak in

public or participate in the political process in order to bring about some change in society—eventually came to be voiced as a basic human right. During the national revolution of 1919–22, Egyptian feminists who had earlier formed philanthropic groups worked actively to free Egypt from British domination but experienced disappointment when they found themselves deprived of the vote in the new Egyptian state. This was when the word feminist (in French) first came into use, claimed by the Egyptian Feminist Union, founded in 1923 (Badran 1995). The move from participation in nationalist or anti-imperialist movements to demands for basic political rights and for social freedoms was a common one throughout the colonized and dependent countries.

As feminist movements developed in different places, they often split along ideological, political, religious, or other lines. In countries such as Germany, e.g., the bourgeois women's movement and socialist women's movement had little to do with each other. In England, and to a lesser extent in the United States, the major divide was between moderate and militant groups. The French women's movement splintered along political lines into Republican, Catholic, and socialist organizations. Because feminism as an ideology and movement emerged earlier in the United States and Europe, feminist movements in the rest of the world often give rise to charges of imperialist influence. Despite feminism's origins as an indigenous movement in Egypt, the fact that the upper and middle-class urban women who claimed the label tended to wear western dress and speak French associated feminism with foreign and imperialist forces (Badran 1995). Korean New Women in the 1920s made use of Japanese, British, and Swedish feminist discourses for their own purposes in developing a critique of traditional Korean marriage and sexuality, giving rise to the notion that they were simply dupes of the West (Kwon 1998).

4. *The Two-wave Model of Feminist Movements*

Most scholarship on the development of women's movements conceptualizes two waves of activism, the first in the mid-nineteenth century to the early twentieth century and the second since the 1960s. Evans (1977) explores a variety of feminist movements in Europe, the United States, and Australasia during the first wave, charting the shifting aims of the movements from economic and educational to moral and then political. Evans concludes that the feminist movements of the first wave declined along with the liberalism with which they were so closely associated by the early twentieth century. But there is more continuity in the existence of women's movements than this model suggests. In fact, movements grew outside the Euroamerican arena precisely when scholars think of the decline of feminism in the aftermath of World War I. It may still be useful to

think of two peaks or waves of feminist activism, as long as we remember that not all movements followed the same trajectory and that feminist movements did not die out between the two waves (Rupp and Taylor 1987). Nevertheless, it is clear that feminist movements burst forth with renewed vigor in the 1960s and 1970s in association with civil rights, student and left-wing movements, and movements of national liberation. Often divided on questions of ideology, strategy, goals, and membership, these late twentieth-century movements mobilized around a broad range of issues, from reproductive rights to sexual and economic exploitation to violence against women. Feminist movements both conceptualized women as sharing basic experiences of oppression, asserting that 'sisterhood is global,' and increasingly came to emphasize differences among women on the basis of race, class, ethnicity, nation, and so on. This was true both within national feminist movements and even more so on the international stage.

In the United States, scholars identify two wings of the second-wave women's movement: the women's rights branch, consisting of older professional women organized in bureaucratic national groups working for change within the existing system, and the women's liberation branch, made up of younger women associated with the civil rights and New Left movements who organized small collective groups on the local level and worked for a radical transformation of society (Freeman 1975; Ferree and Hess 1994). The women's rights branch, dominated by the National Organization for Women, founded in 1966, originally worked for legal and public policy reform, while the women's liberation groups pioneered consciousness-raising as a strategy for change and engaged in dramatic 'zap' actions to protest such things as the institution of marriage and beauty pageants and the stock market. Yet over time the distinctions between the two wings dissipated.

The political contexts of different countries in the late twentieth century have been critical in shaping feminist movements and in facilitating or constraining success in moving toward feminist goals. In Western Europe and the United States, feminist movements have had the most success in policymaking where the Left is either very strong, as in Sweden, or very weak, as in the United States (Katzenstein and Mueller 1987). Likewise, in India, the women's movement in Calcutta, which is dominated by the communist party and has a strong left culture, functions more as a political party, while the movement in Bombay, where there is more political competition, takes on more autonomous forms of organizing, including the formation of groups receptive to Western ideas (Ray 1999).

5. *International Feminist Movements*

Since the 1970s, regional and international organizing among women has blossomed, although the origins of

international women's organizations date back to the closing decades of the nineteenth century. In fact, women from the long-established international groups played a vital role in bringing the issue of women's equality to the founding conferences of the United Nations in the aftermath of World War II (Rupp 1997). It was the United Nations-sponsored International Women's Year in 1975, the Decade for Women conferences in 1975, 1980, and 1985, and the Beijing conference of 1995, with their attendant meetings of non-governmental organizations, that nurtured global feminist dialogue (Miles 1996). Although the official conferences and the affiliated forums have proven extremely contentious, struggling over questions of politics, religion, sexuality, and social custom, they have grappled with such basic issues as women's worldwide economic disadvantage, women's lack of reproductive freedom, and different forms of violence against women. Despite variations in feminist movements around the world, international conferences have diffused feminist ideology and practice throughout the globe.

Feminist Political Ecology

Feminist political ecology offers explanations and analyses of human–environment relations by uniting feminism with political ecology, a subfield prominent within geography and anthropology. Political ecology emphasizes how power relations and politics shape the dynamics of economic development, environmental transformation, and social change across geographic scales of analysis from the local to the global. This approach lies at the interdisciplinary intersection of critical development studies, feminism, and environmental studies. Feminist political ecology analyzes identity, difference, and meanings in their relation to sites of environmental change, degradation, and struggle (Rocheleau et al. 1996). This subfield emphasizes policy relevant natural resource management issues and environmental and social justice concerns in both urban and rural places around the world. Feminist political ecology explains how gender identities and social relations shape, and are shaped by, power relations and social inequality, and how gendered inequalities are linked to questions of liberation struggles, environmental change, and degradation. This article examines the changing dimensions of these cultural, political and ecological intersections through an overview of the emergence of feminist political ecology since the 1980s.

1. Feminism and Environmentalism

Feminism's link with environmental issues and concerns embraces both social and ecological theory and political activism that is rooted in the rise of environmental and feminist activism and intellectual activity of the late 1960s and early 1970s. Ecofeminism, environmental feminism(s), and feminist political ecology all refer to the linkages of people–gender–culture–

environment-nature with varying emphases and frameworks (Merchant 1980, Plumwood 1993, Rocheleau et al. 1996).

Since the 1980s, activists' concerns focused upon nuclear warfare and militarism, toxic waste pollution, and deforestation among others. Ecofeminist work, which spanned academic, popular, and literary texts, emphasized that women were both biologically and socially linked to nature. Women's status and subordination was thus linked to environmental degradation and change so that the oppression and degradation of nature and the environment paralleled the oppression and degradation of women (Merchant 1980). However, when viewed from an international perspective, gendered human perceptions of nature as well as gendered material and sociocultural links to the environment varied over place and time and among cultures. In numerous societies around the world, social scientists have documented and explained how changing cosmologies and geographic histories construct and reproduce key binaries: man/woman; culture/nature; self/other. Structuralism and semiotics influenced much of this initial work. Women are commonly, but not necessarily, associated with nature, and landscape, the fertility of the earth, the waxing and waning of the moon, with passivity, and the hearth (Merchant 1980, Kolodny 1984). These cultural metaphors shaped individual lives as well as public discourse through images of Mother Nature/Mother Earth as contrasted with Spaceship Earth, for example. Early ecofeminist work provided insight as to the ways in which nature and the environment are gendered, and then employed this insight to analyze environmental transformation or celebrate the connection in its spiritual dimension. Ecofeminists defined masculinity and femininity as socially constructed categories which are detrimental to people and the environment and are linked to larger social processes such as colonialism and development. Subsequent critiques pointed to the monolithic and essentialist foundations of earlier ecofeminist work. These critiques argued against a monolithic view of woman that was unmediated by other social categories such as race, ethnicity, gender, age, sexual orientation, and citizenship and pointed to the necessity of site specific empirical case studies (Agarwal 1992).

2. *Critical Ecofeminism*

Critical ecological feminism involves a conscious decision to align human and nature in a move beyond the binary dualism embedded epistemology and ideology in the West. In feminist poststructural critiques, masculinity and femininity as modes of identity are examined in relation to our store of knowledge about the human link to nature and the ways in which nature and environment are gendered and socially constructed. Feminist political ecology rejects the dual-

isms of man/nature and emphasizes multiplicity, diversity, and the complex interconnections among ecologies, societies, and politics in questions of environmental change of both short and long-term duration. This insight is linked to the critical examination of development policies and practices and increasing social inequality. A key question is how identity and difference shape resource control, access, and distribution in multiple historical and ecological contexts initially in Africa, Asia, and Latin America. Research examined how the marginalization and exploitation of local communities and ecologies is linked to larger social and economic networks, institutions, and processes.

3. *Gender, Environment, and Development*

Critiques of mainstream economic development and modernization theory at the international scale revealed how women were invisible in modernization initiatives and within development theory and policy more generally. For example, the majority of women in sub-Saharan Africa are food producers who are responsible for provisioning their households. However, throughout Africa and elsewhere, women were, and still are, unable to gain access to the social, financial, technical, and natural resources that would enable them to provide adequately for their households. As women were incorporated slowly and unevenly into the modernist project through economic development programs aimed at their inclusion, subsequent research revealed how gender bias in development and nesting patriarchal ideologies could exacerbate as well as alleviate their particular vulnerabilities. In addition, this research demonstrated how technology transfer deskilled or did away with working class women's work, and how modernization and development policy and practices in Africa, Asia, and Latin America transformed rural environments and indigenous social and cultural networks, often reproducing or reinforcing gender stereotypes and inequalities. These critiques of mainstream development theory and practice drew from structuralism and Marxian political economy. Studies of the nexus of capitalism, development, populations, and ecologies stressed how oppression and injustice are linked to environmental transformation and change, the industrial geographies of resource extraction and capitalism's creations of surplus (Di Leonardo 1991, Seager 1993).

Examining diverse dimensions of women's work and access to natural resources was critical in revealing the ways in which women were largely disadvantaged by mainstream modernization efforts and policies. Intersections of imperial and indigenous forms of patriarchal power and control could constrict access to land, credit, technology, and education and shape human reproduction. Environmental justice move-

ments and feminist research linked poverty and environmental degradation such as tropical deforestation, irrigation, and pesticide poisoning to gendered relations within the colonialism and to development-induced scarcity. Household vulnerability, changing individual, household, regional and national entitlements, and a lack of democracy are linked to the persistence of poverty and to environmental degradation. Gendered identities and relations crosscut racism, class, age, marital status, ethnicity, and nationality.

Alternatives to mainstream development explore indigenous agroecologies and ecological knowledge, the organization and endurance of social movements linked to environmental concerns, and examine popular struggles and resistance by women and by marginalized and indigenous peoples. The ecofeminist project is one of inclusion and interconnectedness. Feminist political ecology refuses to accept binary dualisms linking gender relations and activities to nature and valuing women and/or nature as inferior or unequal (Plumwood 1993). Thus, ecofeminism and feminist political ecology concern struggles for liberation.

4. Human Ecology Politicized

Political ecology emerged from the subfields of human/cultural ecology prominent in geography, anthropology, and sociology. The next section examines the emergence of political ecology and feminist political ecology from these subfields.

Cultural ecology examines society–environment relations and uses the concepts of adaptation and equilibrium and organic metaphors to explain these relations over time and place. Cultural ecologists focused upon case studies involving extractive economies and peasant societies in Africa, Asia, and Latin America. Critics of cultural ecology pointed out its tendencies to explanations, which were functionalist, teleological and devoid of considerations of politics and power relations. Subsequent critiques questioned whether organic metaphors were appropriate for defining human societies and also indicated that research in ecology had moved beyond conceptualizing environments in terms of equilibrium states and were defining them in terms of dynamism, impermanence, and constant change. Women's access and use of natural resources within a cultural and ecological frame progressed in this period as research focused upon issues of women as resource managers and farmers.

5. Gendering Cultural/Social/Political Ecologies

Since the 1980s, political ecology has examined the political and social dimensions of environmental transformation and change primarily in rural areas of

Africa, Asia, and Latin America. It emerged as a critique of cultural ecology's inattention to power relations and considerations of the politics of resource distribution, access, and transformation. Political ecology combines a broadly defined political economy of resource development and change centering upon the role of social relations and processes to environmental change and degradation, resource distribution, access, and control and the social constructions of nature. In its critique of adaptation and equilibrium, political ecology emphasized agrarian and environmental transformation and change throughout the colonial period up to the present day by examining the ways in which capitalism transformed societies, environments, and the relation between them.

Poverty and environmental degradation are proximate outcomes of the workings of capitalism and world market integration. Peet and Watts (1996) define four contemporary directions in political ecology. First, there are attempts to connect explicitly the dynamics of capitalist growth and environmental outcomes at varying levels and scales. Second, is the integration of power relations and politics into examinations of social and environmental change at varying levels of scale from the global to the micro-politics of the household. Third is the focus examining the roles of ideology and social institutions and organizations. This involves probing the roles of knowledge construction and legitimization as well as state–society relations in terms of the politics of environmental development and change. Fourth, concerns the myriad perceptions of environmental and resource problems and the ways in which these problems are struggled over.

Notably, political ecology is also prominent in its critique of neo-Malthusian explanations of environmental degradation and change. These explanations avoid considerations of social structures and processes and gender identities and power relations within specific historical and geographic contexts as ways to understand the linkage between environment and population growth.

Bryant and Bailey (1997) outline four major research themes in political ecology. The first centers on a particular environmental problem or set of problems such as soil erosion, deforestation, or water. The second studies concepts that are linked to political ecology such as critiques of sustainable development. A third examines political and ecological problems by means of a specific regional case study. The final approach which is explicitly linked to feminism emphasizes individual and group social characteristics such as class, age, ethnicity, gender, and race.

Over roughly the same period, feminist studies in international political economy had taken up considerations of gender and environments, gendered resource access and control, and activism and social movements as they involve the environmental change and degradation ranging across geographic scale.

6. Research Directions in Feminist Political Ecology

Contemporary research directions in feminist political ecology concern how knowledge about society, environments, spaces, and places are gendered. Studies take up questions of local, gendered knowledge about ecologies and agrarian, rural, and urban landscapes. Gendered knowledges refer to particular bodies of knowledge such as that of plant species, agricultural techniques, and food preparation and processing which are frequently the provinces of women or indigenous groups. A second strand of research examines changing environmental rights and responsibilities as they pertain to resource access, distribution, and control. Gendered rights and responsibilities may involve differential access to natural resources such as education, technology, land and trees, and the impacts upon female headed households, the poor, or ethnic minorities. Third, feminist political ecology examines the social struggles that fuse social and environmental concerns and contribute to progressive social change.

Environmental degradation is linked to survival and the quality of life. Survival pivots upon questions of entitlement within rural and urban spaces and is linked in by a diversity of production systems and subject to collective struggles. These microlevel questions and struggles are linked necessarily to broader processes of globalization and ecological dynamics across geographic scales.

Feminist Political Theory and Political Science

In popular discourse the term feminism is normally used to mean support for women's rights, while a feminist is someone whose central concern is with the position of women and their struggle for emancipation (Delmar 1986). The definitions are contested by feminist scholars and subject to change. In the 1970s feminism was frequently defined as opposition to the dominance or subjugation of women. By the end of the 1990s it was impossible to define feminism without reference to the concept of gender and it was unusual to refer to feminism in the singular. Feminisms are therefore standpoints. They are also political practices (most often social movements), and sets of ideas and theories. To complete the definition it is necessary to add the concept of gender. Gender is a category that was developed to explore what counts as 'woman' and what counts as 'man' (Squires 1999, p. 54). Thus, one useful definition of feminisms declares them to be oppositions to gender hierarchy, capturing the different situations and interests of different women in the pluralization of 'feminism,' while the social construction of masculinity and femininity is signaled by the term 'gender.'

1. Gender Studies and Feminist Scholarship

Challenging the approaches and preoccupations of mainstream scholarship has proved to be a continuing focus of feminist politics. Originally mainly concerned with 'women's studies,' the attention of feminist scholarship gradually shifted to the study of gender and especially to gender relations and the nature of masculinity and femininity. Feminist writings include critiques of most areas of contemporary scholarship calling into question their sensitivity to issues of gender. The shift had important implications for the social sciences including the study of politics. In the social sciences an important feminist concern is to establish the category of gender as a fundamental social division. The feminist critiques of political science are part of this tendency, addressing the standard themes of research on politics, questioning narrow definitions of the 'political,' and also drawing upon research and thinking about gender in other disciplines.

Feminist political science is therefore interdisciplinary and radical, offering a broad definition of the

field. Feminist political studies take three main forms: (a) feminist political theory which is predicated on a critique of liberalism and challenges the conventions of political theory, (b) feminist political science which is a critique of political institutions and the ways they have been understood, and (c) feminist accounts of gender and politics which combine explorations of gender as a category, as a hierarchy, and as performance in studies of how gender relations are implicated in power. Each area is work in progress, complicated and contested. Similar patterns of development have characterized each of the three kinds of discussion.

2. Feminist Political Theory

The women's liberation movement of the 1960s and 1970s gave a new impetus to feminist politics. This was at first new social movement politics, suspicious of formal hierarchical organizations which were regarded not only as undemocratic but also as sexist. However, feminism was, and is, profoundly political. The early slogan 'the personal is political,' questioned the nature of power and challenged the conventional restriction of politics to the 'public sphere.' Initially, feminist political theory was a matter of unmasking sexist assumptions and the neglect of women by Western Political Theory. Carol Pateman argued that the subjugation of women was a central underpinning of modern political thought and that gender difference made a public sphere possible at the expense of women. She contended that the distinction between state and civil society is only visible if the family is ignored. If civil society is labeled private then family is forgotten in political discussion (Pateman 1988). Hence the addition of women to the concerns of political theory brought the central assumptions of liberalism into question, notably the separation between public and private life.

Recognizing that writing gender differences into political theory required a major reconsideration of political ideas, feminist theorists addressed issues of equality, justice and representation, initiating debates that grew increasingly sophisticated. Originally theoretical arguments were built around binary oppositions or dualisms such as equality/difference, nature/nurture, justice/care, inclusion/exclusion, all thought to parallel male/female dichotomies. Arguments in the equality/difference debates considered whether men and women should be treated the same or whether differences should be taken into account in order to treat both fairly. The justice/care debates addressed a perceived difference between an ethic of justice (in the liberal distributive sense) and an ethic of care (in a maternalist sense), argued to be male and female, respectively.

Representation arguments considered whether women need women to represent them, reasoning that

the identity of the speaker matters to the interpretation of what is said (Phillips 1995, Young 1990). Discussions of justice, equality, and representation tended to converge into arguments about citizenship in which feminists seek to redefine politics in terms that integrate public and private concerns, breaking through the public/private divide (Dietz 1985, Mouffe 1995, Lister 1997). Since the 1980s a tendency to contest the oppositions has become more prevalent as theorists seek to transcend or displace the hierarchies, often by redefining issues and concepts (Squires 1999, pp. 226–33).

3. Feminist Political Science

Although there were very few links with feminist political theory, feminist political science has followed a similar trajectory, developing from the inclusion of information about women to the subject matter of politics to an intellectual concern to establish a gendered discipline. Feminist political science first sought to eliminate the 'bad science' of exaggerating and misconstruing differences between women and men, assuming a male political universe and using data without their original accompanying qualifications. They were troubled by the distortions present in the mainstream of behavioral political science arising, they believed, from an epistemology that separated facts and value and privileged so-called value-free factual accounts. The effect of concern only with putative facts was to allow behavioral political science to factor women out of consideration as political subjects. An overemphasis on measurable political behavior prevented recognition of '...not only the... exclusion of women from what is traditionally political, but also the inclusion of politics in what women have traditionally done' (Nelson 1989, quoted in Carroll and Zerilli 1993). Families, communities, and voluntary groups all went largely unresearched as constitutive of political life. Inevitably, feminist political scientists sought to expand definitions of politics, lending strength to other challenges to overconcern with electoral behavior and elite participation, at the same time as examining differences in men's and women's political behavior. Discussion of the significance of the public/private split and the confinement of women to the private realm were an important challenge to narrow constructions of political power. So too were studies of the crucial part played by the state in regulating sexuality (see Carroll and Zerilli 1993, Lovenduski 1998).

Once it was necessary (and possible) to study the effects of women on previously male-dominated political institutions and organizations, the need for an adequately theorized notion of gender was accepted. As increasing numbers of women appeared in legislatures, councils, and other representative bodies as well as in executive organizations and public

administrations of various kinds, a considerable debate developed about the causes, stability, and results of gender differences in political activity. An especially powerful line of argument for both feminist activists and their opponents was the contention that women should not seek equal presence to men in powerful positions because they would be 'incorporated' and changed by it, they would become unable to represent women because they had been turned by male created institutions into political men. The counterclaim was that once a significant number and diversity of women occupy decision making positions in previously 'masculine' institutions they would be transformed, their gendering altered.

This argument, so important in feminist debate, has echoes in the conventions of the study of political processes (Randall 1991). Once arrangements, practices, and rules are institutionalized, actors learn them, invest in them, and make decisions accordingly. Particular institutions become associated with particular behavior and outputs that may be classified as masculine or feminine (Duerst-Lahti and Kelly 1995). The practices that insulate the positions of typical members and are notoriously difficult to change are gendered.

4. Feminism and Gender Studies

Feminist intellectual concern about women and power generated research in the arts, humanities, and social sciences. In the fields of history, sociology, social psychology, literature, and cultural studies, a substantial body of work about different aspects of gender and power was produced. In addition a significant field of 'new' men's studies examined masculinity as a category both of privilege and oppression (Carver 1996). Analysis of masculinities has also received considerable attention from feminist theorists who also claimed that differences among women were at least as important as differences between women and men, that race, class, age, ethnicity, sexuality, and physical ability were, like sex, constitutive of political identity and therefore of political behavior and power.

5. Feminism, Gender Studies, and Political Science

When feminist political scientists contested narrow definitions of politics, it was because they wanted to expand their research to aspects of 'private' life and to examine the role of government and the state in constructing and enforcing certain kinds of relationships between women and men. As it became more widely understood that both women and men have gender, debates across disciplinary boundaries became a common feature of feminist research on politics.

Once perceived, the effects of gender cannot be left to one side or held constant for the sake of other experiments. As it has come to be defined, gender is embedded in individuals, relationships, institutions, and organizations. The gender debates are part of a continuing process of definition refinement and theory production that enhances understanding of political institutions and processes. A 'gendered' political science looks 'not just at particular theories and assumptions as they have been applied to women, but as they are constructed and apply in any case' (Sapiro 1991). Institutional research traditions in political science require the close description of contexts, norms, processes, and cultures to which a gendered vocabulary may be applied. It follows that the gendered interests present in political arrangements should be acknowledged and analyzed.

In summary, feminist scholars have shown that it is difficult to think of an aspect of politics that is unaffected by gender. However, gender is not a neat and tidy concept to be slotted into unchanging research strategies. Using the concept of gender involves rejection of the definitions of politics implied by the conventions of the public/private split, re-examination of the productions of conventional political science for gender dimensions and, on that foundation, the construction of a political science that is gender informed.

Feminist Psychotherapy

1. What is Feminist Therapy?

Feminism is defined in Webster's New Word Dictionary (1978) as (a) the principle that women should have political, economic, and social rights equal to those of men, and (b) the movement to win such rights for women. While this is a relatively benign definition, the range of reactions and beliefs attached to the word feminism is vast and often emotionally laden.

These diverse views of feminism have resulted in conflicting definitions in the field of psychotherapy and have led to questions of whether one should more aptly refer to *feminisms* and psychotherapies rather than a unified theory of feminist therapy. In fact in many ways 'feminist therapy' is a moniker for an approach or value system that can be applied to all mental distress. Neither monolithic nor static feminist perspectives can be applied to all therapeutic orientations (e.g., *Interpersonal Psychotherapy*; *Feminist Theory: Psychoanalytic*).

1.1 Core Principles

Although they may vary in their application, at the core of a feminist approach are the following assumptions (Worell and Remer 1992).

- (a) Women's problems cannot be solved in isolation from gender politics which often result in women's lower social status and oppression in most societies.
- (b) Equal status and empowerment are vital not only for women but for all oppressed groups.
- (c) Values enter all human enterprises: neither science nor clinical cases can be value free.

(d) Women's experience and knowledge should be appreciated and studied.

(e) Few individual women can achieve parity alone, individual and collective action is necessary to achieve the social and political change that underpins many stated 'mental' problems.

Brown (1994) captures it well when she says 'what makes practice feminist is not who the clients are or the specific techniques used, but how the therapist thinks about what she does' (p. 2).

2. The Birth of Feminist Therapy

The women's movement in the late 1960s prompted a reconsideration of roles for women and men in western society. Consciousness raising groups provided a forum for women to make the link between their personal experience and the political context in which these experiences were constructed. In spite of their turning away from the accepted expertise of the 'establishment' one of the outcomes of consciousness rising groups was the development of feminist therapists. Through setting up 'women's' groups and 'feminist' supervision, services run by women for women began to develop.

As emergent ideologies challenged traditional views, the field of psychology was also pushed in new directions. This produced revised theories of psychological development and a demand for new explanations to prevent and remediate human problems. In 1975 a new discipline, The Psychology of Women, was established providing a foundation or (at least one academic home) for an applied science dedicated to counseling women.

While the consideration of gender in the prevalence, etiology, diagnosis, and treatment of human problems had long been neglected (*Age, Race, and Gender in Organizations*), there is now increasing awareness that the labeling of illness, the election to seek care, the dialogue between the professional and the 'helper,' and the 'cure' offered are all transactions that are influenced and bound by social organizations, as well as socially constructed themselves.

2.1 Data Supporting the Disproportionate Number of 'Mentally Ill Women'

Studies of clinical and community samples report that a high proportion of individuals with signs of depression, anxiety, panic, and eating disorders are women. Community health and mental health utilization rates are higher for women and a disproportionate share of psychoactive drugs are prescribed to women—many with deleterious or unknown side effects. In addition, it has been suggested that continuous exposure to disempowered positions may be

associated with women's depression (Feree et al. 1999). In addition physical and sexual abuse has been recorded in significant numbers of women seeking mental health care (*Childhood Sexual Abuse and Risk for Adult Psychopathology*).

2.2 Dissatisfaction with Traditional Treatment

Worell and Remer (1992) in a classic text delineate numerous sources of discontent with prevailing treatment options.

(a) Dissatisfaction with traditional theories that depicted male traits as the norm and women as deficient by comparison.

(b) Omission of women from the knowledge base of psychology.

(c) Failure to recognize that psychopathology may reflect power imbalances rather than intrapersonal difficulty.

(d) Uncovering sex bias in psychotherapy.

(e) Disregard by many health professionals for women's self reported experience.

(f) The practice of attributing blame and responsibility to women for their experience of sexual and physical violence.

(g) 'Mother blaming' such that women's interdependence and involvement is pathologized and men's responsibility for their abuses of power remains unchallenged.

(h) Increasing medicalization of women's psychological problems, including misuse of diagnoses and prescriptive drugs.

3. From The Western Individual to The Global Issue: Changing Focus Over Time

The initial focus of feminist therapy was to name the biases indicated above and to create a validated discipline to address them. Consciousness raising groups increased personal insights and improved relationships between women. Although these groups helped women see how the personal could be political, the wider political impact of these groups was limited and the focus was on the individual (Seu and Heenan 1998). The movement was primarily contained to western societies with the experience of the 'other' women of the east infrequently noted.

The next step was to describe and implement clinical practice. Alongside grass roots movements, scholars began to focus on issues specific to women's needs. An important contribution was Gilligan's (1982) *In a Different Voice* in which she argued that women's relationship-oriented concern for care and connectedness is devalued by the dominant androcentric culture's emphasis on logic and reasoning. She called for men and women to embrace a wider range of emotional qualities.

The 1980s and 1990s also saw a proliferation of writing, primarily in the USA, on ways to teach 'empowering behaviors' such as assertiveness training and psychoeducation.

In addition, psychoanalytic scholars in America and Europe explored ways of incorporating feminist object relations theory and its emphasis on connectedness into its framework, while Lacan (1977) provided direction for many professionals working on cultural theory.

Although the field became more adept at questioning, the answers were not forthcoming and indeed the inherent tension between political theory and therapeutic practice has not been resolved. There has, however, been greater attention paid to the global condition of women.

As a result, the third stage within feminist therapy will be the naming of the biases within the profession (Seu and Heenan 1998). Influenced by postmodern deconstructionist thought, there have been continuing challenges to the notion of 'feminist therapy' as a singular idiom. Eurocentric and heterosexual biases in teaching and treatment have been criticised and the esteemed position of gender bias as the 'ultimate' social oppression has been questioned.

Feminist analyses have become increasingly cross-cultural and cross-disciplinary as a greater effort has been made to understand not only the complexity of the social issues 'masquerading' as individual psychopathology but the near universal struggle to achieve and maintain power in a complex, modernizing, global environment.

Studies exploring the social construction of illness—borrowing from sociology, anthropology, and history as well as medicine and psychology have focused as much on gender issues as on power issues. By widening the gender lens to survey hierarchal imbalances more generally, feminist theories have found a way to answer male and female needs in an array of areas from self-definition, personal agency, and respectful care delivery to the negotiation of improved working environments and rejection of limiting fashion norms.

The tension between the individual and the societal approach along with connotations attached to 'feminisms' has led to several interesting questions for the future. For example (a) should a 'true' feminist approach to care even involve treating the individual? or (b) do we even need the term feminist at all if in fact the goal is parity for all humans?

4. Research Questions and Concerns

To amply answer the questions generated by a feminist perspective one must first gain support from societal (governmental, academic, and personal) agencies that manage funding. That questions of female mental health have been omitted in the past reflect that this is

not all easy. However, all who study the mental health of women need not be feminists or utilize feminist research methods, in fact they could be men!

Striegel-Moore (1994) has delineated research guidelines for feminist scholarship in this field: affirmation of a positive view of women (challenges the deficit model of women vs. men), adoption of a 'contextual' approach, utilization of a broad spectrum of research methods (applies qualitative and quantitative methods and establishes a collaborative relationship with research participants), and consideration of the implications of research findings for social change (studies diverse women in natural settings).

The challenge for the future will be to apply these methods across disciplines and across countries to help answer questions such as 'how the outside (environmental influences) get inside (and become individual pathology)?,' and when problems are mostly female specific, Why women? Why now? (at this point in history). It may be that by looking across specific diagnoses to syndromes of female distress that new approaches to treatment and prevention will be found (see *Syndromal Diagnosis versus Dimensional Assessment, Clinical Psychology of*). It may also be possible to better understand societal dilemmas by decoding these personal struggles.

5. Future Directions: The World as Living Laboratory

Changing societies and gender roles may provide *in vivo* opportunities to explore the impact of modifying political and social structures on human adjustment. Cross-disciplinary input will be the key. In addition, access to technology may enhance efforts to distribute knowledge and care to a broader audience (see *Technological Change in a Multicultural Context, Applied Psychology of*). The impact of globalization and technology on women's freedoms and their applications in the therapy environment will be critical areas for study in the twenty-first century.

Feminist Theology

Feminist theology presumes what many world religions have for centuries precluded—namely, women's full humanity, the immediacy of women's relation to the divine, and the cultural import of women's reflections on the sacred. Committed to supporting cultural transformation through the politics of spiritual practice (Spretnak 1994), feminist theology has attempted to dismantle dominative power and hierarchy in all their guises—from the private, familial and sexual to the institutional, ecclesiastical and political.

In the interest of transforming power relations, feminist theology works both to deconstruct the androcentric religious imagination, its philosophical underpinnings and its socio-political incarnations, and to construct or to create livable, religious imaginings that shelter the cultural becoming of women and that generate the formation of open, just and egalitarian communities. The term feminist theology, broadly defined, may include women's re/invention of goddess and wiccan traditions, critical reconstruction of the world religions, i.e., Judaism, Christianity, Islam, and Buddhism, as well as women's philosophical, non-theistic, or spiritualist departures from them.

1. Philosophical Background

Philosophically speaking, feminist theology developed in response to the 'deracination' (Daly 1984) of women's lives within the scope of patriarchal, monotheistic religions. Deracination names the effect on women of those religions whose engagement with 'the transcendent' subliminally assumes an abjection of matter—from the Latin 'mater' meaning mother (Kristeva 1982). Inasmuch as Platonic philosophy—which radically split spirit from matter, while aligning 'man' with enspirited mindfulness and 'woman' with (fallen or corrupted) nature—has served as infrastructure for the western monotheistic religions, women have been engendered theologically as devoid of spirit. As a sexual and reproductive body, woman

was subjugated to male authority, e.g., wife to husband, daughter to father, penitent to male priest, etc. Additionally inlaid with Aristotle's hierarchical 'chain of being,' western religions granted men greater ontological status and the privilege, therefore, of ruling over women, animals and earth—all of which, given their assumed passive and receptive contours, awaited man's invigorating agential influence. Built upon the story of man's 'second birth' into the transcendent realms, a birth without resort to woman, these religions idealized male selfhood and generated essentially homosocial cultures (Irigaray 1985). These religions libidinally installed an androcentric socio-political and economic matrix which feminists named 'patriarchy,' because all 'goods' (in terms of values and political rights as well as economics) were circulated through the generations of the fathers and sons. Consequently, women within the purview of these religions have been, as philosopher Daly put it, 'physically, mentally, and emotionally separated from our Original, elemental Race...' (1984). That is, women have been religiously precluded from exercising historical agency on behalf of ourselves as women and on behalf of the culture at large.

Androcentric religions have in various ways instilled in women a sense of self-loathing, existential shame and fear of autonomy. In Christianity, e.g., women have been blamed for all frustrations with the flesh, rationalized as the consequence of Eve's eating of the Tree of Knowledge of Good and Evil (Genesis 3). According to the normative reading of this story, one woman's exercise of free will ontologically fractured and debased the world, bringing death, disease, suffering, and transience. Since the fleshy body has been viewed as the inheritance of the mother; and since woman has been viewed as a derivative of man (Genesis 2, 1 Corinthians 11:8), Christianity disavowed the flesh and imagined salvation as a resurrection of 'the (ideal or imaginal) body' freed from the 'bondage' of development and decay, death, disease, and sexual desire (Romans 8). Not only do women thus serve as social scapegoats for Christianity, women have been the physical buffers between the projects generated by 'man's self-infinetizing spirit' (Ruether 1983) and the material impingements of finitude. That is, by socially domesticating women, men withhold from the purview of culture the needs and delimitations of physical bodies, including 'bodies' of land, water, etc.

2. Theoretical Contours

Inasmuch as the women's movement initially understood itself to be a 'spiritual' movement (Christ and Plaskow 1979, Spretnak 1994), feminist theology could be said to have been inherent to feminism. Women's exclusion from societal power structures was, feminists surmised, fundamentally linked to

women's exclusion from socio-religious symbol systems. As Daly observed wryly, where 'God is male, the male is God' (1985b)—a sentiment seconded by Spretnak, who observed that '(t)he long-standing justification in Western culture for regarding the male as the norm... has been the implicit acknowledgement that men are the same sex as God' (1994). This insight into the culturally constitutive nature of the religious imagination, a critique supported by Feuerbach's definition of religion as projection (*The Essence of Christianity* 1957), led feminist theologians to attempt to interrupt the cultural absolute of male socio-political power by displacing male religious images and by interrupting their sacred storylines. (Consequent to this insight and owing to feminists' own interest in 'changing the divine subject' so as to authorize women's power thereby, women's theological enterprise has sometimes been named 'feminist thealogy'—'thea-' being the feminine of the Greek masculine 'theo-', meaning 'God.' See Goldenberg (1979).) Given the incarnational relation between religious symbol and cultural power relations, among feminist theologians' first tasks was the critique of the masculine images by which religions have referred to the sacred as God, Father, Lord, King, Son, etc., and to humanity as 'sons' or 'men of God.' Not only do such images exclude women as religious and political subjects, these images—feminist theologians were convinced—led to the abuse and violation of women and children. 'Women's experience,' feminist theology's epistemological locus, referred to women's shared experiences of living under the purview of this exclusive male engendering of power. Specifically, such images religiously legitimated the practice of dominative power in relation to all that the system conversely objectified. Hence, women experienced this 'dominion of God' as 'domination'—specifically as battering, rape, poverty, the dislocation and domestication of our lives, etc.

Citing instead texts such as Genesis 1:27 ('So God created humankind in (God's) image,...male and female...'), Galatians 3:28 (In Christ, 'there is no longer male and female...'), and the Pentecostal outpouring of the Spirit upon 'all flesh' (Joel 2, Acts 2), feminists asserted women's unmediated relationship to the sacred, claiming thereby women's theological authority, the validity of women's spiritual experience, and the theological subject matter of women's daily lives. Authorized by Spirit, feminist theologians began a critique of male clerical and ecclesiastical leadership, of the male authorship and interpretation of the canon, of the functional closure of revelation vis-a-vis the sacred canon. Feminist theology not only supported, but was identified actively with the Women-Church movement and the movement for women's ordination—accomplished in Reformed Judaism as well as within many Protestant (e.g., Presbyterian, Lutheran, American Baptist, United Methodist) and Anglican-Episcopal Christian

circles. Yet the problem for women in the religions of 'the sacred book' remained: sacred texts have been written by and for men and have circulated for centuries in closed circuits of male interpreters. Where females did appear in these texts, feminists soon surmised that men had 'used (these) women to think with' (Karen King). Further, the religious sacraments of these communities have often worked to delegitimize even that which was prescribed as 'women's work,' e.g., in the church birthing becomes baptism, feeding becomes eucharist. Faced with the question of whether sacred texts and existing religious institutions had the symbolic resources to promote women's well-being, some women, beginning in the early 1970s and onward, have left and invested themselves in the recovery of goddess and wiccan spiritualities, traditions which have supported human embodiment (Eller 1993). Among those women who (also) stayed related to the existing monotheistic religions, a 'hermeneutic of suspicion' was employed to generate a critical distance from canonical texts. By invoking 'suspicion,' Biblical scholar Schüssler-Fiorenza discouraged women from expecting to discover truth 'in' a text conceived by men and encouraged feminists instead to deduce the 'truth' of scripture by a text's ability to raze systems of domination and exploitation (1984). Another feminist strategy for creating an authority base has been the recovery of the hidden histories of women, both in canonical texts, e.g., Wire's rhetorical positioning of Paul's otherwise anonymous discourses as *The Corinthian Women Prophets* (1990), and in Christian communities throughout the centuries, e.g., Ruether and McLaughlin's *Women of Spirit: Female Leadership in the Jewish and Christian Traditions* (1979). Nevertheless, Tribble's *Texts of Terror* (1984) reminded feminists that, given the patterns of 'inferiority, subordination and abuse of the female in ancient Israel and the early church' (3), e.g., Hagar, Tamar, and the daughter of Jephthah, women's tragic stories do not always yield to a positivist reconstructive resolution. Along with the recuperative labor of feminist Biblical and historical theologians, women have attempted to re-imagine the sacred, a project that has outraged some denominational leaders and led to heresy charges against some women. First, recovering feminine images of the divine from scripture, e.g., Sophia, Wisdom, Spirit, feminists have then applied themselves to rethinking ritual and theology based upon these images. Among academic theologians, McFague's (1987) *Models of God* developed the metaphors of God as Mother, Lover, and Friend so as to promote a change of consciousness—from a consciousness founded upon the theological notion of transcendence as separation from and ascendance over women and nature, towards a consciousness of belonging to the 'evolutionary ecosystem of our cosmos' (9). In *She Who Is* Johnson (1992), proposed a Christian trinitarian model of Spirit–Sophia, Jesus–Sophia and Mother–Sophia—a

constructive project aimed at thinking women into the economy of divine love, while also thinking divine sociality in terms of the lives of women.

As feminist theology developed, feminists, observing that traditional theology reflected only men's spiritual experience, undertook a reconstruction of the central doctrines of their respective communities. Whereas Christian theology had, following Augustine, psychically repressed the corporeal body, senses, emotions, and relations, feminists made the body—women's minds, wills, desires, and relationships—the central site of revelatory encounter and salvific experience. Whereas God had been conceived as absolutely transcendent, feminists have insisted on divine immanence—hence, the transition from invoking the divine as 'God' to 'Spirit.' Similarly, if according to the androcentric imagination creation was said to have transpired by divine fiat or to have come about through artisanal handicraft, i.e., God as 'Creator' or 'Maker,' feminists have spoken of the divine 'birthing' the world, of the world as 'God's Body' (McFague 1993, Jantzen 1984) and of humans as cocreators of cosmic process.

Finally, whereas for Christians Jesus' crucifixion has been seen historically as the occasion for sacrificial grace entering in to right a recalcitrant and wayward world, feminists have questioned positioning a human injustice as an ontological necessity and have gravitated toward two other views. First, feminists, rather than memorializing a unique individual from the historical past, reconstructed christology as the prophetic practice of justice and egalitarian relations within the on-going Jesus-community. Second, some feminists have shifted the christological focus away from crucifixion and towards incarnation. The use of the incarnational metaphor, pervasive in contemporary feminist philosophical theory, resonates with the histories of Christian women who have asserted their subjective agency in and through this analog, e.g., Proulx Boneta and Guglielma of Milan (Ruether and McLaughlin 1979).

3. Context and History of Development

While prefigured by the late nineteenth century feminists (e.g., Stanton's *The Woman's Bible* 1895), 'feminist theology' refers to the theological critique and reconstruction of religious symbols and systems over the past four decades of the women's movement (1960s–1990s). Initial publications by Schüssler-Fiorenza and Daly took place in Europe (1968), where they had worked with other early European feminists, including Catherina Halkes. By the early 1970s, Schüssler-Fiorenza and Daly re/turned to the United States where they joined the scene that included Rosemary Ruether, Letty Russell, and Judith Plaskow. Women's theological writing swelled during the 1970s and 1980s with publication's such as Daly's

Beyond God the Father (1985a) and *Pure Lust* (1984), Ruether's *Sexism and God-Talk* (1983) and Schüssler-Fiorenza's *In Memory of Her* (1983).

As feminist theory became conscious of the contextual situatedness of knowledge, feminist theology was refracted increasingly through the differences of all who had been forced together under the universalization of history's anonymous 'other,' 'woman.' Inasmuch as 'women's experience' was invoked as the epicenter of feminist theology in the 1970s, and inasmuch as this category was—women soon learned—dependent upon contextual, ethnic, class, and race factors, feminist theology in the 1980s became pluralized. Written now as feminist theologies, the term recognized the distinctive liberative agendas of women of color.

African-American women, protesting that feminist calls for 'sisterhood' glossed over black-white racism and the double oppression of race and gender, gleaned the name 'womanist' from Alice Walker's *The Color Purple*. If feminists read with suspicion, womanists—Delores Williams suggested—read with an eye toward survival; she found the epitome of the black woman survivor in Hagar (1993). Womanists' theological reflection often incorporates black women's literature, especially that of Toni Morrison, Alice Walker, and Paule Marshall, womanists having found in this literary canon models more relevant to the goal of improving black women's quality of life.

As differences continued to refract, Hispanic women like Ada Maria Isasi-Diaz wrote *Mujerista Theology* (1996). The indigenous voice of Paula Gunn Allen in *The Sacred Hoop* (1986) interrupted any too facile linkage of North America with the Christian continent. Jewish women resisted the supercessionist imperialism of Christian women (Plaskow 1990). From the beginning, lesbian voices have checked Christianity and Judaism's too facile heterosexist perspectives (e.g., Carter Heyward 1989 *Touching Our Strength*).

As with women of color in North America, women's theology in the densely populated and economically poorer nations has had to address survival needs and has often been undertaken without standing against men, who may consider the gender question secondary to the community's goal of liberation from neo-colonialism. Significant voices from feminist theology in global perspective include Mercy Amba Oduyoye from Ghana, Kwok Pui-Lan of Hong Kong, Chung Hyun-Kyung from South Korea, Mary John Mananzan of the Philippines, Ivone Gebarra from Brazil and Elsa Tamez from Costa Rica. Women from the nations evangelized by the western religions have come more recently to celebrate the hybridity of their religious subjectivity. The recovery of indigenous traditions—some of which, like Korean shamanism, claim stronger spiritual leadership roles for women—have become significant factors in creating out of the received religious tradition a vital and practical re-

ligious syncretism (Chung, Hyun Kyung 1990 *Struggle to be the Sun Again*).

In summary, the pluralization of 'woman' lead to distinct feminist theologies. Questions remain as to whether 'feminist' can serve as a canopy or whether such a move asks women of color to submit to the universalism of white, western experience. Though European theologians, e.g., Dorothee Soelle and Luise Schottroff, have—given greater impetus by their proximity to socialist analysis—included more economic reflections, feminist theology in general has not done as well at critiquing class as race issues. If feminist theology initially was configured by uniting women around victimization, increasingly feminist theologies have attempted to build constructively around women's shared goals. Parallel to this, a significant shift in the energies of feminist theologies can be felt—a move away from the ensconcing of opposition, especially 'resistance,' a position still within the logic of dualism; a move towards a 'nonapocalyptic' feminism, employing a 'methodological ambivalence' to sift through the 'power lines' so as to transform cultures (Catherine Keller 1996 *Apocalypse Now and Then*).

4. Probable Directions

In her 1975 book *New Woman New Earth*, Ruether noted that '(s)exism and ecological destructiveness are related in the symbolic patterns of patriarchal consciousness...' The disclosure of this symbolic connection between women's oppression and the domination of the earth led to the ecofeminist theology of the 1990s. If the collections of ecofeminist essays are indicative (e.g., Adams), ecological concern may convene an even greater diversity of feminist theologians—including women activists from Buddhism, Hinduism, and indigenous religions worldwide. Since women's bodies have served as buffer from life's material impingements for those who believe in the extraterrestrial transcendence of androcentric religions; and, inasmuch as ecosystemic collapses from industrial, agricultural, and multinational industries appear to be increasing, women—who, according to UN statistics, perform two-thirds of the human work hours, receive 10 percent of the pay, and own less than 1 percent of the world's habitable land—will be increasingly adversely impacted (*Progress for Half the World's People* in issues of the 1980s by the UN Association of the US 1980). Insofar as feminist theologies remain orthopraxic, i.e., committed to good practice, rather than correct belief ('orthodoxy'), a burgeoning of ecofeminist theologies might be expected.

Further, a new interest in the sciences could revitalize a certain stream of feminist theology. In the 1980s, the articulation of a relational ontology, undergirded with the process metaphysics of Alfred North

Whitehead, lead to the process-oriented theologies of Rita Nakashima Brock, Catherine Keller, Marjorie Suchocki, and Sheila Devaney, among others. More recently, feminist philosophers of science, e.g., Carolyn Merchant, Donna Haraway, and Vandana Shiva, have been critiquing Christianity's influence upon western scientific paradigms. Given this alliance of interest, feminist theologians might be expected to further the deconstruction of Western Christian mythemes in hopes of interrupting the planetary destructiveness of current and envisioned biotechnologies. At the same time, feminist theologians could be expected—given the fertile overlap between the new physics and theology—to offer new cosmological articulations.

In the 1990s, feminist theology took on a decidedly philosophical hue. To be sure, women like Daphne Hampson (England) and Daly, convinced that Christianity was and would remain inherently patriarchal, dated themselves 'post-Christian.' Consequent to that move, Daly insisted that she wrote philosophy, not theology. However, for those who continue to work within the sacred texts and traditions of Christianity and Judaism, postmodern discourse—heralding the end of totalizing worldviews and the disappearance of the subject—has caused feminist theology—like feminist theory, upon which it is dependent—to rethink its critical terms. While both a totalizing worldview, i.e., 'patriarchy,' and the evocation of female subjectivity had been used to achieve feminism's early liberative goals, this new philosophically reflective stage should not be seen necessarily as a departure from feminist theology's commitment to political transformation. Increasingly, postcolonial theory—especially in the field of Biblical studies—and deconstruction are being used to revitalize or reshape liberative theologies. Sharon Welch modeled the viability of employing post-structuralism on behalf of emancipatory transformation in her 1985 *Communities of Resistance and Solidarity* as did Rebecca Chopp in her 1989 *The Power to Speak*. More recently, the French psychoanalytic and poststructuralist insights of Kristeva and Irigaray have been used as hermeneutical tools to address topics such as eucharist, belief, the incarnation, spirit, etc. (Kim et al. 1993). Nevertheless, whether or not this philosophical tone might—amidst the transformation of other critical terms, e.g., the divine, transcendence, belief, etc.—represent a reconsideration of what counts as theology remains an unarticulated and therefore unanswered question for the field.

S. V. Betcher

Feminist Theory

Feminist theory encompasses a range of diverse ideas, all of which originate with the following beliefs: (a) society is patriarchal, structured by and favoring men;

(b) traditional ways of thinking support the subordination of women and the neglect or trivialization of issues particularly affecting women; and (c) this patriarchal order should be overthrown and replaced with a system that stresses equality for both sexes. Feminist theory impacts all institutions—medical, legal, academic, and social, for example—and can be used to illumine all issues affecting humans. The diversity of thought within feminist theory lies in the fact that women across the world differ from each other in many ways—including race, ethnicity, nationality, class, sexual orientation, or educational background, for example—and that these differences result in varying views of feminism and gender equality as expressed in liberal feminist, Marxist-socialist, radical ‘libertarian’ and radical ‘cultural,’ post-modern, and global feminist theories. Yet for all the diversity within feminist theory, there remains the belief that despite women’s many differences, women everywhere share some basic ‘sameness.’

In understanding feminist theory or feminist philosophy, it is necessary to understand theory and why humans develop theories. Philosophy helps us understand what it means to be rational beings, to have knowledge, and to express virtues such as benevolence or justice. Humans develop theories to explain elements of reality, how we interact with one another, and who we are as persons.

However, the history of philosophy and those humans who have developed the theories has centered around male humans. Western philosophy is dominated by the writings and thinking of men and, therefore, it often reflects stereotypes or biases against women, or simply omits any point of view that might be particular to women and their lives. For example, basic concepts of political theory—autonomy, freedom, individualism, power, competition, justice—have been designed to fit the experiences of males in male-dominated cultures (Kourany 1998). Particularly reflecting the daily lives of men who do not birth and raise children or provide the major, mundane caretaking duties for a family, these ideas represented for many centuries the heights to which human nature should aspire. Conversely, traits associated with women for many centuries—emotionality, passivity, cooperation, nurturing, compassion—were thought of as inferior and weak. Clearly, here are philosophical ideas that favor the experiences of men over women, relegating women’s experiences to the inferior realm.

Feminist theory, usually described as beginning in the late eighteenth and early nineteenth centuries along with women’s movements and suffrage movements, reconceives these historical theories and includes the experiences or general characteristics of women in addition to men. Women are, after all, the sex with the capacities of gestation, lactation, and menstruation. There are specific differences in the bodily functions of women and men. Traditionally, women have been associated with these bodily functions, associated

with the ‘lesser’ of many hierarchical oppositions: mind/body, sacred/profane, reason/emotion, active/passive, spiritual/material. This duality—particularly where it privileges so-called ‘masculine’ virtues and values over ‘feminine’ ones—is rejected in feminist theory.

Feminist theory, as a ‘new’ way of thinking, is sometimes difficult to understand because it does not represent one uniform view. The basic premise of feminist theory is that women have been excluded from traditional philosophy; moreover, not only have women been excluded, but also people of ‘different’ economic classes, races, ethnicities, or nationalities. Feminist theory recognizes many flaws in traditional (Western, Judeo-Christian, European, male) philosophy and offers a new way of thinking about issues affecting humans and our world. Additionally, feminist theory operates with the understanding that our current society is patriarchal, structured by and favoring men, and that this patriarchal order should be overthrown and replaced with a system that emphasizes equal rights and just and fair distribution of resources for both sexes. Because this element of feminist theory particularly impacts political and moral theory and the basic functions of our society, there are, as mentioned above, different ‘political’ interpretations or understandings of feminist theory, ranging from so-called liberal perspectives to so-called global perspectives. So great is the diversity of feminist theory that some critics fail to see that no matter how they label their particular way of thinking, virtually all feminist theorists agree that in order to be ‘feminist’ a theory must (a) proceed on the assumption that women and men do not share precisely the same situation in life; (b) offer action guides ‘that will tend to subvert rather than reinforce the present systematic subordination of women’; (c) provide strategies for dealing with issues that arise in private or domestic life; and (d) ‘take the moral experience of all women seriously, though not, of course, uncritically’ (Jagger 1992).

1. Different Feminist Theories

Liberal feminism receives its classic formulation in Mary Wollstonecraft’s *A Vindication of the Rights of Woman* and in John Stuart Mill’s *The Subjection of Women*, two nineteenth-century works. Liberal feminists find the roots of women’s oppression in the cultural constraints that hinder women from competing in the public world, including the worlds of politics, medicine, law, and finance. Because traditional society holds the false belief that women are, by nature, less mentally and physically capable than men, society often excludes women from the arenas mentioned above. Insisting this is discriminatory, liberal feminists demand that society give women the same educational and occupational opportunities that men

have. Liberal feminism is clearly reflected in the work of the National Organization of Women, current laws against sexual harassment or discrimination in the workplace, and past lawsuits against same-sex schools that receive funding from the state, including female tax-payers.

In contrast to liberal feminism, radical feminism holds that the patriarchal system that oppresses women is so flawed it cannot be reformed, but must be completely eliminated. In overthrowing patriarchy's institutions and assumptions, radical feminism singles out for attack social and cultural institutions such as the family and church, as well as traditional ideologies about the sexual and reproductive rights, responsibilities, needs, and preferences of men and women.

Initially, radical feminists—sometimes referred to as 'radical libertarian feminists' (Tong 1998)—aimed to explore what they saw as the pleasures of sex: consensual sex between men and women, lesbian sex, sex with both men and women, autoeroticism, sado-masochistic sex, and even intergenerational sex. They sought to free women from the beliefs that 'good' sex could be experienced only in a 'love relationship,' and that sex for sex's sake was somehow 'bad' or promiscuous. In addition, radical libertarian feminists wished to help women avoid the burdens of human reproduction, going so far as to recommend that natural reproduction be replaced by technological reproduction. They agreed with thinkers such as Shulamith Firestone that no matter how much educational, political, and economic equality women achieve, nothing fundamental will change for women so long as their reproductive roles remain the same. Natural reproduction, said Firestone, is not in women's best interests. Pregnancy is 'barbaric,' and natural childbirth is 'at best necessary and tolerable' and at worst 'like shitting a pumpkin' (Firestone 1970) and had best be replaced by *in vitro* fertilization and *ex utero* gestation. What is more, insisted Firestone, natural reproduction is not in men's or children's interests either, for as soon as men and women are truly free to engage in polymorphous, perverse sex, it will no longer be necessary for men to display only masculine identities and behaviors and for women to display only feminine ones. Freed from their gender roles at the level of biology (i.e., reproduction), said Firestone, women would no longer have to be passive, receptive, and vulnerable, sending out 'signals' to men to dominate, possess, and penetrate them in order to keep the wheels of human procreation spinning. Instead, men and women would be encouraged to become either equally masculine and feminine (mono-androgynous) or as differently masculine and/or feminine as they wished (polyandrogynous). As a result, not only would men and women become androgynous persons, all of culture would become androgynous. Furthermore, in this newly-evolved androgynous culture, the categories of the technological and the aesthetic, together with the categories

of the masculine and the feminine, would disappear through what Firestone termed 'a mutual cancellation—a matter–antimatter explosion, ending with a poof!' (Firestone 1970).

Firestone's 'poof' proved too much not only for the general public and most liberal feminists, but also for some radical feminists, particularly those who were beginning to wonder whether women would really gain true liberty by engaging in permissive sex, refusing to bear children, and becoming androgynous persons, that is, persons who are free to develop both 'female' qualities—nurturance, compassion, tenderness, sensitivity, cooperativeness—and 'male' qualities—aggressiveness, leadership, initiative, competitiveness. This concerned group of radical feminists—sometimes called 'radical cultural feminists' (Tong 1998) or 'essentialists' (Alcoff 1988)—began to caution that sex, usually understood as heterosexual sex, is more dangerous than pleasurable for most women. They urged women to extricate themselves from the institution of so-called compulsory heterosexuality (Rich 1994), which they viewed as 'characterized by an ideology of sexual objectification (men as subjects/masters; women as objects/slaves) that supports male sexual violence against women' (Ferguson 1984). Radical cultural feminists insisted that, as it has been experienced so far, heterosexuality is men's sexuality. It is about men seeking to control women's sexuality: representatively in pornography, and actually through the use of prostitutes or the selective harassment, rape, and physical abuse of women in their power. Only if women can free themselves from sex as men want it, can women discover what sex as women want it might be.

In addition to stressing the dangers of heterosexual relations and the pleasures of lesbian relations, radical cultural feminists emphasized that artificial reproduction would more likely disempower than empower women. They urged women to see artificial insemination by donor, *in vitro* fertilization, and plans for an artificial womb not as new procreative options for women but as means for men to exercise complete control over women's procreative powers—their ability to determine whether the human species will continue or not (Rich 1976, Ruddick 1984).

Finally, radical cultural feminists rejected the idea of androgyny as a desirable goal for feminists, replacing it with proposals to affirm women's essential 'femaleness' (Echols 1983). Far from believing the liberated woman must exhibit both masculine and feminine traits and behaviors (traits or behaviors culturally or stereotypically associated with a particular gender), radical cultural feminists expressed the view that it is better to be female/feminine than it is to be male/masculine. Women should not try to be like men, they said. On the contrary, they should try to be more like women, emphasizing the values and virtues culturally associated with women including 'interdependence, community, connection, sharing,

emotion, body, trust, absence of hierarchy, nature, immanence, process, joy, peace, and life' (Jaggar 1992)), and de-emphasizing the values and virtues culturally associated with men including 'independence, autonomy, intellect, will, wariness, hierarchy, domination, culture, transcendence, product, asceticism, war, and death' (Jaggar 1992). Women's liberation, according to radical cultural feminists, exists in women's conviction that it is better to be women than men.

Somewhat unconvinced by the liberal and radical feminist agendas for women's liberation, Marxist-socialist feminists claim it is impossible for anyone, especially women, to achieve true freedom in a class-based society where the wealth produced by the powerless many ends up in the hands of the powerful few. With Engels, Marxist-socialist feminists insist women's oppression originated in the introduction of private property, an institution that obliterated whatever equality of community humans had previously enjoyed. Private ownership of the means of production by relatively few persons, originally all male, inaugurated a class system whose contemporary manifestations are corporate capitalism and imperialism. Reflection on this state of affairs suggests that capitalism itself, not just the larger social rules that privilege men over women, is a primary cause of women's oppression. If all women—rather than the 'exceptional' ones alone—are ever to be liberated, the two-headed beast of capitalist patriarchy or patriarchal capitalism (take your pick) must be killed. Agreeing with this thought, Marxist-socialist feminist Mitchell (1971) stressed that women's condition is determined by the structures of production (as Marxist-socialists believe), reproduction and sexuality (as radical feminists believe), and the socialization of children (as liberal feminists believe). Women's status and functions in all of these structures must change if women are to be men's equals.

Common to liberal, radical, and Marxist-socialist feminist thought is a desire to view women as somehow the same, even if this sameness falls short of the extreme 'essentialism' of radical-cultural feminism. Women's sisterhood and solidarity are the dominant notes of feminist theory as discussed so far. The problem with such a view of women is, however, that women are not only different from men, but also from each other depending on their class, race, ethnicity, nationality, age, religion, marital status, sexual orientation, and so forth. This point about women's difference, about the tendency of some feminist theorists to confuse 'Women' with a particular kind of woman—perhaps white, Western, middle-class—is the core conviction of multicultural feminism. In the 1990s, the buzzword 'cultural diversity' affected social, legal, educational, and religious institutions in the US, and multicultural feminism emerged as part of this diversity. Multicultural feminists stress that although it is hard to be a woman, it is harder to be a woman of

color than a white woman; a poor woman than a rich woman; a lesbian woman than a heterosexual woman; an old or average-looking woman than a young or beautiful woman. Repeatedly, multicultural feminists explain how the idea of 'sameness'—the seemingly benevolent notion that 'down deep' we are all the same—could counter-intuitively be used as an instrument of oppression rather than liberation. In this connection, multicultural feminists reflect in particular upon the works of feminist theorists such as Spelman (1988) who pleaded with feminists not to make the mistake historian Kenneth Stampp made by asserting 'that innately Negroes are, after all, only white men with black skins, nothing more, nothing less.' Why, asked Spelman, is it that black men are really white men 'down deep' and not that white men are really black men 'down deep'? Could it be that white people still think 'white' is definitely the best way to be—the 'gold standard' for all people? Fearing the presence of some well-intentioned 'Kenneth Stampps' within the circle of feminist theorists—most of whom are white, relatively-privileged, and heterosexual—Spelman warned that 'If, like Stampp, I believe that the woman in every woman is a woman just like me, and if I also assume that there is no difference between being white and being a woman, then seeing another woman "as a woman" will involve seeing her as fundamentally like the woman I am. In other words, the womanness underneath the Black woman's skin is a white woman's, and down inside the Latino woman is an Anglo woman waiting to burst through a cultural shroud' (Spelman 1988). If feminist theorists really value equality, insisted Spelman, then they must take care not to use themselves as the measure of 'womanhood.'

In addition to multicultural feminists, so-called postmodern feminists emphasize women's differences. For example, Julia Kristeva, a postmodern feminist, notes that feminism has neglected multicultural diversity. Oliver, author of an article entitled *Julia Kristeva's Feminist Revolutions*, explains:

Feminists in the United States are struggling with this very issue. The feminist movement has had to realize that it is a white middle class movement that has worked to exclude women whose interests and needs are somehow different. Paradoxically as soon as feminism defines 'woman' it excludes all sorts of women (Oliver 1993).

Inspired by a variety of antifoundationalists, especially the deconstructionist Jacques Derrida and the psychoanalyst Jacques Lacan, postmodern feminists resolve the old philosophical debates about the nature of reality—is it 'one' or 'many'?—decidedly in the direction of 'many-ness.' Along the way postmodern feminists such as Hélène Cixous challenge Western dualistic thinking itself (reason/emotion, mind/body, male/female) as the primary cause of human oppression, seeking to liberate human beings from a rigid conceptual grid that privileges some of society's

members over others (Cixous and Clement 1986). Insisting that not being one of society's favored members (white, rich, heterosexual, male) is an advantage, postmodern feminists stress the advantages of being rejected, unwanted, shunned, frozen out, disadvantaged, unprivileged, abandoned, dislocated, and otherwise marginalized. They claim that precisely because women have not been socially favored, women can lead the revolution to let human differences flourish.

Reconsidering their emphasis on the idea of differences as the 'essential' description of the human condition, some multicultural and postmodern feminists now wonder whether they might have gone too far in their rejection of the idea of sameness, thereby endangering feminism's ability to speak on behalf of the best interests of women in general. After all, if women have nothing more in common than two X chromosomes, it is conceivable that women share few, if any, interests in common. If women do not share common interests, then it makes little, if any, sense to insist, for example, that pornography degrades women or that female genital mutilation harms women or that confining women to the domestic sphere limits their human development. If women are essentially different, if they are more different from each other than similar to each other, then 'issues' affecting women in general do not exist.

Increasingly convinced that, like the idea of sameness, the idea of difference can become destructive, many multicultural and postmodern feminists have cast aside or at least modified their perspectives in order to join hands with so-called global feminists and ecofeminists. Although global feminists are well aware that women in the US are very different from women in Kenya or Thailand, for example, they are nevertheless inclined to believe that the women in these countries share enough common interests to become each other's political allies and moral supports. In a recent article, feminist theorist Okin (1998) reminds 'First World' feminist theorists that feminist activists, particularly those in the 'Third World,' are finding that women across the world do have a lot in common. Okin stresses that at several international meetings, women attending from countries throughout the world acknowledged 'that women (everywhere) are greatly affected by laws and customs having to do with sexuality, marriages, divorce, child custody, and family life as a whole;' that they 'are much more likely to be rendered sexually vulnerable than men and boys;' and that their 'work tends to be valued considerably less highly than...men's work' (Okin 1998). First World women, insists Okin, should work with Third World women to achieve for all women the kind of freedom and well-being some women already have. To do so is not an exercise in cultural imperialism, but a simple response to a call for assistance.

Okin's case for cooperation between First World women and Third World women is a cogent one. But

feminists who are sincere about eliminating all forms of human oppression, beginning with gender oppression, will need to do more than talk about the need to help all women achieve all that is rightfully theirs as women. Privileged feminists must, as many global feminists have suggested, be prepared to give up some of their material luxuries so that women far more oppressed than they can attain all of their necessities (Mies 1993a). Stressing that there is only so much of any one material good to be distributed among the world's population, global feminists claim that feminists must take the lead in living more simply so that life on earth can continue through the next millennium and more. Bluntly put, global feminists maintain that if feminists are really serious about ending all oppression, beginning with gender oppression, they must stop being oppressors themselves.

Of course, it is not easy to stop being an oppressor, particularly if one intends to actively carry out the theories of ecofeminists. According to ecofeminists, human beings are connected not only to each other, but also to the nonhuman world: animal and even vegetative. Unfortunately, we do not always acknowledge our responsibilities to each other, let alone to the nonhuman world. As a result, we deplete the world's natural resources with our machines, pollute the environment with our toxic fumes, and stockpile weapons of total destruction. In so doing, we delude ourselves that we are controlling nature successfully to benefit ourselves. In point of fact, says ecofeminist King (1995), nature is already rebelling, and each day the human self is impoverished as yet another forest is 'detreed' and yet another animal species is murdered to extinction. The only way not to destroy ourselves, insist ecofeminists, is to strengthen our relationships to each other and the nonhuman world by refusing to engage in acts of violence, particularly warfare; refusing to eat animal flesh; and refusing to lead luxurious lifestyles. The question remains, of course, whether all feminists are required to lead lives of self-restraint so that not only gender equity but human equity is achieved; or whether, instead, ecofeminist are feminist 'saints' and 'heroes' that all feminists need not follow.

2. Feminist Theory and Other Disciplines

Many of the feminist theories described above center on political or social sciences and systems. Although most work has been accomplished in the social sciences, and much of the feminist movement in the past 200 years has emphasized these areas, feminist theory impacts every discipline and particularly impacts the increasingly important areas of science, medicine, technology, religion, ethics, education, as well as philosophy.

Since it is impossible to describe in a few pages the ways in which feminist theory has transformed the

entirety of human knowledge, I focus here only on the way it has affected two of philosophy's many subfields: epistemology and ontology. Feminist theory challenges the traditional ontological assumption that the more separate the 'self' is from others, the more autonomous, unique, successful, and superior that self is. Traditionally, philosophers have portrayed 'autonomous man' as a biological male—an independent self geared toward maximizing his self-interest effectively and efficiently. Such a self is always on guard against the ominous 'other' who many interfere with his life projects. Even when the 'other' convinces him to establish cooperative relations in a community, autonomous man proceeds cautiously, always seeing every individual he encounters as a potential threat and competitor for resources. Feminist theory, however, offers a different interpretation of how people come to understand their 'selves.' According to feminist ontologists, including Whitbeck (1989), people come to understand their selves through others, not against them. We are historical creatures, shaped by our relationships with other people, our parents, siblings, friends, and colleagues. Although we differ from one another, we relate to each other reasonably well because we also have much in common. This different ontology would result in a different view of the world—one in which we work together for a common good instead of competing against each other in order to secure the best only for ourselves.

Similarly, feminist theory impacts the field of epistemology. As described by Code (1998), 'the issue is less of doing philosophy "in a feminist voice", or even "in a different voice"—as some feminists propose—than of discerning whose voices have been audible, and whose muffled, in the articulation of prevailing theories ...' As with the impact of feminist theory on other disciplines such as history, literature, or art, we find that the story has been told from the male point of view, using a male's voice, and using the experiences of males. At least in the Western world, philosophers and other theoreticians (mostly men until relatively recently) have claimed that the only way to achieve true knowledge is by distancing one's self from the object of one's inquiry and subjecting it to the powers of dispassionate reason. This style of knowing is in estimation of many feminists 'masculine' or 'male.' Because men tend to conceive of themselves as separate, autonomous selves, they favor ways of thinking that permit them to keep their study subjects at arm's length. Keller (1983, 1985) notes that in science, for example, objectivity has been defined in terms of the separation of the subject (the scientist) from the object of study. She believes it is more than coincidence that the men developing science conceived their methodology in terms of what was emphasized as 'masculine'—separative autonomy. Emotional connections with one's subject matter were seen as contaminating knowledge—as subjective, biased, 'feminine.' Keller insists, however, that emotional

connections sometimes yield useful insights. Indeed, some of our deepest insights come from the ability to empathize and to connect with those whose behavior we study; and because women typically understand themselves as intimately and intricately connected to others, it stands to reason that women might be able to see, or first see dimensions of reality to which many men are initially oblivious (Keller 1983, 1985).

3. *First, Second, and Third Waves of Feminism*

Feminist theory, in sum, is an evolving set of ideas. Feminist theory—or 'academic feminism' (Nussbaum 1999) in America—historically has been 'allied to the practical struggle to achieve justice and equality for women. Feminist theory has been understood by theorists as not just fancy words on paper; theory is connected to proposals for social change' (Nussbaum 1999). As a discipline or philosophical approach to other disciplines, feminist theory may not be separated from the very real struggles of the feminist movement.

At this point, the beginning of the twenty-first century, the feminist movement has accomplished great equality in many areas, including politics, the workplace, and the legal system. However, there is much more work needed for true equality in all spheres of life. Feminist theory—understood here as the scholarship or thinking behind such practical feminist actions such as the reform of rape, domestic violence, or sexual harassment laws, for example—changes according to the position of women in society and the world. Just as the feminist movement is often described as having three waves—we are in the midst of the third wave now—feminist theory has evolved similarly. The first wave of US feminism is rooted in eighteenth- and nineteenth-century liberal thought as articulated by Mary Wollstonecraft, John Stuart Mill, and Harriet Taylor Mill, in particular. As described above, liberal feminism emphasized the equal rational and moral abilities of men and women, and the fact that women must be able to leave the domestic realm and enter the public realm if they are to use these equal abilities. One of the major issues of first-wave feminism in the US was securing for women the right to vote, that is, the right to participate as equal members in our political society.

Second-wave feminism centered on the fact that suffrage would never make women equal to men unless women had the same educational, occupational, and professional opportunities that men had. In addition to participating in the public realm, women must be freed from obligations in the domestic world, including sexual and reproductive obligations. Major issues in second-wave feminism included birth control and abortion, and attacks on the images portraying women as sex-objects or baby machines.

Third-wave feminism is very similar to the global and ecofeminist theories described above. In par-

ticular, third-wave feminism emphasizes that the feminist movement in the US does not represent feminism all over the world. Third-wave feminism is aware of women's differences, including race, class, and national origin; but it is also aware that women across the world have much in common, and that women can work together as equals to achieve the particular forms of freedom and well-being that mean the most to them. Like first- and second-wave feminists, third-wave feminists hunger for justice. However, their vision of justice is exceptionally large and demanding for it is based on the assumption that oppression, including gender oppression, will continue to define the human condition unless feminists and other like-minded theorists and activists take it upon themselves to convince humankind as a whole that in order for each person to have enough, no person can 'have it all.' According to ecofeminist Mies, this thought was best expressed by Kamla Bhasin, an Indian feminist. Bhasin stated that:

sustainable development ... is not compatible with the existing profit-and-growth oriented development paradigm. And this means that the standard of living of the North's (First World) affluent societies cannot be generalized. This was already clear to Mahatma Gandhi sixty years ago, who, when asked by a British journalist whether he would like India to have the same standard of living as Britain, replied: 'To have its standard of living a tiny country like Britain had to exploit half the globe. How many globes will India need to exploit to have the same standard of living?' From an ecological and feminist perspective, moreover, even if there were more globes to be exploited, it is not even desirable that this development paradigm and standard of living was generalized, because it has failed to fulfill its promises of happiness, freedom, dignity and peace, even for those who have profited from it' (see quotation in Mies 1993b).

Emerging between the lines of Bhasin's words is, it would seem, the profile of the ideal third-wave feminist, a feminist for a truly new millennium.

4. Conclusion

Feminist theory includes many ideas, and may be frustrating for someone seeking a one-sentence answer to the question 'what makes a view feminist?' However, this characteristic of feminism is not new or particular to contemporary, third-wave, global feminism or ecofeminism. In 1913, a woman wrote: 'I myself have never been able to find out precisely what feminism is ... I only know that people call me a feminist whenever I express sentiments that differentiate me from a doormat, or a prostitute' (Gibbs 1992). In essence, feminist theory is a set of ideas originating with the belief that women are not subordinate to men or only valuable in relationship to men (servant, caretaker, mother, or prostitute), and that the disciplines, systems, and structures in place in our world today may be changed for the better if infused with a feminist point of view. But it is more than this.

Feminist theory sets an agenda for action, the aim of which is justice and equality for women everywhere and, of course, also for the men and children to whom they are inextricably linked.

Feminist Theory and Women of Color

Feminist theory has been at the forefront of new directions in political, social, and cultural theory. These developments are inherently indebted to the internal critique within feminism made by 'women of color' who have been pivotal in raising questions of 'difference' around such social axes as class, racism, ethnicity, sexuality, and the problematic of global inequities. The point is that the experience of 'being a woman' may vary greatly according to class background, color, sexual orientation, religion, and so on. The critique consists of debates that emerged through political contestation both within and outside the women's movements, drawing attention to the centrality of slavery, colonialism, imperialism, and postcoloniality in understanding contemporary gender relations and global predicaments.

1. Emergence of 'Women of Color' as a Political Subject

The terms 'women of color' and 'white women' throw into relief the political nature of discourses and practices in and through which these terms emerged as

political subjects and became conceptual components of social, political, and cultural theory. They show how seemingly neutral words such as 'color' may assume specific meanings in different contexts so that, as in this instance, the color of 'whiteness' is placed into question. The political subject of 'women of color' decenters 'whiteness' as a modality of power constituted in varying forms in different times and places through historical processes of slavery, colonialism, and imperialism. It challenges the ways in which white European-descent woman came to be seen as superior to other categories of women. Although black, brown, and other categories of 'nonwhite women' have been engaged in feminist practices for centuries, the concept of 'women of color' first emerged in post-World War II Northern America and Western Europe, especially Britain. Hence, the primary focus here is upon the anglophone debate in these locations.

Political tensions in Western feminism surrounding the interrelationship between 'race' and other factors such as class and gender in the USA date back to the antislavery campaigns. During the decade of the 1830s, for example, American women became increasingly active in the abolitionist movement where they learnt to champion their own right to engage in political work and where their experience of relative marginalisation compelled them to form separate women's antislavery societies. The first female antislavery society was formed in 1832 by black women in Salem, Massachusetts, followed by similar societies established by white women in other locations. Paradoxically, when the motion for women's suffrage was first introduced amid immense controversy at the Seneca Falls Anti-Slavery Convention of 1848, black women were conspicuous by their absence. This omission was incredible, not least because black women already had brought into the arena of public debate issues such as women's education which the Convention was only just beginning to address. In May of 1866, when women decided to establish an Equal Rights Association incorporating struggles for Black emancipation and woman's suffrage into a single campaign, a number of eminent speakers, including the white feminist Elizabeth Cady Stanton, argued against it. In class terms too, this was predominantly a middle-class women's movement. While a few individual black women, as for instance Sojourner Truth, were able to participate in specific events, nonetheless, the movement overall did not take on board the contradictory relationship between racism and class, or the question of sexuality in any significant way. Nor was the plight of Native American peoples, or non-European immigrants an identifiable feature of these debates and activities (Davis 1981).

As a form of self-conscious protest, feminism in Britain arose in the seventeenth century. Here, as in the USA, the early women's rights movement and later the Suffragists failed to give sufficient priority to the needs of working-class women or the issue of 'race.'

This is not to deny that there were some women as, for example, Annie Besant who was active on the anti-colonial front as well as on gender issues, and Sylvia Pankhurst who placed considerable emphasis on the conditions of the working class. Nevertheless, the effects of racism and class inequality did not become a major feminist concern at this stage. Such amnesia about issues of 'race' cannot be attributed to the lack of presence of Irish, Jewish, African, and South Asian descent people—the primary target of racisms of the period—because they were far from absent in Britain from the sixteenth to the early twentieth century. Moreover, the first usage of the term 'race' in Britain also dates back to the sixteenth century and the subsequent history of the discourse of 'race' is interlinked with slavery, colonialism, and the Holocaust of Jews, gays, gypsies, and others. Racism therefore can be said to be one of the key factors in the formation of Western societies.

The last five decades of the twentieth century witnessed the emergence of a variety of social movements: anticolonial movements for independence, Civil Rights and the Black Power movement, the Peace movement, student protest, and the Workers' movements. The Women's Liberation Movement was formed during the late 1960s and the 1970s as a part of this intellectual and political ferment. Women of color were active in all these groups. Yet, a significant number of early publications by 'Second Wave' white feminists seemed to display a certain disregard of racism as an *internal* feature of Western patriarchal relations. This neglect drew critical scrutiny from women of color. One of the first critiques was launched by the Combahee River Collective, a black, lesbian feminist organization from Boston, USA. In 1977, they produced a document that demonstrates the complexity of theorizing women's subordination when analyzing experiences based on simultaneous intersection of diverse forms of injustice: 'We know that there is such a thing as racial-sexual oppression which is neither solely racial nor solely sexual, e.g., the history of rape of Black women by white men as a weapon of political repression (Smith 1983, p. 275). The Collective saw itself 'actively committed to struggling against racial, sexual, heterosexual, and class oppression' and advocates 'the development of integrated analysis and practice based upon the fact that the major systems of oppression are interlocking (Smith 1983, p. 272). Pointing to the global dimensions of gender, the text speaks of the impact of 'political-economic systems of capitalism and imperialism' and emphasizes the question of institutional racism as well as 'racism in the white women's movement.' It repudiates those political positions which accept that the end justifies the means: '... as feminists we do not want to mess over people in the name of politics' (Smith 1983, p. 282). In taking a stance against biological determinism, this feminist discourse articulates a certain non-essentialism even as its notion of identity

politics would seem to exemplify what Spivak-Chakravorty (1999) was later to call 'strategic essentialism.' The idea of 'simultaneously interlocking oppressions' is one of the most productive insights of this period.

While the composition of 'women of color' in terms of ethnicity may vary from place to place, the generalized category itself remains wide-ranging and global. According to the anthology *Home Girls*, for example, 'the terms Third World Women and women of color... designate Native American, Asian American, Latina and Afro-American women in the USA and the indigenous peoples of Third World countries wherever they may live' (Smith 1983, p. liv). Taken together, women of color comprise the great majority of women of the world and a very high proportion live in conditions of material disadvantage. Hence, the centrality of a concern with social inequality in women of color feminisms.

Writings by women of color have a history of being treated as 'personal testaments' rather than 'theory.' The question of what counts as theory and whose intellectual work gets treated as being theoretical has been the subject of much debate (cf. Collins 1990). A related point concerns the *theoretical* subject of 'women of color.' In her analysis of the book *The Bridge Called My Back*—a seminal American text of the early 1980s—Norma Alarcon argues that the theoretical subject of *Bridge* is a figure of multiplicity, representing consciousness as a 'site of multiple voicings' seen 'not as necessarily originating with the subject but as discourses that traverse consciousness and which the subject must struggle with constantly.' It is associated with subjectivity that is deeply marked by 'psychic and material violence' and it demands a thorough 'reconfiguration of feminist theory' (Alarcon in Anzaldúa 1990, pp. 359–65). In other words, the theoretical subject of 'women of color,' in its very constitution, de-centers the Eurocentric discourse of the rationalist, masculinist subject of modernist philosophy. It challenges essentialist readings of skin tone or physical appearance as inherent 'difference' and disrupts any notion of 'woman' as a unitary category.

2. *Black British Feminism*

A similar yet different process occurred in 1970s Britain when 'women of color' came to be figured as 'black.' This was a consequence of coalition politics among African, Caribbean, and South Asian descent groups who borrowed the Black Power vocabulary but re-signified 'black' to embrace all 'nonwhite' people. The concept of 'black' was designed to substitute the colonial term 'colored people' and interrogate 'chromatism'—the hierarchy based on differences of skin tone—that could potentially threaten unity between these groups. Black British feminism was forged

through the work of local women's organizations active around such issues as wages and conditions of work, immigration law, fascist violence, reproductive rights, and domestic violence. By 1978, local groups had combined to form a national body called the Organisation of Women of Asian and African Descent (OWAAD). This network held annual conferences, published a newsletter, and served as an active conduit for information, intellectual conversations, and political mobilization. The ensuing dialog entailed sustained analysis of racism, class, and gender with much debate as to the best means of confronting their outcomes while remaining alive to cultural specificities:

Our group organises on the basis of Afro-Asian unity, and although that principle is maintained, we don't deal with it by avoiding the problems this might present, but by having on-going discussions... Obviously, we have to take into account our cultural differences, and that has affected the way we are able to organise (OWAAD cited in Mirza 1997, p. 43).

Like its 'women of color' counterpart in the USA, emerging black feminism in Britain came to prefigure later theories of 'difference.' The internal conflicts within OWAAD, especially around homophobia, proved salutary so that, even as British 'black feminism' assumed a distinctive political identity separate from 'white feminism,' engaging the latter in heated debate, it did not become oblivious to the contradictions of its internal heterogeneity. The careful reflection and analysis that went into the deliberations resulted in a very significant corpus of scholarship.

Hazel Carby's essay *White woman listen* is symptomatic of conflicts and tensions that characterized feminist debate during the 1980s. Carby develops a trenchant critique of key feminist concepts—'patriarchy,' 'the family,' and 'reproduction'—drawing out their interconnection with racism and colonial history. Taking issue with the Euro-centric approach of certain white feminist discourses, she stresses that racism is not simply about exclusion but equally about the manner of inclusion itself. As Chandra Talpade Mohanty has argued, Western feminisms during this period tended to reproduce the very categories through which the 'West' constructs and represents itself as superior to others. In 1984, a group of British feminists of color collectively edited a special issue of the journal *Feminist Review* (Issue 17). This text, together with the edited collection *Charting the Journey* (Grewal et al. 1988), represents intellectual intervention through work that was the outcome of collective thinking. Some of the main points addressed in these publications may be summarized as follows:

(a) As a consequence of capitalist colonial relations, labor migrants from former colonies are constituted as a *racialized class fraction* in the metropolitan society.

(b) The institutionalization of racism and gender inequality within global sociopolitical and cultural relations means that 'women of color' may face some

similar injustices all over the world, but they will also share experiences with the metropolitan white working class.

(c) Women of color in Britain are subjected to 'double patriarchy': a generalized, all pervasive, racialized form of British patriarchy; and, specific configurations of patriarchal norms current among particular groups of people of color.

(d) Lesbians of color have to contend with: heterosexism in British society; homophobia among people of color; and, eurocentricity and racism among white lesbians and gay men. These aspects must be addressed as part of feminist theoretical and political practice.

3. Postmodernism and the Theory of Difference

Feminist theories of the 1970s and 1980 were informed by conceptual repertoires drawn largely from 'modernist' theoretical and philosophical traditions of European Enlightenment such as liberalism and Marxism. The 'postmodernist' critique of these perspectives, including their claims to universal applicability, had precursors within anticolonial, antiracist, and feminist critical practice. Postmodern theoretical approaches found sporadic expression in Anglophone feminist works from the late 1970s. But, during the 1990s they became quite a significant influence, in particular their poststructuralist variant. Some of the main points emerging from the encounter between women of color feminism and postmodern/post-structuralist theories are that:

(a) It is no longer tenable to conceptualize 'white feminism' and 'feminism of color' as if they are mutually exclusive entities, each carrying some unchanging transhistorical 'essence.'

(b) Contrary to analysis where process is reified and understood as personified in the bodies of individuals, these two distinctive yet overlapping sets of feminisms are now viewed as representing historically contingent relationships, contesting fields of discourses, or 'reading strategies.'

(c) The concept of 'agency' has been reconfigured through poststructuralist appropriations of psychoanalysis in order to take account of psychic and emotional life. The concept of subjectivity now covers both conscious agency and unconscious psychic dynamics, and it represents a site of multiplicity where effects of racism and ethnicity intersect with other structural and experiential dimensions.

(d) Reassessment of the notion of experiential authenticity has highlighted the limitations of 'identity politics.' Experience is now understood primarily as a 'signifying practice' referring to the process of making sense of the world symbolically and narratively.

(e) Poststructuralist insistence that meaning is relational; that identity and subjectivity are not 'products' but on-going processes; that power can be

both coercive and productive; that subordination can occur through modes of inclusion no less than exclusion means that poststructural paradigm has much in common with theoretical interventions made by women of color over the years.

Overall, critical but productive conversations with theories of poststructuralism have resulted in new theoretical frameworks for refashioning the analysis of 'difference' (cf. Hooks 1990, Grewal and Kaplan 1994).

4. Postcoloniality, Transnationality, and Diasporic Space

One outstanding feature of the work of feminists of color during the 1990s is a concern with the potential of combining strengths of modern theory with post-modern insights. This interest in interdisciplinary 'creolized theory' would seem to stem from the following preoccupations:

- (a) an interest in analyzing the effects of racism without recourse to the discourse of 'race';
- (b) the need for theorizing ethnicity and cultural difference outside the imperatives of racism;
- (c) the importance of understanding political identities as contingent forms of resistance;
- (d) the necessity of distinguishing between political identity as conscious agency and identity conceptualised in terms of subjectivity;
- (e) the importance of analyzing locality and globality as relational categories;
- (f) sustaining the previous emphasis on colonial histories and 'material conditions' at the same time as analyzing cultural issues; and
- (g) the need to attend to the problematic of the category 'mixed race.'

This work has taken several forms. Some developments, especially in the field of literary studies, are known as 'postcolonial' theory. When used in the sense of a reading strategy, postcolonial theory emphasizes the point that both the 'metropolis' and the 'colony' were altered deeply by the colonial process and that these articulating histories have a mutually constitutive role in the present. Postcolonial feminist studies foreground 'Othering' processes underlying colonial and postcolonial discourses of gender. Frequently, such work uses poststructuralist frameworks, especially Derridean deconstruction and Foucauldian discourse analysis. Some scholars have attempted to combine poststructuralist approaches with neo-Marxist or psychoanalytic theories. Other feminists of color have transformed 'border theory' (Anzaldua 1990, Mani 1998, Spivak 1999)

A related development is associated with valorization of the term diaspora. The concept of diaspora increasingly is used in analyzing the mobility of peoples, commodities, capital, and cultures in the context of globalization and transnationalism. The

concept is designed to analyze configurations of power—both productive and coercive—in 'local' and 'global' encounters in specific spaces and historical moments. Brah (1996) addresses the concept of diaspora alongside that of Anzaldua's theorization of 'border' and the widely debated feminist concept of 'politics of home.' The intersection of these three terms is understood through the concept of 'diaspora space' which covers the entanglements of genealogies of dispersal with those of 'staying put' so that the 'native' becomes as much a 'diasporian' as the diasporic subject becomes the native. The term 'homing desire' is used to think through the question of home and belonging; and, both power and time are viewed as multidimensional processes. Importantly, diaspora space embraces the intersection of 'difference' in its variable forms, placing emphasis upon emotional and psychic dynamics as much as socioeconomic, political, and cultural differences. Difference is thus conceptualized as social relation, experience, subjectivity, and identity. Home and belonging is also a theme of emerging literature on 'mixed-race' identities which interrogates the concept of 'race' as an essentialist discourse with racist effects (Tizzard and Phoenix 1993, Zack 1993, Ifekwunigwe 1999). Accordingly, the idea that you are mixed-race if you have black and white parents is jettisoned. Instead the analytical focus is upon varying and variable subjectivities, identities, and the specific meanings attached to 'differences.'

Theoretical perspectives developed by women of color are central features of innovations in feminist theory. They herald a new phase in feminist alliances and coalitions. They promise new ways of formulating democratic futures (Alexander and Mohanty-Talpade 1997).

Feminist Theory: Ecofeminist and Cultural Feminist

Just as there are a variety of feminisms and feminist theories, there are a variety of ecofeminisms and ecofeminist theories. What distinguishes them as 'ecofeminist' is a twofold commitment to analyzing and undoing historical connections between the unjustified dominations of women (and other human

subordinated groups) and nonhuman nature. This article explores the varieties of ecofeminist theories. It reveals similarities and differences among ecofeminist theories, and suggests directions for future ecofeminist theory and research.

1. The Terms 'Ecofeminist' and 'Cultural Feminist'

The term '*ecofeminisme*' was coined in 1974 by French feminist Francoise d'Eaubonne (1974) to call attention to women's potential to bring about an ecological revolution. Ecofeminism has emerged around the globe as a powerful political movement and theory. Despite important differences among ecofeminist theories, they share a common concern for making visible historical associations of 'women' with 'nature,' and, at least in Western societies, the attendant devaluation of both as inferior to men and male-gender identified 'culture' (Merchant 1980).

2. Three Types of Ecofeminist Positions

Historically, the first strand of ecofeminism was *cultural feminism* (sometimes referred to as 'radical' or 'spiritual' feminism). Developed in the early 1970s, cultural feminism reclaims women-nature connections as liberating and empowering expressions of women's capabilities to care for nature. Some cultural ecofeminists argue that women's reproductive capacities provide a biological tie with nature, making women 'closer to nature' than men. Other cultural ecofeminists claim that 'women's closeness to nature' is embedded in deep social and psychological structures, making women's ways of knowing and moral reasoning better suited to solving environmental problems. Some argue for a resurrection of pre-patriarchal religions and spiritual practices (e.g., Goddess worship or pagan rituals) which honored women's bodies and procreative powers. But all cultural ecofeminists agree that women have a special and useful relationship to the physical world (bodies, nature) which can help end the unjustified dominations of both women and nature.

Cultural ecofeminism has been criticized by *social ecofeminists* for making essentialist, universalist, and ahistorical claims about both women and nature. Social ecofeminists claim that there is no essential (biological, natural, innate) nature of 'women' (*contra* cultural ecofeminism's essentialism), no homogenous 'women's experience' or 'women's way of knowing' (*contra* cultural ecofeminism's universalism), and no ahistorical concept of 'women' (*contra* cultural ecofeminism's ahistoricism). Rather, women's identities are socially constructed, historically fashioned, and materially reinforced through the interplay of a diversity of race/ethnicity, class, sexual orientation, age,

ability, marital status, and geographic factors ('social constructivism').

A middle ground is suggested by *materialist* (or *socialist*) *ecofeminism*. Socialist/materialist ecofeminism claims that women–nature connections are both socially constructed *and* biologically predisposed: women's biology (bodies, reproductive capacities) has played a key role historically in the oppression of women and the identification of 'women' with 'nature,' but women's biology is *not* destiny. Rather, it is the social, material, and political relationships between women and nature which are important.

What all three strands of ecofeminism add to feminism is the insistence on the relevance of ecology and environmentalism to feminism. While contemporary feminism has made progress in making visible the interconnections among various forms of human oppression (e.g., sexism, racism, classism, heterosexism, ageism, ableism, ethnocentrism), all ecofeminists insist that feminist analyses be extended to show how the unjustified domination of nonhuman nature (or 'naturism') is connected to sexism and other human 'isms of domination.'

3. The Intellectual Context of Ecofeminist Theory and Practice

Ecofeminism has always been a grassroots political movement motivated by pressing pragmatic concerns: women's and environmental health; deforestation, desertification, and soil erosion; the treatment of animals; science, development and technology; peace, and antinuclear activism. The Chipko Movement in India, Mothers of East Los Angeles, and the Women's Pentagon Actions are examples of the sort of political organizing actions characteristic of ecofeminism (Warren 1997b).

Ecofeminist theory grew out of such grassroots activism. It provides perspectives about gender from a combined environmental *and* feminist perspective, by showing ways human relationships to both 'nature' and 'culture' are gendered, raced, and classed, and how the dominations of women and nature are embedded in patriarchal (and other) structures and practices. Ecofeminist theory offers ecological notions of the self which challenge dominant Western models of rationality, knowledge, and ethics, and which establish connections between biodiversity and cultural diversity.

Ecofeminist scholarship is interdisciplinary. In philosophy, it focuses on conceptual issues by challenging patriarchal world views characterized by value-hierarchical and dualistic thinking, coupled with a 'logic of domination' which 'justifies' relationships of dominance and subordination (Warren 1996, p. 21). Ecofeminist philosophy challenges the 'culture/nature' dualism, as well as related 'reason/emotion,' 'mind/body,' 'mental/physical,' 'objective/subjective,' and

'human/nonhuman nature' dualisms. That is because these value dualisms historically have functioned to sanction as superior the male-identified realm of culture (mind, reason, objectivity) and as inferior the female-identified realm of nature (the physical, the body, emotion, subjectivity). Ecofeminist theorists argue that such hierarchical value dualisms are either false or conceptually incoherent. They incorrectly presuppose a clear separation of culture from nature (mind from body, reason from emotion, human from nonhuman), an ecologically unsound view of humans as discontinuous with nature, and an untenable ethical view which justifies the control, conquest, and mastery of the nonhuman environment in order to serve human needs.

Ecofeminists have offered different historical accounts of the connections between patriarchy, androcentric (male-centered) thinking, and the destruction of nonhuman nature. For example, environmental historian Carolyn Merchant argues in *The Death of Nature* that the change in gender-laden metaphors about nature in the history of science contributed to 'the death of nature.' Merchant argues that the classical Greek metaphor of nature as 'organic,' kindly, benevolent, nurturing female metaphor was replaced in the sixteenth and seventeenth centuries by the metaphor of nature as 'mechanistic,' disorderly, chaotic, instrumental, passive, and inert. While both metaphors feminize 'nature,' only the mechanistic metaphor permitted the removal of ethical constraints against the 'rape of Mother nature,' thereby permitting the 'mining of her womb' for the sole benefit of man.

By contrast, Riane Eisler argues that patriarchal patterns of domination began about 4500 BC E with the invasion of Indo-European societies by nomadic tribes from Eurasia. Ecofeminist philosopher Val Plumwood locates the historical roots of naturism in patriarchal dualisms which originated in classical Greek philosophy and the rationalist tradition (whereby rationality is taken to be both the hallmark of humanness and what elevates humans over nonhuman animals and nature).

Ecofeminist theorists often focus on ways sexist-naturist language maintain, sanction, and perpetuates harmful value hierarchical dualisms. Women are described in animal (nature) terms as pets, dogs, cats, pigs, cows, sows, foxes, chicks, serpents, bitches, beavers, mares, old mares, old bats, old hens, mother hens, pussies, pussycats, cheetahs, bird-brains, hare-brains, elephants, and whales. Animalizing or naturalizing women *in a patriarchal culture* where animals are seen as inferior to humans (men) thereby reinforces and authorizes women's inferior status. Similarly, language which feminizes nature *in a patriarchal culture* where women are seen as subordinate or inferior reinforces and authorizes the domination of nature. 'Mother Nature' is raped, mastered, conquered, mined, controlled, poked, prodded, and pried into; her secrets are penetrated and her womb is put

into service by the 'man of science.' Virgin timber is felled, cut down; fertile (not virile) soil is tilled and land that lies fallow is barren (not impotent) and useless, like a woman who cannot conceive a child. The exploitation of nature and animals is justified by language which is feminizing them; the exploitation of women is justified by language which is naturalizing women (Warren 1997b).

Ecofeminist theory has spawned a new area called 'ecofeminist literary criticism' (Murphy 1995). Focusing on contemporary writing by women (particularly women of color), ecofeminist literary criticism uses ecofeminist insights to develop a body of literature which honors biotic and human (especially gender) differences, while challenging mainstream notions of humans, culture, nature, and wilderness in the traditional Western literary canon (including traditional nature writing by men). Paula Gunn Allen, Margaret Atwood, Rachel Bagby, Annie Dillard, Sally Gearhart, Susan Griffin, Linda Hogan, Ursula Le Guin, Marge Piercy, Leslie Marmon Silko, Alice Walker, and Terry Tempest Williams are just a few of the authors who explore these connections through literature.

One of the first ecofeminist literary texts was cultural ecofeminist Susan Griffin's *Woman and Nature* (1978). In the prologue to her book Griffin writes,

He says that woman speaks with nature ... He says he is not part of this world, that he was set on this world as a stranger. He sets himself apart from woman and nature.

And so it is Goldilocks who goes to the home of the three bears, Little Red Riding Hood who converses with the wolf, Dorothy who befriends a lion, Snow White who talks to the birds, Cinderella with mice as her allies, the Mermaid who is half fish, Thumbelina courted by a mole. (And when we hear in the Navajo chant of the mountain that a grown man sits and smokes with bears and follows directions given to him by squirrels, we are surprised. We had thought only little girls spoke with animals.)

We are the bird's eggs. Bird's eggs, flowers, butterflies, rabbits, cows, sheep; we are caterpillars; we are leaves of ivy and sprigs of wallflower. We are women. We rise from the wave. We are gazelle and doe, elephant and whale, lilies and roses and peach, we are air, we are flame, we are oyster and pearl, we are girls. We are women and nature. And he says he cannot hear us speak.

But we hear (Griffin 1978, p. 1).

Griffin's writing has been controversial because of its essentialist and universalist underpinnings. Still, it is one of the earliest and most powerful pieces of ecofeminist literature to reveal the deeply-seated symbolic and philosophical associations between women and nature in the Western intellectual tradition.

An ecofeminist concern about language, images, stories, rituals, and symbol-systems about 'women' and 'nature' is at the heart of cultural ecofeminism's spiritual claims. Cultural ecofeminists defend earth-based, feminist spiritual symbols (such as Gaia and the Goddess) as a necessary part of ecofeminism. Charlene Spretnak writes:

Ecofeminism grew out of radical, or cultural, feminism (rather than from liberal feminist or socialist feminism) ... In the mid-1970s many radical/cultural feminists experienced the exhilarating discovery, through historic and archaeological sources, of a religion that honored the female and seemed to have as its "good book" nature itself ... We would not have been interested in "Yahweh in a skirt," a distant, detached, domineering godhead who happened to be female. What was cosmologically wholesome and healing was the discovery of the Divine as immanent in and around us (Spretnak 1990, p. 5).

Similarly, cultural ecofeminist Starhawk defends a nonpatriarchal, earth-based spirituality as crucial to ecofeminist politics:

Earth-based spirituality is rooted in three basic concepts that I call immanence, interconnection, and community. The first—immanence—names our primary understanding that the Earth is alive, part of a living cosmos. What that means is that spirit, sacred, Goddess, God—whatever you want to call it—is not found outside the world somewhere—it's in the world: it *is* the world, and it is us ... When we understand that the Earth itself embodies spirit and that the cosmos is alive, then we also understand that everything is interconnected ... The kind of spirituality and the kinds of politics we're called upon to practice are rooted in community ... The goal is the creation of a community that becomes a place in which we can be empowered and in which we can be connected to the Earth and take action together to heal the Earth (Starhawk 1990, pp. 73–4).

On the other hand, ecofeminist theologian Elizabeth Dodson Gray was among the first ecofeminists to examine the roles that sexist-naturist imagery plays in the patriarchal heritage of the Judeo-Christian tradition *without* entirely rejecting those traditions. In her book, *Green Paradise Lost*, Gray claims that a destructive hierarchy of beings is at the heart of biblical accounts of creation:

In this biblical view of the nature of things woman comes after and also below man. Woman was created (according to this chronologically earliest account of the creation of the world in Gen. 2) out of man's body (rather than from a woman's body as happens naturally) ... Then come children, so derivative that they are not even in the Creation story ... Then come animals, who do not have the unique human spirit at all ... Thus animals are below. Further down are plants, which do not even move about. Below them is the ground of nature itself—the hills and mountains, streams and valleys—which is the bottom of everything just as the heavens, the moon and the stars are close to God at the top of everything (Gray 1979, p. 5).

In this hierarchical order of being, the higher up one goes, the closer one is to all that is spiritual and superior:

What is clearly articulated here is a hierarchical order *of being* in which the lower orders—whether female or child or animal or plant—can be treated, mistreated, violated, sold, sacrificed or killed at the convenience of the higher states of spiritual beings found in males and in God ... Nature ... is

obviously a prize candidate for the most ruthless “mastering” of all (Gray 1979, pp. 5–6).

Much of ecofeminist theory involves ethical considerations. Minimally, ecofeminist ethics attempts to develop theories and practices concerning humans, nonhuman animals, and the natural environment which are not male-biased and which provide a guide to action in the prefeminist present. Typically, ecofeminist ethics reconceives humans as both ecological selves and moral agents, and reframes human–nonhuman nature relationships in ways which centralize values of care, appropriate reciprocity, kinship, integrity, and well-being—values typically underplayed in traditional Western ethics.

Ecofeminism also challenges the conception and practice of mainstream Western science and epistemology. As philosopher Lori Gruen states,

Following the arguments made by feminist philosophers of science, Marxists, cultural critics, and others, ecofeminists believe that facts are theory-laden, theories are value-laden, and values are molded by historical and philosophical ideologies, social norms, and individual processes of categorization (Gruen 1994, p. 124).

According to Gruen, ecofeminist theory always grows out of and examines the social contexts in which moral and epistemic claims are generated. Recognition of the interdependence of science and society, facts and values, reason and emotion ‘is the first step towards any legitimate knowledge’ (Gruen 1994, p. 134).

Biologist Donna Haraway concurs. Her arguments for ‘situated knowledges’ and ‘cyborg feminism’ challenge scientific assumptions of impartiality, objectivity, fact, and truth by revealing their embeddedness in structures of power and dominance. Haraway locates the promise of ecofeminism in disrupting the nature–culture dualism by seeing nature as both active, unpredictable, unstable, ungendered subject with agency (not simply some ‘resource to be mapped and appropriated’) and also as constructed artifact (Haraway 1991, p. 199).

Ecofeminism’s deep roots in political activism have led to the emergence of ecofeminist political theory based on coalition-building, direct action, and new conceptions of democracy. Political scientist Noël Sturgeon argues for a conception of ecofeminism as an ‘oppositional political discourse and set of practices imbedded in particular historical, material, and political contexts’ (Sturgeon 1997, p. 3). Sturgeon characterizes ecofeminism as a social movement through which change is produced by numerous kinds of ‘action,’

including that of the deployment of symbolic resources, shifts in identity construction, and the production of both popular and scholarly knowledge—as well as direct action, civil disobedience, strikes, boycotts, demonstrations, lobbying, and other more traditionally recognized forms of political action (Sturgeon 1997, p. 4).

Sturgeon argues that, as a social movement, ecofeminism is and must be involved in theorizing about concepts (e.g., of nature, women, race).

The power of ecological feminist theory lies in its ability to provide insights into the interconnections among the dominations of women and other human ‘others’ and the domination of nonhuman nature. The future of ecofeminist theory and research is to continue to show why, where, and how to accomplish the dismantling of interlocking human systems of unjustified domination.

Feminist Theory: Liberal

Liberal feminist theory is liberal political theory and feminist political theory—meaning that it advances the theoretical tradition of liberalism while it contributes to a political theory based on the foundation that men and women are of equal human worth. It is also a critical practice of assessing the laws and social practices sustained by liberal theory which might inhibit the realization of men's and women's equality.

Classical liberalism describes a limited government intended to secure the individual freedom and the political equality of (some) men (Locke 1998). Rational, free, and equal men contract in the public sphere to organize limited government that will protect their autonomy. Contemporary welfare liberals respect the rational autonomy and freedom of individuals but interpret equality more broadly and accept a role for the state in fostering political equality.

Because liberal feminists respond to theoretical traditions, laws, and social practices that have changed over time, liberal feminism is not defined quickly or narrowly. Some liberal feminists, particularly early liberal feminists, work within the framework of classical liberalism and seek to extend equality to women based on the assertion that women like men are rational individuals. More recently others challenge the public/private dichotomy that is sustained by the theory of the state as a contractual arrangement among autonomous rational individuals (Pateman 1988). Thus, some liberal feminists work within liberal theory to change its implications for women while others stretch the bounds of liberal theory to adapt it to feminist demands (Phillips 1993). In addition, due to their concern about inclusion, many liberal feminists engage in criticism of some aspects of liberal feminist thinking itself. Thus, the boundaries between liberal feminist inquiry and the broader feminist project of making theory, law, and social practice and the criticism thereof more inclusive social processes are not tidily delineated.

1. The Historical Tradition of Liberal Feminism

Liberal feminists of the eighteenth, nineteenth, and early twentieth centuries asserted women's ability and right to participate in public life at least through the suffrage, examined the institution of marriage and the legal framework of divorce and property laws, and

challenged the practices of denying women access to the same quality education as men and to the professions. Liberal feminists sought to end the treatment of women as legal dependents on their husbands or fathers. Through examination of laws and practices, liberal feminists including Mary Astell (1666–1731), Mary Wollstonecraft (1759–99), Harriet Taylor (1807–58), John Stuart Mill (1806–73), Elizabeth Cady Stanton (1815–1902), and Virginia Woolf (1882–1941) drew on the liberal tradition's value of equality and individual freedom to argue that, just as social status at birth was no longer a legitimate basis on which to discriminate among men as liberals argued, so also sex at birth was no longer a legitimate basis on which to discriminate against women.

Among liberal feminists, justifications varied. To defend their claim, some feminists argued that men and women were of equal human worth; some argued that some women were superior to some men and thus all women should be given opportunity to demonstrate their worth; and some argued that women's virtues were superior to men's and thus warranted influence on public economic and political activity. Mill drew on each of these when it was strategically prudent. However, in general, the liberal argument took the form of asserting that individual development required the ability to educate and expand one's faculties such that to deny women access to education and the professions was to deny the development of their full human potential. Further, liberal feminists argued that society as a whole would benefit from the public contributions of women.

While liberal feminists asserted that society in general would benefit from educated women's contributions, generally these early liberal feminists did not pay adequate attention to the circumstances of working class women. The male model of life experience to which they wanted women to gain access was that of a white professional class man. However, more activist liberal feminists such as Maria Stewart (1803–79) and Susan B. Anthony (1820–1906) did pay attention to the circumstances of Black women and working class women.

In the latter twentieth century the arguments for women's equal access to education and the professions and for treatment as autonomous individuals (rather than individuals assumed to be dependent on a father or husband) by the law were heard from feminists again. However, although some feminists focussed their attention on the plight of the white, middle class, heterosexual, married Western woman (Friedan 1974), in general the theoretical and practical attention of liberal feminists switched from equality to inclusion. While demanding that women get the same opportunities as advantaged men, feminists also interrogated the very desirability of a western male model of life experience where professional and public activities were seen as more important and fulfilling than community and family activities. Instead, these

feminists sought to change the gendered practices of men and women at home and in public such that domestic caregiving was given social, legal, and economic recognition commensurate with its social value (Okin 1989; Steinem 1983) (see *Gender and Feminist Studies*).

Further, women of color, lesbians, and women from around the world encouraged western feminists to think beyond the bounds of white, middle class, Western experience (Lorde 1979, Mohanty 1984). Consequently, during the twentieth century, the political agenda of liberal feminism moved beyond a focus on married women's property rights, divorce laws, and the suffrage to include labor laws, social issues including child-care, welfare, health-care and education, access to safe legal abortion, international development, the distribution of economic resources, and human rights (NOW 1967, Sen and Grown 1987, Bunch 1990).

Even as the liberal feminist agenda expanded, theorists and activists wondered if liberal feminism was theoretically adequate for challenging norms of colonialism, global inequality, racism, patronage politics, and other forms of hierarchy that complicate analysis of gender inequality. For example, at the dawn of the twenty-first century, women's human rights activism is a global movement of national and international feminists acting in locally specific ways and sharing their experience globally. This movement ostensibly promotes the liberal values of freedom and equality, but the scope of freedom and equality extends well beyond classical liberal bounds to include global provision of basic needs, education, and healthcare and access to development resources (Tinker 1990, Kabeer and Subrahmanian 1996). Thus, the social interests of contemporary liberal feminists extend far beyond those of early liberal feminists. Most early twenty-first century liberal feminists seek to challenge fundamental values, practices, and norms within and across societies (Charlesworth 1994, Afkhami 1995, Okin 1999).

2. Feminism within Liberal Theory

In the tradition of liberal feminist theory, theorists have not only promoted liberal values of freedom and equality for women but also re-examined those same values in light of women's experiences. While working within the liberal tradition, liberal feminists work to change liberal theory by examining its accepted arguments and underlying assumptions. Thus, liberal feminists advance feminism and liberalism. For example, Carole Pateman (1988) shows that liberal theory's use of contract doctrine assumes freedom and equality that do not exist among the contracting parties. In a private contract between the sexes, women lose their ability to contract as autonomous individuals with others in public. Thus, women are not

equal parties to the original political contract on which classical liberal social contract theorists' base liberal democracy. For women the 'sexual contract' is not an exercise of freedom. Rather than wanting to rewrite the sexual contract and the political contract as some feminist theorists have argued, and as some political theorists have done by sanitizing their texts of sex-specific language, Pateman criticizes the use of classical liberal theorists' fundamental tool, consent theory or social contract theory. Pateman undermines the oppressive roots of contract theory and reveals its use in the validation and regulation of slavery, employment contracts, marriage and divorce, prostitution, and surrogacy. She reveals that the liberal premise of natural individual freedom and equality is a fallacy and as such is an inappropriate basis for political theory.

MacKinnon (1993) argues that liberal notions of equality are based on an historical tradition dating back to Aristotle according to whom treating people equally means treating likes alike, and unlikes differently. MacKinnon argues that contemporary liberal theory sustains this perspective. Consequently, although equality is an important foundation of liberal theory, as defined it is not an adequate basis for challenging exploitative inequality where the inequality is the result of a difference that is perceived to be natural or ordained by God. MacKinnon proposes an alternative conception of equality as the absence of hierarchy. Such a definition enables the 'unlikes' to demand equality.

In addition to challenging the underpinnings of liberalism, liberal feminists also challenge the scope of liberal inquiry. For example, Okin (1989) challenges the liberal assumption that justice can be assumed to exist within families and between family members and instead argues that the social institutions of marriage and childrearing practices create a vulnerability of women in marriage that is unjust and leads to harm to women and children. Okin proposes either changing the traditional gendered division of private and public work and related gender differentiation of men's and women's roles in families and in public or compensating those women and their children who are made vulnerable by the existing gendered system. Specifically, until society does not perpetuate gender difference in economic means and opportunities, wives are entitled to and should receive half of their husbands' incomes. Such an arrangement should continue even in divorce for as long as the gendered arrangement existed during the marriage. With these and related proposals, Okin challenges society to take responsibility for the vulnerability of women and children that is created by the institution of gendered division of work in marriage and its impact on other social institutions.

Because they challenge the root norms of liberalism—freedom and equality—these feminists might be classified as 'radical'; yet their contributions

to liberal theory's cornerstones of freedom, equality, and justice make them liberal feminists as well. By re-examining the meanings of freedom and equality and the institutions that liberals rely on to promote them, liberal feminists advance liberal theory while advancing the feminist agenda of promoting theory, law, and social practices that respect men and women as having the equal worth of all human beings (see *Feminist Theory: Radical Lesbian*).

3. Feminist Critiques of Liberal Feminism

While engaged in a critical project of its own, liberal feminist theory has also been the target of criticism. However, liberal feminists generally respond to criticism by expanding their collective agenda and self-understanding such that liberal feminism continues to evolve.

Marxist feminists have criticized capitalism as causing the sexual division of labor in the family and have criticized liberal feminists' focus on equal opportunity (see *Feminist Theory: Marxist and Socialist*). Liberal feminists likewise are concerned about the sexual division of labor in the family (see *Family and Gender*) but they seek to change social norms regarding male and female roles in family maintenance—increasing women's role in providing the economic resources for the family and promoting equal opportunity for women in economics and politics while increasing men's role in providing for the care of the family (Okin 1989). In addition liberal feminists working in development have challenged the global distribution of resources and economic power without objecting to a capitalist organization of economics (Sen and Grown 1987).

Radical and lesbian feminists accuse liberal feminists of accepting patriarchy and the heterosexual model of family such that any challenge to gender norms within the family is not radical enough. In other words, according to their radical critics, liberal feminism does not get at the root causes of gender inequality (see *Feminist Theory: Radical Lesbian*). Liberal feminists respond by proposing family related policies that incorporate the experiences and needs of single and lesbian women and do not assume that families are headed by heterosexual married couples.

Although generally responding to its critics in ways which expand the scope of its own agenda, liberal feminist theory is less responsive to postmodern feminist theory. Postmodern feminists interrogate categories and challenge analyses that rely on norms of 'woman' and 'gender' as being exclusionary and limiting even in their attempt to be critical and analytical (see *Feminist Theory: Postmodern*). Liberal feminists respond by being self-conscious about their own ability to exclude through their assumptions (as liberal theorists exclude through their assumptions), but they are unwilling to abandon the use of categories of analysis as a tool for their critical endeavor

(Benhabib 1995). Moreover, they accuse postmodern feminists of abandoning a genuine concern for the excluded by undermining the tools necessary to analyze their exclusion (Okin 1995, Nussbaum 1992).

In sum, because it responds to theoretical traditions, laws, and social practices that have changed over time, liberal feminism is not narrowly definable. Moreover, due to their concern about inclusion, many liberal feminists not only engage in a critique of liberalism but also incorporate into their analyses criticism that has been directed toward certain aspects of liberal feminist thinking. Thus, liberal feminism is part of the broader feminist project of making theory, law, and social practice and the criticism of these a more inclusive social process.

B. A. Ackerly

Feminist Theory: Marxist and Socialist

1. Definition of the Field

Socialist feminist and Marxist feminist theory has been a major form of both feminist theory and of socialist theory. Key elements include: the analysis of gender in its intersection with class; a focus on the material, economic, and political dimensions of social relations; a prioritization of the analysis of inequality rather than difference; a focus on social transformation rather than either the recognition of difference or of equal opportunities; and location within the Enlightenment tradition with its commitment to reason, rather than postmodernist scepticism about the possibility of objective explanation.

It was conventional in the 1980s to distinguish three major types of feminist theory in which socialist and feminist theory was one alongside liberal feminism (with a focus on individuals and equal opportunities) and radical feminism (with a focus on men's oppression of women). Since then the major division in feminist theory has become that between modernist theories such as socialist feminism and postmodernist theories (described below). There is a fuzzy rather than clear-cut boundary around socialist and Marxist feminist theory. For instance, there is an issue of how much autonomy can be granted to gender relations from class relations before the theory is better classified in materialist feminism or radical feminism rather than socialist feminism. Or again, it is unclear how much significance can be accorded to culture before a different categorization becomes appropriate.

There are various sources of variation within socialist feminism including among others: the extent of the centrality of class relations as against the centrality of men's direct exploitation of women and the relative importance of economic and cultural dimensions.

Marxist feminist and socialist feminist theory overlap significantly, though the extent of this varies in different times and places. Sometimes the terms are used interchangeably, while in other contexts there are specific demarcations. When there are demarcations, this most often involves Marxist feminism being more focused on class analysis and socialist feminism on the specificity and autonomy of gender dynamics. Further, materialist feminist theory overlaps with socialist feminism, in that it has an emphasis on the material exploitation of women by men, though the extent of the priority given to gender is such that it is sometimes distinguishable from socialist feminism.

2. Historical Development

Socialist feminist theory first developed in Western capitalist societies in the eighteenth century, initially in the context of radical communitarian forms of social-

ism which embraced women's liberation as a core part of their practice, such as that of Owenism. Marxist feminist thought developed a little later, in the nineteenth century, in the context of Marxist socialist practice and theory and of both class struggle and first-wave feminism.

While Marx himself had little to say about feminism, Engels (1941) did, writing of the changing forms of the family using a historical materialist method. He drew attention to reproduction as well as to production, and the way in which the different social organization of the form of reproduction in the family affected many other dimensions of society. The merit and precise meaning of the distinction between reproduction and production has been the subject of extensive later analysis. Gilman (1896), a materialist feminist and a major theorist of first-wave feminism, focused the analysis of women's labor onto the way that men were the beneficiaries of the exploitation of women. This theoretical focus is echoed in the work of contemporary theorists such as Delphy (1984), who likewise see the expropriation of women's labor in the household as key to the explanation of women's subordination. Materialist feminism shares with socialist and Marxist feminism a concern with the centrality of labor, but pulls away from it as a result of the assumption of the independence of gender dynamics from those of class. In the revitalization of feminism in the West from the 1960s, there was a flowering of many hues of socialist feminist and Marxist feminist thought, both within and without the academy. This led to a major rethinking of the significance of gender for social theory and the social and behavioural sciences more broadly. Specific attention was paid to the analyses of women's labor both at home and in the labor market. During the 1970s and 1980s there was a significant extension in the range of substantive concerns which were subjected to a socialist feminist analysis, including the state, sexuality, culture, and male violence.

3. Domestic Labor Debate

The domestic labor debate of the 1970s set out to theorize the relationship between housework and capitalism. Housework was understood broadly in the context of domestic labor. This was intended to include childcare as well as housework, and indeed other forms of care work and servicing that women did at home without a wage. The protagonists debated the possible benefits of domestic labor for capitalism, and for husbands and fathers. Capitalists were seen to benefit from the nurturance and care of male workers who were more productive as a consequence, and also from the rearing of the next generation of well-socialized workers. The debate explored the extent to which it was possible to utilize traditional Marxist terminology and apply it to gender inequality, and the extent to which a new set of concepts was needed. In

particular, they asked whether domestic labor was productive, unproductive, or nonproductive, of value, and surplus value. This was important to Marxist theory of capitalism, since labor that was productive of value and surplus value was considered to be more central to the workings of capitalism than work that was unproductive or nonproductive. These feminist writers thus challenged successfully the traditional Marxist assumption that women's domestic labor was marginal to capitalism, as part of their argument that Marxist theory needed a better appreciation of the significance of gender relations, and of women as a potential political force.

The debate was a highly sophisticated exploration of these theoretical issues, which eventually left far behind its starting point in the everyday oppression of women—too far behind for some critics of the entire debate. The whole field was criticized for economism and its use of arcane technical language. With the fall of the kind of socialism practiced in Eastern Europe Marxist conceptualization has become regarded as less significant. Today, Marxist concepts are utilized rarely in the understanding of housework. Nevertheless, the question of the nature of the relationship of domestic labor to the market economy remains an important one, and one pursued by socialist feminists using a less overtly Marxist terminology. Today the focus is on domestic labor as care-work (Gardiner 1997), and on the variations in the extent to which the state provides for the collective and social performance of this labor, rather than its being left as a private matter for individual households (Folbre 1994).

4. Women's Waged Labor

The inequality between women and men in the labor market was theorized as resulting from capitalism, with major debates as to the mechanisms by which the connection was to be understood. The inequalities include: lower wages; lesser job security; fewer fringe benefits such as employer-based pension schemes; occupational segregation. The nature of the causes of the greater vulnerability to exploitation of women's labor than men's was the subject of much debate. This greater vulnerability was seen sometimes as stemming from women's position in the family that ill-prepared them with the skills needed for the labor market. Further, divisions and lack of solidarity between workers as a result of gender and racialized divisions were seen to facilitate such exploitative strategies by employers (Cockburn 1983).

A variant of socialist feminism, sometimes referred to separately as dual-systems theory, theorized the subordinate position of women in the labor market and family as a result of the interlocking of the system of capitalism with a system of patriarchy (Hartmann 1976). Here the subordination of women in the system of patriarchy interacted with that of women's subordination within capitalism, and was, in certain

periods and locations, fuelled by the organization of men on their own behalf, such as in the male-only or male-dominated trade unions of the late nineteenth century. Dual-systems theory played an important role in the development of analyses of occupational segregation, since it was hard to see that this form of labor market rigidity was in a simple sense a result of employers' interests, or indeed women's interests, but rather that to be understood it was necessary to include a notion of male workers' interests. The relationship between patriarchy and capitalism was sometimes seen as harmonious, in that the subordination of women in one system supported their subordination in the other, and sometimes in tension, as when the demand for labor by expanding capitalist economies pulled women out of patriarchal households (Walby 1986).

Recent socialist feminist analysis on women's labor has included analysis of the strategy for delivering comparable worth, that is, equal pay for work of equal value using a legally-based intervention. This focuses on the extent to which patriarchal work systems are resilient to feminist campaigns rooted in equality politics. While most of the analysis of comparable worth has taken place in the US, with largely pessimistic conclusions as to the tenacity, depth, and flexibility of patriarchal practices in the workplace, the strongest legislation is actually within the EU, where analysis is still in its early stages.

Economics as a discipline has integrated a feminist perspective to a lesser extent than some other disciplines, for instance, sociology. Yet, there has been a sustained critique of and engagement with mainstream economics, in which socialist feminist theoretical leadership has played a significant role (England 1992, Cook et al. 2000).

5. *Class Divisions*

In socialist and Marxist feminist theory class divisions are important in a number of ways. First, the class divisions between capital and labor structures women's lives, both their domestic labor and their participation in waged labor. Second, the class divisions between women mean that it is not possible to generalize about women as a whole, since women in different class locations will have different interests. For instance, a woman who works as a cleaner in a private household will not have the same economic interests as the woman who employs her.

6. *Culture*

Most socialist and Marxist feminist theory has conceptualized culture as a secondary dimension of women's lives. While patriarchal ideologies that support women's oppression are noted, these are not usually seen as the most important part of the explanation.

However, since the late 1980s the perceived importance of culture has grown within much Western social science, although the extent of this change is uneven and is more acute in the UK than some other countries. This 'cultural turn' has had an impact upon socialist and Marxist feminist theory in two ways. First, the turn to culture was incorporated within a self-defined Marxist feminism, as part of a new and more sophisticated interpretation of Marxism. For instance, there were attempts to address questions of sexuality and to integrate Marxism with Freud and with Foucault. Second, there was a turn away from socialist and Marxist feminism, and a critique of this school of thought as economistic. The overall impact was to displace the concern with women's paid and unpaid labor from its central location in theoretical questions within feminist theory, even though empirical studies continued on women's labor.

7. *'Race,' Ethnicity, and Gender*

Since the 1980s there have been criticisms of feminist (and other) academic writing for insufficient attention to issues of 'race' and ethnicity. This was not only a criticism of the scarcity of studies focused on issues of race and ethnicity. More importantly, it was a criticism of the lack of theoretical centrality given to race and ethnicity in feminist theory. The strongest criticism was that socialist and Marxist feminist theory was inherently unable to deal with the complexity needed to theoretically engage with 'race' and gender simultaneously.

However, attempts at analyzing the relationship of gender and ethnicity by the critics have themselves been subject to problems, not least of which have been tendencies to, first, empirical depth at the expense of explanatory power; and second, a concern with difference at the expense of inequality. These issues are re-articulated in the debate on postmodernist developments in feminist theory.

The integration of issues of analyses of ethnicity, gender, and class remains an important theoretical debate today, and re-emerge in different forms in the topics discussed below, especially those of: postmodernism/modernism; recognition/transformation; agency/structure; development and globalization.

7.1 *Postmodernism/Modernism*

Socialist and Marxist feminist theory is modernist rather than postmodernist and draws strongly on an Enlightenment heritage. This involves several elements of which two will be noted here. First, there is an assumption that explanation, while fallible, is both possible and desirable, and that merely describing the world, albeit in complex and interesting ways, is too modest an ambition for social science. The search for an explanation of the world is necessary in order to understand how to change the world. Without an

explanation of the way the world works, attempts at change, such as a feminist political project, are directionless. Second, there is a search for simplicity in the explanation of large and complex phenomena, in terms of powerful underlying motors of change, and of underlying large-scale social structures. This is in contrast with the postmodernist fascination with complexity that has a tendency to merely descriptive accounts of processes.

7.2 Recognition/Transformation

Socialist and Marxist feminist theory seeks to analyze processes of transformation rather than simply recognizing existing social relations or limiting demands for social justice to that of equal opportunities (Fraser 1995). There has been a vigorous debate in feminist (and other social) theory as to the merits of the politics of recognition and the politics of equality, as to which is more effective in achieving social justice. Equality politics has been criticized because, in its focus on the unequal distribution of material privileges, it neglects the significance of cultural differences that are alleged to be more important. Recognition politics focuses on cultural dimensions of social life and on the positive valuation of difference in the political arena. Two examples of recognition politics are the demand for respect for religious customs and for quotas for the representation of subordinate social groups in political bodies, such as parliaments. An example of equality politics is a drive for equal pay through equal opportunities laws. The socialist feminist critique of this debate holds that the strategy of recognition politics can merely embed existing inequalities even as it recognizes the cultural specificity of subordinate groups, while equal opportunity politics, by seeking redistribution within an existing hierarchical system, does not fundamentally alter that system. By contrast, the socialist feminist argument is that a focus on transformation is needed since it is the overarching system of social inequality which needs to be changed, not just which groups, such as women or racialized minorities, are disadvantaged. This entails a less hierarchical division of labor and less unequal distribution of income. It is argued that the goal of transformation demands reasoned argument to build a new social project, rather than embracing existing differences and the projects of existing groups, or seeking the redistribution of existing privileges. This debate has echoes in many branches of contemporary social and political theory, as it grapples with integrating theoretical concern with difference into traditional social theory.

7.3 Agency/Structure

Socialist and Marxist feminist analysis uses concepts of social structure. This is in contrast to some forms of feminist theory that focus primarily on agency and

performativity. This conceptualization of the social world is needed in order to capture the deep rootedness of social processes, their persistence over time, and to enable an analysis which connects large-scale processes of different kinds into an overarching system. This does not deny the relevance of agency, despite many criticisms of structural analysis to this effect, since collective political agency is regularly theorized by socialist feminists as a key route to social change. But rather it involves rooting agency in structure, so as to understand that while people choose, they do not do so under conditions of their own making.

7.4 Globalization and Development

While within some branches of Western feminist theory there was a move away from structural accounts of gender inequality during the 1980s and 1990s, this change has not been universal. In particular, within Development Studies the socialist feminist tradition has remained strong (Moghadam 1996). This has been partly because of the agreed significance of the issue of economic poverty and of the role of international capital in the shaping of the process of development.

Since the late 1990s the interest in the issue of globalization is leading to a resurgence in the types of analysis which traditionally have been at the core of socialist feminist analysis, such as the transformation of work and collective political agency. This is because of the desire to understand the interconnectedness of large-scale global processes, and the role of international capital in the changes associated with globalization.

8. The Mainstreaming of Socialist Feminist Theory?

It would be conventional to suggest that socialist and Marxist feminist theory has lost most of its vibrancy during the 1980s and 1990s and that the ascendancy in feminist theory has passed to theories which are more cultural and literary in substantive and theoretical focus. Indeed since the fall of the Wall between East and West Europe Marxist theory has become unfashionable, being regarded as disproven by historic events. Certainly hypotheses about the revolutionary potential of the proletariat need to be rejected.

However, this should not lead to the underestimation of the impact of socialist feminist theory and the continuing significance of its core theoretical concerns. Several of the initial positions of socialist feminist theory which were once regarded as unusual and original have become accepted by traditions which might once have been hostile opponents of such theory. These include, for example, arguments as the importance of labor to understanding gender inequality, and of the centrality of gender to the understanding of the labor market, which are now mainstream assumptions. Today, it is rare for main-

stream social science to deny the relevance of a gender perspective to their subject matter, unlike in the 1970s. Once gender issues were confined to family studies, but today the relevance of gender to a wider set of issues, such as the labor market, is much more readily accepted. To a significant extent then, socialist feminist theory has become mainstreamed and in so doing has lost some of its distinctive identity. In parallel the broadening of the substantive and theoretical concerns within socialist feminist theory has meant the loss of the specificity of some dimensions of a distinctive socialist feminist project (Walby 1997).

However, the move to postmodernism in much feminist theory in the 1980s and 1990s, left socialist feminism as an important carrier of the commitment to modernist forms of theorizing, with a focus on explanation, a search for deep structures and their interconnections, and an interest in the conditions under which gender relations might be transformed. With the development of analysis of globalization the core theoretical concerns of social feminism are again central to current debates, even if they are no longer labeled as socialist feminist.

Feminist Theory: Postmodern

The work of postmodern theorists has been a major influence in feminist theory since the 1980s. Building on the work of theorists such as Michel Foucault, Jacques Derrida, and Jean-Francois Lyotard, postmodern feminist theory emphasizes the constituting function of language and discourse in the construction of sexuality and the structure of gender relations. Breaking from modernist feminist theories such as liberal feminism and Marxist/socialist feminism, postmodern feminists reject the founding assumptions of modernist/Enlightenment thought: the attempt to find universal truth, to comprehend the totality of social reality and to define the essential nature of 'woman.' Through the postmodern method of deconstruction they attempt to displace these certainties. They emphasize the discursive nature of social reality and analyze the mechanisms by which gender identity is constituted discursively.

1. Postmodern Theories

Theories termed postmodern have their roots in Nietzsche's challenge to the fundamental values of the Western tradition, his 'transvaluation of values.' French structuralism and psychoanalysis also played a major role in the development of postmodernism. Levi-Strauss's structuralism focused on the way in which the overall structures of cultures create meaning for social actors. Jacques Lacan's psychoanalytic theory asserted that language constitutes the psyche, specifically the definitions of masculinity and femininity; he defined the possibility of meaning in language as deriving from the phallus. These and related theories produced a generation of thinkers, particularly in France, who looked to language and discourse as the constituent elements of social reality. They turned away from the quest for universal truth, what they called 'metanarratives,' and turned instead to the specific definition of 'truth' established by discourses within particular societies.

Lyotard's influential *The Postmodern Condition* (1984) defined the parameters of the postmodern

project. Lyotard argued that 'knowledge' in the contemporary world was necessarily plural and diverse, that the metanarratives that defined modernism no longer hold sway. Identifying postmodernity as discontinuous with modernism, Lyotard argued for new definitions of truth and knowledge appropriate to the postmodern condition. Michel Foucault and Jacques Derrida further challenged the modernist definition of a single, absolute Truth. Their distinctive contribution to postmodern thought was the theory of the death of 'man' or the subject. Foucault argued that the subject of modernism, the autonomous agent who constitutes meaning, is neither universal nor absolute, but, rather, the product of specific discourses at a particular juncture in Western thought. Derrida's work attacked the opposition between the rational, autonomous subject of the Western tradition and the object of knowledge that this subject constitutes. His critique called into question a particular aspect of this subject: the author who creates the meaning of the text. Both Foucault and Derrida argued that this subject, the centerpiece of modernism and humanism, is doomed to extinction.

One of the principal aspects of postmodern theories is an attack on the binaries—dichotomous, hierarchical oppositions—that are at the center of modernist thought. Postmoderns argue that modernist thought is structured by a series of binaries: rational/irrational, nature/culture, subject/object, reason/emotion, absolute/relative, male/female. A major aspect of the postmodern project is the attempt to displace these binaries. Postmoderns argue, first, that they are the result of historically situated discourses and, second, that they distort and limit understanding. The focus of postmodern method is the attempt to 'deconstruct' these binaries, to reveal the unstated presuppositions informing them and the strictures they impose on thought.

2. The Convergence of Feminism and Postmodernism

There is widespread agreement among intellectuals that Western thought is witnessing a major shift at the end of the twentieth century: the turn away from the absolutes of modernist thought and its central figure, the autonomous subject, and the embrace of situational, perspectival knowledge and a relational, constituted subject. Both postmodernism and feminism are at the forefront of this intellectual shift. Both engage in a radical critique of modernist thought, attacking the roots of its understanding of knowledge and the subject. They agree that the binarisms that inform modernist thought are necessarily gendered, rooted in the central opposition between male and female and the subordination of the feminine entailed by this opposition. Postmoderns attack this binarism

on the grounds that it distorts knowledge and presupposes a false opposition between the essentially feminine and the essentially masculine. At the heart of the modern feminist movement is an attack on the male/female binarism on the grounds that it presupposes the inferiority of women. The postmodern and feminist convergence on this central issue was the initial basis of the attraction of postmodern theories for feminists. The postmodern project of deconstructing 'man' converged in many ways with the feminist project of challenging patriarchy.

Many feminists first encountered postmodern themes in the work of what are now called the 'French Feminists.' Luce Irigaray, Julia Kristeva, and Helene Cixous theorized about the construction of the feminine within language, particularly the construction of female sexuality. Building on the work of Jacques Lacan who defined the position of women in language as a 'lack,' they argued that the oppression of women in Western societies is rooted in language and what they identified as its 'phallographic' assumptions. They emphasized that language creates subjects, particularly the subject 'woman,' and that this creation both defines and distorts female sexuality. The French Feminists accepted Lacan's thesis that the basis for meaning in language is the phallus, but, instead of accepting his conclusion that women are, therefore, erased by language, they attempted to fashion a 'feminine writing' that would give women a voice.

The work of the French Feminists, although not strictly postmodern, presaged many of the themes of postmodern feminism. The French Feminists identified language as the source of meaning, subjectivity, and sexuality. They questioned the binarisms that structure Western thought and the inferior status for women that they entail. Their attempt to define a 'feminine writing,' however, appears to contradict the postmodern impulse to reject essentialism. This aspect of the French Feminists' thought continues to be controversial for postmodern feminism.

3. Postmodern Feminist Theories

The clearest statement of the major issues surrounding postmodern feminism is found in an influential article by Fraser and Nicholson (1990). They argued that feminism and postmodernism are the most important political-cultural currents of the 1980s and that the two approaches can both profit from a closer alliance. Their central thesis is that the strengths of each movement could and should correct the weaknesses of the other. The strength of postmodernism, its rejection of metanarratives, can counter feminism's tendency to construct such narratives. Conversely, feminism's orientation toward social criticism can rectify postmodernism's avoidance of social critique. Calling for an integration of the two approaches, Fraser and Nicholson argued that a postmodern feminism would

be an approach that avoids the metanarratives of modernism but could nevertheless engage in large historical narratives and analyses of societal macro-structures.

The late 1980s and 1990s witnessed an explosion of discussions of postmodernism and feminism. Two books outlined the issues facing a postmodern feminism (Hekman 1990, Weedon 1987). Butler's (1990) book defined the distinctive approach to the subject that would characterize postmodern feminism. Relying on the postmodern critique of the modernist subject as well as psychoanalytic theory, Butler argued that there is no essence to gender identity but, rather, that gender is constituted through the performance of gender roles. Butler's thesis was that gender identity is a regulative ideal that grounds the norm of heterosexuality. She asserted that it is precisely the belief in gender identity, a belief that has been central to feminist theory and political practice since the advent of the feminist movement, that prevents us from identifying the political processes that produce that coherent identity. She thus concluded that gender identity, far from being the means of women's liberation, was the ground of women's oppression.

Butler's book served as a kind of lightning rod for both defenders and critics of postmodern feminism. A series of books and articles in the 1990s further established the parameters of the approach. A notable element of this formulation was the connection to Marxism/socialism. Several prominent postmodern feminists argued for a redefinition of socialist feminism along postmodern lines. Haraway (1990), in her influential article, argued that women need a new identity for the postmodern age that can replace the constructed revolutionary identity of socialist feminism. Like Butler, Haraway attempted to demonstrate how the postmodern critique of identity could be used to formulate a feminist politics appropriate to the postmodern era. In addition to extending the discussion of gender identity, her work also brought postmodern themes into another area of feminist concern: the critique of Western science. Another argument for the connection between postmodern feminism and Marxism/socialism came from Gayatri Spivak. Proclaiming herself a Marxist feminist deconstructionist with an overtly political agenda, Spivak argued for the political usefulness of postmodern feminism. Arguing against critics of the approach who defined it as exclusively a white, male theory, she also demonstrated how deconstructive methods could be used to critique issues involving race and colonialism.

Psychoanalytic theories became important in the emerging definition of postmodern feminism as well. Flax (1990) argued for the convergence of postmodernism, feminism, and psychoanalysis. Identifying feminist theory as a type of postmodern philosophy, Flax argued that, together with psychoanalysis, postmodernism and feminism contribute

to the fundamental questioning of the certainties of the Western tradition. Together, she asserts, these three movements force a redefinition of those certainties and encourage questioning of the need for imposing order on social reality and defining its universal structure.

Another influential postmodern feminist theorist, Drucilla Cornell, applied postmodern theories to feminist legal studies. Although legal theory would seem to be an inappropriate subject for postmodern deconstruction, Cornell (1991) argued that legal theory needs a new choreography of sexual difference that can only be supplied by postmodern deconstruction. In a series of books on deconstruction and the law, Cornell developed the ethical dimensions of deconstruction and argued for its usefulness in liberal legal theory.

Postmodern themes have appeared in nearly every aspect of feminist thought. The strongest proponents of a postmodernism feminism are found in English literary criticism where the influence of Derrida and Foucault is pervasive. But postmodern themes also appear in women's history, political theory, philosophy, cultural studies and feminist critiques of science.

4. Critiques of Postmodern Feminist Theories

Since it was first introduced in feminist theory, postmodernism has had a mixed reception in the feminist community. The well-known collection, *Feminism/Postmodernism* (Nicholson 1990), is representative of this reception: the articles are almost evenly divided between critics and defenders of a post-modern feminism. The feminist critiques of postmodern feminism that have emerged in the 1980s and 1990s have focused on the fundamental aspects of the postmodern approach, questioning its appropriateness for feminist theory and practice.

The most pervasive critique of a postmodern feminism is that it precludes the possibility of a feminist politics. Di Stefano, for example, argued that feminism is 'firmly, if ambivalently, located in the modernist ethos' (1990). The basic concepts of the contemporary women's liberation movement, 'woman' and 'liberation,' are, she asserts, thoroughly modernist concepts. These concepts are deconstructed and rejected by postmodernism, thus destroying the foundation of feminist theory and politics. Di Stefano also questions the possibility of founding feminist politics on an approach that ignores gender altogether.

Ebert (1996) elaborates on this critique in one of the most comprehensive attacks on postmodern feminism. Ebert decries what she defines as the dominance of 'ludic feminism.' She argues that a feminism founded on postmodern assumptions about linguistic play, difference, and the priority of discourse will result in the substitution of a politics of representation for

radical social transformation. Ebert laments the fact that many socialist feminists have embraced postmodernism and thus abandoned the revolutionary resistance politics that defines Marxism. Ebert and other critics of postmodern feminism claim that by reducing everything to discourse and rejecting the notion of the truth of social reality, postmodernism precludes the possibility of a feminist politics. Far from fostering a politics of resistance, these critics claim, postmodernism entails either nihilism or an ultimately conservative defense of the *status quo*.

Defenders of postmodern feminism argue that politics in general and feminist politics in particular do not require the metanarratives of modernist politics. They also point to the work of postmodernists such as Foucault who clearly place their work in a tradition of political resistance. But, although Ebert and other critics of a postmodern feminism concede that some postmodern thinkers are interested in resistance, they assert that without a view of the truth of social reality, feminists cannot proclaim the truth of women's oppression, a necessary element of any feminist politics.

This critique is related closely to another pervasive criticism of postmodern feminism: its failure to produce systematic knowledge of social reality. Although Fraser and Nicholson argued that systemic social critiques are not precluded by postmodernism this argument has not been persuasive for many feminists. On the contrary, many feminists have argued that postmodernism's approach to knowledge produces nothing but meaningless textual analysis of the infinite differences of social reality (Hartsock 1990). Bordo (1990) argued that this aspect of postmodernism leads to 'gender scepticism' and the infinite play of differences without distinction. These critics conclude that postmodernism's resistance to comprehensive theories precludes a coherent understanding of social reality without which social change is impossible.

Another major focus of critiques of a postmodern feminism is the concept of the subject. Butler and other postmodern feminists' deconstruction of the modernist subject is central to their theoretical project. Yet their critics have claimed that this deconstruction leaves feminism with nothing to replace this subject. The modernist subject, they claim, had agency and autonomy, the postmodern subject has neither. Worse, postmodern theories of the subject produce what its critics call a 'social dupe,' a subject which is wholly constituted by discourse and thus incapable of agentic action. This not only produces passivity but fails to explain the possibility of resistance, including feminist resistance politics. The defenders of postmodern feminism claim that this critique is rooted in modernist assumptions that falsely link agency to the modernist subject. But the question of agency and the 'social dupe' remain central to critiques of postmodern feminism.

Postmodernism's emphasis on texts and discourse is

at the root of another critique of postmodern feminism: the charge that deconstructing materiality denies the reality of women's pain. Critics such as Bordo (1993) argue that a central concern of feminism must be an account of the very real, material pain inflicted on women's bodies by the structures of patriarchy and that postmodern feminism's rejection of materiality precludes this. The postmodern feminist rejoinder formulated by Butler (1993) is that focusing on discourses does not ignore the materiality of pain, but, rather, offers the possibility of transforming it. Butler claims that materiality must be the object of feminist inquiry, not its ground.

The origins of postmodern theories have also been the object of feminist critiques. Postmodern theorists, critics charge, are elite white men who ignore gender issues and write jargon-filled discourse that excludes the uninitiated. Feminists writing on race and ethnicity have been particularly vehement critics of this aspect of postmodern feminism. They claim that what Barbara Christian called the 'race for theory' marginalizes women of color. Specifically, these critics assert that the unique perspectives and theorizing formulated by women of color are ignored and negated by postmodern feminist theory.

One consequence of these critiques of postmodern feminism has been a return to the universals of modernism on the part of some feminists. Okin has argued that the anti-essentialism and hyperconcern with differences among women that characterizes contemporary feminism is a dangerous trend. She claims that the result of these emphases is a paralyzing degree of cultural relativism and the impossibility of making any generalizations about women's condition. A similar concern motivates the recent work of Martha Nussbaum. Nussbaum asserts that without a concept of universal human functioning feminists will be unable to address the wrongs done to women throughout the world. Like Okin, she is concerned about the extremes of what she sees as cultural relativism fostered by postmodern feminism and other approaches that emphasize differences among women.

In summary, the jury is still out on postmodern feminist theories. They have had a pervasive influence in contemporary feminism and have generated vehement defenders and critics. On the positive side postmodern theories have aligned feminism with the intellectual shift that characterizes contemporary Western thought and brought it into the era of differences. On the negative side postmodernism has raised questions about the foundations of any feminist politics and the status of the truth claims feminists advance.

Feminist Theory: Psychoanalytic

Psychoanalytic theory, originated by Sigmund Freud and elaborated by numerous competing camps of

disciples, has been a major influence on feminist theory throughout the twentieth century. Feminists were among the earliest proponents of psychoanalysis because it acknowledged sexual desires in all people including women, who at the time were considered asexual. But over the course of the century, the theory fell out of favor among feminists, many of whom maintained that it contributed to women's oppression instead of their liberation. In the 1970s interest in psychoanalysis among feminists enjoyed a renaissance, and by the end of the century it formed part of the canon of feminist theory in the humanities. However, the theory still faces a great deal of resistance from feminists in the social sciences.

The most important aspect of psychoanalysis for feminists is its theory of sexual development. In the Freudian account, all infants are polymorph perverse, meaning that humans are not innately predisposed to heterosexual genital activity, but also capable of homosexuality, fetishism, perversions, and all other sexual variations. Freud argued that boys and girls begin life with similar psychological dispositions, but they follow different paths to adult heterosexuality owing to their anatomical differences and the expectations placed upon them by their families and society in general. Boys' development diverges from girls' around age three, during the oedipus complex, when they must relinquish their erotic longing for their mother in the face of castration threats from their father. To maintain their physical integrity, boys will typically project their aggressive fantasies onto their fathers, identify with their fathers, and then internalize the aggression imputed to the father in the form of a punitive superego. Freud wrote relatively little about girls' development, which is surprising since he treated many women patients, some of whom were the subjects of his published case studies. He did note that as beings without penises, the threat of castration was useless against girls' incestuous desires. But he maintained that the inherent superiority of the penis as a satisfying sexual organ inspired such envy among women that they are (unconsciously) compelled to seek a substitute penis of their own, typically by subordinating themselves to men in the hopes of obtaining a male offspring.

Freud's description of the childhood stages of sexual development recognized that individuals could and often did stray from the typical patterns of resolution, due to idiosyncracies of their physiology and the peculiar configurations of their family lives. When individuals did not successfully progress through the stages of development, mental illness could result. Freud maintained that unresolved early childhood traumas associated with these stages of sexual development become lodged in the unconscious and reappear in neurotic symptoms. These symptoms can be relieved through psychoanalytic therapy, a technique that involves free association, recovery of repressed traumatic memories and affects, and trans-

ference, all in the context of a uniquely structured relationship between analyst and patient. Thus, his theory provided both an account of typical sexual development, and a method for curing adult neurosis produced by deviations from those typical patterns.

This theory of sexual development appealed to many feminists who were contemporaries of Freud. Although several of Freud's women proteges, including Karen Horney, rejected his notion of penis envy in women, she and other feminist theorists applauded his emphasis on the psychological similarities between men and women. At a time when most of his notable contemporaries emphasized essential differences in men's and women's natures, Freud observed that individuals contain both masculine and feminine characteristics, and that women are as passionate as men, ideas that resonated with feminists Emma Goldman and Margaret Sanger. Feminists also took from Freud an indictment of women's proscribed roles in society. In Freud's view, marriage and family arrangements demanded an enormous and inordinate amount of repression and sacrifice on the part of women which made them hostile to civilization and often generated mental disorders. But where Freud saw few options or alternatives to these conventional practices, some feminist theorists, including Elsie Clews Parsons, saw this as a critique of Western marriage and an inspiration to experiment with alternative forms of sexual relationships.

Feminism was dormant in mid-twentieth century, but psychoanalysis at the time was experiencing a period of growth and popularity. When feminism re-emerged in the 1960s and 1970s, psychoanalysis was targeted as an enemy of women's liberation. Instead of being associated with sexual modernism, which it had represented in the 1920s, psychoanalysis had become alloyed with social conservatism. Feminist activists and theorists, including Betty Friedan, charged that psychoanalysts typically blamed strong and assertive mothers for causing mental illness in their families and a whole host of other social problems. The concept of 'penis envy' was again criticized for defining women as innately inferior to men. Therapy was seen as a tool of patriarchy for enforcing submission to sex roles and brainwashing women into accepting compulsory heterosexuality by diagnosing lesbians as sick and deranged; Mary Daly noted that 'therapist' could be read 'the/rapist,' symbolizing the attitude of psychoanalysis to women's oppression and suffering (Buhle 1998, Gardiner 1992).

In this climate of feminist antagonism to psychoanalysis, two books appeared that eventually inspired a reassessment of Freudian theory by feminists: Juliet Mitchell's *Psychoanalysis and Feminism*, published in Great Britain in 1974, and Nancy Chodorow's *Reproduction of Mothering*, published in the US in 1978. Both writers were active in the women's liberation movement, and both identified themselves as socialist feminists. They turned to psychoanalysis

because it offered a compelling explanation of the origin and the intractability of gender domination. Psychoanalysis was unique, they argued, in its ability to explain how patriarchal attitudes and practices are inscribed and internalized in both men and women. They read Freud as showing how, through the normal course of sexual development, both men and women learn to unconsciously desire and reproduce male domination and devaluation of women. In other words, they understood the theory as a description of the inner workings of a patriarchal society—not a proscription for one. Freud had in fact elided this distinction in his work, but Mitchell and Chodorow insisted that there were critical moments in psychoanalytic theory that could be emphasized to enhance its usefulness for feminists intent on changing society to benefit women.

For example, Chodorow demonstrated that the psychoanalytic theory of sexual development could account for why women typically conform to society's expectation that they bear primary responsibility for rearing children. She agreed with radical feminists who argued that this primary mothering is ordered by a sexist society that provides few options for emotionally fulfilling productive activity for women. But she used psychoanalytic theory to uncover the unconscious dynamics that caused women to willingly embrace this family role. She argued that when women do all the mothering, this sets up asymmetries in boys' and girls' sexual development that leads to gender differences in adult men's and women's ability and unconscious desire to render adequate care to infants. Girls develop their primary identity through connectedness to their mothers, whereas boys develop a sense of self as separate from their primary caretaker and all the nurturing qualities she typically embodies. Boys learn that to be 'masculine' requires that they deny and denigrate feminine qualities in themselves and in others. Thus, Chodorow demonstrated that psychoanalysis provides a compelling account of the origin of gender differentiation, helps to explain the desires and proclivities of women to nurture infants, and offers an explanation of men's general devaluation of women, without succumbing to either biological or social determinism, pitfalls that feminist critics of Freud seldom avoided. Psychoanalysis also suggests a strategy for changing these patterns—co-parenting. Chodorow argued that if men were equally involved in childcare, women would be freed to perform other creative and productive work. Also, children would learn to associate nurturing activities with both men and women, so boys would no longer denigrate women (and qualities currently associated with femininity) in the course of developing a masculine sense of self.

Chodorow's approach draws heavily from the 'objects relations' branch of psychoanalysis, which emphasizes the importance of social relationships and interactions with other people (unfortunately termed objects in the development of the self). This tradition

is the most popular one among the sociologists who advocate psychoanalysis, including Chodorow, Jessica Benjamin, and Miriam Johnson. Miriam Johnson, for example, analyzes the function of the peer group in male psychological development, focusing on its importance in directing men's aggression against women. Political theorist Jane Flax also uses objects-relations theory to challenge notions of universal reason and justice, which she regards as undergirding male domination and other forms of political inequality. The goal of these and other feminist works in the objects relations tradition is to explore the gendered psychological underpinnings and consequences of various forms of social organization with the ultimate aim of criticizing those forms and advocating social and political change.

The other major branch of psychoanalysis that feminists have appropriated is associated with the work of French psychoanalyst Jacques Lacan. This tradition is strongest in the humanities. Juliet Mitchell, who began her career as a literary critic, endorsed a Lacanian approach in her appropriation of psychoanalysis for feminism, arguing that language is an important mechanism through which socialization occurs and unconscious conflicts are expressed. Because of its emphasis on fantasy and imagination, this perspective lends itself more readily than objects-relations theory to the analysis of literature and culture. Other feminist theorists who are associated closely with the Lacanian tradition include Julia Kristeva, Jane Gallop, and Elizabeth Grosz. While all criticize Lacan as sexist, they share his view that acquisition of the culture's dominant symbolic language is the means through which male subjectivity is privileged and male domination is enforced. They also use Lacan's methods of textual analysis to uncover feminine resistance to this symbolic order through hidden expressions of women's unique sexual desire. These theorists reject the notion of a stable self or gender identity; masculinity and femininity are considered the products of discourse, not the psychological attributes of individuals (e.g., Grosz 1990).

The popularity of this perspective is reflected in the fact that familiarity with this branch of feminist psychoanalytic theory is now expected in most graduate gender programs in English, literature, and cultural studies. Psychoanalysis has been less successful at integrating the canon of gender scholarship in the social sciences, however. The perspective is virtually ignored, if not vilified in most psychology departments, and sociologists have generally been wary about embracing the theory.

Feminist social scientists have been reluctant to endorse psychoanalytic theory for a variety of reasons, some of which reflect resistances common among social scientists in general. First, the methodology of psychoanalysis—the in-depth, case study of a neurotic individual typically compiled through prolonged one-

on-one discussions with a therapist—is considered incompatible with accepted research methodologies in the social sciences. Psychoanalysis violates principles of random selection, and its emphasis on the abnormal or pathological to explain the normal patterns of development, goes against the social science logic of focusing on central tendency.

A related problem concerns the different levels of analysis in psychoanalysis and the social sciences. It is very difficult to detect patterns of group behavior based on personal, idiosyncratic information about an individual's unconscious motivations, or to infer anything about individuals' experiences based on broad-based, impersonal social forces. Feminists are not alone among social scientists in detecting this incompatibility, but it has special consequences for theorizing about gender. Since feminism begins with the premise that women as a group are disadvantaged compared to men, generalizations about gender differences are central to the project of feminist theory. But psychoanalysis focuses on individual uniqueness; the assumption is that no two people share identical unconscious needs, desires, or motives. Consequently, gender identity itself can and does have different meanings for different individuals, a point that has been emphasized by Chodorow in her later work, aptly titled *Femininities, Masculinities, Sexualities* (1994). Not coincidentally, Chodorow's movement away from large-scale sociological generalizations about gender identity followed her completion of training as a professional psychoanalyst.

The psychoanalytic focus on the unconscious and the irrational is a second obstacle to its incorporation into feminist social science. In general, social scientists trained in positivistic and quantitative methodologies have raised questions about the reliability of psychoanalytic data. In addition to this generic concern, feminist social scientists have voiced some reluctance to attribute nonrational motivations to women's behavior. For some, this theoretical approach reproduces sexist beliefs about women's reputed emotionalism and inability to act rationally. Interestingly, sociologists specializing in the relatively new field of masculinity studies have been more open to psychoanalytic theory, perhaps because the emphasis on the irrational motives of men is less worrisome to feminists (e.g., Connell 1995, Segal 1990, Williams 1995).

A third set of criticisms made of psychoanalytic theory by a number of feminist social scientists concerns the possibilities for social and political change. Many object to psychoanalytical emphasis on treating the individual neurosis without addressing the social problem that causes the illness. To the extent that feminist psychoanalytic theory has concerned itself with social change, the focus has been exclusively on changing the family, and not the economy, the political system, or other public institutions that contribute to discrimination against women. Even the changes that psychoanalytic feminists endorse have

been criticized: some feminists reject the co-parenting strategy because it ignores, if not demonizes, family patterns that deviate from the conventional heterosexual nuclear form, such as gay and lesbian families and single-parent families. Although theoretically these family types are not incompatible with feminist psychoanalysis, critics are correct that little attention has been paid to the psychodynamic consequences of being raised in these alternative family settings.

Incorporating diversity is one of the major challenges facing feminist psychoanalytic theory in the future. For the most part, feminist psychoanalysis has focused on white middle class heterosexuals, leading some feminists to reject the theory as irrelevant for understanding the lives of those suffering from the effects of racism, poverty, and heterosexism. Some efforts are being made to broaden the scope of feminist psychoanalytic theory to incorporate these experiences, but more work is needed (e.g., Abel et al. 1997).

A second challenge for feminist psychoanalytic theory is to move beyond the critique of the family as the mainstay of male domination and privilege in society. Other institutions, including schools, the popular media (especially television), and day-care centers, are increasingly important in the development of children's gender identity. Our understanding of childhood socialization in these settings could be enriched with a psychoanalytic account (e.g., Martin 1996).

Finally, feminist psychoanalytic theorists must develop the interpretive tools needed to demonstrate the operation of psychodynamic forces outside the therapeutic environment. Lacanian feminists have been successful at applying psychoanalytic concepts to the interpretation of literary texts. What is needed is a similar effort directed to understanding the unconscious motives that underlie lived engagement in the social world. Sexual harassment, workplace segregation, domestic violence, and obsession with body image are all examples of seemingly intractable social problems that call out for the kind of deeper analysis of male domination that psychoanalytic theory can provide. But this will require new psychoanalytic methodologies that will permit generalization, and a greater willingness on the part of social scientists to incorporate unconscious and irrational motives in their explanations of social behavior.

Feminist Theory: Radical Lesbian

Perhaps what most obviously differentiates mainstream liberal feminism from her more radical sisters is that while the former continues to hope that the master's tools can be deployed to dismantle and then rebuild a better version of the master's house, the latter has largely quit this project and jettisoned its tools in favor of building not merely a house but an entire conceptual village whose collective mission it is to embody the experiences, values, and desires of

women. That is, while the primary focus of mainstream liberal feminist theory has been the critical evaluation of patriarchal or male-dominated institutions such as government, medicine, family, and religion in the interest of retooling these institutions to affect greater equality or inclusion for women within them, radical feminism takes its point of departure to be the position that any thoroughgoing critique of patriarchy must include an analysis of the tools themselves.

How, in other words, do concepts like 'woman,' 'man,' 'body,' and 'mind' inform the maintenance of these institutions? How have we defined notions like 'the rational,' 'the desirable,' 'the good,' 'the moral,' and 'the beautiful,' such that being born male virtually guarantees greater access to opportunities and resources? What are the conceptual and ideological anatomies of patriarchies as we find them across culture and history? How do patriarchal ideologies help to maintain patriarchal institutions?

Perhaps, however, the central issue which gave birth to contemporary radical feminism in the late 1960s and early 1970s was the emerging recognition that it could never be enough to agitate for an equality of inclusion within a conceptual framework which defines women's value only in reference to men. The liberal feminist project cannot fail to risk the self-defeat that accrues to retaining a conceptual framework—the master's tools—which systematically inferiorizes women. The merely cosmetic improvement produced in some women's lives (mostly Caucasian, middle-class, and educated like their male counterparts) inevitably fails to address the very real life and death issues which confront many women both locally and globally. Equipped with this insight, radical feminists undertook the conceptual as well as political quest to discover, for example, how the inferiorizing of women is accomplished, and how the domination of women varies with respect to class, ethnicity, culture, ability, age, sexual orientation, and institution. As late feminist philosopher Audra Lorde put it, the master's tools cannot be used to dismantle the master's house. The revolutionary change necessary to produce lasting improvement in all women's lives requires that we fashion our own tools.

Some radical feminists argue, for example, that the notion of equality is itself tethered to a view of human nature which so privileges attributes traditionally associated with men such as aggression, hierarchical forms of organization, rugged individualism, competition, and ethical systems that strongly favor impersonal rule-following over relationality, that women are only able to be included within such conceptual frameworks as honorary men. It is little wonder, they argue, that examples offered to young women by liberal feminists as role models and heroines are modeled after male heroes; the accomplishments of women like Harriet Tubman, or Marie Curie (or movie heroines like those found in *Terminator II*,

Aliens, or *Femme Nikita*) are valued according to a standard that rewards domination over domesticity, conquest over caring, and militarism over mothering, in short masculinity over femininity. This is not to imply that these are not examples of very real valor, but that what is rewarded in them goes further to reinforce a male-centered or masculinist vision of the good than it does to foster a vision centered around values identified as feminine such as cooperation, compromise, collective decision-making, or compassion. It is thus simply not enough, argue radical feminists, for women to settle for reformist programs that aim at equality. For given the conceptual constraints that determine value, such programs will either fail or, even if they succeed, will do so only at the cost of continuing to devalue qualities associated with femininity, and hence with women.

Liberal feminism does not, in other words, necessarily represent the desires or interests of all women, whether we take these desires to be culturally constructed or endowed by nature. Here, however, we arrive at another important juncture in radical feminist theory: if what conceptual analysis shows is that the ways in which we conceive of gender operate consistently to privilege men, ought we to consider these ways a reflection of natural propensity, and then aim to elevate the value of feminine characteristics like nurturing, emotional responsiveness, and the tendency to focus on relationships over abstract autonomy? Or, alternatively, should we eschew traditional femininity as the construction of patriarchal culture, arguing that there are no *essential* qualities that importantly distinguish men from women? If so, at least two other possibilities present themselves: One meaning of *androgyny* favors the promotion of the masculine and the feminine in all of us, acknowledging that while gender may be constructed, such qualities may still be salvageable reinterpreted in a nonsexist context. Another meaning of *androgyny*, however, suggests that we ought to abandon notions of femininity and masculinity altogether as unworkable in favor some other notion of personhood. Here the question that arises concerns what such a notion would look like, and whether it is possible to envision a conception of human being that can comprehend biological differences without merely reproducing an atomistic individual so divorced from the bodily that it becomes subject to the same criticism radical feminists level at liberal feminism. That is, can we envision a concept of 'embodied person' which, irreducible to the determinations of either biology or culture, is also rich enough to account for differences relevant to and affected by both?

Whatever the resolution to the essentialism/anti-essentialism debate among radical feminists, their main critique of liberal feminism remains unaffected, namely, that what the history of patriarchy demonstrates is that the oppression of women is sanctioned through the denigration of whatever qualities are

identified with femininity. Whether we seek liberation through the elevation or the abolition of femininity what remains clear is that reformist programs for inclusion can never by themselves be adequate. We have not, however, exhausted our avenues of critique, for there remains another possibility: Marxist/socialist feminism whose primary aim it is to show how, given the marriage of patriarchy to *capitalism*, it is illuminating to conceive of women not merely as a group but as a *class* whose oppression is maintained first and foremost through economic means. Combined with a radical feminist analysis of patriarchal concepts of motherhood and domestic labor, a Marxist/socialist account shows how divisions of labor are themselves typically sexed in at least two ways: first, because women's *labor qua* procreation (the reproduction of human life itself) is assigned to the 'natural' and hence is not counted as labor at all, and second, because the domestic labor performed almost exclusively by women, (the reproduction of the conditions of life) has itself become naturalized in a capitalist economy that identifies all labor as *paid* or *wage* labor; that is, if it is not paid, it is not labor. Cast as the vehicle for the reproduction of both life and the means to life, 'woman' appears a paradox. 'She' is unexploitable in the sense that her labor is not counted as labor within a capitalist conceptual framework at all, yet 'she' also epitomizes the very prototype of exploitability in that 'her' labors are systematically and maximally undercompensated.

Again, the valuable point can be made without entering the essentialism/anti-essentialism debate: regardless what qualities we assign to nature or nurture, *that* women's oppression is intimately linked to the relationship between her economic status and her status as provider of hearth, home, and progeny *for men* well supports the radical feminist claim that there exist no social institutions in which men do not have a controlling interest, including economy and family. What recommends this approach over liberal feminism, then, is the emphasis on the role of economic class, for whereas the best that liberal feminists can hope for is an equality of competition between men and women within capitalism, the radical Marxist/socialist feminists are free to imagine a world within which neither sex nor class oppression are operative; radical feminist theory is thus utopian in a way that liberal feminism cannot be. However, though no doubt radical Marxist/socialist feminism goes further than liberal feminism or than radical feminism alone, even it ultimately fails the project of genuine emancipation. For while such a critique of capitalism shows something important about the specifically sexed parameters of economic oppression, there remains considerable work to be done to show the relationship between economic and other forms of oppression such as sex, sexual orientation, race, age, ability, and so on.

Given the need for this work, many radical feminists distinguish themselves from both mainstream liberal

feminism and Marxist/socialist feminism by taking a more skeptical, self-reflective approach to theorizing, arguing that it is *at least* an open question whether any patriarchal institution is salvageable in any form. There is little more revolutionary a declaration than that capitalism must be overthrown, but if this is not accompanied by the overthrow of other patriarchal institutions, the status of women could remain unchanged or worsened as men's conditions improve. What revolutionary changes would institutions like the family be required to undergo to achieve equality not only with respect to gender, but with respect to any number of other axes of oppression, including race, ability, economic class, indigenous culture status, age, sexual orientation, and gender expression?

Some radical feminists such as Mary Daly argue that patriarchy must be overthrown or abandoned in favor of *separatist* or women-only cultures and societies. In her 'radical elemental feminist manifesto,' *Quintessence*, Daly describes the fundamental ideology of patriarchal institutions as *rapist*, 'characterized by invasion, violation, degradation, objectification, and destruction of women and nature; the fundamental paradigm of sexism, racism, classism, speciesism, and all other oppressive-isms' (1998, p. 8). Not unlike the radical Marxist/socialist feminist's view that the sexed division of labor lies at the root of economic exploitation, Daly argues that at the root of all forms of oppression lies that sexual domination—the male prerogative to rape—on the basis of which degradation and objectification, in short, *enslavement*, becomes the naturalized condition of virtually all nonmale, nonwhite, nonheterosexual, non-Western, nonhuman, nonaffluent, persons.

If Daly is correct, (a) all forms of oppression and exploitation take sex as their essential archetype. Hence, (b) feminism's emancipatory objectives cannot be achieved without serious attention paid to the ways in which sexism informs the other 'isms' which sustain a patriarchy that (c) is malignant in all of its past and present forms, and whose beneficiaries, primarily Caucasian, affluent, heterosexual males continue to have a stake. Finally, (d) to whatever extent sex oppression is archetypal of all oppression so too must heterosexuality become *compulsory*, that is, a characteristic of the *heteropatriarchal* way we define sex and hence sexuality such that other sexualities are either completely occluded or, when acknowledged at all, identified with the perverse and unnatural. Within compulsory heterosexuality, an action only counts as sex if (a) it involves a penis-penetrating-a-vagina, (b) it is compulsory in the sense that no other option counts as an acceptable choice, and (c) it negatively associates abstinence with frigidity, mental illness, or homosexuality. On this view, then, the domination of sex cannot be accomplished without the domination of sexuality. Given the combined compulsion of (a)–(c), moreover, it is little wonder that Daly characterizes heteropatriarchy as *rapist* urging the view that re-

sistance to patriarchy must be accompanied by resistance to heterosexuality. Radical feminism thus becomes radical *lesbian* feminism as both the rejection of male sexual access and as the radical embrace of the value, lives, and bodies of *women*. Such is the meaning of dismantling the master's house with *new tools*. That is, radical lesbian feminists (or radical feminist lesbians) argue for two distinct but intimately related claims: first that compulsory heterosexuality must be repudiated, and second, that lesbianism must itself be theorized as a positive, life-affirming, morally responsible choice.

One potentially compelling objection to this view is that it is surely possible to embrace the political goals of lesbian feminism without jettisoning sexual relationships with sympathetic men. However, because even the best of men are still disproportionately empowered in heterosexual relationships such intercourse cannot fail to remain compulsory, and hence self-defeating. This is not to say that heterosexual sex either is or is not *inherently* harmful to women, but rather that because male sexual access can be identified as one of the primary sources of women's oppression, cauterizing this source of harm is instrumental to ending heteropatriarchal power. Indeed, whether heterosexual sex is inherently harmful or not is largely beside the point given that from a radical lesbian feminist point of view it is hard to imagine conditions under which the potential for harm could be sufficiently deflated, given men's history of sexual and domestic violence, to make the risk worth taking. Nothing, moreover, requires us to theorize men's 'essential' natures as aggressive or women's as passive; it is enough to simply recognize that history and culture are so saturated with the glorification of male sexual conquest and violence, that the prospects for change, and the likelihood of that change being initiated by men is less than compelling. Not unlike Marx's conception of the permanent revolution of the working class, radical lesbian sexual separatism constitutes much more than a political strategy; it constitutes part of the bedrock of a burgeoning *lesbian culture* in the sense that what propels this revolution is a *positive choice to live one's life among women*, not to live among women until men learn to behave better. To opt merely for the latter is tantamount to abandoning in advance the worth of having chosen the former at all.

Philosophers such as Sarah Hoagland, for example, argue that a constitutive feature of a coherent lesbian ethic includes the repudiation of all forms of domination and subordination. To the extent, then, that heterosexuality is entrenched in and defined by these values, it can find few comfortable bedfellows—literally or figuratively—among radical lesbian feminists. Is a nonoppressive, nondominating heterosexuality possible? In theory, no doubt it is. But, as feminist philosopher Marilyn Frye points out, the practical likelihood of this given the stakes men have and are likely to continue to have in heteropatriarchy

seems illusive at best. Lesbians, she argues, are simply impossible within the heteropatriarchal conceptual framework; indeed, they are like 'arm wrestling ducks.' That is, no arms, no wrestling, no penis, no sex. Hence while gay men can be condemned for having perverse sex, lesbians cannot have sex at all, and without the possibility of sex, there can be no lesbians. As a clever male college student was once heard to put the point: 'There can be no arm-wrestling ducks, but a good arm-wrestling fuck, now that's sex.' Frye goes on to argue that given the biological facts of reproduction as well as the social and political expectations attached to child-rearing, it is hardly a wonder that exercising control over the conditions under which pregnancy, birth, and lactation take place becomes imperative for men who are likely to experience the termination of privilege as the unjust withdrawal of something owed. As Frederick Engels had shown more than a century earlier, men's investment in sexual domination is rooted first and foremost in their investment in the products of their own (hetero)sexuality, namely, the offspring who represent a paradigmatic form of property, a reflection of self-interest, and the potential for future inheritance. To deny men sexual access, then, is in effect to deny them the opportunity to control the conditions of women's reproductive lives, and hence of women's lives in general, particularly in nations or regions where access to contraceptives and abortion is heavily regulated if not banned by heteropatriarchal laws, mores, and religion.

The affirmation of women's lives, bodies, values, and choices forms the second critical axis of any radical lesbian feminist theory. Yet, while this affirmation has often been theorized as necessitating some variety of separation from men—*separatism*—it is less clear what exactly this might mean, for whom it is realistically practicable, and to what extent it requires physical and material independence from both men and patriarchal institutions. This much, however, seems clear: the choice to no longer engage with men sexually constitutes a minimal criterion of separatism whereas the choice to embrace a life composed primarily or even exclusively of 'women-loving-women' goes much further—and is also far more difficult to realize in practice. There are several reasons why this is the case: first, because we live in a capitalist economy, regionally, nationally, and globally, where-withal *is* economic wherewithal. Hence, the creation of any women-only space, permanently (a communal farm, for instance) or temporarily (such as women's music festivals) is an economic undertaking which, in virtue of this, is always at risk of excluding some in favor of those who can afford the price of separatism. As some lesbian feminist women-of-color point out, separatism continues to be a luxury of whiteness to whatever extent economic affluence does. Second, because every institution, economic, social, cultural, medical, to which we have access is imbued with heteropatriarchal values, it remains somewhat obscure

what separatism could mean short of wholesale abandonment. Third, short of the invention of parthenogenesis, a contribution of male-produced sperm is still a requisite of human reproduction.

Such a characterization of separatism may, however, be guilty of a straw fallacy, that is, perhaps separatism appears impracticable only because its parameters have been defined too narrowly or too simplistically. Whether this is so, however, depends precisely on what kind of conceptual work such a notion is supposed to be able to do, for whom, and for what duration. The range of other potentially separatist choices is very wide and includes at least the following: the formation of one's primary affective relationships, sexual or otherwise, with women and girls only, choosing a woman-centered spirituality, adopting and rearing girls within a lesbian culture, creating woman-centered works of art, dance, music, poetry, comedy, film, philosophy, and literature, rejecting other male-centered practices such as non-human animal flesh consumption, hunting, or other hierarchical forms of organization, choosing political affiliations and activities that are consistent with a woman-centered life. The difficulty here, of course, is twofold: first, how ought we to define what counts as woman-centered or lesbian (and do these mean the same thing?)? How do we avoid reproducing the same forms of oppression which so disable us within heteropatriarchy? (Should preoperative transsexual men-to-women be allowed into women-only spaces? Can a woman-centered life include rearing sons? Should radical lesbian feminists form political alliances with gay men? If so, should we sign on to their political causes such as the promotion of legalized marriage for gays and lesbians?)

Second, if 'separatist' is itself subject to evolving cultural, ethnic, and historical interpretation, surely it is as dangerous to treat it ahistorically as it is to treat 'woman,' 'man,' and so on. What, then, does separatism require beyond the refusal of sexual access to men? Does anyone's refusal matter more than others? Can lifelong lesbians who do not identify as feminists be separatists? Can women who have left long-standing heterosexual relationships and now identify as lesbian qualify as separatists in mid-life? How separate is separate? The point, of course, is that many questions attend the endeavor to create new tools, and much more attention needs to be paid to the ways in which oppressions related not only to sex, but to race, ability, age, gender expression, and class intersect with compulsory heterosexuality. There is much to worry and much to celebrate. Nonetheless, if the radical lesbian feminist critique of capitalist heteropatriarchy is correct, this endeavor is more than just important; it is necessary to the emancipation of women.

Fertility and Culture: Anthropological Insights

In its narrowest meaning, fertility refers to the production of a living child that adds one person to a population. Between this biological event and the level of culture, which defines and shapes the events that produce a child, lies an engaging set of issues. The mainstream of anthropology has never been interested in the question of numbers of children in the way that demography has, in its focus on the stocks and flows of population. Conversely, the anthropological penchant for rich, contextualized cultural meaning draws limited interest from demographers seeking parsimonious ways to explain fertility levels. Still, the

two disciplines are finding increasing common ground in the domain of reproduction. This article describes anthropological attempts to derive cultural insight in studies of fertility.

Demography seeks to identify and measure key variables related to population and to demonstrate relations among them. But to frame its questions and explain the results, it has tended in the past to draw on other disciplines, particularly on sociology, economics, and history. In recent years, demographic interests have turned as well to anthropology and to its methods. There have been two principal reasons for this growth of interest. The first was the impact of the Princeton European Fertility Project (Coale and Watkins 1986). The most important finding of this project was that the decline in marital fertility in Europe was explained less by the expected economic factors of income and level of development than by factors such as religion, dialect, ethnicity, and region—factors the project termed ‘cultural,’ although the awkwardness of the nomenclature was recognized. In Belgium, for example, villages experienced fertility decline in consonance with linguistic groupings. Wall-oon villages tended to experience the transition to lower fertility earlier than did Flemish villages, irrespective of their locations or economic characteristics (Lesthaeghe 1977). The implication drawn was that information diffused more readily within culturally or linguistically similar regions. The second reason why demography has turned to anthropology has been an increasing interest in patterns of fertility and mortality in developing countries. Questions were emerging particularly about the social supports for high fertility and about such tremendous variation in reproductive practices that researchers trained largely in the Western quantitative disciplines felt poorly equipped to handle. Because anthropology is the discipline that has so routinely attempted to study non-Western societies, anthropological works have drawn increasing demographic attention.

1. What is Anthropology, and How Has it Been Applied to Demographic Studies of Fertility?

Anthropology seeks to understand why people behave the way they do and to understand their beliefs and values within particular socioeconomic contexts. Anthropological work begins with the premise that the cultural frames from which our understandings of human motivation and action spring are likely partial, if not altogether wrong. They are therefore misleading. This is true, no matter how familiar the culture appears to be to the researcher. In fact, the more familiar the culture appears to be, the greater the risks of being misled and the more wary the analyst should be. To a field whose practitioners start with the expectation of being wrong, most valued are data that embody local people’s own ideas about the world, in contrast to

those based only on the researcher’s predetermined constructs. To this end, open-ended approaches are critical. A key goal is to achieve a subjective understanding: that is, to comprehend how local people’s experience the world and the logic that may underlie their choices. Doing so, it is felt, should lead not simply to better insights into the cultural beliefs of people living in remote places, but to a more encompassing view of reality and hence to better theory.

Whereas anthropology was an exotic oddity 15 or 20 years ago in demographic circles, demographic studies increasingly integrate methods and concepts conventionally associated with anthropology into their enterprise. Many demographic projects have begun to supplement their survey analyses with field projects, which include an anthropologist or individuals trained in ethnographic methods and qualitative methods are increasingly common in demographic project designs. Even the international Demographic and Health Surveys (the DHS) now have a ‘focus group’ component in which statements and explanations, rather than simply numeric and short-answer responses, can be elicited from groups of people.

1.1 Operationalizing Cultural Traits in Statistical Taxonomies

What anthropology has had to offer the demographic enterprise has been largely a function of the state of its own field. When significant demographic interest first turned to anthropology in the middle of the twentieth century, a particular methodological approach, sometimes called the cross-cultural method, dominated American anthropology. This was a kind of statistical taxonomy in which societies were described by traits that were typed and ‘operationalized’—that is, cast in the form of discrete variables—and coded in order to test quantitative hypotheses and look for cross-cultural patterns. The primary data used in this endeavor was the Human Relations Area Files (Murdock 1975), which contained detailed codes of the organizational features of hundreds of ethnic groups. Prevalent as well in American anthropology at this time were questions about the relationship of culture to personality from Freudian perspectives. A number of anthropologists sought to combine this theoretical perspective with the cross-cultural methodology. Whiting et al. (1958), for example argued from HRAF data that life under harsh environmental conditions required parents to protect a child by a long period of breastfeeding and a ban on sexual relations. Such practices, because they led to strong psychological attachments of the child to the mother, were said to necessitate dramatic manhood initiation rituals for boys, to separate them from their mothers and to foster the development of their masculinity. While personality development drew little demographic interest, there was considerable interest in the potentials of such studies to shed light on facts such as the

duration of breastfeeding and postpartum sexual abstinence, which had more direct connections to fertility. Applying this kind of analysis to data on kinship and economic subsistence, demographer Frank Lorimer (1954) argued that populations like those on small islands, with highly constrained and intensively utilized resources, developed types of social organization and customs that checked family size. In Polynesia, he maintained, such customs included coitus interruptus, abortion, infanticide banning further reproduction to the mother of a married son, and encouraging sea voyaging for young men.

1.2 Culture as Ideas and Mental Schemes

The taxonomic approach drew considerable interest in demography. Yet within anthropology itself, it encountered increasing antipathy. Critics charged that the approach, in extracting practices from the contexts in which they drew meaning and treating them as a checklist of discrete, modular traits, effectively froze what was in reality a multifaceted and fluid entity. Particularly with the impact of Clifford Geertz (1973), anthropology's conception of culture shifted decisively away from such approaches and moved toward one of shared mental schemes or symbols that signaled meanings and interpretations of the world. By contrast to efforts to operationalize cultural data in order to break them down into pieces and assimilate them to our own analytical categories, most anthropologists now have the opposite purpose. They stress that culture cannot be broken down into separable pieces. Such pieces would in any case have no meaning apart from a context. Anthropologists also take cultural oddities as possible signs of some facet of a reality that the analyst has not seen and hence has not coded into his or her own cultural ideas.

Anthropologist's efforts to reclaim culture from the domain of operationalizable concepts have not always been easy to explain to other disciplines. The work of demographer John Caldwell, however, took a notable stand in its efforts to make culture figure more explicitly as ideas or attitudes. The most notable example is his description of the proliferation of Westernization: the rise of new attitudes about work, family relations, and fertility practices, particularly through schooling. By comparison to traditional values of authoritarian family structures, a distant and severe father, and marriage as an arrangement between elders, Caldwell (1980) describes infant and primary school textbooks in three African countries as attempting to convey messages of parental closeness to children: kindly, understanding fathers and love-match marriages. So powerful are such ideas that with the shift to mass education, all members of the population, including those who have not attended school, may be affected by the changes generated by a new cultural climate of an educated populace. These ideational changes, he argues, have facilitated a shift

to nuclearization of families and to smaller family size goals.

The evolutionary implications associated with traditional/modern frameworks have fallen out of favor with sociocultural anthropology. Contemporary anthropologists reject any necessary assignment of labels of traditionalism or modernity, and they recognize all societies as inherently fluid and changing. Nonetheless, the move toward seeing culture as a set of shared mental schemes that can shed light on ideas and behaviors has opened up significant possibilities for understanding demographic phenomena.

An engaging example that attempts to link forms of belief to fertility behavior is *Mussallam's* (1983) account of the allowable uses of contraception for men in classical Islam. Islamic practice has often been cast by analysts as opposing the use of contraceptives. *Mussallam*, however, describes a more complex picture. Although contraception was seen as an act that fell short of religious perfection for a man, Islamic practice allowed a wide range of exceptions. Contraception was allowed to preserve health and well-being. A man could contracept to protect his wife from the dangers of childbirth, especially if she were young or sickly, or simply to protect her health and beauty from the wearing effects of childbearing. He could contracept as well to protect a young nursing child from the nutritional competition posed by a new pregnancy. Another salient domain of concern was economic welfare. A man who found himself tempted to engage in theft to meet his economic responsibilities to his children could practice contraception to limit the number of his offspring to a manageable size. Analogous concerns emerged in the desire to safeguard human property. Because a man could not sell a slave after she became the mother to his child, using contraception was seen as a lawful measure to retain liquidity of slave assets. A man could use contraception as well when having sex with another man's slave to prevent his own children from being born into slavery. Related to this was the need to safeguard the welfare of the Islamic community under conditions of warfare. If a man had sex with a woman behind enemy lines, he risked not only losing his own children by procreating but swelling the numbers of the infidels unless he took contraceptive precautions.

1.3 Culture in Flux; Culture in Contestation

Despite the intrinsic appeal of pursuing cultural pathways of logic like this, it is risky to assume that behavior reflects cultural beliefs in straightforward ways. Most contemporary anthropologists hold that people have multiple cultural templates, and that culture is a fluid set of interpretive resources that people can draw on in particular political and historical contexts. Even a body of religious canon, as powerful as its injunctions may seem, has the potential for numerous interpretations.

Among the most lively examples of new research in anthropology that demands a fluid, resourceful vision of culture is the topic of male fertility. Fertility research is by far the largest sub-discipline in contemporary demography. Yet until a very few years ago, women comprised virtually its sole objects of study. Men, if they appeared at all, were shadows, partners-by-implication of those engaged in childbearing. Even if genetic tests could verify the relationships among household members in a survey, this would hardly begin to solve the challenges surrounding the analysis of male fertility. While some men do not know how many children they have or deny connection to offspring born outside of wedlock, other men claim to have fathered children they have never seen. The fact that men so often redefine parenthood can work to the disadvantage of children, but also to their advantage. For example, Townsend (2000) shows that in rural Botswana, where the demands of migrant labor are so taxing, a young man who lives full time with his children is an oddity. At the same time, men provide considerable support for children, even though it is often not their own children but those of other men, whether these are uncles, grandfathers, or distant cousins. Thus, despite the widespread perception in the current international population policy world of massive male disengagement from parenthood responsibilities, Western cultural preoccupations with a biological definition of paternity have masked some critical variations in the cultural assignment of parenthood.

One of the most important points of debate in current socio-cultural theory that is now being brought to demography is the question of societal forces of politics and economics versus individual agency. That is, to what extent are people's choices limited by wider powers beyond their control? Can people, on the other hand, make their own decisions about reproductive actions by resisting or evading state powers? The increasing answer to this question is that both forces are invariably at work, and that cultural ideologies are often at the center of the contestation. Greenhalgh and Li's account (1995) of the heavy-handed Chinese state policy of one child per couple that was implemented in 1979 reveals a dynamic of mutual influence. Greenhalgh and Li show that women began to resist the formal one-child policy, strategizing to have two children, especially if the first was a girl. Women attempted to adopt out daughters, move to another city to give birth to a second child, or remove state-imposed intrauterine devices. They might also attempt to conceal unauthorized pregnancies until it was too late for a state-required abortion, or (as ultra-sound technology spread) engage in sex-selective abortions. By 1991, the state, faced with such resistance, was forced to rewrite policy. It 'encouraged' one child for all and prohibited third children, yet allowed two children if the first was a girl. In sum, individual women may have been liberating themselves indi-

vidually from unwanted daughters, yet their strategies of resistance effectively reinforced the state's gender hierarchy.

The fact that culture is increasingly seen in anthropology as a resource that people may put to use is best examined in a context in which reproductive volition has been seen as low. For this reason, some of the best examples are found in topics related to high fertility: a pattern that has been seen in demographic convention as an outcome of biology and custom and not as the calculus of conscious choice (Coale 1973). In populations said to have what has been called natural fertility (Henry 1961), the demand for children is high, and the number of children women produce is assumed to be limited only by how quickly they can be supplied, given the biological rhythms resulting from specific customary regimes. In sub-Saharan Africa, for example, most people continue to report on surveys that they want 'all the children God gives them,' and typical reactions to suggestions to reduce fertility range from polite interest to outrage. By contrast, in societies where desires for large numbers of children have abated, couples are said to engage in parity-specific behaviors, especially the use of modern contraceptives, in order to control completed family size.

However, ethnographic accounts of practices such as infanticide, child fosterage, child abandonment, adoption, and abortion make it clear that people in all societies exert some form of control over reproduction. Whereas Western models assume that reducing fertility is the best way to address economic troubles, families in many African societies see the diverse skills and social ties that they manage to cultivate through children as the key to their future capacity to cope with economic and political adversity. Adults treat the original biological event of parenthood not as a secure hold on a child's future support, but as the beginning of a long, continuously negotiated relationship in which they try to influence children's obligations. Young children are commonly fostered to 'grannies.' Later, when they are older, they may be sent to urban households that offer training in specialized apprenticeships or a chance to attend a respected school. In short, rather than trying to reduce child numbers, many African families would find this a drastic solution to economic problems. They prefer to have a number of children, cultivating differentiated opportunities for them (Bledsoe 1994). Yet although the effects of certain practices on cutting reproductive costs may be analytically discernable, they do not necessarily constitute people's motivations for taking actions that have effects on fertility or household composition. Most anthropologists insist that it is wrong to reduce family structure to economic or demographic terms alone.

Another example of people's efforts to exert control over childbearing appears in the cultural reinterpretation of contraceptive technologies in sub-Saharan Africa (Bledsoe 1994). In Western cultural per-

ceptions, contraceptives are devices that limit fertility, and people who do not wish to limit births would be unlikely users of devices that would do so. In West Africa, however, people see contraceptives more as devices to ensure the survival of many children by spacing their births carefully than to limit births. Some of the most common contraceptive users are thus breastfeeding women who want to avoid overlapping children, one in the womb and the other nursing, but who have resumed their menses before the breastfeeding child can be weaned. As this suggests, families exert prodigious efforts to control the timing and circumstances of children's births, though, again, not necessarily to limit numbers of children.

1.4 Reconciling Local Cultural Knowledge and Western Science

Pursuing threads of counterintuitive cultural logic that are opened up by scrutinizing demographic patterns can yield not simply observations about culture but empirical truths that have been lost to contemporary scientific view. An example comes again from the use of contraception in West Africa (Bledsoe 2001).

Contemporary Western writings, both scientific and humanistic, depict the ability to bear children as one limited by time. That is, Western culture posits a time-dependent ability to conceive as the key to achieving fertility. Accordingly, the number of children a woman may bear is calculated by dividing the total amount of time she can conceive by the interval required for each pregnancy. The use of contraception plays directly into this presumed calculus. To the extent that the use of contraception or abstinence blocks off time in this potential reproductive span, a woman's fertility will remain low. In the African cultural view, however, the ability to reproduce is limited not by time but by bodily resources. Among the forces that drain bodily resources and erode the ability to reproduce, childbirth is by far the most powerful. Each birth takes a mounting toll on a woman's physical reserves, cumulatively 'aging' her body (or wearing it out, in many local translations), and eventually making further childbearing dangerous, irrespective of her chronological age. In this vision, aging is not the same thing as age. Although aging tends to be equated with the passage of time in Western analyses, its pace, in the African view, is contingent on the physical ordeals the body suffers. Difficult and/or closely spaced births, combined with a poor diet, illness, and strenuous work responsibilities, can exact a disproportionate toll. In such situations, a woman who is trying to have all the children God gives her will almost certainly run up against the anatomical and energy limits of the body before she runs into any temporal boundaries on the ability to conceive. Because contraceptives allow women more opportunity to recuperate between births, and because reproductive capacity is seen as governed by taxing events rather than by time, it is

clear why contraceptives can be used to produce more, rather than fewer, children and even to stem the pace of aging.

The African vision of contingent wear and cumulative physical toll over a reproductive lifetime might appear to be 'just common sense.' It is more accurate, however, to say that our increasing personal distance from the high-and-risky end of the fertility horizon, combined with our unprecedented levels of preventive care and copious backup in case of emergencies, has sharply truncated our vision of the tolls that reproduction can take under conditions that we no longer experience or fully understand.

2. Future Possibilities for Anthropology and Demography in Studies of Reproduction

In the evolving relationship between anthropology and demography, the spectrum of topics continues to broaden. Common interests can be found in the politics of fertility control, gender relations, the negotiation of fertility decisions among spouses, and the re-opening to scrutiny of taken-for-granted associations between fertility and variables such as educational achievement. Anthropology's current interests in the new reproductive technologies holds the potential for studies of the timing and circumstances of entry into parenthood. Finally, it can be noted that although anthropology made itself as a discipline on the study of exotic people living in distant places, increasing numbers of practitioners are coming 'back home,' studying social and cultural phenomena in the urban United States and Europe. This trend may facilitate fresh collaborations with demographers on studies of reproduction in Western societies. Some of the most productive areas of common ground in studies of reproduction for the two disciplines may thus lie in studies of migration. New anthropological interests in global flows of people, ideas, and technologies are coming at the time when demographers are taking up the challenges of studying international population movements and refugees. The opening of the European Union and, in the United States, the removal of national-origin quotas for immigrants has spawned migration across national borders on an unprecedented scale. Such a mix of national ideologies and policies of social support that must underpin these dynamics as people envision a reproductive career invoke are virtually uncharted areas. It will no longer be possible to rest on conventional notions either of a population boundary or of local cultural practices. Clearly, in any case, anthropology's style of engagement with demography and the insights to be gained from such mergers will continue to change as the fields themselves change.

Fertility Change: Quantum and Tempo

In the measurement of fertility the term 'quantum' usually refers to the average number of births occurring over the lifetime of a cohort of women (Ryder 1980, Pressat 1985). This number is called the cohort

total fertility rate. More generally, quantum can refer to the average numbers of births that occur in a group of women under certain defined circumstances, such as marriage, or its measurement can be limited to births of a certain order, such as first births. The term 'tempo' usually refers to the average age at which births occur in a cohort of women who have reached the end of the childbearing years (Ryder 1980, Pressat 1985). More generally, tempo can refer to the average time elapsed between a birth and a specific preceding event (e.g., marriage) or its measurement can be limited to births of a certain order.

Estimation of the quantum and tempo of childbearing for a cohort of women is straightforward provided the required data are available and accurate. These variables quantify key dimensions of a cohort's reproductive history but they have the considerable disadvantage of representing past experience: women currently aged 50 did most of their childbearing two to three decades ago when they were in their 20s and early 30s. Trends in cohort measures therefore do not reflect current conditions, and they are not often used to monitor recent developments because fertility can change substantially in a short period of time. Instead, an alternative measure, the period total fertility rate (PTFR), is used far more widely as an indicator of current fertility. It is defined as the average number of births a woman would have if she were to live through her reproductive years (ages 15–49) and bear children at each age at the rates observed in a particular year or period. It is a hypothetical measure because no real group of women has experienced or will necessarily experience these particular rates. The advantage of the PTFR is that it gives up-to-date information on levels and trends in fertility. The PTFR is a quantum indicator of period fertility, and the mean of the age-specific fertility schedule is a tempo measure.

The simplicity and wide availability of the PTFR have contributed to a neglect of some deficiencies in this fertility indicator. The demographic literature on the measurement of fertility includes a number of criticisms of the PTFR (Ní Bhrolcháin 1992). The most important of these is the distortion of the PTFR that occurs when the timing of childbearing changes. During years in which women delay childbearing, period fertility rates are depressed relative to cohort fertility; in years when childbearing is accelerated, period fertility is raised (Hajnal 1947, Ryder 1956, 1964, 1980, 1983). The quantum and tempo dimensions of period fertility interact.

To demonstrate how these tempo distortions operate, it is helpful to examine a set of simple illustrations as presented in Fig. 1. In these hypothetical illustrations, every woman is assumed to have exactly one birth so that the cohort total fertility rate equals one for all cohorts, and these births are assumed to take place at exactly the same age within each cohort. Figure 1(a) depicts the reference situation in which this age is set at exactly 20 years. Since there are no tempo effects,

Figure 1

Hypothetical patterns of childbearing, with and without tempo effects

period fertility as measured by the PTFR is also constant and equal to one birth per woman. Assume next that the age at childbirth is raised by one year starting at time T , as shown in Fig. 1(b). In this case, women who would have given birth at age 20 immediately following T have to delay their childbearing for a year until they reach their 21st birthday. As a consequence, no births occur during the year between T and $T+1$ and the PTFR then equals 0. In other words, one year's worth of births is lost because the mean age at childbearing increased by one year. In reality, the mean age at childbearing rarely changes suddenly and rapidly. A more typical situation is summarized in Fig. 1(c), which illustrates the effect of a slow rise in the age at childbearing. Starting at time T , successive cohorts delay childbearing so that the mean age at first birth rises linearly from 20 to 21 years over a 10-year period from T to $T+10$. In this case the PTFR drops from 1 to 0.9 at time T , remains at 0.9 from T to $T+10$, and finally returns to 1 after time T . The PTFR is distorted by 10 percent or 0.1 birth per woman during the interval T to $T+10$. Over the 10-year period, one year's worth of fertility is lost from the PTFR as a result of a one-year increase in the mean age at childbearing. Conversely, as shown in Fig. 1(d), if the mean age at first birth declines linearly from 20 to 19 years over the same period of 10 years, the PTFR

rises from 1 to 1.1 at time T , remains at 1.1 from T to $T+10$, and returns to 1 birth per woman after T . Bongaarts and Feeney (1998) present a fuller discussion of these effects.

The existence of timing distortions is readily documented when the age at childbearing is declining significantly. In that case, implausible results are often obtained for the birth-order components of the PTFR, computed as the sum over age of the period-specific f_{pj} fertility rates of the second kind by age and birth order (see *Demographic Techniques: Rates of the First and Second Kind*). For example, the component for births of order one ($PTFR_1$) equals the average number of first births women would have by age 50 if they were to bear first births at the age-specific rates of the second kind observed in a given year or period. In most years during the late 1940s and early 1950s, the $PTFR_1$ in the US exceeded 1 (Whelpton 1954), a fact which seems to imply that women had more than one first birth on average. This is impossible and these $PTFR_1$ estimates must therefore be reinterpreted. The main explanation of why $PTFR_1$ exceeded 1 during the baby-boom years is that the age at childbearing declined, resulting in a temporary inflation of the PTFR and its additive birth-order components:

$$PTFR = \sum_n PTFR_n \quad (1)$$

An extensive analysis of the effects of variations in the childbearing tempo on period fertility indicators was undertaken by Ryder in a series of influential papers (Ryder 1956, 1964, 1980, 1983). Ryder proposed 'translation' equations to calculate the period fertility measures from corresponding cohort measures when the timing of cohort fertility is changing. These procedures have not found wide acceptance for two main reasons. First, in his work on the translation issue, Ryder assumes that the tempo and quantum of cohort fertility are the determinants of the PTFR and other period fertility measures. However, extensive empirical analysis of this issue has demonstrated that this is not the case (Ní Bhrolcháin 1992). Period effects are clearly the prime source of variation in fertility rates, and the completed fertility of cohorts is largely determined by the period fertility rates during the cohort's reproductive years, rather than the other way around. Second, the two dimensions of aggregate cohort fertility—quantum and tempo—are not independent in practice. When cohorts reduce their fertility, they do this primarily by reducing childbearing at higher birth orders. As a result, the mean age at childbearing for all births to the cohort declines even if the timing of individual births does not change. In other words, a decline in the cohort quantum can lead to changes in the cohort's mean age at childbearing that do not cause tempo distortions. Such distortions only occur if the mean ages at births of specific orders rise or fall. Ignoring this effect—as

Ryder does in much of his writing—therefore gives biased results except when cohort fertility is constant. Fortunately, this second problem can be solved by analyzing fertility trends separately for each birth order rather than for overall fertility.

In a recent study Bongaarts and Feeney (1998) propose a procedure for removing tempo effects from the PTFR. The approach is an outgrowth of Ryder's original translation equation. The above objections to Ryder's approach are addressed by assuming that fertility is only affected by period effects, and by applying adjustments separately to the birth-order components (PTFR_n) of the total fertility rate rather than to the total fertility rate itself. Under these conditions, it is possible to estimate a tempo-free total fertility rate in any given year (or period) from the conventional PTFR_n at each birth order n with the formula

$$PTFR'_n = PTFR_n / (1 - m_n) \quad (2)$$

where PTFR_n is the observed total fertility rate component for birth order n , PTFR'_n is the tempo-free total fertility rate component for birth order n , and m_n is the annual *change* in the mean age of the age-specific fertility schedule for birth order n . By dividing the observed total fertility rate by $(1 - m_n)$ at any given birth order n , we obtain an estimate of the total fertility rate that would have been observed if there had been no change in the timing of childbearing. Adding up results for the various birth orders gives the overall tempo-free total fertility rate

$$PTFR' = \sum_n PTFR'_n \quad (3)$$

The PTFR' equals the distortion-free quantum component of the PTFR, and the difference PTFR'–PTFR equals the tempo distortion.

According to this argument, an annual increase of one-tenth of a year in the mean age at childbearing ($m_n = 0.1$) reduces the PTFR_n by 10 percent below its tempo-free level, because PTFR_n = 0.9PTFR'_n. Similarly, an annual decline in the mean age at a rate of just 0.1 years per year ($m_n = -0.1$) inflates the PTFR_n by 10 percent. Clearly, rather modest changes in the timing of childbearing at any birth order can produce substantial changes in observed fertility.

It should be emphasized that the above simple formula for removing tempo distortions assumes that the shape of the age-specific period fertility rates at each birth order does not change over time. Kohler and Philipov (2001) have suggested a more general equation that incorporates variance effects. Their formula reduces to the simpler version presented here when the shape of the fertility schedule is invariant.

The existence of tempo distortions of period fertility measures has recently become an important issue in contemporary developed countries. In most of these societies, fertility has dropped below the replacement

level. If future fertility remains at these low levels, populations will decline in size and age rapidly. The fact that ages at childbearing have been rising quite rapidly since the 1970s implies that the PTFRs of these countries contain a downward tempo distortion. The size of this distortion can be estimated with the above equation, but the required data—age-specific fertility rates by single age and birth order for successive years—are available only for a restricted number of countries. Bongaarts (1999) estimates the tempo effects for seven post-transitional societies in the late 1980s and finds downward distortions ranging up to 0.4 births per woman. This effect may appear modest, but in some cases it is the primary reason why the PTFR is below the replacement level.

Assessment of fertility levels and trends should include an analysis of the tempo effects because the conventional PTFR gives a misleading estimate of the actual rate of childbearing when the age at childbearing is changing. This is the case in many post-transitional populations. Childbearing is being delayed and women are actually bearing more children than is indicated by the observed PTFRs. This distortion in the PTFR will continue for as long as the mean age at childbearing rises, but once the deferment ends the distortion is removed, and the PTFR will then rise unless there are offsetting declines in the quantum component of period fertility.

Fertility Control: Eastern Europe

This article reviews the decline of fertility in the countries of Eastern Europe, broadly defined to include all regions of the former Soviet Union. Direct data on contraceptive utilization which have recently become available are examined, together with indirect measures of fertility limitation.

1. Total Fertility

Fertility levels in Eastern Europe and the former Soviet Union span most of the range of variation observed around the world (see Fig. 1). As recently as the mid-1970s, Uzbekistan, Turkmenistan, and Tajiki-

stan registered total fertility rates (TFRs) from six to seven, well within the range of high-fertility Third World countries. At earlier dates (in the 1950s) this was also true of Albania and Azerbaijan. However, the vast majority of the countries in question qualify as low-fertility countries, having experienced TFRs on the order of two to three for most of the period since World War II. In general, all of the countries in question have experienced fertility decline during the postwar period. This includes the period after the dissolution of the Warsaw Pact and the breakup of the former Soviet Union.

It is possible to group the countries under consideration according to their phase of the 'Demographic Transition' from high, natural fertility to low, controlled fertility (Anichkin and Vishnevskiy 1994, Vishnevskiy and Volkov 1983). For the purposes of the present discussion, 'low fertility' is taken to refer to fertility at or below the 'replacement level,' which is the level of fertility that would be consistent with a stationary population in the long run; a TFR of 2.1 is considered conventionally to be equivalent to the replacement level. The vast majority of East European countries, together with the European republics of the former USSR, were in the intermediate stages of the transition prior to World War II, and completed the transition during the postwar period. However, certain of these countries, such as Estonia, had actually

Figure 1

Total fertility rates in selected countries of Eastern Europe and the former Soviet Union

achieved below-replacement fertility prior to World War II. Azerbaijan has completed the transition from high to replacement-level fertility since 1959. The trend in Albania's fertility level resembles closely that of Azerbaijan, although Albania's fertility has not fallen quite to the replacement level. At the opposite extreme, in the indigenous population of former Soviet Central Asia, fertility decline did not take hold until the mid-1970s. These populations remain in the early phases of the demographic transition, exhibiting sustained fertility decline.

There is little evidence of any fundamental difference between the fertility levels and trends of the countries which comprised the former Soviet Union, and other East European countries (see *Fertility Trends in the Formerly Socialist Countries of Europe*). Fertility levels in the European former Soviet republics have fallen below replacement. Russia and Latvia, whose respective TFRs were 1.28 and 1.09 as of 1998, figure among the lowest-fertility countries in Europe. The only major difference between these regions (former USSR and East Europe) at the time of writing is that the former Soviet Central Asian populations, in which fertility decline is a comparatively recent phenomenon, have not yet attained the low fertility levels which typify the European populations. The fertility levels of most of the former Soviet republics discussed here are adjusted for underregistration of births according to the procedures of the International Programs Center of the US Bureau of the Census.

Both the low-fertility formerly Socialist countries of Eastern Europe and the republics of the former USSR, whose governments were pronatalist in orientation, experimented with policy measures to stimulate child-bearing (David and McIntyre 1981, David and Skilogianis 1999). The East European countries were the first to introduce these measures, and did so in the late 1960s and the 1970s. In most cases (e.g., Bulgaria, Hungary, Poland), these measures involved financial incentives such as extended maternity leave, cash awards, and housing subsidies. Typically, the introduction of such measures was followed by a modest rise in fertility of relatively brief duration, and a longer-term slackening or cessation of fertility decline. These pronatalist policies were generally unsuccessful in bringing about increases in fertility to levels substantially above replacement. Only Romania achieved a major rise in TFR, which rose spectacularly from below replacement to over 3.5, then stabilized in the neighborhood of 2.5 for more than ten years. The Romanian achievement owed much to the absence of modern methods of family planning coupled with a draconian ban on abortions, enforced to the extent of subjecting women to regular gynecological examinations to ensure that they were not employing any modern means of fertility limitation. Once these restrictions were lifted, Romania's fertility declined to a level close to that of Russia, one of Europe's lowest.

The Soviet Union introduced a major set of pro-

natalist incentives in 1981. Shortly afterwards, fertility began to rise in the European republics of the USSR, together with Armenia and Georgia. Intriguingly, the fertility levels of these countries converged to approximately the replacement level in the mid-1980s. In Azerbaijan, fertility decline was halted temporarily in the mid-1980s. Concurrently, levels of fertility rose somewhat in Tajikistan, and to a lesser extent in Turkmenistan and Uzbekistan. Although various legislative articles were implemented to enhance the effect of the pronatalist measures throughout the 1980s, they succumbed ultimately to inflation and to the collapse of the Soviet economy. By 1990, the TFRs of the European Soviet republics had returned to approximately their 1980 levels, while fertility decline had resumed in Soviet Central Asia. After the breakup of the USSR, fertility levels continued to decline in all former Soviet republics (Vishnevskiy 1999).

2. Contraceptive Utilization

Direct data on utilization of contraceptive methods in the countries of Eastern Europe and the former Soviet Union is available in many cases from surveys conducted at various points since World War II, especially recently. Table 1 summarizes the data available from the International Demographic Database maintained by the US Bureau of the Census. Two aggregate categories of contraceptive methods are distinguished. The category of 'All' methods of contraception includes traditional methods such as abstinence and withdrawal, whereas 'Modern' methods include the contraceptive pill, IUDs, condoms, sterilization, and a variety of other chemical and mechanical interventions. According to the figures, in all of the East European and former Soviet countries with available data on both forms of contraception, a majority of the population of reproductive-age women were practicing contraception in one form or another at all dates of observation. However, the same cannot be said with regard to modern means of contraception: In most instances, less than half the population were using modern methods.

The data in Table 1 depart from conventional expectations in that the East European countries register levels of modern contraceptive utilization that are usually no greater than those of the former Soviet countries. In several instances, the East European levels are substantially lower than those of former Soviet countries. The levels of modern contraceptive utilization exhibited by Bulgaria and Romania in the 1970s are comparable to that observed in Zaire in 1991. Although this is to some extent a function of time, as access to modern contraceptives improved after the dissolution of the Warsaw Pact and the former USSR, the level of modern contraceptive utilization registered by Romania in 1993 remained well below what is typical for industrialized countries.

Table 1

Percentage of reproductive-age women using contraception

Country	Year(s)	All methods	Modern methods
Bulgaria	1976	76.0	8.0

With regard to the former Soviet countries, the data on contraceptive utilization also depart from standard expectations in that the high-fertility Central Asian countries exhibit levels of modern contraceptive utilization as high as, or higher than, a number of European former Soviet republics with much lower fertility levels. Perhaps this reflects the emphasis placed on fertility reduction in these republics in the population policies of the former Soviet government, as well as those of several international organizations that have been active in promoting contraception in Central Asia after the breakup of the USSR.

The above discussion raises the question of the extent to which contraceptive utilization as measured in available surveys relates to realized fertility levels. The answer to this question is positive with respect to modern means of contraception: use of modern contraception has a decidedly negative and statistically significant correlation ($r = -0.534$) with the total fertility rates registered by the countries for which data are available at the appropriate dates. However, when traditional means of contraception are included, the

relationship deteriorates into a minor positive correlation ($r = 0.153$) which is not statistically significant.

3. Overall Fertility Limitation

The limited coverage of, and unexpected results obtained with, the available direct data on contraceptive utilization in the East European and former Soviet countries justifies the use of indirect estimation methods to assess the extent of fertility reduction in a fuller range of countries and dates. Table 2 contains estimates of Coale's m (Coale and Trussell 1974) as of 1995 for those countries for which there were sufficient data available to permit calculation of this measure. The results leave an overall impression of greater conformity with general expectations than obtains for direct measures of contraception. In particular, the Czech Republic exhibits a higher level of fertility limitation, as reflected by a higher value of m than any of the former Soviet countries, while Hungary and Slovakia register levels comparable to the Slavic former Soviet countries (Russia, Ukraine, Belarus), along with Moldova. These former Soviet republics, in turn, register higher levels of fertility limitation than any of the Transcaucasian or Central Asian former Soviet republics. The principal departure from standard expectations is that the Baltic countries of the former USSR (Estonia, Latvia, Lithuania) register lower values of m than one would anticipate. This may partly reflect the fact that these countries had achieved

Table 2

Index of fertility limitation (m) for former Soviet and certain East European countries, 1995

high levels of fertility control earlier during the former Soviet period, and that the recent further reductions experienced in these countries have caused the resultant marital fertility schedules to deviate from the model age pattern of fertility regulation.

Fertility Control: Overview

The primary immediate, or proximate, biological and behavioral determinants of the levels and patterns of human fertility are (a) the extent and effectiveness of contraceptive use; (b) the degree to which abortion is practiced; (c) the intensity and duration of breastfeeding behavior; and (d) the degree of exposure to sexual intercourse, often proxied by various measures of the extent of marriage. The levels of the various proximate determinants are, in turn, functions of social structure, which differs across populations and over time (Davis and Blake 1956).

The term ‘fertility control’ can be taken to refer to any or all of the proximate determinants. However, while marriage patterns clearly affect fertility, it is often thought that marriage behavior is motivated and explained by factors that are not related directly to a desire to control fertility. The same could be con-

sidered true regarding breastfeeding behavior. Thus, some demographers would define ‘fertility control’ only in terms of those behaviors known to be motivated by a desire to control fertility: contraception and abortion. The primary focus of this article is to provide an overview of these two determinants of fertility.

1. A Variety of Reasons Humans Have Desired to Control Fertility

Judging from what is known about nineteenth- and twentieth-century preliterate populations, as well as from a variety of written evidence left behind by ancient through early modern societies, it appears that men and women have been motivated to control fertility—so that there would not be too few, nor too many children—for at least the last several thousand years (Himes 1970). Additional evidence of the (post-natal) desire to control fertility is seen in the resort to infanticide, child negligence, and child abandonment in the ancient world and throughout much of the Middle Ages and beyond (see *Infanticide and Induced Abortion*). The focus here is on the various reasons humans have desired to limit fertility.

Health concerns have always been an issue; pregnancy and childbearing still present serious medical risks to women in much of the developing world, as they have until fairly recently in the currently industrialized world. Even if continuous pregnancy and childbirth did not prove fatal, the sickness, pain, and suffering involved were motivation enough for wanting to postpone, avoid, or terminate the next pregnancy. A rapid pace of childbearing presented risks to surviving children too, particularly the youngest, since it taxes parents’ ability to care for their family. For example, birth spacing was seen as desirable in order to prolong breastfeeding, often considered important for a child’s health and development.

In addition, there has often been the motivation to prevent or terminate pregnancy that resulted from extramarital or premarital sexual relations, either because such relations were socially sanctioned or because the consequent childbearing was deemed undesirable. Offspring born as a consequence of such sexual relations could prove extremely inconvenient to the fathers (and their legitimate children) and devastating to the mothers.

Within marriage, there has also been the desire to space and limit the number of births, for various social and economic reasons (see e.g., McLaren 1990). In terms of the timing of fertility, there was a desire to avoid childbearing during the busy agricultural seasons, since women would be working hard in the fields. In other contexts, parents who wished to avoid dividing their estates into too many parts may have wanted to limit the number of their descendants. Later on, upwardly mobile middle-class and working-class families may have chosen to have smaller families

because of increasing costs of raising children or in order to invest more in the education and health care of each child. While there have been many reasons for men and women to want to control their fertility in different periods and in different cultures, that desire is found in all societies and is very old indeed.

2. A Variety of Fertility Control Methods

Over the thousands of years that humans have desired to exercise control over their fertility, various methods have been developed, many through trial and error, some partially effectively, some highly effective, and some not effective at all. Some methods have been medically harmful to the women who used them, while others harmless. In this section, descriptions of the types of methods used, their historical significance, mechanisms of action, degrees of efficacy, and where possible, extents of use in the past, are presented.

Regarding efficacy, it is important to keep in mind that a contraceptive method which does not guarantee that any one woman will not conceive while the method is applied, can nonetheless have a profound effect on the overall probability of conceiving in a population. To see this, consider the following: It is estimated that if 100 couples exposed to vaginal intercourse do not use any form of contraception, approximately 85 of the women will become pregnant within one year. A contraceptive method such as *coitus interruptus*—one which is not considered by modern standards to be among the most effective—dramatically reduces the annual risk of pregnancy from 85 percent to approximately 19 percent. In this article, references will be made, when possible, to contraceptive failure rates which indicate the proportion of women who would become pregnant during the first year of typical use among couples in the United States. Typical use refers to method use which may be imperfect or inconsistent. The failure rates cited should always be compared with the probability of pregnancy when no method is used—that is, approximately 85 percent. The reader should also keep in mind that ‘perfect-use’ failure rates—the proportion of women who would become pregnant within one year of correct and consistent use of a specific method of contraception—are often substantially lower than typical-use failure rates (Hatcher et al. 1998).

2.1 Methods Which are Completely Ineffective

The application of ineffective methods provide evidence for the widespread desire and hope for fertility control, rather than for human ability to translate those hopes into effective action. A long list of amulets, symbolic magic, and rituals that have no contraceptive

or abortive effect have nonetheless been known and practiced in ancient and contemporary populations. For example, written evidence from the Middle Ages in Europe describe a belief that lying or sitting down upon fingers will prevent conception for a number of years that is equal to the number of fingers. In addition, it has long been believed that the passivity of women during sexual intercourse, or their ‘holding back’ an orgasm will prevent conception. A wide variety of herbal preparations have also been used with the intent of fertility control; doubt remains as to whether any of these potions do indeed have contraceptive or abortive effects in humans (Riddle 1997, Santow 1998).

2.2 Behavioral Methods of Contraception

This section reviews methods of preventing contraception which do not require the use of any type of physical or chemical substance, but which rather rely on the modification of sexual and reproductive behavior. In this category fall some of the oldest effective methods known. Reduced coital frequency, even if practiced without regard to the timing of sexual intercourse during the menstrual cycle, will affect the monthly probability of conception to an extent which is roughly proportional to the percentage decline in coital frequency (Trussell 1979). Clearly, sexual abstinence, or continence—that is, refraining from vaginal intercourse—reduces fertility. David and Sanderson (1986) argue that sexual restraint of these kinds were important factors in bringing about the nineteenth-century decline in fertility in the United States.

Fertility awareness methods of periodic abstinence, by which the fertile days during the cycle are correctly identified and avoided, will be more effective than a simple overall reduction in coital frequency. Various types of methods are in use today (e.g., Calendar Rhythm Method, Basal Body Temperature method, Cervical Mucus charting), but historically, these are fairly new developments. It was not until the early 1930s that the timing of ovulation within the menstrual cycle was correctly identified and a chart was worked out for use by women desiring to identify the days it was ‘safe’ to have sexual intercourse. Typical-use failure rates of periodic abstinence hover around 25 percent. Prior to the second quarter of the twentieth century, attempts at periodic abstinence, based on incorrect beliefs about the timing of the fertile period, while often discussed, were generally ineffective.

Prolonged and intensive lactation have the effect of delaying the return of ovulation after a live birth. There is evidence that certain preliterate societies, as well as the ancient Egyptians, were aware of the fertility-inhibiting function of breastfeeding, and practiced prolonged lactation for the purpose of increasing the spacing between births. Such practices were com-

mon in the currently developed nations in the 1900s, and they are still in use there among various religious groups. In addition, throughout history, it has often been believed that semen would spoil the milk of lactating women. Customs of post-partum abstinence during lactation, more common in polygynous societies, enhance the fertility-inhibiting effect of breastfeeding, whether or not they are practiced for the purpose of fertility control (see *Fertility Control: Prevalence and Consequences of Breastfeeding*).

Modifications of sexual practices, such as oral sex, anal sex and *coitus reservatus*—vaginal penetration without ejaculation—may have been used for the purposes of preventing conception. Probably the ancient Peruvians, Greeks, and Hebrews, among others, performed such practices. However, the behavioral modification invoked most universally, both in terms of time and space, and most certainly for the purposes of fertility control, is *coitus interruptus*, or withdrawal, whereby male ejaculation occurs outside the vaginal cavity, following vaginal penetration.

Evidence indicates that preliterate populations, the ancient Hebrews, ancient Islamic societies, and others used withdrawal. The Bible mentions *coitus interruptus* in *Genesis* 38:7–10 in the story of Er and Onan. Numerous references to the practice can be found afterwards, some in favor, many denouncing it. Santow (1995) provides a compelling argument for the demographic importance of *coitus interruptus*, even centuries before the modern transition to low fertility. There is no doubt that its use was very important in bringing about the decline in fertility in many parts of Europe during the last part of the nineteenth century and early part of the twentieth century. Even in countries like the USA, where its prevalence declined relatively early, *coitus interruptus* was among the most frequently cited, if not the most cited, method of birth control reported in studies undertaken in the 1930s. In France and Belgium, significant reliance on withdrawal continued into the 1970s. Today, *coitus interruptus* remains a frequently-used method of birth control only in some parts of Southern and Eastern Europe, as well as in parts of the developing world, such as West Asia (Santow 1993).

2.3 Physical, Mechanical, and Chemical Means of Contraception

Various techniques have been developed over time to remove semen from the vagina after ejaculation. Physical methods of sperm removal cited in early literature include such means as the woman squatting and straining, or jumping following intercourse (Himes 1970). Probably the most widely known and used technique for sperm removal in past times was douching, referred to, for example, in Hindu writing of around 1,500 BC. Some primitive douches have an additional spermicidal effect, such as those which use

solutions of vinegar, salt, lemon juice, or tannic acid. Charles Knowlton, an early American birth control advocate, recommended postcoital douching with a solution of zinc and alum in his 1832 book *The Fruits of Philosophy*. David and Sanderson (1986) suggest that douching was a method frequently used by urban American birth controllers in the early nineteenth century, perhaps in conjunction with reduced coital frequency and abstinence. Woycke (1988) also writes that douching was popular in nineteenth-century Germany, partly because it could be seen as a having a legitimate hygienic function, even by those ambivalent about the moral rectitude of pregnancy prevention. Typical-use failure rates of douching are probably close to 40 percent (Kestelman and Trussell 1991).

Other physical and mechanical means of contraception include those that attempt to prevent entry of sperm into the cervix. Barrier methods described by ancient Greek writers include smearing of oils on the cervix. Similar strategies are discussed in ancient Indian writings. A description of the use of crocodile dung as a pessary appears as early as 1850 BC in the ancient Egyptian Petri papyrus. In other references, alternative sticky substances, such as honey or melted beeswax were suggested for use as pessaries (Himes 1970).

A tuft of wool or cotton, frequently referred to in some Jewish theological writings (Talmud) as a *mokh*, was probably placed in the vagina before coitus or after coitus, in order to absorb the semen and prevent it from entering the cervix (Feldman 1995). In certain contexts, the wool or cotton was used as a vehicle for some type of sticky substance or primitive spermicide. Modern-day sponges are small and pillow-shaped, made of polyurethane, imbued with spermicide, and have typical-use failure rates of approximately 20 percent among nulliparous women, 40 percent among parous women.

Another important barrier method of birth control, the male condom, also has a long history. In use in various forms by preliterate peoples as well as early Egyptians for noncontraceptive purposes (e.g., for decoration), condoms became associated with prostitution during the sixteenth century, when they were used primarily for protection against sexually transmitted diseases. Even today in some contexts, condoms carry a negative stigma associated with promiscuity or prostitution. At least from the second century AD, condoms were often made from animal membranes. It was not until the middle of the nineteenth century that the development of the vulcanization of rubber allowed for production of less expensive condoms. However, even rubber condoms were probably too expensive in the mid-nineteenth century for widespread use by the lower classes. In the 1930s, the improved technology that allowed for latex condoms made condoms even cheaper and more appealing for use. Their popularity spread, so that

surveys of the 1930s show condoms competing with withdrawal for popularity in the USA. At the beginning of the twenty-first century, unlike in the past, condoms are high quality and reliable, so that breakage is rare. However, typical-use failure rates approximate 14 percent, largely because of inconsistent use.

Various other barrier methods, forerunners of the modern-day cervical caps and diaphragms, included the hollowed-out rinds of lemons, discussed, for example, by Casanova in the eighteenth century. The vaginal barriers cover the cervix in order to prevent the entrance of sperm. The rubber cervical cap and diaphragms were developed and perfected by German physicians and scientists in the nineteenth century—the cap by F. A. Wilde in 1838 and the diaphragm by W. Mensinga in 1880. The use of the latter method spread from Germany to Holland, and then to England, where it became known as the ‘Dutch Cap.’ Use of the diaphragm and cap have been supplemented with various spermicidal elements, such as quinine compounds, and later, modern spermicidal creams, introduced into the interior cavity of the objects before being inserted into the vagina or placed on the cervix. Promoted by birth control propagandists both in England and in the USA in the 1920s and 1930s—Dr. Marie Stopes in England advocated use of the cervical cap, Margaret Sanger the diaphragm in the USA—use of these vaginal barrier methods was limited largely to the middle classes, but apparently well accepted in this sector of the population. Modern-day diaphragms, used in conjunction with spermicidal cream or jelly, have typical-use failure rates in the range of 20 percent. Failure rates for the cervical cap are generally higher, especially among parous women.

2.4 Hormonal Methods

The search for an oral contraceptive has a long history in herbal formulations. However, only in the mid-1920s did scientists discover the antifertility effects of estrogenic compounds, and it was not until 1960 that the United States Food and Drug Administration approved the first hormonal oral contraceptive. Modern-day combined oral contraceptives, among the most extensively studied medications ever prescribed, are safe; in many countries, but not in the USA, oral contraceptives are available without a doctor's prescription. The pills are highly effective and prevent pregnancy primarily by suppressing ovulation through the combined actions of estrogen and progestin. Typical-use failure rates are approximately 5 percent.

Following its introduction in 1960s, there was rapid, widespread acceptance of the pill in the US, especially among young women. By 1965, 24 percent of all married contraceptors were relying on the pill, and by 1970, the pill was the single most popular method used

by married American women. Increasing reliance on the pill was accompanied by a reduction in use of barrier methods, rhythm, and withdrawal (Westoff and Ryder 1977). In many other currently industrialized nations as well, pill use has eventually overtaken older methods of contraception at various times, depending on when it was introduced and made easily available. Today, the pill is the most widely-used reversible method of contraception in the Western developed countries. It is important to recall, however, that the major declines in fertility in the currently industrialized nations began in the late nineteenth and early twentieth centuries, well before the development of the oral contraceptive, and even before the mass production and distribution of barrier methods such as condoms and diaphragms.

For a variety of reasons, some women want to avoid hormonal contraceptives which contain estrogen. In these cases, progestin-only methods of contraception, such as injectibles, implants, and pills can be safe, highly effective alternatives. In the USA, Depo-Provera injections and Norplant implants have typical-use failure rates of less than 1 percent. The progestin-only pill, or minipill, is probably only slightly less effective than combined oral contraceptives (Hatcher et al. 1998).

Emergency contraceptive pills (ECPs)—consisting of progestin only or a combination of estrogen and progestin—can be used within 72 hours following unprotected intercourse. Emergency contraception acts to prevent pregnancy, and is not an abortifacient. If 100 women had unprotected intercourse once during the second or third week of their menstrual cycle, about eight would become pregnant. Following treatment with ECPs, only one or two would become pregnant. Thus, there is a reduction of about 75 percent–88 percent in the probability of pregnancy resulting from use of ECPs (<http://ec.princeton.edu/>).

2.5 Intrauterine Devices (IUDs)

Physicians began experimenting with intrauterine pessaries for women in the middle of the nineteenth century. However, use of early IUDs, made of silk and silver wire, often led to serious pelvic infections, and their use was thus considered by most physicians to be unwise up through the middle of the twentieth century. The use of plastic instead of wire, begun in the late 1950s, improved the safety of IUD use.

The modern-day IUD is inserted by a physician into the uterus, with a string that should protrude from the uterus to aid in removal. The device can remain in the uterus and provides contraceptive protection for a number of years. The IUD is thought to work primarily by preventing fertilization; it is not currently thought to be an abortifacient. Highly effective, the method has typical-use failure rates that generally lie below the 2 percent level. Some types of IUDs can also

be used as emergency contraception, whereby they are inserted into the uterus within a few days of unprotected intercourse.

2.6 Contraceptive Sterilization

Primitive attempts at producing sterility in men have taken the form of drastic actions such as the castration of male servants chosen to safeguard female residents of imperial palaces in ancient China circa 1,100 BC. In an attempt to make women infertile, surgical removal of the ovaries was used by the ancient Egyptians, and retroflexion of the uterus to block the cervical canal was used by certain tribes of Java, as reported in the late nineteenth century (Finch and Green 1963).

During the nineteenth and twentieth centuries, more effective and safer methods of sterilization were developed with improvements in asepsis and anesthesia. Today, female sterilization is accomplished through various methods of mechanically blocking the fallopian tubes to prevent the sperm and egg from uniting. Male sterilization (vasectomy), medically even simpler, safer, and less expensive than female sterilization, involves blocking the *vas deferens* in order to prevent passage of sperm into the ejaculated seminal fluid. Although it is sometimes possible to reverse the procedures, neither male nor female sterilization is considered reversible. Highly effective, both methods have typical-use failure rates of less than 1 percent.

In the first half of the twentieth century in the US and in Europe, sterilization was thought to be appropriate primarily in the eugenic context of those thought mentally unfit to be parents. However, since the 1960s, there has been widespread acceptance of voluntary sterilization, so that now roughly 50 percent of married contraceptors of reproductive age in the USA rely on either female or male sterilization. Worldwide, female sterilization is the dominant form of contraception used today.

2.7 Induced Abortion

A popular notion of the difference between contraception—the prevention of pregnancy—and abortion—the termination of pregnancy—is a modern-day distinction which did not usually exist in the past. At least during the early modern period, if not before, and to the end of the nineteenth century, abortion performed prior to quickening was viewed traditionally by European women as just another point on the continuum of fertility-control practices, and not generally less legitimate or acceptable than the rather indelicate means of contraception available at the time (McLaren 1990).

Abortion was probably more commonly used than was contraception before modern times (Himes 1970). Various traditional and folk methods were employed

throughout the ages, and some are still in use today, where legal or safe abortion is not widely available. Examples include jumping off tables or down stairs, engaging in vigorous exercise, and performing abdominal massages. Purportedly emmenagogic or abortifacient potions and pills made of lead, arsenic, phosphorus, gin, quinine, or different herbal extracts, to name a few, were often either poisonous and potentially lethal to the pregnant woman or, at most partially effective (Santow 1998, Woycke 1988). Insertion into the uterus of objects such as hat pins, knitting needles, and infamously, coat hangers, is dangerous, primarily because of risk of infection and hemorrhage. Sometimes these mechanical abortions are self-induced, sometimes they are performed by abortionists of varying reputation.

Over time, improvements in techniques and asepsis allowed for the development of safe and effective surgical abortion. By the 1930s, the dilation and curettage method was recognized as being as safe as full-term delivery. Today, legally induced abortion is significantly safer medically than continuing a pregnancy to term. Introduced to the USA in 1967, vacuum aspiration is currently the most commonly used method of abortion there. Recent developments in medical abortion have the potential of reducing the need for these types of surgical abortion. For example, mifepristone (formerly known as RU486), in combination with prostoglandins, is used widely to abort early pregnancies in several European countries, and has been found to be safe and effective.

The contribution of abortion to the decline in fertility in currently industrialized countries cannot be quantified, but there is strong reason to believe that it is significant. Probably no country has been able to attain replacement-level fertility without the recourse to induced abortion. Generally, use of abortion increases during the early stages of fertility decline, and then decreases as more effective contraception is adopted by a larger proportion of the population (Ross and Frankenberg 1993; see also *Infanticide and Induced Abortion*).

3. Recent Trends in Contraceptive Use

Accurate information on the use of abortion is not available in many countries, even when abortion is legal, but especially when it is not (Henshaw 1990). Tracking trends in this sort of data is even more difficult. Therefore, this section focuses only on levels and trends in contraceptive use. One important measure of contraceptive use is contraceptive prevalence, defined as the percentage of couples (with the woman of reproductive age) who are currently using contraception.

Systematic surveys of contraceptive prevalence and method use began to be conducted only in the 1960s in developing countries, as well as in most developed

Table 1Contraceptive use^a by method type and by region of the world, circa 1993

^a Contraceptive use among currently married women of reproductive age, including, where possible, those in consensual unions. ^b Contraceptive prevalence is the percentage currently using contraception among couples with the woman of reproductive age. ^c Other methods requiring supplies or medical services, including injectibles, diaphragms, cervical caps, and spermicides. ^d Including periodic abstinence or rhythm, withdrawal, douche, total sexual abstinence if practiced for contraceptive reasons, folk methods and other methods not separately reported. ^e Excluding Japan.

**Figure 1**

Trends in contraceptive prevalence, selected developing and developed countries (Sources: United Nations (1996, 1999))

countries. Increased concern over rapid population growth and high fertility levels in post-World War II developing countries led to the employment of large-scale surveys of contraceptive use that allow for documentation of prevalence and trends in those regions that is more comprehensive and up-to-date than in currently developed regions. Table 1 presents contraceptive prevalence rates in different regions of

the world, based on the most recent data that is currently available. Data in the table refer roughly to the period around 1993.

Contraceptive prevalence was approximately 58 percent for the world as a whole in the years around 1993, but there are important differences between regions. Overall, less developed regions have somewhat lower proportions who use some method of

contraception (55 percent) than do more developed regions (70 percent). The very high level of prevalence in China, currently estimated at 83 percent, raises substantially the average for the less developed regions because of China's large population size. It is estimated that in less developed regions, excluding China, contraceptive prevalence is only 42 percent. In Africa, particularly Western Africa, the prevalence level is lowest in the world (8 percent). Most countries in Latin America and the Caribbean have moderate to high levels of contraceptive use, with nearly all countries reporting prevalence rates of at least 40 percent. Among the more developed regions, the range in prevalence levels is much smaller than among the less developed regions.

Eighty-seven percent of couples who currently use contraception worldwide rely on supply methods—that is, methods which require supplies or medical services. The major supply methods used by couples today are female and male sterilization, the pill, the IUD, and condoms. Supply methods actually comprise a larger percentage of total contraceptive use in developing regions (91 percent) than in developed regions (74 percent). This is probably a function of the role in developing countries of family planning programs, which began massive supply work just when modern methods became available in the 1960s (see *Family Planning Programs: Development and Outcomes*). Only in certain areas such as Southern and Eastern Europe, and parts of West Asia, are nonsupply methods, primarily *coitus interruptus* and rhythm, still widely used among married couples.

Worldwide, and in less developed regions overall, female sterilization is the method most often used. In China and in India, between a quarter and a third of all married women of reproductive age are sterilized. In developed regions overall, the pill is the most commonly used supply method among married couples, but sterilization is the most dominant method in North America and Australia/New Zealand. Condom use is more common in the more developed regions, particularly in Japan, than in the less developed regions, while IUD use is more common in the less developed regions, especially in China. In the more developed regions, IUD use is relatively common in Northern and Eastern Europe. Use of vaginal barrier methods is negligible everywhere.

Nearly all developing countries for which trend data is available have experienced increases in contraceptive prevalence between the years 1970–2000. It has been estimated that contraceptive prevalence for less developed countries has risen by approximately 41 percentage points since the period 1960–5, when it stood at only 14 percent. Increases in prevalence rates among developed countries have been much more modest than among developing countries, in part because the latter started from lower levels (see *Fertility Control: Eastern Europe*). Figure 1 provides a few examples of changes in prevalence rates for a

selection of less and more developed countries. In terms of method mix, rising use of supply methods, particularly female sterilization, is the dominant trend in more developed as well as in less developed regions, but the experiences of individual countries is varied. In many more developed countries, increasing use of supply methods has been accompanied by decreasing use of non-supply methods.

Fertility Control: Prevalence and Consequences of Breastfeeding

The fertility inhibiting consequences of breastfeeding have been known for centuries. Among the ancient Greeks, Aristotle noted that women who nursed their infants for extended periods of time were able to delay the onset of postpartum menstruation and conception. Yet only recently have demographers begun fully to appreciate breastfeeding's impact on global fertility levels. Since the 1960s a large number of scientific studies from many parts of the world have consistently demonstrated that breastfeeding is closely associated with prolonged periods of postpartum amenorrhea, long birth intervals, low completed fertility, and optimal health and wellbeing for the mother and infant. Breastfeeding is now recognized as an important determinant of fertility, especially in the developing world, where modern contraceptive usage is low and breastfeeding rates are high. In this article we review the recent transition in thinking regarding the contraceptive role of breastfeeding.

1. Early Demographic Research

Beginning in the 1950s researchers hypothesized that variation in breastfeeding behavior contributed to fertility differences among populations. Studies showed that the survival of one child is positively associated with the mother's succeeding birth or pregnancy interval. In Senegal, researchers noted that the interval between one birth and the next increased by at least nine months when the age at weaning of the first of those children increased by one year. Also, average birth intervals were 25 months when Senegalese mothers breastfed their children for 12 months

or less, but were as long as 41 months when they breastfed for up to 35 months. Still other studies demonstrated that in the absence of any breastfeeding the average duration of postpartum amenorrhea is one or two months with a corresponding birth interval of just over one year. By the 1970s the weight of the accumulated demographic evidence led one researcher to conclude that, in developing countries, breastfeeding prevents more pregnancies than all modern forms of contraception combined (for details see Rosa 1975).

By the mid-1970s other researchers using linear regression techniques found that when regressing the average duration of postpartum amenorrhea on the average duration of breastfeeding, each additional month of breastfeeding increases amenorrhea by somewhat less than one month. These types of empirical findings helped form the basis for what has become known in demographic circles as the 'proximate determinants of fertility' framework. This modeling approach tries to account for variation in fertility between populations by quantifying a limited and exhaustive list of variables having a direct bearing on fertility. The period of time in which nursing mothers are not menstruating or ovulating and are unable to conceive following a pregnancy is referred to as lactational infecundability. As the name implies, breastfeeding is assumed to be the leading or sole cause of the delayed return to the fecundable state in nursing mothers. Used widely as an analytical tool, the proximate determinants of fertility framework has demonstrated, worldwide, that lactational infertility is an important determinant of the total fertility rate between populations. For example, in an analysis of World Fertility Survey data (1974–84) using the proximate determinants framework, demographers estimated the relative contributions of breastfeeding and artificial methods of contraception to the restriction of fertility in 29 developing countries in Africa, the Americas, and Asia. The analysis showed that in Africa the amount of potential fertility reduced by modern contraceptive use is relatively low, whereas breastfeeding inhibits an average of four births per women. In Asia, breastfeeding remains important for fertility control, but overall, modern contraceptive use is more important than in Africa. In Mexico, Central America, and South America, modern contraceptive use plays the predominant role with only one-fifth of the total fecundity reduction due to breastfeeding. In poorer developing countries like Bangladesh, Peru, and Haiti, however, breastfeeding still plays the dominant role in reducing fecundity. Similar results have been found using more recent data from the Demographic and Health Surveys (DHS) for currently developing countries. Results using the proximate determinants framework in 25 DHS countries showed that for each additional month increase in the duration of breastfeeding there is a one-half to three-fourths month increase in the duration of postpartum amen-

orrhea (for detailed treatment see Goldman et al. 1987, Guz and Hobcraft 1991, Thapa et al. 1992).

Others have developed models incorporating the underlying physiological processes of postpartum infertility. In doing so they have pointed out an important limitation of the proximate determinants approach. The proximate determinants framework uses the total duration of breastfeeding to assess postpartum lactational infecundability, when in fact amenorrhea typically ends well before breastfeeding is terminated. Thus simply showing empirically that the duration of breastfeeding is highly correlated with the duration of postpartum amenorrhea in a regression model reveals little about the underlying causal relationship between the two. Furthermore, physiological models provide a means of assessing the contribution of full, unsupplemented breastfeeding, not simply the total duration of breastfeeding used in linear regression approaches. Results suggest that for each month of exclusive breastfeeding, anovulation and/or amenorrhea would on average be postponed by *more* than one month. Nonetheless, the strong statistical relationship between the duration of breastfeeding and the duration of postpartum amenorrhea, whether measured at aggregate or individual levels, is remarkably robust, and indicates a strong underlying biological link between the two (see details in Habicht et al. 1985, Santow 1987).

2. Neuroendocrine Control of Postpartum Lactational Infertility

Thanks to a series of clinical studies carried out in a small homogeneous group of breastfeeding mothers in Edinburgh, Scotland, the neuroendocrine regulation of lactational infertility is now fairly well understood. When breastfeeding is initiated, afferent nerve impulses pass directly along nerve axes leading from the mother's nipple to the hypothalamus in the brain, directly disrupting the release of the hormones responsible for ovulation. Disruption continues until the neural suckling stimulus declines sufficiently to allow for normal hormonal release to be restored. When suckling is reduced or stopped, ovulation, fertilization, implantation, embryogenesis, and pregnancy are once again biologically possible. Therefore, it is the suckling stimulus itself that plays the key role in the neuroendocrine control of postpartum lactational infertility, not the direct effect of delayed weaning. Only in cases where weaning or the death of a child terminates breastfeeding prior to the resumption of menses can the total duration of breastfeeding, *per se*, be considered causally related to the return of postpartum menstruation.

Apart from elucidating the underlying neuroendocrine mechanisms of postpartum infertility, the Scottish studies also revealed significant new insights into the relationship between postpartum infertility and

specific aspect of infant feeding behavior. The research showed, for example, that both the number and the duration of suckling episodes played key roles in suppressing ovarian function. None of the Scottish women in the study ovulated if they breastfed six or more times and more than 60 minutes a day. The introduction of supplemental foods prompted a decline in both suckling frequency and duration with suckling duration declining somewhat earlier than frequency.

The more abrupt the introduction of supplements the more rapid the decline in duration compared to frequency and the more rapid the resumption of ovarian function. Women who maintained regular night-time feeds tended to breastfeed with a greater frequency and longer duration and to remain anovulatory for a longer period of time than those who did not. Overall, supplementation undermined and reduced the intensity of the infant's suckling stimulus (however measured) and led to an earlier resumption of ovarian activity and menstruation than if exclusive breastfeeding were maintained (for details see Tay et al. 1996).

3. Hazard Model and Life Table Studies of the Fertility Inhibiting Consequences of Breastfeeding

To date only a handful of large-scale, longitudinal studies, including those in India, Taiwan, Bangladesh, Guatemala, Indonesia, and the Philippines, have been undertaken to investigate, either directly or indirectly, the determinants of postpartum lactational infertility in nonclinical settings. The strength of these studies derives, in part, from their prospective data collection frameworks and their measurement of nursing behavior. The investigations lasted for periods of one to three years or longer in some cases. They prospectively collected information on infant nursing behaviors, supplemental feeding practices, maternal and infant health, the duration of postpartum amenorrhea and birth interval, as well as a rich array of other socio-demographic and control variables.

An additional strength of these prospective studies arises from their use of an alternative body of statistical techniques known as event history or hazard model analysis. These statistical procedures have been developed since the 1980s specifically to handle duration or event variables, censoring (when a subject, for whatever reason, leaves a prospective study before it has ended or the event of interest does not occur before the study ends), and other problems inherent in longitudinal study designs. Hazard model analysis provides the ideal statistical framework for unambiguously quantifying the effects of nursing behavior on the duration of postpartum amenorrhea in non-clinical settings while simultaneously controlling for the joint effects of confounding variables (see *Event-history Analysis in Continuous Time*).

To cite one example, women living in rural Indonesia were interviewed monthly about their current menstrual status and their average daily breastfeeding pattern. The women were classified into four groups based on nursing intensity. Univariate life-table analysis revealed that low-intensity nursing mothers resumed menses at 11.5 months, while high-intensity nursers resumed menses at 20.4 months. Medium-low and medium-high intensity nursing groups resumed menses at 14.0 and 17.7 months, respectively. A series of multivariate proportional hazard models showed that, when controlling for confounding factors, the higher the intensity of suckling the slower the rate of return of menses. Further multivariate analysis also showed that partial breastfeeding (with supplements) significantly increased the risk of resumption of postpartum menstruation when controlling simultaneously for nursing intensity and other confounding factors.

In the Philippines, research also demonstrated that partial (supplemented) breastfeeding significantly increases the risk of early return of postpartum menstruation. Hazard model analysis showed that factors such as active suckling, the use of two breasts versus one, and breastfeeding on demand vs. a fixed nursing schedule significantly decreased the risk of early return of postpartum menstruation. By contrast, the feeding of milk other than breast milk and nonnutritive or low caloric nonmilk liquids increased the risk of early resumption of postpartum menstruation.

In the final analysis, these longitudinal studies and the clinical research from Edinburgh share an emergent consensus concerning breastfeeding and fertility. The consensus is that, in spite of the wide range of variability in infant feeding patterns and practices across populations and individuals, it is the sum total of all direct and indirect breastfeeding activity affecting the intensity of the suckling stimulus, and thus the strength of the neural input to the brain, that is the most important determinant/mediator of postpartum infertility. (For references and details see Jones 1989, 1990, Popkin et al. 1993, Zohoori and Popkin 1996.)

4. Breastfeeding and Family Planning

The emergent scientific consensus regarding the reproductive consequences of breastfeeding represents a marked departure in thought and sophistication from that of just a few decades earlier. After carefully reviewing the evidence at hand, a group of researchers meeting in Italy in the late 1980s issued a statement regarding the contraceptive role of breastfeeding. Known as the Bellagio Consensus Statement, the announcement noted that, if three conditions prevail, postpartum mothers could expect a pregnancy rate of less than 2 percent. These three conditions are: a woman must remain amenorrheic since delivery, she must be fully or nearly fully breastfeeding (little or

no supplements), and she must be within six months of delivery. This is referred to as the lactational amenorrhea method (LAM) of family planning (for details see Kennedy et al. 1989, 1990).

5. Conclusion

The accumulation of scientific evidence since the 1960s has confirmed what many, especially women, have known intuitively over vast stretches of human history and prehistory: that breastfeeding acts as nature's way of keeping human fertility rates low and of guaranteeing enough time between births for the child to be adequately nourished and developed and for the mother to sufficiently recover from the rigors of child bearing and rearing. Prospective research undertaken in both clinical and real-life settings has confirmed the contraceptive effects of breastfeeding. Knowledge gained from these studies has led to the development of guidelines to enable breastfeeding mothers to use lactation as a means of fertility control, at least during the first six months postpartum, or possibly up to 12 months postpartum, if mothers are actively pursuing breastfeeding and are receiving appropriate family planning counseling.

Worldwide it is estimated that more than 90 percent of mothers with infants still breastfeed, at least for a short period of time. If women were to be counseled on LAM use, this could potentially provide a natural way to prevent pregnancy immediately after birth, much as it has for most of humankind's evolutionary history. Unfortunately, however, the initiation, intensity, and duration of breastfeeding are declining due to urban lifestyles and other changes in the postindustrial years. The recent Demographic and Health Surveys have shown that today in many developing countries young women who are educated, urban, and affluent are abandoning breastfeeding in favor of bottle-feeding. Often these women are the trend setters in their communities, and their influence is spreading to the other urban and rural poor women who are the least likely to have access to or use modern contraceptives and whose infants have the most to gain from breast milk.

In recent years, however, the advent of the HIV pandemic presents a potentially more dangerous public health problem than declining rates of breastfeeding. Even though HIV, the virus that causes AIDS, can be transmitted by breastfeeding, WHO and UNICEF have advised that where other infectious diseases and malnutrition are the primary cause of infant deaths, breastfeeding should remain the standard advice to pregnant women, including those who are known to be HIV-infected, because their baby's risk of becoming infected through breast milk is likely to be lower than its risk of dying of other causes if deprived of breastfeeding. Whether or not this advice can or should be implemented is currently a matter of strong debate. Only time and more research will be

able to resolve these important social, medical and ethical issues (see details in Kennedy et al. 1990, Family Health International 1992, World Health Organization Global Programme on AIDS 1992, Trussell et al. 1992; see also *HIV and Fertility*).

Fertility: Institutional and Political Approaches

Much of fertility analysis is based on the model of an autonomous actor like the one assumed in micro-economic theory, characterized by a preference set against which responses to price and other signals are determined. In fertility studies, the actor is a woman (rarely a man) of reproductive age or a composite 'couple.' Fertility surveys relating individual child-bearing patterns to individual characteristics, family-size desires, and practice of birth control help to maintain this focus. Fertility, however, is also a societal process and outcome. It is affected by the powerful close-range forces at work within the micro-society of the family. Moreover, both individuals and families are enmeshed in larger social groups—clans, villages, and other communities, castes, social classes, religious groups, nations—which may affect their fertility preferences and are the locus of institutional constraints within which their fertility-related decisions are taken. The ways in which fertility is influenced by these broader social organizational and institutional settings, and by the patterns of social control that operate within them, are the subject of this article.

1. Institutional Determinants of Fertility

Institutions are enduring clusters of behavioral rules, known but often unwritten, governing human actions and relationships in recurrent situations. They are not rigid constraints requiring compliance, though there may be external or self-imposed sanctions for violation. They are not unchanging: they are constantly being made and remade by those coming into contact with them—and sometimes by deliberate efforts at policy design. They have to do with 'structure,' but not only in the sense of tangible reality. Cultural values and ideational systems may also be institutionalized.

Marriage and the family are familiar examples of institutions—more precisely, the sets of behavioral

rules and expectations characterizing marriage and the family. Clearly, both are closely linked to fertility outcomes. Other institutions that potentially influence fertility, some more distantly, include the body of family and property law, whether customary or codified; the formal authority structure in the community and local government; the stratification system, and the mobility paths (class- and gender-specific) that it supports; public systems of interage transfers, such as child allowance and pension schemes; and the labor market, particularly as it affects employment of women. The forms such institutions take, emerging from each society's unique history, support a 'fertility regime'—a distinctive pattern of family formation and array of fertility preferences, behaviors, and outcomes. This can be illustrated by some examples of different regimes.

1.1 Social Regulation of Fertility in Preindustrial Agrarian Societies

Many societies facing static land resources and productivity, and recurrent high mortality found institutional means of keeping population growth low, with fertility well below its maximum level and able to respond promptly to mortality crises. In English parishes, for example, prior accumulation of property was required before a person could marry and set up an independent household; in periods of economic hardship, saving took longer and marriage was delayed. A similar kind of community-level social control of household formation existed in preindustrial Japan. In China, social pressures, particularly from the family or lineage, applied not to marriage (which for women was near to universal) but to fertility within marriage, through expectations of lengthy interbirth intervals. Other institutions—'service' in England (sending children to work for a period as servants in other households), adoption in China—helped to smooth family consumption and production imbalances (see Smith 1981, Lee and Wang 1999; *Family Systems in Europe*).

In most traditional societies it is possible to discern distinctive patterns of institutional regulation of fertility that yield somewhat comparable demographic outcomes. The patterns vary with the nature of the family system, with the strength or weakness of territorially-based communities, with the kind of economy, and with the structure and roles of the larger political and administrative systems in which the local society is set. Very high fertility is not a feature of such societies: where it occurs it usually indicates the disruption of customary, institutionalized behavior.

1.2 Institutional Factors in Demographic Transition

Early accounts of and explanations for demographic transition—the secular declines in mortality

and fertility from high to low levels—were largely cast in institutional terms. Social institutions like those just discussed constituted a normative order that sustained high fertility in the face of the prevalent high-mortality risks. As those risks lessened and as technological advances created new economic opportunities, that normative order was slow to change. Hence the pressures and incentives facing individuals tended for a time to maintain the earlier patterns of fertility. Ultimately, however, families discerned their economic interest in having fewer children and acted accordingly. Institutional control was supplanted by rational individual or family-level decision making (see Szreter 1993).

More recent explanations of the transition do not emphasize this supposed shift from institutional to personal and conscious control. Fertility decisions are seen as rational (or boundedly rational) throughout—in the sense of being related to the actor's knowledge and perceived constraints and options at the time. Fertility is also institutionally conditioned throughout: those constraints and options are set by the society's institutional configuration as well as by its members' individual backgrounds and circumstances. This is the case no less in periods of rapid social and economic change than in the 'stable' pre-industrial situation. Indeed, such change is in large part a change in that institutional setting (see North 1990). For example, industrial development creates new avenues of social mobility, but ones that require education and often relocation to urban centers; the social capital of kinship and other ties within the community is supplanted by human capital, transforming the economics of the family. High fertility is increasingly seen as inconsistent with the new conditions. (For various accounts of demographic transition as institutional change see Davis 1963, Caldwell 1982, McNicoll and Cain 1990, *Fertility: Political and Political-Economic Perspectives*.)

Demographic transition in turn induces institutional change. The faster population growth occurring with sustained high (or even rising) fertility but falling mortality early in the transition is a factor promoting change to more intensive agricultural systems (Boserup 1965). A rapid decline from high fertility levels, such as took place in many countries since the 1960s, substantially lowers child dependency rates (its effect in increasing old-age dependency is felt only later) and provides a boost to development performance.

1.3 Institutional Factors Perpetuating Low Fertility

The social pressures that support high fertility do not long survive in the conditions of urban industrialized societies. Other institutional influences come to bear on fertility with the opposite effect. The labor market offers new career opportunities to women, but ones difficult to combine with childbearing. With women's

greater economic independence the institution of marriage erodes; the individual rather than the family becomes the basic unit of society in matters such as public finance. The state intrudes further in the education of children, lessening parental roles in socialization; more generally, peer influence becomes more significant, intergenerational influence less so. At the same time, the cost of childraising—both the direct cost of education and the opportunity cost of forgone income and leisure time—increases markedly in the new knowledge-based economy, much of it having to be borne by the parents.

There is little agreement on how low fertility will become in modern affluent societies, and whether there are inherent forces that might cause it to rebound (see *Demographic Transition, Second*). Some observers foresee an emerging retreat from individualism and restoration of family and community roles as a natural cyclical phenomenon (Fukuyama 1999). Others point to innate biological drives that may sustain fertility. But many see little likelihood of a return to near-replacement levels. Once the lingering effects of earlier high fertility have worked their way through the age distribution, however, the prospect of natural population decrease of 20 percent or more per generation is likely to provide a strong rationale for pronatalist interventions by the state in the design of social and economic arrangements (see Chesnais 1996, Sect. 3.3).

1.4 Linking Institutions to Fertility

Fertility at its simplest is a summary measure of reproductive outcome. Institutional arrangements in a society sometimes deal directly with that outcome, as in systems rewarding or penalizing births in a family beyond a certain prescribed number (China's one-child policy, for instance). But fertility is also a process—a series of individual decisions and biological events—providing many opportunities for indirect institutional influence on outcomes.

The biosocial process leading to a birth can be decomposed into its elements, the so-called intermediate variables or proximate fertility determinants such as age at marriage, duration of breastfeeding, and use of contraception. Each such element is potentially subject to separate institutional influence. Where an intermediate variable is distant from the fertility outcome, the effect on fertility may be merely incidental. For instance, the institutional shift from arranged marriage to love marriage is likely to be accompanied by a rise in average ages of marriage and first birth, tending to depress fertility. Labor market changes affecting women's employment may lead to shortened breastfeeding and hence (through shortened amenorrhea) to higher fertility—to be offset eventually by greater use of contraception (see Davis and Blake 1956).

If the intermediate variables are strongly interdependent, with individuals or couples having some given family size goal in view, subject to economic circumstances, then the main institutional determinants of fertility are those that affect that goal or its attainment. The intermediate variables in this case lose much of their behavioral interest. Where the preferences of one spouse differ from the other, changes in power relations within the family, or in the broader gender system in the society, may be a significant source of fertility change. Greater gender equality is widely believed to promote lower fertility. Other institutional effects on fertility goals would be those that change the perceived costs and benefits of children to parents or, more fundamentally, alter people's concept of the family and its role in the society. Effects on the attainment of fertility goals would include any overt social or political pressures bearing on reproductive behavior (see McNicoll 1994, Potter 1983).

2. Origins and Maintenance of Fertility Regimes

The theory of institutions investigates the origins of conventions and other institutionalized behavior, drawing particularly on transaction-cost economics and game theory. Institutional change bears an analogy to technological change, in being characterized by path dependence and possibilities of multiple equilibria. Some of this theory illuminates fertility regimes.

2.1 Transaction Cost Approaches to the Family

Transactions among members of a society entail 'transaction costs' associated with advertising or acquiring information, negotiating terms, and enforcing contracts. Social institutions, such as a banking system, may lower such costs and thus make market transactions more efficient. It is also possible to economize on transaction costs by internalizing some transactions within an enduring group or organization, members of which come to know and trust each other and thus do not need to fully specify the contractual terms. The firm is such an organization; so is the family (see Ben Porath 1980). The kinds of transactions that are best dealt with in such organizations are those where the identity of the parties matters. Examples are exchange of labor services in situations where effort cannot readily be measured, and parental investment in a child's education in expectation of a much later return.

The family, from this perspective, is the most important institution for nonmarket transactions. Its form is influenced by the emergence of market institutions, such as savings institutions, that lessen its transaction-cost advantages. The implicit contract between parent and child is one such intrafamily

transaction subject to change over the broader course of institutional development in the society, with strong implications for fertility. (See Pollak 1985.)

2.2 *Path Dependent Institutional Change*

Fertility, however, is not sufficiently described as an output of the family treated as a miniature firm-like organization. Family and gender systems require a fuller institutional specification to accommodate their distinctive patterns and fertility outcomes. The persistence of such systems over many generations in pre-industrial societies suggests that they were stable solutions to fundamental problems of organizing reproduction and dealing with child and old-age dependency. Such problems include how children are to be protected and socialized, how sexuality is regulated and parenthood affirmed, how claims to property are maintained and transmitted, and how the dependent elderly are supported. Each admits of many different solutions. Institutionalized, some combinations of those solutions dominate over time, partly through characteristics of the resulting society—among them, its reproductive success—and partly perhaps by fortuity. Belief systems develop alongside such structures, generating explicit rules of practice and sanctions for violation. Ties beyond the immediate family are an essential means of risk-spreading in high mortality conditions, and the reciprocal relationships thus established acquire cultural validity as a ‘moral economy.’ Social groups or statuses advantaged by a given structure have evident interests in its maintenance, entrenching a system of social control.

Such an account suggests that variant family and gender systems are stable institutional equilibria, and their resulting fertility regimes are to some degree fortuitous. Different regimes subjected to the same pressures for fertility change (new resources, new technologies, larger surviving birth cohorts) would respond differently, some more resistant to change than others. Variant paths of fertility transition are in fact observed.

The insight is quite general. A society’s institutional structure is historically contingent and thus in some measure accidental. Institutional change, like change in technology, is path dependent: the direction of change is constrained not merely by its existing state but by its history. Institutions, in part the residues of past social action, limit the possibilities of subsequent social action (see David 1993). But change is also influenced by hopes and expectations about the future, which are not just reflections of immediately perceived options but are formed out of information about the world and the opportunities it seems to present. A role for expectations introduces the possibility of bandwagon effects in social change, as individuals, in making their own decisions, take account of how they anticipate others will decide. Fertility outcomes derive from both history and expectations.

Fertility policy, of course, is also path dependent. Governments do not have a blank slate on which to make policy changes in accordance with the best advice from experience elsewhere; they deal with the politically feasible, meaning a situation inherited from the past.

2.3 *Institutions and Culture*

One strand of economic theorizing on fertility assumes a largely ‘institution-free’ world, in which, in Becker’s (1976) words: ‘all human behavior can be viewed as involving participants who maximize their utility from a stable set of preferences and accumulate an optimal amount of information and other inputs in a variety of markets.’ The need to specify preferences, or tastes, introduces a domain of values, hence presumably a cultural system, but one kept in the background. A second strand, institutional economics in the manner of Ben Porath, or North, derives from the analysis of transactions and iterated games. It is structurally more sophisticated but at its core assumes the same model of a utility-maximizing agent. Institutions, by implication, are economic institutions—or at least institutions amenable to economic analysis.

A consequence of this situation is that an institutional perspective on fertility is often contrasted with a cultural or ideational perspective, as if the two were entirely distinct. The antithesis is false. Even in the study of economic development, where resources and technologies are dominant realities, economic incentives and constraints are necessarily interpreted through a cognitive lens. Controversies over the role of the Protestant ethic or the Confucian ethic in promoting development are not just about abstract values, but about rules of conduct. For fertility, the relevant systems of social control typically combine tangible rewards and sanctions with the symbolic. Ideational systems provide a structure of meaning and a framework against which to evaluate life-course opportunities and options, to determine the scope of tradeoffs in economic calculation, and (internally) to assess gratification or guilt. Where those ideational structures are widely shared, behavior that accords with them can be described as institutionalized. (For discussions of the role of cultural systems and ideational change in fertility determination see Kreager 1986, Kertzer and Fricke 1997. See also *Fertility Transition: Cultural Explanations; Family Theory: Complementarity of Economic and Social Explanations.*)

3. *Governance and Fertility Change*

Since societies, and nations in particular, have an evident interest in their demographic futures, fertility (along with migration) is an object of policy attention.

For most societies most of the time it is not high on the policy agenda, but it typically becomes so in situations of very high or very low fertility. However, governments are routinely engaged in maintaining and modifying systems of law and administration which, though having no deliberate demographic intent, have a significant influence on fertility.

3.1 Incidental Effects of Government Action

There is a wide consensus on the kinds of political and administrative setting that are conducive to economic growth. In establishing such a setting a government is likely also, but incidentally and perhaps unintentionally, to be promoting fertility change along the path of demographic transition. Individuals in seeking economic opportunity are likely to see low fertility as advantageous. A striking illustration of this is seen in those Western countries, including the United States, which attained close to replacement-level fertility early in the twentieth century in the face of strong government disapproval of birth control (see Watkins 1991).

In modern welfare states a range of other government measures bears unintentionally on fertility. Elaborate social policy objectives are pursued through family law, employment regulation, and tax expenditures. Recognition of individual rights and entitlements, translated into social policy, sometimes works against the interests of families. The general social interest in reproduction—the issue of bearing and raising the next generation—is left to the private actions of individuals and families, with no assurance that the latter will aggregate to the social interest (see Demeny 1986).

3.2 Political and Administrative Pressures to Lower Fertility

Many governments pursuing economic development have sought to lower fertility by offering economic incentives to participants (or to recruiters of participants) enrolling in birth control programs. The effects, when discernible at all, have been small. More forceful measures, however, have sometimes attained significant results. Examples are China's campaign of the 1970s for later marriage, longer birth intervals, and fewer births per woman, and China's subsequent one-child policy; and India's sterilization program during the period of rule under the declaration of national emergency in 1975–7. In these campaigns the government's political authority and administrative apparatus were drawn on to implement central policy directives that might otherwise have lain within the duties of a relatively powerless line ministry. In some other countries more routine family planning programs have also sometimes made use of the local civil administration in securing clients (see McNicoll 1997).

The personal costs of coercive measures are high. The political costs are also potentially large: they were,

for example, a factor in the change of government in India in 1977. Even authoritarian governments have limited political capital to allocate over the policy spectrum, and may be loath to expend much of it on birth control programs. A program's unpopularity at the grass-roots level can provide a source of solidarity that spills over into other kinds of opposition to government authority.

3.3 Institutional Innovation in Very Low Fertility Settings

Under a continued rate of fertility well below two children per woman, a country will experience declining population size and rapid population aging. It is likely to seek ways of raising fertility closer to replacement level. Direct state subsidies in the form of child endowments are expensive and have not proven very effective. The amounts offered typically are dwarfed by the actual costs of childraising, especially for more affluent parents; moreover, large windfall gains to those recipients who would not have required the subsidy are inescapable. Symbolic rewards have fared even worse. More promising are measures that increase the compatibility of women's (and more generally, parents') employment and childrearing. Examples are flexible working hours, provision of childcare, job-sharing, and telecommuting. These may sometimes be in the employer's interest; in other cases their cost would have to be allocated between employer and government. A third category would cover efforts to reaffirm parental interest in childrearing by providing parents with a greater tangible return to them. (For proposals of this kind see Coleman 1993 and Demeny 1987.)

The diverse efforts of the many societies likely to be seeking to raise their fertility if very low birth rates persist will provide a natural experiment that will help to determine the relative efficacy and costs of alternative measures.

G. McNicoll

Fertility of Single and Cohabiting Women

Historically, fertility outside formal marriage has been referred to variously as bastardy, illegitimacy, or out-of-wedlock childbearing, with such terms typically

connoting the inferior status of children born in such circumstances. More recently, the use of these terms has declined, in part because they presume an answer to the question of whether 'inferior status' is a necessary consequence of being born to an unmarried woman or whether some of this disadvantage might stem from other causes. Instead, terms such as nonmarital fertility or childbearing by single or cohabiting women, which carry more neutral connotations, have seen increasing usage.

1. Measurement

Measuring nonmarital fertility requires knowledge of at least two demographic statuses—fertility and marriage—and ideally a third—whether a birth occurs within a cohabiting union. By and large, identifying births as occurring within or outside formal marriage is a straightforward matter given sufficiently detailed data. However, it is useful to identify potential inconsistencies across alternative definitions of nonmarital fertility; for example, 'the fertility of single or cohabiting women' vs. 'childbearing to unwed parents.' Consider a birth conceived within a marital union in which the father dies before the child is born. Viewed one way, the child was conceived to married parents; viewed another way, the mother was single at birth by virtue of the death of her spouse. Similar issues arise for legitimated births or births to separated parents. In the latter case, because the birth occurs prior to the dissolution of a formal marital union, one might view it as a marital birth. However, the child may have been conceived by the woman and a man other than her husband, either before or after marital separation; thus, another definition might classify such a birth as nonmarital. Furthermore, note that the period between separation and divorce can be lengthy, with the timing of a formal divorce decree often a response to various factors, including the outcome (e.g., childbearing) under study. Consequently, some researchers have adopted an operational definition that shifts emphasis from formal to *de facto* marital status, thus including as nonmarital those births that occur between separation—marking the informal but behavioral dissolution of a union—and divorce—marking the formal dissolution of a union.

Additional measurement issues arise when attempting to distinguish between nonmarital births to cohabiting women and to women in neither a marital nor cohabiting union. It is sometimes difficult to determine when or whether a cohabiting union has begun, a problem similar to that posed by common law marriage in historical studies. These issues have led some to argue that cohabitation might be better conceptualized not as a discrete status but rather in terms of a continuum capturing the extent to which a couple might be said to have formed a union. Nevertheless, estimates from alternative data sources are typically in substantial agreement, providing evidence, albeit of an

indirect nature, suggesting that female respondents can report accurately on their union status at birth, even retrospectively.

As a general accounting principle, one might suppose that the number of births to males and females should, in the aggregate, be identical as when data are available from official birth registers. Still, this principle need not hold under some definitions of nonmarital fertility (e.g., when both parents are married, but not to each other) given the types of data typically available to the analyst. Moreover, comparisons of survey and registration data often reveal that marriage and fertility data supplied by male respondents are markedly inferior in quality to those from female respondents. One consequence has been that nearly all research on nonmarital fertility to date has focused on the nonmarital fertility of women. Although such an emphasis is often sensible, in that childrearing responsibilities continue to fall most heavily on women, it has nevertheless produced an asymmetry in research findings, with little being known about the men who have fathered children outside marriage.

2. Demographic Trends

Nonmarital fertility has increased substantially in both Europe and the USA. Official statistics for the USA suggest that, as of 1998, roughly one in three births (32.8 percent) were to unmarried women, a level about three times higher than that in 1970, at which time one in ten births (10.7 percent) were to unmarried women. These levels are mirrored in much of Europe. More than every third birth occurs outside marriage in France, the UK, Finland, and the former East Germany, and roughly every second birth is nonmarital in the Scandinavian countries of Iceland, Sweden, Norway, and Denmark (Kiernan 2001).

In the USA, nonmarital first births have been and continue to be prevalent among teenage women; however, the composition of nonmarital births (counting all parities) increasingly consists of those at higher birth orders to nonteenage women. As of the early 1990s, second and higher-order nonmarital births accounted for 48 percent of births to unmarried white women and fully 60 percent of births to unmarried black women. Nonmarital fertility in the USA has also increased substantially among women over age 19. In 1970, one-half of all nonmarital births were to teenage women, but by the early 1990s, nonmarital births to women aged 20 and older accounted for more than two-thirds of all nonmarital births. These period trends have been accompanied by marked declines in the likelihood of marriage following a nonmarital first birth, with some attributing this decline in marriage to changes in men's economic circumstances and others to period change in both men's and women's economic circumstances.

Nonmarital fertility in the USA continues to exhibit striking differentials by race and ethnicity. In 1998,

slightly more than one in four white births (26.3 percent) were nonmarital, while nearly seven in ten black births (69.0 percent) were nonmarital. These differences also extend to births in cohabiting unions. Births to cohabiting white women rose sharply in the last two decades of the twentieth century, accounting for virtually all of the observed increases in white nonmarital fertility (Bumpass and Lu 2000). By contrast, births to cohabiting black women accounted for a far smaller proportion of nonmarital black births. Fewer than one out of five of recent nonmarital births occurred to cohabiting black women and, over time, births within cohabiting unions have constituted a declining fraction of nonmarital births to black women (Wu et al. 2001).

Nonmarital fertility in the USA and Europe differs in several important respects. The overlap between teenage and nonmarital fertility, characteristic of the USA, is largely absent in the European context. In addition, births within cohabiting unions constitute a far larger fraction of European than of US nonmarital births. Fewer than half of US nonmarital births are to parents cohabiting at the time of the birth (Wu et al. 2001), whereas the overwhelming proportion of nonmarital births in Europe are to cohabiting couples (Kiernan 2001). As a result, recent cohorts of US children are likely to spend more years, on average, growing up without a father present in the child's household than are their European counterparts.

One might expect that the decoupling of both sexual activity and childbearing from marriage and the accompanying erosion of norms proscribing nonmarital fertility would imply that nonmarital fertility has increasingly diffused beyond poor and disadvantaged populations to the non-poor and more highly educated segments of society. The available empirical evidence is in fact quite mixed on this point. On the one hand, the prevalence of cohabiting births in Europe, particularly Scandinavia, has been interpreted by some as consistent with this view. On the other hand, the expected diffusion is difficult to detect in the USA and Great Britain, where nonmarital fertility continues to occur predominantly among those with the least education and where there is accumulating evidence of diverging trends in the sociodemographic characteristics of married and unmarried mothers (see, e.g., Wu et al. 2001, Haveman et al. 2001).

3. Functionalist, Historical, and Policy Literatures

The distinction between social and biological parenthood implicit in the discussion of measurement of nonmarital fertility was an explicit emphasis of early functionalist authors in anthropology and sociology. A classic statement is Malinowski's:

The most important moral and legal rule concerning the physiological state of kinship is that no child should be

brought into the world without a man—and one man at that—assuming the role of sociological father, that is guardian and protector, the male link between the child and the rest of the community. I think that this generalization amounts to a universal sociological law, and as such I have called it ... *The Principle of Legitimacy*. (Malinowski 1930, pp. 137–8)

Accumulating empirical evidence of violations of this principle led Goode (1960) to argue that it was more likely to be followed or enforced when fathers were high in status, as when a father possessed substantial income or assets, or when his stake in the child was high.

By contrast, historians have typically regarded nonmarital fertility as a rough empirical proxy for premarital or illicit sexual activity, although many historians have also emphasized the ebbs and flows in both the incidence of ‘bastardy’ in different historical periods and the tenuous connection between levels of nonmarital fertility and the intensity of social or moral disapproval. Moreover, while public and moral authorities often reacted to nonmarital childbearing as concrete evidence of fornication and adultery, real concern appears to have often centered on the financial burdens posed to the community by children born out of wedlock. Wells (1979), in particular, concludes that local authorities in colonial America were by and large ‘unwilling to punish children for the sins of their parents,’ noting, for example, that ‘both William Franklin, the last royal governor of New Jersey, and Alexander Hamilton were able to achieve political eminence ... despite the fact that their parents were not legally married.’

The question of whether the sins of parents should be visited on children remains highly relevant to contemporary policy debates. A continuing policy dilemma is that social and economic resources directed to children born outside marriage also in effect provide assistance to parents—it is often difficult to target social policies and provisions in ways that benefit children but not parents. This concern has been less evident among policy-makers in Europe, with many European nations having had a longer and more generous tradition of social welfare provisions. It has, however, played a central role in US policy debates, where concern that welfare programs such as Aid to Families with Dependent Children (AFDC) may have had the unintended consequence of increasing nonmarital births was a key factor in the dismantling of these programs in favor of those intended to discourage nonmarital childbearing.

The specific issue of whether more generous AFDC benefits have produced increases in nonmarital births in the USA has spawned an extensive research literature. The available evidence, constructed largely from cross-sectional US data (see Moffitt (1998) for a review), finds support for such an association, with most researchers finding that this association is small in magnitude. However, a persistent puzzle generated by these cross-sectional findings is that they appear

inconsistent with period trends in nonmarital births and welfare generosity, with nonmarital births increasing and the inflation-adjusted value of AFDC and other benefits falling between 1975 and 1995. One possibility is that there is in fact no real inconsistency between the time-series and cross-sectional evidence, in that falling AFDC benefits may have acted to reduce nonmarital births, but that other factors may have operated in the opposite direction to increase nonmarital births. Surprisingly little work has been done with respect to this issue, save for Moffitt (2001), who presents evidence in support of this possibility.

4. Socioeconomic Determinants

A consistent finding in the US literature (see, e.g., McLanahan and Sandefur 1994) is that the risk of a nonmarital first birth is associated with family structure, with the standard finding being that these risks are higher for women who resided in a single-mother family at some point during adolescence. This empirical association appears remarkably robust, for example, to adjustments for unmeasured factors shared by siblings or the tendency for women with nonmarital first births to have initiated sexual activity slightly earlier than other women.

A difficulty with many of these studies is their reliance on a ‘snapshot’ of family structure, typically measured at age 14 or 16, which makes problematic the interpretation of what exactly it is about family structure that may account for the higher observed risk of a nonmarital first birth. Somewhat surprisingly, evidence to date suggests no support for widespread expectations concerning the intergenerational transmission of nonmarital childbearing—that being born outside marriage raises the risk that a young woman will herself bear a child outside marriage (Wu and Martinson 1993, Wu 1996, Haveman et al. 2001). Instead, what appears to be transmitted across generations is the propensity to bear a child at an early age (Haveman et al. 2001). Another consistent finding is that low income and low educational attainments of parents appear substantially associated with premarital first birth risks (Haveman and Wolfe 1994, McLanahan and Sandefur 1994, Wu 1996, Ermisch 2001). Three studies (Wu and Martinson 1993, Haveman and Wolfe 1994, Wu 1996) found that turbulent family environments, in the form of repeated changes in family structure, are associated with higher risks of a premarital first birth.

5. Consequences for Women and Children

Nonmarital childbearing is commonly thought to carry adverse consequences, both for the women bearing the child and for the children born into such families. An early view capturing this sentiment (Campbell 1968) held that:

The girl who has an illegitimate child at the age of 16 suddenly has 90 percent of her life's script written for her. She will drop out of school; even if someone else in her family helps to take care of her baby, she will probably not be able to find a steady job that pays enough to provide for herself and her child; she may feel impelled to marry someone she might not otherwise have chosen. Her life choices are few, and most of them are bad.

Although this view remains highly influential in many respects, the research community has increasingly regarded it with some skepticism. For example, Furstenberg et al. (1987) reported substantial variability in the life-course outcomes for women who began childbearing while in their teenage years, many of whom had births while unmarried. These findings have caused many to question whether a woman's life script is in fact '90 percent written' as a consequence of teenage (and nonmarital) childbearing. Wu et al. (2001), using nationally representative US data, have documented similar variability for women with nonmarital births, suggesting that the results of Furstenberg et al. may also hold for more recent cohorts of women. Another basis for skepticism is the realization by researchers that previous studies may have overstated the magnitude of the negative effects of teenage childbearing. Indeed, a considerable controversy has arisen over whether teenage childbearing might be held to have any causal relationship to the later social and economic disadvantages observed for teenage mothers (Geronimus and Korenman 1993, Hoffman et al. 1993a, 1993b).

Although a large empirical literature has examined outcomes for children who resided at some point with a single parent, this literature rarely distinguishes between whether such families were formed through divorce or nonmarital fertility. Thus, surprisingly little is known concerning outcomes for children born to unmarried mothers, aside from the fact that these children are substantially more likely to grow up in poverty. As noted above, several studies have found no empirical evidence in support of the transmission of nonmarital childbearing across generations. Korenman et al. (2001) found that the higher prevalence of unintended births among unmarried mothers relative to married mothers appears to account for little of the observed differential in parenting behaviors, infant health, or child development between marital and nonmarital births. Haveman et al. (2001) have found that children born to unmarried mothers are significantly less likely to complete high school than children born to married parents.

Even less is known about the consequences of being born to cohabiting parents. Empirical studies of Great Britain and the USA (Ermisch 2001, Wu et al. 2001) have found that children born within a cohabiting union are more than twice as likely to experience the loss of a parent—most typically the father—through the dissolution of their parent's cohabiting or marital union as children born within marital unions, but this

instability appears far less true in the continental European context (Kiernan 2001). As a result, it is difficult to know whether outcomes for children born within a cohabiting union would more closely resemble those of children born to single mothers or married parents. It is also worth emphasizing that what is observed—the presence or absence of a marital or cohabiting union—is but a crude proxy for the economic, social, and emotional commitments of the parents to the child, commitments which may, in turn, vary substantially over time.

6. Conceptual and Theoretical Challenges

Unlike empirical research, theoretical work to date has taken seriously the 'two-sex' nature of nonmarital fertility—for example, how nonmarital fertility might respond to both men's and women's characteristics. Notable examples include Wilson's (1987) argument concerning a dearth of 'marriageable' males in the US black community and Willis' economic models of nonmarital fertility (Willis and Haaga 1996, Willis 1999), in which different distributions in the relative wages of men and women may produce behavioral equilibria in which men move from a pattern of high to low paternal investment in the children they father. Neal (2000) has proposed a model in which the prevalence of nonmarital fertility can vary substantially if the choice set for women is expanded to consist not only of giving birth within or outside marriage, as assumed by both Wilson and Willis, but also of the option of foregoing a birth entirely.

The study of nonmarital fertility poses other unusual challenges for both theoretical and empirical researchers. One is that nonmarital fertility lies at the intersection of several joint (and potentially endogenous) processes by which families are formed—childbearing, marriage, and, increasingly, the formation of cohabiting unions. Many researchers have only begun to grapple with the additional analytic issues that arise when including cohabitation in their behavioral and statistical models. A second challenge concerns the likely life-course dynamics underlying nonmarital fertility. Advancing knowledge is complicated by the fact that many key aspects relevant to this process are typically unobserved by the researcher, including the timing of initial (and ensuing frequency) of sexual activity and how the resolution of a nonmarital pregnancy is weighed by the woman and by other relevant actors. A final challenge is that recent trends in nonmarital fertility may well reflect an evolving response by individuals to fundamental changes in the long-term contract represented by marriage, a contract that has itself changed in response to other social forces, including the nearly universal levels of sexual activity prior to marriage, the increasingly widespread diffusion of cohabitation, changes in the nature and levels of labor force participation of men and women,

and continuing high levels of divorce and union instability.

Fertility: Political and Political-Economic Perspectives

Since the rise of modern demography in the early twentieth century, fertility has largely been the province of demographic research. In the 1980s other fields—in particular anthropology, but also gender studies, social history, and cultural studies—began to take an active interest in childbearing as sociocultural and political-economic process. Concerned less with the numbers of children born than with the macro- and microlevel dynamics surrounding the reproduction of families, societies, and politics, these perspectives have flourished along the borders between sociocultural anthropology, population studies, gender studies, and cultural studies of science and technology. This article traces the development of three of the most vigorous streams of such research: the culture and political economy of fertility, the politics of reproduction, and Foucauldian perspectives on 'population.' Although these fields of research are multidisciplinary, because anthropologists have been at the forefront of these intellectual developments, and because of limitations of space and knowledge, this

article emphasizes anthropological work, especially that of US-based scholars.

These three perspectives are rooted in different sets of substantive concerns and theoretical preoccupations. This article describes each analytic framework in turn, tracing its intellectual and political sources, its analytic agenda and research concerns, and its status at the end of the twentieth century. It then turns to some of the methodological, ethical, and political dilemmas faced by scholars conducting research on reproductive politics and political economy. Whereas conventional research places social and economic forces at the heart of fertility change, the perspectives reviewed here emphasize instead the political, political-economic, cultural, and linguistic or discursive dimensions of reproductive transformation. With their political and cultural interests, qualitative research methodologies, and concern about researcher reflexivity, these perspectives do not so much supplant as supplement the more conventional quantitative research of demography. Their emergence on the intellectual scene in the 1980s and 1990s marks a significant broadening of interest in reproduction across the human sciences. As anthropologists and other students of social life have turned their attention to reproduction, the study of fertility has grown in theoretical sophistication. At the same time, human reproduction, long peripheral to theory in the human sciences, has assumed a more central place in social, cultural, and political theory. The appearance of these fresh ways of understanding human fertility may turn out to be one of the more exciting developments in social theory in the late twentieth century.

1. The Culture and Political Economy of Fertility

The first of these broadly political perspectives, the culture and political economy of fertility, grew out of the dissatisfaction of anthropologists in the mid- to late 1980s with conventional demographic approaches to fertility. A highly quantitative social science, demography has relied on relatively simple theoretical formulations to guide its research. The field's main contribution to theorizing about fertility, demographic transition theory, posits a universal fertility 'transition,' or decline from high to low levels of childbearing, that follows urbanization, industrialization, the spread of education, and the fall in infant mortality associated with the worldwide process of 'modernization.' These changes are thought to alter the economics of childbearing, lowering desired family size. Developed in the mid-1940s, demographic transition theory was part of the larger body of modernization theory that dominated social science research on Asia, Africa, and Latin America for roughly the first 25 years after World War II. In the 1970s, the consensus surrounding transition theory began to

erode; by the early 1990s it was no longer an area of active theory building. What undermined faith in transition theory was the massive European Fertility Project, which failed to show the expected connections between the theory's socioeconomic variables and the historic decline in European fertility. The only 'variable' consistently related to fertility was culture, defined operationally as language, ethnicity, or geographical region. Accordingly, in the 1980s and 1990s, demographers increasingly turned their attention to 'culture,' understood primarily as ideational change, more specifically, diffusion of new ideas about the acceptability of modern contraception.

As the disciplinary experts on 'culture,' anthropologists were invited to join the search for the forces underlying fertility change. Yet anthropological notions of culture were embedded in disciplinary traditions that rooted individual behaviors such as childbearing in larger-scale structures and processes ranging from family economy and community, kin and class relations all the way to global processes such as the historic spread of capitalism and, today, the transnationalization of cultural, social, and economic life. Out of one such tradition, anthropological political economy, known now as the anthropology of globalism, emerged a culture and political economy of fertility that sought to broaden, politicize, and historicize research on childbearing across space and time. This body of work traces its intellectual lineage to Marxian models of global capitalism that emerged as critiques of modernization theory in the 1960s and 1970s, namely, dependency theory, world-systems theory, and the anthropological political economy of Eric R. Wolf. More recently, this perspective has drawn inspiration from theories of disorganized capitalism and flexible accumulation advanced by critical geographers such as David Harvey, as well as work on transnationalism by anthropologists such as Ulf Hannerz and Arjun Appadurai.

From the vantage point of these larger global political economies of social life, demographic research on fertility carves out too narrow and too micro a slice of social organization. It also underestimates the importance of power and politics, employs a relatively static notion of culture, has difficulty capturing human agency, and takes too unilinear, evolutionary, and progressivist a view of history. Demographic work also tends to adopt a Eurocentric stance according to which fertility transition is caused by and in turn causes further Westernization and reproductive Westernization is beneficial for all. Underlying these latter notions is the problematic assumption that Europe and its offshoots are superior to the rest of the world and the source of all significant change.

A culture and political economy of fertility takes as its object the location of reproductive subjects at the conjuncture of historically developed local, regional, national, transnational, and global processes. It directs attention to the embeddedness of community inst-

institutions shaping fertility in structures and processes operating at supracommunity levels, and to the historical roots of those macro-micro linkages. Students of the culture and political economy of fertility read demographic history as saying there are many reproductive transformations, each driven by a combination of forces that are to some extent institutionally, culturally, and temporally specific. Accordingly, they focus on specific transformations in different parts of the world, using generalizations derived from case studies as the building blocks of general theory. Aiming to create 'whole demographics' of particular sites, they attend to political and economic as well as social and cultural forces underlying reproductive change, stressing the interrelations among these. Emphasizing the political negotiation of all aspects of social life, the culture and political economy of reproduction places gender, class, race, and other forms of inequality at the heart of reproductive dynamics. It views culture as a cluster of negotiated meanings and motivations that, taken together, form larger cultural logics that shape reproductive aspirations and practices. In this perspective people are seen as active agents of their own reproduction, who ongoingly and often strategically tinker with biology in what Caroline Bledsoe (1990) calls the 'social construction of demographic reality.'

The social constructedness of reproductive outcomes illuminates the limitations of the biological notion, 'fertility,' though students of reproductive political economy generally continue to use the term because it facilitates communication with other population specialists. In the culture and political economy of fertility, history is indeterminate and contingent because it is actively constructed by situated actors. People everywhere are seen as part of an interconnected world in which non-Euro-Americans actively shape not only their own childbearing, but also the reproductive dynamics of the world at large. Clearly, the implied research agenda of such a perspective is very large. It includes such topics as the reproductive impact of the extension of capitalist relations of production, the rise of states interested in counting, surveilling, and policing their families, and the spread of family planning institutions and ideologies to the most remote corners of the third world.

While a great many authors incorporate political-economic insights into their work, the most explicit theoretical statements of the political-economic embedding of reproductive practices can be found in Greenhalgh (1990), contributions in Greenhalgh (1995), and Schneider and Schneider (1996). Exemplary book-length case studies include Kligman (1998) on political demography and the medicalization of reproductive repression in Ceausescu's Romania; Schneider and Schneider (1996) on the capitalist-driven, class-specific reproductive transitions of Sicily; Jeffery and Jeffery (1997) on the classed and gendered political economy of reproduction in rural India;

Inhorn (1994) on the devastating consequences of infertility for Egyptian women; and Kertzer and Hogan (1989), and Kertzer (1993) on the economics and church and state politics of infant abandonment and family change in Italy.

With its global reach and historical stretch, the culture and political economy of fertility presents a vast array of important research problems, few of which have yet been resolved for any time and place. In the early 1990s, however, as anthropologists working on demographic topics began to link up with those working on the political dynamics of reproduction, this field of research began to lose its distinct character and merge with other, more political, feminist, and poststructuralist (or Foucauldian) perspectives on population.

2. The Politics of Reproduction

A second stream of innovative research, the politics of reproduction, coalesced into an identifiable body of work in the early 1990s. A product of the encounter between the social sciences and post-1960s feminism, with its critical views of the reproductive status quo, this work takes issue with the biomedicalization of reproduction in the industrialized world, and with the ideologies and practices of population control in the third world, both of which treat women as objects of control rather than subjects or active agents of their own reproductive lives. The politics of reproduction is not only an intellectual field of activity, although many of its participants are university based. It is better described as a scholar-activist movement aimed at transforming the politics of reproduction in a way that places control over whether, when, and how to have children in the hands of women themselves. The development and internationalization of this feminist project on reproduction were greatly stimulated by the events surrounding the United Nations International Conference on Population and Development (ICPD) held in Cairo in 1994. At that meeting women's health advocates gained significant influence over international population policy, transforming its agenda from one based on demographic concerns with population numbers to one focused on health and equity concerns with women's sexual and reproductive well-being and rights. Work on reproductive politics, then, is rooted in both intellectual and political developments.

Two relatively distinct clusters of research on reproductive politics can be distinguished: multidisciplinary critiques of international population control activities and broadly anthropological analyses of the local/global dynamics of reproductive practices, policies, and politics. The multidisciplinary critique of international population policy combines broadly neo-Marxian concerns with contemporary capitalism and class relations with feminist concerns

with the consequences of large-scale political and economic developments for poor women. Perceiving shared political and economic interests linking transnational pharmaceutical corporations, the international population control establishment, and third world population policymakers, this view holds that the top-down, technocratic, too often high-pressured interventions of third world family planning programs sacrifice women's health and safety in the name of a neo-Malthusian ideology that wrongly blames third world poverty on population growth. The ideology of population control, it suggests, obscures the true cause of growing poverty and inequality in the world. The real source of these problems is not population growth, but the post-1973 global spread of neoliberal capitalism, with the attendant privatization of state sectors of the economy and retreat of the state from support for social programs.

Some writers believe that new, post-Cairo policies have appropriated the feminist language of ICPD to advance a newly antifeminist population agenda. Whatever their position on current policy, these writers agree that the only effective solutions to these problems are to empower women economically, install popular-based health care systems that give women a voice in their own health care, and guarantee women's sexual and reproductive rights as human rights. Important statements of these critiques and proposals are, from a southern feminist perspective, Correa (1994); US-based feminist angles, Dixon-Mueller (1993) and Hartmann (1995); and, a neo-Marxist feminist approach, Bandarage (1997). Petchesky and Judd (1998) illuminate the diverse understandings of sexual and reproductive rights held by grassroots women around the world, crucial information to guide the transformation of international population policy into policies guaranteeing women's sexual and reproductive rights.

The anthropological work steps back from these charged policy debates to reflect on the complex intersections of global-to-local politics of reproduction in different cultural settings. Scholars working in this vein are interested less in the number of children women have than in the dynamics by which child-bearing is negotiated by actors situated differently in hierarchies of gender, class, race, sexuality, and so forth. Starting with Friedrich Engels' insight about the mutual determination of reproduction and production, this work draws on the social anthropology of kinship, marriage, and parenting, adding to it a new interest in women's agency in negotiating the contradictory forces shaping their reproductive lives. Viewing reproduction as an aspect of the distribution of power in interconnected local and global arenas, this perspective pays particular attention to ways people use local cultural logics and social relations to incorporate, revise, resist, and sometimes even reshape larger-scale processes. Its aim is to produce accounts of reproductive politics that are culturally grounded,

ethnographically nuanced, and theoretically multi-layered. Key problems for research include the stratified nature of reproduction, in which certain ethnic, class, gender, sexual, and national categories of people are empowered to reproduce and nurture while others are not; the micropolitics attending the spread of Western biomedicine and its reproductive technologies worldwide; and new cultural understandings of kinship and social life that are produced as people imagine and enact the creation of the next generation. Important theoretical statements and broad-based collections on reproductive politics include Ginsburg and Rapp (1991, 1995) and Franklin and Ragone (1998). Recent case studies include Rapp's (1999) study of prenatal testing in the US, Franklin's (1997) account of assisted conception technologies in Britain, and Strathern's (1992) reflections on the implications for English kinship of the new reproductive technologies.

At the end of the twentieth century, the politics of reproduction was a burgeoning field of research activity. As new technologies for 'perfecting' reproduction continue to proliferate and spread around the world, and the politics of Cairo work themselves out in diverse transnational and southern settings, scholarly-activist interest in the gendered, raced, classed, and north-south politics of reproduction can only be expected to grow.

3. Foucauldian Perspectives on 'Population'

Emerging in the mid- to late 1990s, a third stream of political research reflects the extraordinary influence of the French 'poststructuralist' philosopher and social critic, Michel Foucault, on the human sciences in general and anthropology in particular. Foucault's writing have left their mark on both of the above perspectives, but in the work discussed here his voice is more pervasive, shaping not only some of the terms of discourse, but the central problems addressed. Given limitations of space, this article covers only a few of his most provocative ideas on the interlacing of power and population.

In *Discipline and Punish, History of Sexuality*, and other works, Foucault (1978, 1979) identified a new, modern form of power, biopower, which takes as its object life itself. Biopower operates by constituting its objects of knowledge, to which it then responds with the development of new knowledges, technologies, and arts of government. Far from being 'neutral' and power-free, the biological, medical, and social sciences are seen as parts of the apparatus of modern power. Through their scientific discourses, analytic categories, and intellectual practices, the natural and human sciences help to construct 'fertility,' 'the body,' 'population,' and 'the social,' in the process subjecting people to new, distinctly modern forms of power that affect how they constitute themselves as subjects.

Given the sciences' close relationships with bureaucratic states in most settings, scientific knowledges of reproduction have often served the political objectives of regimes in promoting such goals as socioeconomic modernity, eugenic purity, and national power. In Foucault's view, modern power is embodied in discourses and practices that are not concentrated in any institution, such as the state or medical establishment, but widely dispersed throughout the social system. Yet hegemony is never complete, for 'where there is power, there is resistance,' leading to unstable configurations of power that are always open to contestation. Even this brief review of some Foucauldian concepts makes clear that Foucault's ideas unsettle the received terms of debates over reproduction. Among other things, they make language a central focus of analysis, redefine power, problematize the categories in which reproduction is understood, and turn the sciences, long thought to be beyond politics, into objects of political study in their own right.

Anthropologists and other students of reproduction have taken Foucault's broad, Eurocentric ideas, grounded them historically and culturally, and given the human subject of biopower more agency as a political actor. In the 1990s, two interrelated programs of research on reproduction have emerged, one focusing on the individual body, the other on the social body, or population as a whole. These are the two poles around which biopower is said to operate. Foucauldian work on the individual reproductive body focuses largely on the discourses and practices of biomedicine, which 'medicalizes' ever more phases of the female reproductive life cycle, turning what were once 'normal' aspects of procreation into 'abnormal' medical conditions, which it then proceeds to treat. Viewing the female body as a site of biomedical domination and resistance, researchers have explored the medicalization of pregnancy, childbirth, and menopause, and the accommodations and subversions of women for whom medical interventions are simultaneously seductive and dangerous. Key collections of anthropological work on such issues are Lock and Kaufert (1998), which examines the 'microphysics of power' and its operation in everyday life, and Davis-Floyd and Sargent (1997), which traces how authoritative knowledge about childbirth is produced, displayed, resisted, and challenged in different social, political, and clinical contexts.

While the anthropological research tends to work in the present and from the bottom up, focusing on the daily encounters between ordinary subjects and the agents of reproductive power, it exists in productive conversation with research in cultural studies of technoscience. The technoscience studies more often work historically and from the top down, tracing the development of the biological life sciences and their construction of the discourses, practices, and technologies over which contemporary reproductive contests are waged. Two exemplary studies of this sort are

Oudshoorn's (1994) account of endocrinology and the hormonally constructed, sex-differentiated body, and Clarke's (1998) history of the scientific study of reproduction in biology, medicine, and agriculture, which resulted in the technoscientific production of modern means of contraception.

Foucauldian work on the population as a whole focuses on the role of demography, sociology, social work, social hygiene, urban planning, and other fields in constituting inappropriate ('too high' or 'too low') fertility as a 'social problem.' Working in and with state bureaucracies, these fields first identify fertility as an object of knowledge and management, and then foster the creation of new social technologies—the census, the social survey, the urban plan, the family planning program—designed to manage it at the level of the reproductive body, the home, the family, the city, and the nation-state. A relatively new research topic, the disciplinary and bureaucratic production of 'population' has so far yielded one major monograph, Horn's (1994) study of modernity and social reproduction in 1920s and 1930s Italy. Yet the Foucauldian notion of 'population' is an exciting and important construct that is certain to produce more such studies in the years ahead.

While these three political and political-economic perspectives grew out of different sets of intellectual and political concerns, by the late 1990s, as population had moved closer to the center of social theory, the lines between them, always thinly drawn, had begun to fade and disappear. This blurring of boundaries can be expected to continue into the future, giving rise to a broad politics of reproduction and population that is multilevel in scope, multidisciplinary in approach, and politically engaged in the policy implications of the research.

4. Methodological Issues; Ethical and Political Dilemmas

With their interests in the political and cultural dimensions of reproduction, these perspectives require research methods that are more akin to those of anthropology than of demography. Conventional demographic research relies on the social and demographic survey, aimed at reducing sociodemographic behavior to a series of discrete, measurable variables whose relationships can be mathematically modeled. Such research produces knowledge that, although empirically useful, is thin and undercontextualized, individual in level, and collected in categories developed by the analyst. Led by John Caldwell, since the 1970s a small but growing number of demographers have recognized the shortcomings of survey methods for gathering nuanced data on multiple levels of social reality. In place of large-scale surveys, they have turned to 'microdemographic' research in the field. While microdemographic fieldwork marks an impor-

tant departure from the survey method, such fieldwork is usually short in duration, often conducted through translators, and rarely informed by cultural and political theories of the sort discussed above.

In contrast to these demographic approaches, anthropological work on political and cultural process entails what Tom Fricke (1997) calls 'thick, cultural demography.' In thick demography, or reproductively thick ethnography, the ethnographic ear of the anthropologist is coupled with the textual eye of the cultural analyst and the documentary eye of the historian, and all are informed by in-depth knowledge of the language, culture, history, and social relations of the area studied. Thick reproductive ethnography is based on long-term ethnographic fieldwork in one or a small number of locales. Such fieldwork generally involves the use of a variety of specific methods: participant observation; small-scale censuses and/or surveys; structured and semistructured interviews; the gathering of life histories, textual materials, and so forth. The forces of interest are interconnected processes that exist on multiple levels of social reality: social, institutional, cultural. These processes are embedded in local systems of meaning and are negotiated by local actors differently placed with regard to class, clan, and other systems of social inequality. Concerned with gathering local knowledge in culturally relevant categories, the research aims to 'situate fertility,' that is, to show how it makes sense given the historically developed sociocultural and political-economic context in which it is embedded (Greenhalgh 1995). Situating fertility is an interpretive task well accomplished through narrative modes of explanation. Such forms of explanation offer 'readings' of cultural texts, oral expressions, or social situations that give coherence to something that was poorly understood.

Students of reproductive politics and culture are especially concerned with promoting self-reflexivity in their work. By self-reflexivity is meant explicit attention to the politics of one's own research practices. Attention to one's own politics entails recognition by the researcher that, despite every effort to be objective, the social scientist inevitably is a political actor whose scholarly representations have the power to create a reproductive 'other' (often 'traditional,' non-Western, high fertility) who is different from, and somehow less than, one's (scientific, Western, low fertility) self. This recognition is based not only on critiques of objectivity in science and social science generally, but also on critical studies of actual reproductive research. Two such studies have been particularly influential. Mahmood Mamdani's (1972) early account of the Khanna birth control study in northern India suggests that the scientific apparatus underlying the large-scale promotion of family planning may be based on village research that is marked by profound misunderstanding of village life on the part of foreign researchers and deliberate fabrication of lies on the part of

bemused yet polite villagers. Mamdani found that demographic research of the sort conducted in Khanna strips facts of their social context, producing analytic results and policy suggestions that contradict the vital interests of local people. Agnes Riedmann's (1993) more recent and theoretically motivated study of demographic fieldwork among the Yoruba of Nigeria reveals the exercise of power at all stages of demographic research, from gaining entree to the study population to deciding on the questions to be asked, negotiating the interview process, analyzing the data gathered, and writing up the research results. Funded by first-world donors, Reidmann argues, 'world-system demography' serves first-world interests of prediction and control, while neglecting the concerns of third-world study populations and willfully disrupting traditional cultures and societies. In short, population research serves as a tool for cultural imperialism in which Western values of family and fertility are aggressively imposed on third-world study populations, legitimizing the purposeful limitation of family size. While these arguments misread the motivations of first-world researchers and understate the agency and resistance of third-world study populations, what cannot be gainsaid is that the stakes involved in fertility research are very high, and that research *sans* reflexivity involves a risk that the research itself may exacerbate inequality in the name of enhancing welfare.

Research like this generates suspicions about the power relations embodied in the numbers demographers use. In response to such concerns, some have called for a 'demography beyond, or even without, numbers.' In place of number collection, Nancy Scheper-Hughes (1997) proposes a critical interpretive methodology that ongoingly questions the neutrality of the research process, ponders the multiple and contradictory meanings that attach to the 'facts,' and recognizes the partiality of all truths—biomedical, demographic, and anthropological. Other students of reproductive culture and politics believe that numbers are useful and important—after all, they point out, without numbers one has no measure of the levels and trends of fertility, the subject of primary interest. Yet even the most vocal advocates of quantification insist that the numbers be gathered in a culturally sensitive manner and used in ways that are sensitive to the political implications of population research.

Closely related to these political problems are ethical dilemmas that attend research on such intimate topics as reproductive politics and culture. Ironically, in some ways the ethnographic methods that are preferred by scholars in these fields are more exploitative than the positivistic methods of survey research, for the ethnographer intrudes deep into his or her informants' private lives, leaving them vulnerable first to exposure and later to misinterpretation or even distortion of their viewpoints. The dilemma is that the more sensitive the method, the greater the ethical risk

of exploitation of researched by researcher. While there are no easy solutions to this dilemma, researchers can at least strive for ethical accountability by acknowledging that their own knowledge is both partial and positioned—that is, influenced by their social locations of class, gender, race, sexuality, nationality, and so forth. In research that spans difference—national, racial, class, and so forth—researchers can employ collective decision making about procedures, and commit themselves to give something back to the community in which they work. Petchesky and Judd (1998) describe an exemplary project of this sort. Finally, at the point that research becomes the basis for policymaking or other forms of political action, they can engage in a politics of coalition and affinity, in which apparently incompatible elements join together to promote a shared cause. Given the policy and programmatic consequences of reproductive research, ongoing reflexivity about its politics and ethics is of great importance. These issues have been worked and reworked with particular care in Brazil, where scholar-activists attentive to the political and cultural dimensions of reproduction have been unusually active in the formulation of population policy (Pitanguy 1994, Barroso and Correa 1995). Students of reproduction everywhere have much to learn from them.

S. Greenhalgh

Fertility: Proximate Determinants

1. Background

Fertility in human populations is determined by a broad variety of factors. Specifying the relative importance among them as well as understanding the mechanisms through which they affect fertility long eluded scientists. Davis and Blake (1956) brought about an invaluable advancement by creating a conceptual analytical framework which distinguishes 'intermediate' (direct) from social, economic, political, environmental, and other (indirect) fertility determinants (see *Fertility: Political and Political-Economic Perspectives*; *Demographic Measurement: General Issues and Measures of Fertility*; *Fertility Transition: Cultural Explanations*; *Fertility Transition: Economic Explanations*; *Fertility Transition: China*; *Fertility Transition: East Asia*; *Fertility Transition: Southeast Asia*). The principal revelation was twofold. The distinction between the two types of determinants and the penetrating insight that societal factors affecting fertility can operate only indirectly through the intermediate or proximate determinants, which directly modify fertility by affecting conception, gestation, and successful parturition. In other words, social, economic, and cultural circumstances affect human behavior regarding patterns of entering into and remaining in or exiting from stable sexual unions, and practicing breast-feeding, contraception, or induced abortion. It is this behavior which produces the level of fertility and its changes generate fertility trends.

Further crucial advancements were achieved two decades later. Bongaarts (1978, 1982)

(a) identified a simplified set of proximate fertility determinants (seven rather than eleven);

(b) established which of these are central in creating fertility differentials and trends (four out of the seven); and

(c) devised formulas to measure these factors from generally available data, and how to quantify their respective impact on fertility levels and trends in a comprehensive reasonably simple model.

The direct relationship between the proximate determinants and fertility is embodied in the fact that

the direction of change of fertility is given by the direction of change of the respective proximate determinant. If, for instance, breast-feeding declines, fertility increases. An increase in contraceptive prevalence or the practice of induced abortion will engender a fertility decline. To generalize, if a proximate determinant changes then fertility necessarily changes also, and the change is in a predictable direction, provided the other proximate determinants remain constant. This is not true for an indirect determinant. An increase in educational attainment may lead to a decline in breast-feeding which in turn signifies increased fertility. A similar rise in education in another population may cause contraceptive prevalence to increase which in turn signifies a fertility decline. Also, both of these mechanisms may be operating simultaneously in which case they cancel each other out and fertility will not change. Detailed analyses are required to determine how changes in the social, economic, cultural, religious, and environmental circumstances affect proximate determinants so that their effect on fertility trends can be understood.

2. The Proximate Determinants

The proximate determinants can best be identified by examining the events that most immediately influence the duration of the reproductive period and the rate of childbearing within it. A more detailed discussion follows a brief overview.

The beginning and end of the reproductive period are biologically determined. The potential reproductive years start at menarche, the woman's first ovulation which reveals itself in the first menstruation. The childbearing years end with the cessation of ovulation, i.e., the onset of permanent sterility, which occurs before or at menopause. The effective reproductive period is equal to the time women spend in stable sexual unions, marriages, and consensual unions. Consequently, the level of fertility is dependent directly on the length of time women spend in stable sexual unions.

The next important circumstance shaping the level of fertility is the average number of children borne by women during their reproductive life span. It is inversely related to the length of the periods between births. Short periods between births imply high fertility, i.e., a relatively large number of children born per woman, and vice versa.

The period between births has several components. A birth is followed by postpartum infecundability, a fecundable or ovulatory period, and a subsequent pregnancy. The length of the postpartum infecundability interval after a birth during which a woman cannot conceive is determined mainly by the length and intensity of breast-feeding. This period lasts through the first postpartum ovulation which is at the same time the beginning of the fecundable interval,

also called the ovulatory interval or the waiting time to conception. The length of this period is determined by fecundability, the monthly probability of conception, by the monthly risk of conception in the absence of contraception, and by the effectiveness of any contraception practiced. Once conception takes place it can be followed by a full-term pregnancy of nine months, or by an incomplete pregnancy terminated by a spontaneous or induced intrauterine death. Postpartum infecundability after an intrauterine death tends to be much shorter than following a birth.

The overview of the reproductive process identifies the following proximate determinants:

- (a) The beginning and discontinuation of stable sexual unions, marriages, and consensual unions.
- (b) The onset of sterility.
- (c) Postpartum infecundability.
- (d) Fecundability.
- (e) Contraception.
- (f) Spontaneous intrauterine mortality.
- (g) Induced abortion.

2.1 The Beginning and Discontinuation of Stable Sexual Unions

Fertility is related directly to the duration of time a woman is exposed to conception, which basically is the period she is in a stable sexual union. A widespread form of such unions is formal marriage. In Latin America and the Caribbean, in parts of Africa and in the Nordic countries of Europe consensual unions have traditionally been common. In the second half of the twentieth century informal cohabitation is increasingly practiced throughout Europe and other developed countries. Occasional sexual encounters can also have an effect on fertility, but this tends to be small. The average age of union formation varies considerably. Traditionally it has been relatively early with the exception of most European countries. There the mean age of marriage was often about 25, whereas elsewhere it was frequently around 17. In recent decades of rapid social change the mean age of marriage has been increasing almost everywhere, including the developing countries. The considerable postponement of marriage taking place in many developing countries is an important factor in lowering fertility. Trends in the formation of consensual unions may have been similar, however, data to confirm this assumption worldwide are lacking.

Proportions of women who never marry differ among populations. Such women were rare in traditional societies, whereas in the developed countries their proportions have at times been 10 percent or more.

Widowhood is an important factor modifying fertility as long as mortality is high and women bear children late in their reproductive period. With declining mortality only small proportions of women

lose their spouses before the end of the childbearing period.

In recent decades divorce rates have been increasing, mainly in many developed countries. The impact of this trend on fertility has been insignificant as remarriage is frequent.

2.2 The Onset of Sterility

The average age of menopause is around 50. Effective sterility starts several years earlier due to irregular ovulation among many aging women and the higher risk of spontaneous intrauterine death with increasing age. A certain increased sterility of spouses has an additional effect of lowering the age of couple sterility. An average age of last birth around 40 in societies not practicing contraception confirms the assumption that combined sterility sets in when women are in their lower forties.

2.3 Postpartum Infecundability

Breast-feeding is nature's contraceptive. The mother provides the infant with food and protection and the process of suckling acts as a contraceptive for the mother. In some known contemporary hunter-gatherer societies, infants are constantly with their mothers and can suckle up to several times an hour. Here births tend to be spaced four years apart without the use of any contraception. Suckling on the nipple produces nervous impulses which pass from the breast to the brain thus inhibiting the release of hormones responsible for ovulation from the pituitary gland (see Potts and Short 1999 and *Fertility Control: Prevalence and Consequences of Breastfeeding*). In the absence of breast-feeding menses return shortly after birth, on average after 1.5–2 months. In developed countries periods of exclusive breast-feeding have been reduced to only a few months. In developing countries profound changes are also underway, but the postpartum infecundability period may still be considerable. The longest average duration documented by a national survey was in Bangladesh in 1975, namely 18.6 months.

2.4 Fecundability

The monthly probability of conception, fecundability, is at most 0.15–0.25 among newlyweds and declines with increasing age and duration of marriage. It is this low because fertilization can occur only during about two days around the time of ovulation in the middle of the menstrual cycle. In addition some cycles are anovulatory and a substantial proportion of fertilized eggs fail to implant or are aborted spontaneously during the first two weeks after fertilization. Typical

delays to conception range from five to ten months. It is assumed that there are no significant differences between populations in this respect. The overall effect of involuntary sterility tends to be minor and significant variations between populations are the exception.

2.5 Contraception

Contraception is arguably the main factor modifying fertility in contemporary societies. There have been exceptions in eastern Europe where for some periods of time the practice of induced abortion was extremely high and thus more important in inhibiting fertility. In a few developing countries the use of contraception is still low, but practically everywhere it has been growing. During the second half of the twentieth century the unprecedented increase in the use of contraceptives and the availability of new modern more effective contraceptives have led to the perception that a 'contraceptive revolution' has taken place (see Westoff and Ryder 1977).

The effectiveness of contraception is measured as the percentage reduction in fecundability. For instance, a contraceptive with a 95 percent effectiveness used by women with a 0.2 fecundability will yield a 0.01 monthly probability of conception. Actual contraceptive effectiveness of a method depends primarily on the extent to which it is used as prescribed. Improper use results in contraceptive failure. The effectiveness of modern methods, such as oral contraceptives and intrauterine devices, is more than 95 percent in developed countries and that of conventional methods, such as the condom, diaphragm, or spermicides, about 90 percent. Depending on the knowledge and motivation of the average user, those levels tend to be lower in developing countries. In a number of countries female and/or male sterilization is popular and is 100 percent effective. The mix of methods used differs very much from one country to another.

2.6 Spontaneous Intrauterine Mortality

While there is no doubt that many conceptions are spontaneously aborted, it has proven difficult to estimate the magnitude of this factor. Not only retrospectively but even for women in prospective studies it is very difficult to accurately determine and report intrauterine deaths in the early stages of pregnancy. Carefully designed studies have provided estimates of 20 percent of conceptions not resulting in live births with half of these occurring before the third month of pregnancy. It is known that the rate of intrauterine mortality is the lowest in the middle of the reproductive period. Differences between societies appear to be insignificant, except with regard to stillbirths, defined as intrauterine deaths after the twenty-eighth week of pregnancy. These occur more frequently in some poor countries, 4 percent of conceptions compared with 1 percent in developed countries, presumably due to health and environmental factors.

2.7 Induced Abortions

Induced abortions have been practiced in every society and usually play a meaningful role in some stage of a country's fertility transition. The incidence depends mainly on motivation to restrict childbearing, the availability and use of contraception, and to some extent on the legal status of induced abortion (see *Demographic Techniques: Family Reconstitution*). The practice of induced abortion was exceptionally widespread in some countries of eastern Europe in the second half of the twentieth century where they were legalized earlier than elsewhere and where access to contraceptives, especially modern ones, was restricted. Around 1990 in Romania, for instance, three-quarters of all pregnancies were intentionally terminated. In contrast, the incidence was low in west European countries with easy access to modern contraceptives.

Table 1
Rating of proximate determinants with respect to sensitivity and variability among populations

Proximate determinants	Sensitivity of fertility to determinant	Variability among populations	Overall rating
1. The beginning and discontinuation of stable sexual unions, marriages, and consensual unions	+++	+++	+++
2. The onset of sterility	++	+	+
3. Postpartum infecundability	++	+++	+++
4. Fecundability	++	++	++
5. Contraception	+++	+++	+++
6. Spontaneous intrauterine mortality	+	+	+
7. Induced abortion	++	+++	+++

Source: Bongaarts (1982)

+++ = high; ++ = medium; + = low or absent.

During the second half of the twentieth century the number of countries with liberal induced abortion legislation was increasing steadily. By the end of the twentieth century over 60 percent of the world's population was living in such countries. In contrast, 25 percent resided in countries where induced abortions were generally prohibited. Almost all of the latter are developing countries, where induced abortions are performed frequently by unqualified personnel under unsanitary conditions and thus women's health is often seriously impaired.

3. The Relative Importance of Proximate Determinants

The joint effect of all the proximate variables determines fertility levels and trends. For the analysis of fertility differentials and trends only those determinants are meaningful whose effect differs in time and space. If large variations of a determinant have only a small effect on fertility trends and differentials, or if a determinant hardly varies among populations, its analysis will not yield useful scientific or policy relevant insights. Thus the selection of the analytically important factors depends on how sensitive fertility is with respect to a particular determinant and the variability of the determinant among populations. In Table 1 the proximate determinants are rated according to these criteria.

Abundant evidence confirms that fertility is the least sensitive to the risk of spontaneous intrauterine mortality and the most sensitive to time spent in sexual unions and contraception. Variability is the lowest for onset of sterility and the risk of spontaneous intrauterine mortality. Altogether, for the analysis of fertility levels and trends, the four most important proximate determinants are the time spent in stable sexual unions, postpartum infecundability, contraception, and induced abortion.

Fertility Theory: Caldwell's Theory of Intergenerational Wealth Flows

1. Introduction

John Caldwell's wealth flows theory proposes a direct link between family structure and fertility (Caldwell 1976b). According to the theory, there are only two major forms of family structure, differing principally in the direction of wealth flows among generations. In 'primitive' and 'traditional' societies, net wealth flows are primarily upward from younger to older generations, and individual interests are subjugated to corporate interests. In developed nations, family structure is organized in terms of downward wealth flows where parents are expected to provide for children's economic well-being.

The theory proposes that fertility decisions in all societies are economically rational responses to familial wealth flows. In societies with net upward wealth flows, the economically rational decision is to have as many surviving children as possible (within the constraints imposed by biology), because each additional child adds positively to a parent's wealth, security in old age, and social and political well-being. In societies with net downward wealth flows, the economically rational decision is to have no children or the minimum number allowed by a psychological disposition that derives pleasure from children and parenting. The worldwide transition from high to low fertility is the result of a change in family structures from upward to downward wealth flows.

This change in family structure was due to the spread of new values that placed a premium on individual satisfaction and achievement (Caldwell 1980). Those values emanated from the educated, middle-class in the west and are now being exported to the developing world through mass formal education. Implicit in the educational materials and expectations of schools is the individualistic value system that

produces downward wealth flows. Labor markets make the adoption of these individualistic values, which are adversative to the family or group production characteristic of pretransition societies, economically feasible. The transition from 'traditional' to 'modern' family structure occurs when a critical mass of individuals adopt the new values, and respond with low fertility. The attainment of mass education in a country should therefore precipitate and predict the fertility transition.

The most serious challenge to the wealth flows theory has come from evolutionary biologists. The argument that prior to modernization, upward wealth flows characterized human family structures is inherently antithetical to theory in evolutionary biology (Turke 1989). Biologists expect net wealth flows to be downward in all organisms, including humans. This research generated by the evolutionary biological critique of wealth flows theory has stimulated the development of a new theoretical framework for understanding human demographic patterns (see *Fertility Theory: Embodied-capital Theory of Life History Evolution*).

2. Historical Context

Wealth flows theory is not unique in proposing a link between costs of children and fertility. Notestein (1945, see *Fertility Transition: Economic Explanations*) proposed that the cost of children and their economic value are major determinants of fertility. Becker (1960) also developed formal models of the demand for children based on the household production function, focusing on the tradeoff between quantity and quality of children. Leibenstein (1957), also building on Notestein, argued that two forms of utility derived from children in pretransition (agricultural) societies were the proceeds of child labor and old age security. Evidence regarding the value of children's labor in agricultural societies was offered by Boserup (1965), Clark (1967), and Mamdani (1972). During the 1970s Cain (1978), Caldwell (1976b), Mueller (1976), and Nag et al. (1978) all developed theories concerning the economic contribution of children and the importance of child labor in peasant societies and how these factors impact family size and structure.

Caldwell's 'wealth flows' theory differs from the others by expanding the definition of intergenerational transfers across the life course and by directly linking changing value systems regarding intergenerational transfers of wealth to fertility transition. Defining wealth as 'all the money, goods, services, and guarantees that one person provides to another' (Caldwell 1982, p. 333), the theory directly incorporates effects on status and political position as well as on material wealth. Together, those material and nonmaterial transfers across the life course determine the net flow of wealth between generations and also affect societal

norms regarding the emotional value of children. As with economic models, Caldwell's theory recognizes technological impacts on wealth flows, such as the changing economic value of education. While there is unique pleasure derived from having children, pleasure will be derived from fewer children as their economic value decreases or the costs of educating them increase (Caldwell 1982, p. 338). However, unlike the more strictly economic models (Becker 1981), value systems regarding support in old age and the relationship between the individual and the larger family are the primary determinants of intrafamilial wealth flows in Caldwell's view.

3. The Economic Contribution of Minor Children

Wealth flows theory has been tested in several ways. Some tests are designed to determine if changes in the economic roles of children are associated with changes in fertility. Several researchers have found evidence of such effects in sub-Saharan Africa. In addition to Caldwell's (1976a) original microlevel study in southwest Nigeria, DeLancey (1990) and Makinwa-Adebusoye (1994) both found through meta-analysis of sub-Saharan African national level survey data that parents perceived upward wealth flows in high fertility contexts.

Similar results have been reported in several Asian countries with national level data. Chang (1990) reports that the adoption of socialist economic principles in China may reduce the economic contribution of children and result in fertility decline, but Moore (1998) suggests recent economic policy initiatives encouraging family economic independence may promote higher fertility. Some studies, using micro-level data, do not find evidence of upward intergenerational wealth transfers in high fertility contexts in India, (Das Gupta 1994 (in Punjab), Vlassoff 1982).

Willis (1982) has criticized Caldwell's hypothesis strongly on theoretical grounds, arguing that members of an altruistic older generation will see offspring success as a substitute for their own, and will therefore be willing to invest in offspring human capital at a higher rate than would be predicted if parents were acting solely in their own self-interests.

In general, the tests discussed above are weak because they do not measure the absolute flow of wealth but rather indicators of changes in the economic contributions of children. Strong tests of the theory require that children provide *net* economic benefits (i.e., amount provided minus amount received) to parents in high fertility societies and net economic costs in low fertility societies. Studies that have actually measured the net flow of wealth in high fertility societies do not support a strict interpretation of the theory. On the basis of data on net production and consumption through the life course, Kaplan (1994) has shown that in three lowland South Amer-

ican indigenous populations engaged in traditional economic pursuits of foraging and swidden horticulture, offspring do not become net producers until their twenties and never compensate their parents in terms of economic investment. Mueller (1976) in a study of 27 peasant agricultural societies found that while children were able to contribute to the household economy at a far higher rate than those in Kaplan's study, they still do not become net producers until their late teens and never repay the initial parental investment. In a review of all published studies, Lee (1996) concludes there are no data showing a net wealth flow from children to parents for any society—ironically, net upward wealth flows between generations are found in *low* fertility societies when public transfers, such as Medicare and social security, are included (Lee 1996).

4. *Old Age Security*

According to wealth flows theory, a second period in the life course for parents to receive economic benefit from their offspring is during old age. Those benefits motivate high fertility in traditional societies where adult children are expected to support their aging parents. In modern society, the ethic of individualism and public supports for the aged remove this motivation. Empirical evidence bearing on this hypothesis is also mixed. Hugo (1997), using national level data in Indonesia, found high fertility to be associated positively with perceptions regarding the likelihood of receiving old age support. Using historical data from England and Wales, Schellekens (1993) also found that old age security was correlated with high fertility. Cain has argued that children provide risk insurance for the elderly in south Asia (Cain 1981). Using micro-level data from Bangladesh, he also suggests that women desire high fertility to receive support from sons in old age as insurance against the loss of support from husbands in this patriarchal society. In contrast to Caldwell, however, Cain also argues that the breakdown of extended kin networks makes women even more dependent on sons for security. Vlassoff and Vlassoff (1980), using microlevel data from India, found no evidence that old age security motivated high fertility levels. (See Dharmalingam (1994) for a review of the debate between Cain and the Vlassoffs.)

Several studies using national level data have found that there are high expectations or levels of old age support in peasant agricultural societies in sub-Saharan Africa (De Lancey 1990), Mexico (regional level data) (Nugent and Gillaspay 1983), Malaysia (Lillard and Willis 1997), and Taiwan and the Philippines (Lee et al. 1994). Many studies have found extremely low levels of support or expectations of support of the elderly by adult children in the United States and other industrialized countries (Eggebeen 1992). None of these studies in the developing or

developed world were explicitly concerned with the relationship of fertility to old age security.

Critiques of wealth flows theory concerned with the economic contribution to the household of minor children are equally appropriate with regards to a net upward flow of wealth realized as support of the elderly. The evidence in support of wealth flows theory is based upon associations of high fertility with expectations of support. There is no solid evidence about whether high fertility actually increases the likelihood of support at the individual level, nor about the net flow of goods and services between older people and their descendent kin in high fertility societies. In fact, there is some evidence that older men and women make contributions to household economics in peasant agricultural societies through the skills and knowledge they bring to crisis situations. Researchers working with hunter-gatherers and forager-horticulturalists also observe that elderly individuals are often net producers and engage in other forms of work to support members of younger generations (Hawkes and Jones 1997).

5. *Mass Education*

Education plays a prominent role in many theories of fertility transition. In the wealth flows theory, education affects fertility through three routes, all affecting the net costs of rearing children. First, education subverts traditional communally-oriented value systems and trains children to pursue individual goals at the expense of supporting their parents (see also Cochrane 1979); second, it reduces children's ability to contribute to the household economy through diversion of time and loss of traditional skills and knowledge (Bock 2001, Caldwell 1980); and third, it increases the direct and indirect costs of children by increasing their demand for consumer goods and by establishing childhood as a period for receiving investment rather than contributing to the household economy (Caldwell 1980).

While there is a great deal of empirical evidence regarding the relationship between education and fertility, less is known about the relative contributions of these alternative causal routes, and particularly about education's impact on fertility through changing values regarding familial wealth flows. The empirical evidence regarding the impact of education on values is mixed. A meta-analysis of national level data from 37 sub-Saharan African countries found that primary school enrollment for both males and females in 1960 and 1980 had no significant effects on total fertility rate 15 and 30 years later. Secondary school enrollment for males and females in 1960 had a weak negative effect on total fertility rate, while only male secondary school enrollment in 1980 had a strong negative effect on actual and estimated total fertility rates 10 to 25 years in the future (Adamchak and Ntseane 1992).

Several studies show that children's school attendance affects parental fertility, (see, for example, Axinn (1993)). However, the causal process underlying this association is unclear, especially since parents who actively seek formal education for their children may differ from parents who do not with respect to characteristics that are themselves determinants of lower fertility. Lloyd et al. (2000) also found that children's school attendance predicts the timing of fertility transitions in a cross-national sample of African countries. Many studies report a negative impact of women's education and fertility, but again several alternative causal hypotheses are consistent with the data. At present, there is no strong evidence for or against the strict interpretation of fertility transition as a cultural watershed generated by mass education.

6. Summary of Wealth Flows Theory

Consistent with the logic of wealth flows theory, there is a great deal of suggestive evidence that changes in the costs of rearing children and in parental perceptions of those costs are associated with fertility transition. People in many high fertility societies also report higher expectations regarding economic support during old age than do people in low fertility societies. Also consistent with the theory is that education and fertility are negatively related in virtually every study measuring their association.

There are two major deficiencies in the theory, however. The first is that the data do not support a strict interpretation of the wealth flows hypothesis. There is no direct quantitative evidence of net-upward wealth flows in any traditional high-fertility society. Virtually all studies supporting the theory have used national-level, cross-sectional data, and have relied on proxy measures and informant reports. Actual measures of wealth flows in micro-level, longitudinal, ethnographic studies, using behavioral observation and measurement of intrahousehold productivity and exchange, all show *downward* wealth flows in traditional high fertility societies. Caldwell recognized that adequate tests of theory would require longitudinal, microlevel, ethnographically oriented research due to the subtleties and complexity of intra-familial wealth flows (Caldwell 1982).

The second deficiency is that the theoretical foundations for the determination of familial wealth flows are not well specified. This is evident in the treatment of education. In the theory, education is at once a vehicle of values transmission, a response to micro- and macroeconomic forces, and a direct cost to parents. The theory does not specify why certain value systems governing wealth flows arise, nor the relationships between exogenous economic factors, human psychology, and cultural evolution.

7. Conclusion

According to wealth flows theory, cultural transmission of new family values is the principal driving force in fertility transition. However, without a theory which can link ecological conditions to cultural features and their distribution, the concept of culture risks being vague, both cause and effect, the unexplained explanator. Culture is many things: a body of accumulated information, a set of customs and rituals, group beliefs, and a mindset about the organization of the social and physical environments. Each of these components may be related to fertility; but a generalized culture concept cannot be successfully used to explain patterning and variation in fertility without risking causal circularity (Bock 1999).

The wealth flows theory of fertility transition is a major contribution to demography. The theory is general in that it explains both high and low fertility regimes. A second strength is that it addresses both exogenous variables and the psychological and social processes that translated those exogenous variables into individual behavior, emphasizing both economic and social factors in understanding fertility transitions. The theory helped to lay the groundwork for theories of the family to become a major perspective within the field of demography, and broadened the scope of demography by directing attention to culture. It also inspired and influenced a large number of empirical studies. However, in the strict sense of predicting two fertility regimes to be associated with upward and downward wealth flows, empirical evidence does not support the theory. In the weak sense of predicting a negative relationship between net wealth flows to children and fertility, there is a good deal of empirical support.

Fertility Theory: Embodied-capital Theory of Life History Evolution

The goal of this article is to provide an introduction to the embodied-capital theory of life history evolution and the empirical research upon which it is based. The embodied-capital theory generalizes existing life-history theory in biology by treating the processes of growth, development, and maintenance as investments in stocks of somatic or embodied-capital (see Kaplan (1996, 1997) and Kaplan et al. (2000) for more complete treatments). In a physical sense, embodied capital is organized somatic tissue—muscles, digestive organs, brains, etc. In a functional sense, embodied capital includes strength, immune function, coordination, skill, knowledge, and other abilities. Since such stocks tend to depreciate in response to metabolic

activity (e.g., the production of free radicals and mutations associated with mitosis) and aging, allocations to maintenance can also be seen as investments in embodied capital. The general theory is introduced and then applied to human hunting and gathering societies, which characterized most of our species' evolutionary history. This framework is then used to develop models of modern fertility behavior as the result of an interaction between historically novel conditions and the evolved psychological, cultural, and physiological mechanisms governing human parental investment and fertility.

1. The Embodied-capital Theory of Life History Evolution

Hominids lived as hunter-gatherers for the vast majority of their evolutionary history (more than 2 million years). Agriculture originated only 10,000 years ago and has been practiced by the majority of the world's population for just two or three millennia, a relatively brief period of time for selection to act. The shift to a fully mercantile, highly urbanized economy with competitive wage-labor markets and a vast array of consumer goods since the mid-nineteenth century is completely novel. Since natural selection is a historical process, humans should be well adapted to the foraging lifestyle, but there is no reason to expect that they will respond adaptively (in the sense of maximizing reproductive fitness) to today's novel circumstances (see Kaplan et al. (1995a, 1995b) for evidence that modern fertility behavior does not maximize fitness). Therefore, an evolutionary explanation of human fertility and parental investment has three requirements: it must be consistent with our general understanding of evolution by natural selection; it must explain the behavior of humans living under traditional hunting and gathering conditions characteristic of our evolutionary history with adaptive models; and it must be able to predict the pattern of modern responses to novel conditions. Our approach to these requirements has been to follow a four-step procedure (Kaplan 1996, Kaplan and Lancaster 2000). The first step is to develop a model of natural selection on fertility and parental investment for organisms in general. The second step is to apply that model to the specific selection pressures acting on human hunter-gatherers. The third step is develop a model of the proximate physiological, psychological and cultural mechanisms produced by selection and how they would interact to determine fertility and parental investment behavior. The fourth step is to generate predictive models of how those mechanisms would respond to conditions currently prevailing in the world. The theory is both ecological and psychological, integrating socioeconomic influences with a theory of mind to identify the processes by which salient features of the social and physical environment

relate to people's reproductive and parenting behavior across diverse social, cultural, economic, and ecological contexts.

2. The Action of Natural Selection on Fertility and Parental Investment

Natural selection acts on variability in the traits of individual organisms within populations. Traits (and the genes which code for those traits) whose *average* effects on the individuals possessing those traits act to maximize their long-term production of descendents through time increase in frequency relative to other traits. (Technically, selection acts on the 'inclusive fitness' of genes coding for traits. Inclusive fitness includes effects both on the reproductive success of the individual bearing the gene and on other individuals, related by common descent, who also bear the gene. For example, selection on genes affecting alarm calls in response to predators depends both on their effects on the reproductive fitness of the caller (who may risk a greater threat of predation) and on relatives bearing those genes (whose lives may be saved by the call).) Fertility is the most direct contributor to an organism's fitness (i.e., the number of descendents it produces). In fact, all other fitness components, such as mortality, only affect fitness through their effects on fertility (for example, mortality rates affect fitness by affecting the probability of living to the next reproductive event). All else constant, any increase in fertility increases an organism's fitness. However, there are two trade-offs affecting natural selection on fertility.

The first is the trade-off between present and future reproduction. By growing, an organism can increase its energy capture rates in the future and thus increase its future fertility. For this reason, organisms typically have a juvenile phase in which fertility is zero until they reach a size at which some allocation to reproduction increases fitness more than growth. Similarly, among organisms that engage in repeated bouts of reproduction (humans included), some energy during the reproductive phase is diverted away from reproduction and allocated to maintenance so that it can live to reproduce again. Natural selection on age of first reproduction and on the adult reproductive rate is expected to maximize total allocations of energy to reproduction over the life course, and it depends on ecological factors, such as mortality rates (Charnov 1993) and the effects of body size on both energy capture (Charnov 1993) and vulnerability to predation (Werner 1986).

The second trade-off is between quantity and quality of offspring, where quality is a function of parental investment in offspring and reflects its ability to survive and reproduce. In general, natural selection on offspring number and investment per offspring is expected to maximize the number of offspring that survive to reproduce themselves during an organism's lifetime

(Smith and Fretwell 1974). Ecological factors, such as food supply, disease and predation rates, also affect the optimal fertility rates and optimal expenditures on offspring.

Virtually all complex organisms exhibit flexibility in both age at first reproduction and fertility rates. Natural selection has resulted in physiological and psychological mechanisms by which individuals adjust fertility onset and fertility rates in relation to changing environmental conditions. For example, plants often exhibit many thousand-fold variations in fertility rates in relation to yearly and seasonal variations in rainfall and other environmental factors. Extensive research on many bird species has shown that this phenotypic plasticity tracks fitness fairly well (see Godfray et al. (1991) for a review). Birds under variable conditions adjust clutch sizes in ways that tend to maximize the number of surviving young produced during the life course. The pervasiveness of adaptive phenotypic plasticity in fertility among nonhumans suggests that humans are also likely to possess adaptations to adjust fertility onset and fertility rates in relation to changing environmental conditions.

3. The Embodied-capital Theory and its Application to Fertility and Parental Investment Among Traditional Humans

The embodied-capital theory treats the present–future reproduction trade-off in terms of optimal investments in own embodied capital vs. reproduction, and the quantity–quality trade-off in terms of investments in the embodied-capital of offspring. Models based on the theory allow us to address problems that have not been addressed with standard life history models. First, an exclusive focus on physical growth *per se* is an impoverished way of understanding human development. The large human brain, a stock of embodied capital, supports a great deal of learning and knowledge acquisition during both the juvenile and adult periods. Second, parental investment among humans affects not only survival to adulthood, but also the adult socioeconomic status of offspring. This is true not only in modern societies, but also among traditional hunter–gatherers. These models of investment in embodied capital have produced some fundamental results. Of central interest here, the models show that investments in embodied capital affecting adult income or energy capture co-evolve with investments affecting mortality and longevity. The longer the time spent growing and learning prior to reproducing, the more natural selection favors investments in staying alive to reap the benefits of those investments. Similarly, any investments that produce increased energy-capture rates later in life select for additional investments to reach those older ages. The converse is also true. Ecological features or investments that increase the probability of survival to older ages also produce

selection for greater investments in income-related embodied capital. These co-evolutionary effects have been particularly important in human life-history evolution.

The human adaptation is broad and flexible, in one sense, and very narrow and specialized, in another. It is broad in the sense that as hunter–gatherers, humans have existed successfully in virtually all of the world's major habitats. This has entailed eating a very wide variety of foods, both plant and animal, both within and among environments. It also has entailed a great deal of flexibility in the contributions of different age and sex classes of individuals. The relative contributions of men and women to food production vary from group to group, as do production profiles by age.

The human adaptation is narrow and specialized in that it is based on extremely high investments in brain tissue and learning. In every environment, human foragers consume the largest, highest-quality, and most difficult-to-acquire foods, using techniques that take years to learn (Kaplan et al. 2000). This adaptation has profound effects on fertility, mortality, and wealth flows. Compared with other primates and mammals, there are at least four distinctive characteristics of human life histories: (a) an exceptionally long lifespan, (b) an extended period of juvenile dependence, resulting in families with multiple dependent children of different ages, (c) support of reproduction by older postreproductive individuals, and (d) male support of reproduction through the provisioning of females and their offspring.

The co-evolution of brains, learning and life histories is evident in Fig. 1. This figure plots net expected cumulative productivity by age (cumulating the probability of being alive at each age times the net productivity at that age) for human hunter–gatherers and wild-living chimpanzees, averaging over all available data from different groups (see Kaplan et al. (2000) for details). The long human training period is evident when the troughs in the human and chimpanzee curves are compared. Humans are not net producers until about age 18–20 years, but are very productive as adults, whereas chimpanzees begin to produce as much as they consume by about age 5 years and are much less productive as adults. In fact, peak production rates for both human males and females do not occur until the mid-thirties for the most difficult-to-acquire resources. Humans also have an expected adult lifespan of about 40 years when they become net producers, whereas chimpanzees have an expected adult lifespan (beginning at about age 13) of 14 years. The dashed line is a hypothetical cross of human production profiles with chimpanzee survival rates. It shows that the human production profile would not be viable with chimpanzee survival rates, because expected lifetime net production would be negative. The human adaptation depends on about 20 years of parental support and a long life span to recoup the investments in learning.

Figure 1
Cumulative expected net caloric production by age: humans and chimpanzees

The first major demographic transition separating our species from apes is a shift to low mortality, an increased lifespan, a long dependent development period, a large commitment to learning and intelligence, and an age profile of production shifted towards older ages with downward wealth flows across generations.

4. Ecology and the Proximate Mechanisms Governing Fertility and Parental Investment

The mortality and production profiles discussed above have direct implications for fertility regulation. Since human parents and grandparents provision children,

it is likely that natural selection would have produced mechanisms by which fertility could respond to the number of children parents could afford to raise at any given time. Figure 2 presents a conceptual model of the evolved mechanisms of fertility regulation in humans and its responsiveness to physical, biological and social conditions (*socioecology*). The figure depicts two classes of socioecological factors, one affecting survival and the other embodied capital, and three domains of evolved responses, psychology and culture, behavior, and reproductive physiology. The plain text and bold arrows refer to the traditional hunting and gathering lifeway, which we consider first. The italicized text and lighter arrows include additional factors and causal pathways existing under modern conditions.

Figure 2
A mode of fertility determinants in traditional and modern societies

4.1 Traditional Foraging Societies

There are two main causal pathways regulating fertility that are both related to the energy constraints in provisioning offspring, one involving breastfeeding and the other involving the age profiles of work and rate of weaning. Natural selection on the timing and quantity effects (favoring earlier weaning) and quality effects on survival and growth of offspring (favoring later weaning). Socioecological conditions, such as the availability of easy-to-digest weaning foods and disease threats, are likely to impact the relationship between age at weaning and survival. Similarly, infant condition is likely to be individually variable and differentially affected by weaning. We expect that natural selection has acted on both infant and maternal psychology to make them responsive to those variable conditions. For example, sickly infants may be more demanding of the breast, and larger and healthier babies more interested in weaning foods. In the human case, maternal perceptions regarding breastfeeding are not only guided by her individual experience and sensitivity to her infant's condition,

but also by the cumulative experience of her group, as reflected in cultural conventions and ideas about proper breastfeeding practices. Maternal and infant psychology interact in determining the length and timing of breastfeeding. The evolved reproductive physiology translates this pattern of breastfeeding into differing degrees of fecundity.

The second causal pathway is due to the additional energy constraints involved in provisioning children. The age/sex profile of work and productivity determine the total energy available for consumption. Given some age profile of food distribution and of mortality, the fertility rate must be constrained so that energy consumed does not exceed energy produced. The longer children are provisioned and the greater proportion of their food needs subsidized by parents and grandparents, the lower the reproductive rate that can be supported with a given adult income. Natural selection should therefore act both on psychological abilities to assess the short- and long-term costs and benefits of different activity profiles and on fertility regulation so that energy flows are balanced. One fundamental trade-off with respect to activity profiles

is between present and future production (Kaplan 1996, Bock 2002). If children engage in easy-to-perform foraging activities, such as fruit collection, this will provide immediate caloric benefits and lower the parental subsidy required. However, time allocation to those activities detracts from time spent learning more difficult activities, such as hunting and extractive foraging. During the learning phase, those activities produce very little food, but generate high rates of production in the future. Another fundamental trade-off is between production and mortality risks, since foraging exposes people to predation, accidents, and getting lost. This suggests that parental psychology should be responsive to age-specific mortality rates and how they are affected by alternative activity profiles, and on their short- and long-term consequences for production/productivity.

There is a growing body of evidence supporting the view that people in foraging societies are sensitive to these trade-offs and adjust behavior accordingly. In a seminal series of papers, Blurton Jones and co-workers (Blurton Jones et al. 1994a, 1994b, Hawkes et al. 1995) show that Kung hunter-gatherer parents consciously assess foraging risks to children and that differences between Kung and Hadza children's productivity are due to features of the local ecology related to ease of resource extraction and dangers associated with productive tasks. Bock (1995, 2002), in a study of forager/agropastoralists in Botswana, shows that the age profiles of children's activity budgets reflect immediate skill and strength requirements as well as opportunities to learn. In all foraging societies for which data are available, people are aware of the many years of learning required to become a competent hunter and young men are provisioned while they learn those skills (Kaplan et al. 2000).

These time-allocation decisions affect fertility through maternal energetics. In addition to breast-feeding effects, fecundity responds to women's net energy flows. Seasonal changes on food intake (Bailey et al. 1992), net energy expenditure (Hurtado and Hill 1987) and weight (Bailey et al. 1992, Tracer 1996) all have been shown to predict fecundity as do individual differences among women (Hill and Hurtado 1996).

To summarize, in this model fertility is determined by the interaction of individual psychology and cumulative cultural knowledge, beliefs and practices, behavior, and reproductive physiology. Each of these domains co-evolved by natural selection to respond to ecological variability in mortality regimes and payoffs to parental subsidization of skill acquisition. The connection between psychology and fertility is indirect in that psychology adjusts parental investment (through productive behavior, wealth flows, and breastfeeding) and reproductive physiology translates parental investment decisions into fertility. The key to this system is that maximizing lifetime expected resource production through the optimal allocation of activities and wealth flows will tend also to maximize

fitness when all wealth is in the form of food and extra food translates into higher fertility.

4.2 Fertility Under Modernizing Conditions

In Fig. 2, the additional socioecological factors and causal pathways proposed to result in fertility transition are shown with italicized type and thin arrows. Our proposal is that this fertility regime results from the interaction of new socioecological conditions with the psychological processes governing parental investment and wealth flows, evolved in response to the hunting and gathering lifeway. The two critical new factors are the existence of extrasomatic capital and changes in the payoffs to embodied capital, especially in the form of education.

Physical capital, such as land and money, is stored and invested in children in the form of inheritance and parental support for education. Unlike the traditional case where all wealth is embodied, there is no guarantee that a wealth-maximizing psychology will maximize fitness, because much wealth may never be converted into offspring and remain stored in other physical forms.

Changes in the payoffs to embodied capital occur for two reasons. Changes in the technology of production to education-based labor markets have led to very high returns on parental investments in children's education. There are multiple inputs into the production of education-based embodied capital. Parental time inputs prepare children for school and affect their progress in school. Variation in the quality of those inputs, perhaps based on parental education, may predict both levels of parental investment and fertility. Teachers, educational materials, and the quality of student preparation all affect rates of learning (Card and Krueger 1992).

Changing medical technology and public health efforts greatly reduced mortality rates for all age groups. Increased survival rates during the period of parental investment increase the expected costs per child born, favoring further increases in offspring quality (Kaplan 1996). Increased survival during the adult period increases the expected years of return of educational investments, further increasing the incentive to invest in children's education. It will be especially productive to investigate the public and private dynamics involved in this process. Increased private interest in education may have inspired more public investment in education. The quality of public education, in turn, increased the rate of return on private investments in education. Similarly, increased private interest in health (perhaps inspired, in part, by increased investment in education) also stimulated increased public investment in health. This, in turn, increased payoffs to educational investments.

These factors, in combination with parental psychology, result in fertility being regulated by a consciously determined childbearing plan realized

through birth-control technology and/or controlled exposure to sex. In response to the increased payoffs to investments in education and the expected costs of those investments, parents determine the number of children they can afford to raise, given their wealth. The low mortality rates also allow parents to plan reproduction at the outset, because the number of children born accurately predicts the number of children that will be raised to adulthood. Reproductive physiology affects fertility in the present in that it sets the broad limits within which a childbearing plan can be realized, and may actually lower fertility when plans include significant delays to first reproduction (Kaplan et al. 2001).

A great deal of further research is necessary, however, before we can understand why these changes in socioecology have resulted in such low levels of fertility and high levels of parental investment and wealth consumption. It does not appear that people are simply maximizing family wealth because net wealth of families would be maximized by higher fertility than is currently observed. It is also clear that people are not maximizing personal consumption; in that case, they would have no children. One possible hypothesis is that the social dynamics of small groups in hunting and gathering economies resulted in greater fitness for those of higher social standing and selected for a psychology in which relative social position of self and offspring is valued highly. Such a psychology would also emerge if people judged the well-being of themselves and their children based upon the wealth and consumption of others. This psychology may have been fitness maximizing under traditional conditions. If relative, as opposed to absolute, wealth and social standing guide human decisions regarding wealth flows, parental investment, and fertility, it is possible that 'run-away' consumption and investment in children's education result from the interaction of this psychology and modern education-based labor markets and consumption possibilities.

5. Implications of Embodied-capital Theory for Understanding Current Fertility Transitions

Embodied-capital theory links several existing theories of demographic transition and, in so doing, provides a new perspective on each one. It rationalizes the shift from natural fertility to parity-specific fertility in terms of a changing quality/quantity trade-off, as a transition from high fertility/low parental investment to low fertility/high parental investment. It also shows why the shift to lower mortality rates can lead to lower fertility, but for reasons that are very different from what traditional demographic-transition theory proposes. According to the latter, lower mortality precedes and drives lower fertility, because fewer children are required to maintain the population equilibrium and cultural ideologies evolve to maintain population

equilibrium. According to the present view, mortality rates are but one important factor in the overall rate of return on investments in embodied capital.

This model can further serve to organize research on fertility transitions, with the fundamental expectation that exogenous factors affecting the rate of return on parental investment in the embodied capital of offspring will predict the timing of fertility decline and its distribution within populations. Understanding these dynamics may provide insights into the course of fertility reduction and its variation across countries and among individuals within countries. For example, most studies of predemographic transition societies show that there is a positive association between wealth and fertility (Borgerhoff Mulder 1992). There is some evidence for a negative relationship during the demographic transition. (Kaplan et al. 1995a, Vining 1986) and no relationship after the transition is complete (Kaplan et al. 1995a). It may be that only the wealthy can take advantage of high levels of investment in children's embodied capital when there are few schools and limited public expenditures on health and education. The process of demographic transition may progress through different sectors of the society as more and more people can take advantage of increased rates of return due to changes in the economy and changes in public investments. These same dynamics, in combination with international transfers of educational and health technology, may also explain the national differences in the timing of fertility reduction.

Understanding these dynamics also requires an understanding of how people process the mix of information derived from direct assessment, observation of others, and cultural guidelines. Theoretical work modeling the action of natural selection on information processing suggests that the relative reliance on direct experience and on cultural sources should vary according to environmental conditions (Bock 1999). Cultural learning should be a better guide for behavior when environments are relatively stable than when they are changing (Bock 2001). The rapid change in economics of production, public education and public health may lead people to reject existing cultural models, look for new models, and assess costs and benefits of alternative courses of action more consciously on the basis of direct experience.

International family planning programs present one set of new models, promoting lower fertility and greater investment in children's education. When those models are consistent with individual assessments of costs and benefits, the direction of change is clear. It is less clear, however, how people will respond to family-planning messages in the short and long run if the payoffs to investment in embodied capital are low, either because schools are poor or because employment opportunities for educated people are limited (as appears to be the case in many sub-Saharan African countries).

6. Conclusion

According to embodied-capital theory, fertility and parental investment behavior result from the interaction of exogenous conditions with an evolved response system shaped by natural selection. In addition, a distinctive feature of the learning-intensive nature of human psychology is that information about the environment and guidelines for behavior are obtained through cultural sources as well as through direct personal assessment (Bock 1999, 2001). Given the very limited capacities for cultural transmission displayed by nonhuman primates (Lefebvre 1995), it is evident that the capacity for culture itself evolved by natural selection. We still know very little about the mix of physiological, psychological, and cultural processes underlying decisions regarding wealth flows, educational investments and consumption patterns, or how those processes relate to fertility decisions. Understanding the complex interplay of exogenous conditions, cultural forces, and evolved response systems in the determination of family structure and fertility presents a formidable challenge, but one that promises great rewards.

Fertility Transition: China

Between 1970 and 1980, in one decade, China's national fertility level was cut in half. This is his-

torically the most drastic fertility decline among all human populations of significant size, aside from wars, epidemics, and famines. As the largest population in the world, China's fertility transition has also had the greatest impact on the slowing down of the world's population growth. China's fertility decline alone reduced the world's population growth by at least 250 million individuals during the second half of the twentieth century. This entry reviews the process, its historical background, the roles of the government programs and other factors, and the consequences of this transition.

1. The Process of Fertility Transition

At the national level, China's fertility transition began in the early 1970s. In 1970, the total fertility rate was 5.8, close to the highest national level ever recorded for China. In the following decade, a most drastic reduction in fertility occurred. China's total fertility rate declined to 3.6 by 1975, and to 2.3 by 1980. The fertility level fluctuated between 2 and 3 throughout the 1980s. By the early 1990s, it reached and thereafter stayed at the replacement level of 2.1. China, in other words, completed its fertility transition in two decades, from 1970 to 1990.

In China's urban areas and among the more educated subgroups of the population, the fertility transition began much earlier, dating back to the early 1950s (Lavelly and Freedman 1990). Since 1957, urban Chinese fertility declined almost consistently, with only one exception, when fertility rebounded in 1963 after a plunge caused by the Great Leap Forward famine. By 1966, total urban fertility dropped to 3.1, and since 1974, it has never been higher than 2. In Shanghai, China's most cosmopolitan city, the total fertility rate dropped to below the replacement level (of 2.1 births per woman) for the first time in 1964, and to below 1 in 1975. By 1970, on the eve of China's first national family planning program, use of contraception and abortion among young women had already risen to 35 and 20 percent, respectively, in cities. Even in the countryside, over 15 percent of women at age 35 had already used a modern contraceptive method, and 7 percent had had at least one induced abortion.

In China's rural areas, where close to 80 percent of the population resided in the 1970s, fertility transition did not begin until much later—around 1970. In fact, during most years between 1950 and 1970, rural fertility showed signs of increase under the collective commune system. Fertility generally stayed at a level of above 6, with the exception of the Great Leap Famine years of 1959 to 1961, when rural fertility was nearly halved. Consistent fertility decline in rural China began after 1970. The total fertility rate dropped to 5 by 1973, to 4 by 1975, and to 3 by 1979. After 1980, the total fertility rate has fluctuated mostly between 2 and 3.

There were also regional variations in the fertility transition in rural China. In provinces with a more advanced economy and a stronger tradition of population control, such as the Lower Yangtze provinces of Jiangsu and Zhejiang, rural fertility declined earlier. In 1973, when the national level was 5, the total fertility rate was only 2.8 and 3.5 in these two provinces. By comparison, rural fertility was much above the national average in economically less developed provinces: it was 7.4 in Guizhou and 6.5 in Gansu (Coale and Chen 1987).

2. Historical Background

China's large population size along with a strong cultural preference for sons and a practice of early and universal marriage among Chinese women have often led many to believe that the Chinese did not attempt to control fertility before China's contemporary fertility transition. Malthus, for instance, stated that 'To account for this population, it will not be necessary to recur to the supposition of Montesquieu, that the climate of China is in any peculiar manner favourable to the production of children, and that the women are more prolific than in any other part of the world.' Among the causes he identified is 'The extraordinary encouragements that have been given to marriage, which have caused the immense produce of the country to be divided into very small shares, and have, consequently, rendered China more populous, in proportion to its means of subsistence, than perhaps any other country in the world' (Malthus 1971, pp. 101, 103).

Contrary to such earlier observations, many Chinese controlled their demographic outcomes in the past by relying on multiple mechanisms. The best-documented and most widely cited examples pertain to infanticide, especially female infanticide (Lee 1981, Lee et al. 1994, Lee and Campbell 1997). Chinese families killed some of their newborns in order to achieve their desired goals for the number and sex composition of their offspring. Poor harvests and economic difficulties also exacerbated the practice of infanticide.

Moreover, studies of Chinese historical population data also reveal that Chinese fertility within marriages was also significantly lower than their pretransition European counterparts (Barclay et al. 1976, Lee and Wang 1999). This lower marital fertility level was achieved by a much longer interval between marriage and first birth, longer interbirth intervals, and an earlier ending of childbearing. The same rationales that motivated infanticide also operated for fertility control. Chinese parents sped up or slowed down reproduction according to the number and sex composition of their existing children, and according to their economic familial circumstances (Wang et al. 1995, Lee and Campbell 1997, Zhao 1997). Fertility control in the past relied mainly on sexual abstinence,

prolonged breast-feeding, and, to a lesser extent, abortion and traditional contraceptives (Hsiung 1994, Lee and Wang 1999).

These behaviors suggest that controlling births is not a novel idea to the Chinese population. The modern fertility transition did not require new ideas for regulating population behavior, but rather a new environment in which fertility control could be seen as necessary and feasible. In contrast to traditional birth control that relied on both prenatal and postnatal methods, the modern fertility transition is mostly prenatal, facilitated by new contraceptive and abortive technologies. Historical traditions of demographic control not only lay the foundation for contemporary fertility transition in mainland China, but they also help to explain the similarities in the pace and patterns of fertility transitions observed in several populations. In spite of having different political and economic systems, mainland China, Taiwan, Hong Kong, and Singapore all exhibited highly similar patterns of fertility transition, partly due to a shared cultural tradition (Coale and Freedman 1993). The Chinese fertility transition process is therefore fundamentally a continuous process, extending a long tradition of demographic control.

3. Government Programs and Other Factors

The most prominent feature of China's fertility transition is the role played by government family planning programs. The most drastic fertility decline coincided with the launching of the most forceful government policies and programs of population control. Development of government policy can be traced to the early 1950s. Early concerns about rapid population growth and the need for a government family planning program emerged in the early 1950s, when China's 1953 census confirmed its large population size. Abortion was legalized and contraceptives began to be provided on a limited scale. Unlike later programs, which were motivated by government birth control goals, these early provisions were largely to meet an increasing demand among the population for birth control. These early efforts, however, soon became entangled in ideological debates about whether China needed to control its population growth and were interrupted by a series of political campaigns. As a result, it was not until the 1960s that the government seriously promoted birth control in urban and densely populated rural areas. Overall, government family planning programs at this early stage may have facilitated the early decline, but they were not the main driving force.

Government intervention in reproduction reached a new phase in the early 1970s when the policy of *wan* (later marriage), *xi* (longer birth intervals), and *shao* (fewer births) was formed. Although largely accepted by most people on a voluntary basis, the implemen-

tation of the policy became increasingly intensified and regularized. The government utilized its control over the media to promote family planning as a national policy, and mobilized a whole system of vertically controlled work and political organizations to implement the policy. Special government organizations in charge of family planning were also organized and expanded during this period. The official marriage age was stipulated to be 25 and 23 for urban males and females, and 22 and 20 for rural youths. Two children were considered the proper family size for an urban couple and three for most rural couples. Under this program, Chinese ages at marriage rose sharply and fertility declined swiftly. Nationally, the female mean age at first marriage rose from 21 in 1970 to 23 in 1979, and the fertility level was halved (Banister 1987).

In spite of this rapid fertility decline of the 1970s, the Chinese government was not content. Instead, motivated by a keen desire to increase quickly the per capita living standard within a short period of time, it launched an even more ambitious and much more controversial family planning program in 1979. Known as the one-child policy, it required each couple to have only one child, and was an emergency measure to further reduce China's population growth rate. Under the pressure of such an unprecedented and extreme policy, officials and especially family planning cadres resorted to all methods, including physical abuse in some locales, to meet the goals established by various levels of government. Women with two children, sometimes even only one, were required to have an intrauterine contraceptive device (IUD) inserted, and women with three or more births were required to undergo sterilization. Pregnancies not meeting the requirement of family planning had to be aborted. Family planning campaigns were also launched in the 1980s, resulting in sharp increases in the numbers of abortions and sterilization (Hardee-Cleaveland and Banister 1988).

This extreme policy met strong resistance from the Chinese population from the very beginning, especially from the vast population in the countryside. Whereas the earlier policies of family planning were by and large acceptable to Chinese peasants, this new extreme measure required them not only to forgo their traditional perceptions of family and kinship, but also to reduce or even remove their reliance on children for labor and support in old age. Such resistance led to a relaxation in implementation in the Chinese countryside and to changes in the policy. As a result, Chinese couples in cities (accounting for about 20 percent of the population in the late 1970s) obeyed the one-child policy, whereas most rural couples had two, and some more than two, children (Wang 1996, Feeney and Yuan 1994).

The draconian government policy may have masked the roles of many other factors underlying China's fertility transition process. In addition to the historical tradition of demographic regulation, many contem-

porary social and economic changes contributed to China's fertility transition, especially before the 1980s. These changes included a drastic decline in mortality, especially infant mortality, a rise in nonagricultural and nonfamilial employment, a rapid reduction in female illiteracy, and increased provision of social welfare, especially to the urban population (Peng 1989). A changing social and economic context thus produced rapid adaptation to changes in childbearing in the Chinese mainland, just as it did elsewhere in East Asia (Greenhalgh 1988). At both the regional and the individual level, fertility differentials associated with employment type, residence, education, and income existed from as early as the mid-1950s (Lavelly and Freedman 1990).

4. Consequences

In its speed and intensity, the Chinese fertility transition has produced several distinctive consequences. The first is a whole generation of single children; and a whole generation of parents with only one child. These families are almost all in urban China, where the one-child policy was effectively implemented. Children who grew up in these families have no siblings, and in the future their children will not have any uncles, aunts, or cousins, all of whom are important members of the traditional Chinese kinship network. Moreover, there will be a severe shortage in familial support in their old age. At least half of all parents of these single children will not be able to co-reside with their married children in their future old age, when emotional and functional support from children may be needed.

Second, rapid fertility decline also means an accelerated process of population aging. This is again especially true for China's urban population, in which the ratio of the elderly aged 60 and above to those at the working age of between 20 and 60 will reach an unprecedentedly high level, the highest in the world, around the year 2040. Nationally, the rate of population aging will also be high, but not as high as in urban areas due to a higher fertility rate in the vast rural areas. Rural to urban labor migration, therefore, can alleviate the shortage of labor in urban areas.

Lastly, China's rapid fertility transition has also led to an acutely unbalanced sex ratio between male and female births. During the 1980s, the sex ratio at birth rose steadily, from 107 boys to 100 girls in 1981 to 115 boys to 100 girls in 1991. The sex ratio among births of higher orders rose even more. Among second births, the recorded sex ratio rose from 107 in 1981 to 116 in 1985, and to 130 in 1993 (Gu and Roy 1995). Much of this increased sex ratio is due to the widespread use of sex-selective abortion. Whereas the increase in the sex ratio may be attributable in part to its government program, the fact that similar increases in sex ratio are also observed in several other East Asian populations suggests this may at least be a temporary by-product of the fertility transition process in these societies. In

China, such a lopsided sex ratio will have long-lasting effect on marriage patterns and on population growth in the long run.

Fertility Transition: Cultural Explanations

1. Introduction

Demographers have used two approaches to culture in their attempts to understand fertility transitions, both borrowed from anthropology and, to a lesser extent, sociology. The first sees culture as a set of largely inflexible shared beliefs that constrain action, and thus as a barrier to fertility transitions. The second sees culture as shared interpretations that are subject to negotiation by actors; whether these hinder or facilitate fertility transitions is contingent. Demographers have made considerably more use of the former than the latter, although the more flexible and contingent view of culture is evident in some recent work. This article describes these two approaches to culture, giving examples of their uses in the demographic literature and their links to anthropology and sociology. Although the following begins with the introduction of culture in analyses of fertility transitions in Europe in the nineteenth century, the focus is on fertility transitions in third world countries. Much of the literature cited concerns Africa, but the approaches to culture in understanding fertility transitions are similar in other parts of the world.

2. The Princeton European Fertility Project

The interpretations of culture by scholars participating in the Princeton European Fertility Project set a persistent pattern. An influential paper summarized the project's findings with respect to culture: 'cultural setting influenced the onset and spread of fertility decline independently of socioeconomic conditions. Proximate areas with similar socioeconomic conditions entered the transition at different times, whereas areas differing in the level of socioeconomic development but with similar cultures entered the transition at similar times' (Knodel and van de Walle 1986, p. 412; see also Coale 1973). By cultural setting, the project meant region, taken to be a proxy for ethnicity and language (which were considered synonymous); other potential markers of regional cultures, such as gender, were not explored (Watkins 1993). Regional cultures were assumed to be exogenous and inflexible. Culture was also assumed to hinder rational action. Thus, the Princeton Project's model of

culture was one that has its roots deep in the European Enlightenment: individuals are assumed to be fundamentally rational, but their vision could be clouded by superstitions and myths.

3. Culture as Barrier

As demographers began studies in the third world, interest in culture increased. This interest had several sources. First, researchers saw third world couples as profoundly different from Western couples—even more different than, say, the differences among regions in Europe. They emphasized aspects of culture that appeared quite exotic from a Western perspective—polygamy, strong son preference, long post-partum abstinence—and were seen to be associated with ethnicity (sometimes a specific ethnicity, sometimes a broader category of 'African' or 'Asian' culture). Second, those promoting family planning programs intended to alter the reproductive patterns of third world couples interpreted their initial failures as due to the 'cultural beliefs' of those who should want fewer children and who should use family planning but who were resistant to reproductive change.

The literature on third world fertility declines is replete with views of culture as barriers to change. These views that are expressed by analysts from third world countries as well as from the West, suggest that they inhabit the same cultural space. The solutions both propose are also similar: education to dispel ignorance and 'myths and rumors,' and cultural change. The latter is either presented as the inevitable accompaniment of modernization, or as something that can be promoted through appropriate policies.

The definition of culture implicit in much of the literature on cultural barriers draws on the view of culture that dominated cultural and social anthropology of the 1920s to the 1940s (Hammel 1990). Because of their far-flung empire, British social anthropologists were particularly influential. For the British social anthropologists who worked in Africa, this was structural functionalism, which emphasized the integrated social wholeness, indigenous morality, and the logical coherence of societies; particular attention was paid to kinship as a central aspect of culture (S. F. Moore 1994, p. 23). Culture was viewed as external to the individual, a set of beliefs shared by a local group, with little attention to differences within a culture or to change. Moreover, it was 'traditional' societies that had culture, whereas 'modern' societies did not.

Despite the views of anthropologist that there was a logical coherence to culture or that reproductive behavior might be the outcome of motivations that were far from reproduction (Kreager 1985), demographers focused on customs or practices thought to be closely related to reproduction, particularly those believed to support high fertility such as polygamy and social control by clan or lineage elders, but also local

practices that reduced fertility such as extended postpartum abstinence (Lesthaeghe 1989, Caldwell and Caldwell 1987). Again, other aspects of local cultures were ignored. The analytic models of demographers sometimes included ethnicity or region, but no other indicators of local culture, and much of the attention was focused on aspects of modernization that were expected by sociologists and economists to diminish the hold of culture.

4. Theoretical Shifts in Anthropology and Sociology

Between the 1940s and the 1960s, the interpretation of culture in anthropology—and in sociology—changed substantially. Anthropologists working in third world countries began to focus on the break up of local cultures associated with modernization, especially migration to urban areas (S. F. Moore 1994), and even ethnicity—the stalwart of demographers' views of culture—has come to be seen as fluid and socially constructed (Ekeh 1990). Beginning roughly in the 1970s, there was an even more significant reorientation of theory towards social actors and their strategies for everyday life. A particularly influential figure on this reorientation is the interpretative school associated with Clifford Geertz, who turned attention to meaning in terms of the actors rather than the models of analysts. Geertz proposed attempting to understand the perceived world of actors and their motivations: 'the trick is to figure out what the devil they think they are up to' (Geertz 1983).

Geertz's insights were extended and modified, particularly in the direction of recognizing more within-culture diversity and strategic agency. For example, although the cultural anthropologists of an earlier era, and demographers, saw a close correspondence between beliefs and behavior, in the new interpretations of culture, beliefs and norms were diverse and often contradictory, and which ones were chosen to guide (or perhaps rationalize) behavior was negotiated (Holy and Stuchlik 1983). Pierre Bourdieu (1977) and others emphasized the extent to which individuals know the rules of the game, and use them strategically.

In this approach, culture remains supraindividual, as it was for the structural-functionalists, but it is clearly endogenous, altered, and adapted to specific circumstances. Although local actors may invoke 'our culture since time immemorial' and they themselves may speak of the customs that appear to outside analysts to be exotic, culture is flexible, and concerns rules for daily living. Anthropologists and sociologists began to speak of culture as a 'spice rack' or a 'tool kit' from which various items may be drawn as needed (Greenhalgh 1988, Swidler 1986). Thus, it is argued, analysts need to pay attention to the process by which norms and behavior are evaluated, i.e., what people can expect regarding appropriate behavior, how they

assess motivation, behavior, and the social worth of others (H. Moore 1986, p. 40).

In this interpretive view, then, culture changes through communication. An important part of this communication takes place in 'microcultures,' where 'shared meanings [are] directly tied to specific, likewise shared, experiences of people, settings and events' (Hannerz 1992, p. 77, Watkins 2000). Some of it occurs through gossip, a mechanism by which people not only interpret the behavior of others but also discover other people's interpretations; they can thus learn and change cultural rules at a distance. Culture may provide ideal rules to apply to particular circumstances, but the contingencies of life themselves restructure the rules, even change them over time. Thus, in gossip people may justify different conclusions in the same way: for example, in a community in Malawi, one respondent, when asked how many children she wanted, replied 'Only a few, I am too poor to have more,' whereas another said 'Many, I am poor so I need many children to help me.' Much of this communication is local, but it may also be global, following the 'cultural flows' that appear to be increasingly linking societies and are collectively interpreted not only in villages but in global agencies and international meetings and among functionaries of national agencies such as the Ministry of Health (Appadurai 1990, Meyer et al. 1997, Bongaarts and Watkins 1996, Renne 1996).

5. What Role Do Interpretive Views of Culture Play in Demography?

The interpretive views of culture have been a basis of vigorous critiques of demographers' interpretations of culture (Greenhalgh 1995, Kerzer 1995, Kertzer and Fricke 1997). Although many demographers have continued to draw on 'fossilized' views of culture drawn from an older era of anthropology (Hammel 1990), the newer views of culture have made some inroads, primarily through anthropologists with an interest in reproduction (many of the younger ones of whom received training in demography through a program established by the Mellon Foundation). Three articles illustrate the sorts of insights that derive from analyses informed by the newer views of culture.

Alaka Basu and Sajeda Amin (2000) emphasize the role of culture in the region of Greater Bengal, but interpret region very differently from the Princeton Project model. Their region is characterized by a common language and a high degree of identity with that language. But the region crosses the border between Bangladesh and West Bengal in India, such that the Bengali language is shared by groups that do not share political or religious boundaries. Nonetheless, they say, cross-border interaction has long been sustained and intense among the elites, as well as between urban and rural areas. More significantly—

and in stark contrast to the common view among demographers that the culture shared through the common language is a barrier to fertility change—they argue that in this specific context culture has been characterized for several centuries by its openness to innovation, evident in receptivity to Western contraception as well as to social reform in other areas of social life.

Tom Fricke's (1997) analysis of fertility control among the Tamang of Nepal shows that the same cultural value can lead to precisely opposite reproductive action when the frame shifts. Between his fieldwork in 1981–2 in the village of Timling and a subsequent visit in 1987, he found that some men had undergone a vasectomy. These men were not characterized by more education than others, nor by more contact with the world outside their village. In listening to their explanations of why they had made such a move, he found that they referred constantly to an underlying cultural value: that of reciprocity and exchange, which 'provides Timling actors with an interpretive model for their own actions and the actions of others' (p. 262). The ethos of reciprocity and exchange is a core cultural value among the Tamang and has associated secondary values, including having many children in order to reproduce broader exchange and social networks and providing their children with a share of inheritance.

Over time, these secondary values had come in conflict. Thus, the men justified their decision to undergo a vasectomy as necessary to protect the inheritance shares of the children they had already borne. The conflict was provoked by changes in the material context and individual experience, but it was the actors' commitment to preserving a core cultural value that led them to vasectomy.

An even more radical step is taken by Caroline Bledsoe, Fatoumata Banja, and Allan Hill (1998), who contrast the cultural model of high fertility that population scientists use to guide their analyses with the cultural model of reproduction that rural Gambians use to guide their behavior. The former is familiar to demographers: age and number of children lead a woman to change her fertility behavior, those who use contraceptives intend to limit live births, and early contraceptive users are expected to be educated and relatively autonomous from family pressure. Some users of contraception in the Gambia conform to this Western model of reproduction. For others, however, their behavior is inconsistent with this model: they are motivated to use Western contraception because they want to *protect* the woman's reproductive potential so that she may bear more children, either in the current marriage or, should this marriage fail and another be necessary, in a future marriage.

Moreover, reproductive potential is measured not in terms of age, as in Western models, but in terms of 'body resource expenditure,' the loss of 'muscles,'

strength, and blood that accompany childbearing. Indeed, the authors found that the highest rates of use of Western contraceptives to be among women who had experienced reproductive mishaps—abortion or miscarriage, or child death—and who wanted to 'rest' in order that they might bear more children. Fertility is highly important in this society, but it is less the number of children that matter to the women than marriage.

There are other examples of the way that a more interpretive and activist view of culture has informed demographic analyses of fertility transitions, not only in the work of these authors but in the work of others (e.g. Szreter 1993, Townsend 2000, Kaler 2000).

6. *Conclusions*

Both the older and the newer views of culture can be useful in understanding fertility transitions. Culture may at times be a barrier to fertility change, but it may also facilitate fertility change, and culture itself may change as people alter old reproductive models or adopt new ones. The critics of the use of culture by demographers are fundamentally correct in arguing that the perception that culture is a barrier to rational action—a view that has been adopted by those writing on the spread of HIV/AIDS—is based on a view of third world people as implausibly passive. Indeed, the transformation in reproductive behavior in much of the third world between 1960 and 1990 suggests that new cultural models of reproduction can supersede old ones, or old models can lead to different behavior in new circumstances.

What are the implications of this newer view of culture for demographic analysis? Most demographers will undoubtedly continue to do the kind of statistical analyses they have always done, and are not likely to abandon these for the methods of cultural anthropologists or sociologists of culture. Thus, they will continue to require labels for aspects of culture, labels that can be attached to individuals or groups. The emphasis of the new approaches on communication as a source of cultural flexibility and change suggests that linguistic labels may still be useful, supplemented by attempts to open the 'black box' of culture in order to understand better differences in perceptions and behaviors across (and within) groups. Considering other ways of categorizing individuals and groups may also be fruitful for statistical analysis.

The newer view of culture suggests, however, that what these categories mean may change as the perceptions and motivations of actors change, as well as how that change might occur and the implications for demographic behavior. Most importantly, the recent empirical work guided by the newer understanding of culture suggests that demographic analysis would benefit were our analytic models closer to the models that actors who produce fertility transitions use to guide their behavior.

When demographers have taken culture seriously, it has typically been local cultures in third world countries. A few, however, have suggested new directions. One is the interpretation of what might be called governmental and bureaucratic cultures, both national and global. The second is that demographers examine their own culture, one that has a particular model of reproduction and views culture as a barrier to reproductive change. The newer approaches to culture as explanations for fertility change suggest that the current interpretations of culture in anthropology and sociology may change, and that the culture of demographers may also be flexible.

Fertility Transition: East Asia

East Asia experienced extremely rapid declines in fertility after World War II. In the last decades of the twentieth century, fertility declined further to below replacement levels in some countries of the region, notably in Japan, the Republic of Korea (called 'Korea' hereafter for linguistic simplicity), and the

Republic of China (called 'Taiwan' hereafter for the same reason). Focusing on these three countries, this entry looks at the patterns and factors associated with the postwar fertility transition. After an overview of trends in fertility levels, the entry discusses changes in the two major demographic factors that influence fertility: the timing of women's marriage and fertility within marriage. The article then discusses socio-economic factors that influence fertility including women's education and employment.

1. Fertility Trends

Although there were differences in timing and magnitude, Japan, Korea, and Taiwan all experienced a dramatic downturn in fertility after World War II (see Fig. 1). In Japan the total fertility rate (TFR) declined from 4.5 children per woman in 1947 to 2.0 in 1957. After this rapid decline, fertility stabilized at about the replacement level (a TFR of 2.0 to 2.1 children per woman) until it started to decline again in the mid-1970s, reaching an all-time low of 1.3 children per woman in 1999. High fertility persisted in Korea until rapid economic development began in the early 1960s. Then the TFR dropped precipitously from 5.9 children per woman in 1963 to 1.6 in 1987. This remarkable decline was followed by a modest upturn in the early 1990s and subsequent stabilization at a level of 1.6 to 1.8 per woman. Taiwan's fertility transition was equally dramatic. Starting in the early 1950s, the TFR declined steadily from 7.4 children per woman in 1951 to 1.9 in 1985. Since the mid-1980s, TFR has stabilized at 1.7 to 1.8 children per woman.

In summary, Japan experienced two fertility transitions, the first a rapid decline from historically high to replacement levels of childbearing, which occurred

shortly after World War II, and the second an ongoing decline from replacement to very low levels of fertility. Korea and Taiwan both experienced one continuous fertility transition from very high to below replacement levels.

2. Demographic Factors in Fertility Decline

In all three of these countries the fertility transition is related to two demographic factors, namely delayed marriage among women and declining fertility within marriage. Because out-of-wedlock childbearing is minimal, these two factors determine the overall levels of fertility. Demographic analysis indicates that roughly 90 percent of the decline in Japan's TFR between 1950 and 1975 was related to a decline in marital fertility, and the remaining 10 percent was related to delayed marriage among women (Tsuya and Mason 1995). Similarly, approximately 80 percent of the TFR decline in Korea from 1960 to 1990 was due to declining fertility within marriage, and the remaining 20 percent was due to delayed marriage. In Taiwan, around 75 percent of the decline in fertility between 1960 and 1985 was due to a decline in marital fertility, and the remaining 25 percent was due to delayed marriage. By contrast, the fertility decline in Japan after 1975 was due solely to delayed marriage among women, while marital fertility showed moderate increases. In a corresponding manner, around 40 percent of the fertility decline from 1980 to 1990 can be attributed to delayed marriage in Korea, and around 85 percent in Taiwan.

2.1 Decline in Marital Fertility

The dramatic fertility declines in these three East Asian countries were caused primarily by a reduction in fertility among married women, who gained control of their family size through contraception and induced abortion. The rate of contraceptive use among married women under the age of 50 increased steadily in Japan from around 20 percent in 1950 to 62 percent in 1979 (Kobayashi 1990). After 1979, the prevalence of contraception stabilized. With the expansion of government family-planning programs, contraceptive practice spread even more rapidly in Korea and Taiwan. In Korea contraceptive use among married women aged 15 to 44 increased from 20 percent in 1966 to 70 percent in 1985 (Palmore and Bulatao 1989). In Taiwan contraceptive use among married women aged 20 to 39 was 23 percent in 1965; among married women aged 15 to 49 it was 78 percent in 1985 (Freedman et al. 1994).

Induced abortion is a traditional means of fertility control long practiced in East Asia. Along with the rapid increase in contraceptive use, rates of induced abortion also increased in the three countries. In Japan the proportion of married women of repro-

Figure 1
Total fertility rates in Japan, Korea, and Taiwan after World War II

ductive age reporting having experienced an abortion increased from 15 percent in 1952 to 41 percent in 1961 (Muramatsu 1990). Since the early 1960s, this proportion has remained in the range of 30–40 percent. In Korea the proportion of married women of reproductive age reporting having experienced an abortion increased from around 10 percent in the mid-1960s to nearly 40 percent in the late 1970s (Cho et al. 1982). Although the rate declined somewhat in the 1980s, abortion remains an important option for terminating unwanted pregnancies. The reported use of abortion among married women of reproductive age also rose steadily in Taiwan from the 1960s to the 1980s (Freedman et al. 1994).

2.2 *Delayed Marriage*

As we have noted already, being older at the time of marriage has also played an important role in the fertility transitions. The postponement of marriage for women in the three countries is remarkable in light of the East Asian tradition of universal marriage and the cultural expectation that women should marry by their mid-twenties. Between 1975 and 1995 the proportion single rose from 21 percent to 48 percent among women aged 25 to 29, and from 8 percent to 20 percent among women aged 30 to 34 in Japan. Korean women are also marrying later, although almost all marry by their mid-30s. Between 1955 and 1995, the proportion never married increased from 21 percent to 83 percent among women aged 20 to 24, and from 3 percent to 29 percent among women aged 25 to 29. Taiwan has experienced an equally dramatic delay in women's first marriage. From 1956 to 1995, the proportion single rose from 29 percent to 79 percent among women aged 20 to 24, and from 5 percent to 40 percent among women aged 25 to 29. Since the mid-1970s, the percentage single has also risen among women in their early thirties—from 3 percent in 1975 to 16 percent in 1995.

3. *Socioeconomic Factors in Fertility Decline*

3.1 *Women's Educational Attainment*

Dramatic socioeconomic changes after World War II brought about important changes in women's status; educational attainment and employment grew, and these changes have also affected fertility. Women's education is a key factor affecting fertility through the timing of marriage, marital fertility, employment, and earnings. In Japan most women were already receiving primary education before World War II; the most notable postwar change has been the steady, rapid increase in the proportion of women with higher education. The proportion of female high-school graduates advancing to higher education increased from 6 percent in 1960 to 48 percent in 1995. The proportion of women aged 25 to 29 who had higher

education increased from 10 percent in 1970 to 43 percent in 1990, reaching a par with men in the same age group.

In contrast with Japan, the educational attainment of Korean women was very low in the early postwar years and a sizable proportion of older women had no formal education. This situation has changed dramatically. Only 3 percent of women born in 1936–40 had higher education, compared with 41 percent of women born in 1971–5. The corresponding proportion for men increased from 16 percent to 44 percent; thus the once vast gender gap has almost disappeared. Taiwan has also made impressive improvements in women's education. Educational attainment among Taiwanese women was very low in the early postwar years, with a sizable proportion of older women illiterate. Only 20 percent of women aged 20 to 24 had a high-school education in 1974, increasing to 34 percent in 1995. Since the mid-1970s, about 11 percent of women in this age group have experienced higher education.

3.2 *Economic Changes*

Japan, Korea, and Taiwan all experienced extremely rapid economic growth after World War II. Since the mid-1950s, Japan's per capita GNP in constant prices has quadrupled every ten to fifteen years, so that Japan is now the second largest economy in the world after the USA. Between the mid-1960s and the mid-1980s, Korea's per capita GNP also quadrupled every 10 to 15 years. Over the same period, Taiwan's per capita GNP doubled every 10 years.

In the course of rapid economic growth, Japan, Korea, and Taiwan experienced rapid urbanization. In Japan, the proportion of the population living in urban areas increased from 37 percent in 1950 to 63 percent in 1960 and 78 percent in 1995. Korea has experienced even more rapid urbanization, with the urban population rising from 21 percent in 1950 to 81 percent in 1995. In Taiwan the proportion of the population living in cities of 50,000 or more increased from 27 percent in 1952 to 73 percent in 1988.

Along with rapid economic growth and urbanization, these countries experienced dramatic changes in the structure of their economies. In Japan the proportion of the workers employed in primary industries fell from 49 percent in 1950 to 6 percent in 1995. In Taiwan it dropped from 56 percent in 1952 to 11 percent in 1995. In Korea the proportion of workers engaged in agriculture fell from 66 percent in 1960 to 12 percent in 1995.

3.3 *Women's Employment*

With economies shifting rapidly from primary to secondary and tertiary industries, female employment also underwent notable changes. In Japan, although the overall female labor force participation rate has

remained roughly 50 percent over the past 40 years, the type of female employment has changed dramatically. The proportion of employed women who were family workers declined steadily from 43 percent in 1960 to 12 percent in 1995, while the proportion of employed women in paid employment increased from 41 percent to 78 percent. Although Japanese women are still more likely to work before and after rather than during their peak childbearing and child-rearing years, they are increasingly likely also to work between the ages of 25 and 34.

In Korea, female labor force participation increased from one-quarter in 1960 to about one-half in 1995, but women in their peak childbearing and child-rearing years are still much less likely to work than younger or older women. Whereas labor force participation among women aged 20 to 24 increased considerably in the last decades of the twentieth century, participation rates for women aged 25 to 34 have remained stable. This suggests that while employment of young (mostly single) women has increased, paid employment among married women has remained limited. In Taiwan, overall female labor force participation rose from 19 percent to 45 percent between 1956 and 1995, and rates for women at peak childbearing and child-rearing ages increased especially dramatically—from 17 percent to 65 percent among women aged 25 to 29, and from 15 percent to 58 percent among women aged 30 to 34.

Fertility Transition: Economic Explanations

1. Approaches of Economics and Demography to the Fertility Transition

With the establishment of modern economic growth, fertility has tended to decline, first across high income countries starting largely in the last quarter of the nineteenth century, and then occurring even more rapidly across most low income countries in the last quarter of the twentieth century (Kuznets 1966, Schultz 1981). Economic models of the allocation of time and wealth of families among production and consumption activities suggests several hypotheses linking changes in the economic environment in which people live to their reproductive demands and fertility (Becker 1960, Mincer 1963). Empirical counterparts for the price, income, and environmental constraints on people's fertility choices have been used to explain aspects of fertility and other related outcomes of the family, strengthening the view that this household demand model is a source of insights into the determinants of the historic fertility transition (Schultz 1974, Becker 1981).

This economic approach to fertility determinants has been criticized by those who believe that fertility is not a rational response to changing economic conditions (Cleland and Wilson 1987). The proposed alternative to the economic approach, called 'ideational change' emphasizes social interactions, but has not yet evolved to a form that is empirically distinguishable. However, research is trying to quantify the role of groups external to the family such as peers and neighborhoods, and to interactions between family members as postulated in cooperative and non-cooperative game strategies within families. But because these groups are generally self selected, it is complex to specify the factors that affect the formation of the group and do not also affect the behavior of individuals who enter such groups (Heckman 1979, Manski 1995). There is active debate on how to apply the economic framework and to exploit statistically cross sectional and time series variation in fertility to improve our understanding of the determinants of fertility (e.g., Schultz 1997).

There is a fundamental methodological divide between those who want to describe a 'structural model' that involves interactions between choices made at the household level, including those choices spanning an adult's lifetime, such as between a woman's fertility, marriage, and labor force history, and those who

investigate a 'reduced form model' where only the fixed constraints on household choice are considered as potential explanatory variables—market prices, income sources, technologies, and the environment. It is widely recognized that the associations between lifetime choices represent more (or less) than a simple causal effect of one choice on the other. These covariations between family choices embody possible effects transmitted in both directions, effects of unobserved factors which impact both outcomes, and heterogeneity due to unobserved differences, perhaps in individual preferences (Schultz 1981). Strong identification restrictions are generally required to estimate from nonexperimental data the critical parameters to such 'structural models,' and therefore the empirical conclusions drawn from them are often controversial, because they depend on a host of untested and debatable modeling choices (Manski 1995).

The alternative approach is to estimate fertility as a function of explanatory variables that are not family choice variables or are not likely to be impacted by unobserved factors that could also affect fertility. By delimiting the potential list of explanatory variables, these 'reduced form' relationships represent a summation of the direct effect of the environmentally fixed constraints on the couple's fertility, plus the possible indirect effect of the same constraints on fertility that operate through the modification of other lifetime choice variables, such as the woman's age at marriage, extent of labor force activity outside of her home, contraceptive and sexual behavior, etc. The limitation of reduced form estimates is that they do not necessarily clarify the mechanism by which the constraints impact fertility, for example through the timing of marriage, or the adoption within marriage of various so-called 'natural' or 'unnatural' forms of birth control. The strength of reduced form estimates is that they claim to provide an unbiased approximation for the total effect of the constraint on fertility, which is often a central concern of the social scientist, forecaster, or policy maker.

Some historical demographers assign special importance to the moment when married women begin to restrict their birth rates in response to their prior number of births, or surviving children (Coale and Watkins 1986). Although this may be a well-defined and interesting threshold that predicts the onset of the long term decline in fertility in certain European populations, other populations may adopt other mechanisms to reach their changing fertility goals, such as a change in median age at marriage (i.e., Malthus' preventive check), an increase in celibacy or the proportion who never marry in a birth cohort, an increase in the spacing of births within marriage, as appears to be evident in Africa today (Caldwell et al. 1992, Shapiro and Tabashe 2000), or a change in non-marital fertility. Even in the region of Northern Europe, standard measures of the emergence of parity-specific fertility control within marriages are not

precisely defined by existing data (Guinnane et al. 1994). Thus, economists generally consider comprehensive measures of cohort fertility, and do not focus on one component, such as marital fertility.

2. Stages of the Demographic Transition

The 'demographic transition' refers to a sequence of three periods. In the first period, fertility and mortality rates are high and mortality tends to be highly variable, with population growth fluctuating widely about a moderate long run trend of growth or decline. Short run responses in fertility (and mortality) can be attributed to cycles in weather or harvests or possibly to other exogenous variables using time series statistical methods, such as vector-auto-regression.

In the second period, age-specific mortality rates decrease gradually, raising life expectancy at birth from 30–35 years in pre-industrial Europe, to 70–75 today in the high income countries, and from 25–30 years in the low income countries in the 1920s, to levels which today range from about 45–73, excluding countries ravaged by war or the AIDS epidemic. This second period is one of accelerating population growth, which some observers such as Malthus attributed to improved food supplies, and more specifically to nutrition, often initiated by technical progress in agriculture, followed by improved industrial productivity, and advances in transportation and communication (Fogel 1999). A free press capable of publicizing food shortfalls in the twentieth century may have further alleviated excess mortality in the wake of periodic famines. Improvements in private and public health technologies are assigned an important role in reducing mortality, but not much before the start of the twentieth century.

In the third period, the secular decline in fertility begins, after which the number of births per woman falls by more than half, from five or six to about two, in the high income countries, and six to eight to about two or three in most low income countries. When historically high fertility levels have declined by more than 10 percent, they are not expected to rise again on a sustained basis (National Research Council 2000). Medium-term swings in fertility are nonetheless distinguished from time series, occurring in response to business cycles (e.g., the post-World War II baby boom), wars, and economic shocks, as during the transition from centrally planned to market oriented economies in the 1990s in Eastern Europe and Russia, or recently due to reversals in sub-Saharan Africa.

3. Economic Determinants of Fertility

Notestein (1945) described the early dimensions of the demographic transition, and speculated on the economic pressures which he expected to reduce fertility in

the low income world: rising cost of children in urban life, individualistic promotion of child health, and education. Economic models of a lifetime fertility choice emphasize different facets of this decision process, but the trade-off between quantity of children and their quality (i.e., education and health) has become a central feature (Becker 1960, Mincer 1963, Schultz 1981). Because women's time in child-care is a large fraction of the modern opportunity cost of fertility, her allocation of time is treated as jointly determined with fertility. Many cross-sectional and a few time-series studies have proceeded to relate statistically these fixed constraints to fertility outcomes.

A couple's lifetime wealth (endowments of human capital and nonhuman capital) is expected to increase with modern economic growth, and to encourage parents to demand more children, if the relative costs and functions of children did not change (Becker 1960, Schultz 1981). However, for reasons discussed below, the opportunity cost of children increased along with the cost of other goods and activities that complement the rearing of children, whereas the private price of some substitutes for children, such as old-age pensions and healthcare, have been socialized and subsidized by governments. Marked improvements in the technology of birth control were developed in the 1950s, translating into the rapid diffusion of the pill (oral steroid contraceptive) and the IUD (inter-uterine device) to most regions of the world. The monetary and psychic cost and inconvenience (independent of coitus) of avoiding too many births was reduced, and should thereby have reduced the number of births. Family planning programs are not, however, a necessary condition for the occurrence of a fertility transition, because birth rates declined in high income countries without the benefit of new control technologies, or of family planning extension activities designed to foster the adoption of birth control. Finally, improvements in child health technology increased the proportion of births that survived to adulthood. These health developments put downward pressure on birth rates, under two assumptions: parent reproductive goals are defined primarily in terms of their number of surviving children, and these demands for survivors are highly price inelastic (Schultz 1981).

The actual expenditures of a couple on each of their children is not a suitable indicator of the 'market price' of a child on which a couple would base their demand for children. Expenditures per child are also a family choice, which Becker called the demand for 'child quality.' The market-determined prices of the inputs that households combine to rear children are the relevant prices that condition fertility. There is no consensus on which inputs to children are most important and how their unit prices are measured.

If one accepts Becker's (1960) hypothesis that quality and quantity of children are viewed by parents as substitutes, and much of the variation in child quality is embodied in the education parents give their

child, then the net price of schooling would affect negatively the demand for quality and affect positively the demand for quantity of children. There is growing evidence in the twentieth century that wage returns to schooling increased, and this can be viewed as a decline in the price of schooling, encouraging parents and societies to invest more resources in the education of children. If parents view schooling per child as a substitute for numbers of children, as is now often empirically confirmed (e.g., Rosenzweig and Wolpin 1980), the increasing wage return to schooling among workers should encourage parents to substitute child schooling for number of children. The increase in wage returns to schooling can be attributed to a technological bias favoring skilled labor, or to a complementarity in production between the schooling of workers and the accumulating stock of technical knowledge available in the global economy.

Becker (1981) also assumed that the income effect on the demand for child quality was a larger positive magnitude than the income effect on the demand for child quantity. This might also have encouraged parents to substitute child quality for child quantity as their incomes increased from one generation to the next. Here was a second possible explanation for the anomalous fall in fertility in a period when *per capita* income was increasing.

4. The Increasing Value of Parents' Time as an Opportunity Cost of Children

In the twentieth century, the fraction of national income paid out to labor has risen, despite the increase in capital employed per worker and the decrease in hours worked/year per worker (Kuznets 1966, Fogel 1999). Wage rates have grown relative to *per capita* income, implying that consumption activities that use more time of the consumer have become relatively more expensive over time. Children are thought to be a more 'time-intensive commodity' than the average of all consumption commodities, and thus the opportunity costs for household's to produce and consume a child have risen as parent wages have risen, offsetting some part of the increased demand for children that might have been expected in a period when *per capita* income is rising (Mincer 1963, Becker 1965).

The household production-consumption model drew attention to gender specialization in social production, and to the 'female time-intensity' of children, thereby suggesting the woman's value of time could be a key component in the price of children. In environments where the opportunity cost of female (i.e., mother's or child-care giver's) time is higher, fertility is expected to be lower, other things equal (Schultz 1981). The market wage of women might thus be an 'opportunity price' variable, and it has notably increased in many countries in the twentieth century at a time when fertility has fallen. But just as 'parental

expenditures per child' does not represent a fixed market-determined price of a child, the woman's market wage does not represent a fixed price of a woman's time input to child rearing. First, the wage a woman receives in the labor force is affected by her prior job experience, which accumulates at different rates depending on her preferences among types of work and the allocation of her time. Consequently, a woman's wage is an endogenous choice variable closely linked to her lifetime allocation of time, which in turn is intimately related to her fertility decisions (Mincer 1963).

A second problem with the woman's wage variable is that it is observed only for a self-selected fraction of women who work for a wage in the survey period, and this fraction has tended to rise over time in many populations, and to differ by socioeconomic strata within a population. It is possible that women who work for wages are those who receive an unusually high market wage offer, suggesting that the observed average wage of women overstates the value of time of an average woman. Conversely, women who are unusually productive in nonwage work, and thus are less likely to participate in the wage labor force, may still have an above average market-wage offer, in which case the observed average wage of women would understate the value of time of an average woman. Sample selection bias could distort the wage as a measure of the value of women's time, and thus bias estimates of the woman's wage effect on fertility, probably overstating the causal connection in time series (Heckman 1979, Schultz 1981).

5. Determinants of the Value of Women's Time and the Cost of Children

The variation in the opportunity price of children that arises from the variation in women's opportunity value of their time remains a key economic determinant of fertility, and econometric procedures are required to estimate the importance of this connection for the fertility transition. In other words, because the observed wage of women cannot be treated as a fixed determinant of fertility, it cannot be included in a reduced form equation for fertility. How then, does one approximate in a more structural model the effect of employment and productive opportunities for women on the opportunity cost of a woman's time, which in turn affects fertility?

One approach to this problem is to employ the woman's education as a proxy for her wage; schooling tends to be the best variable available for predicting in the cross-section women's wages, just as it is for men's wages. For most women their human capital investment in schooling is completed before childbearing starts, and thus the schooling decision can be viewed as predetermined with respect to fertility. If the schooling decision is made by the child's parents, it

may also be argued that the woman's schooling is unaffected by her adult preferences between labor market and fertility choices, and then schooling may be a satisfactory 'instrumental variable' for predicting the adult lifetime wage opportunities for women, which constrain the choice of fertility.

A second approach is to treat the structure of wages in the local labor market as fixed and thus independent of the woman's preferences. This appears to be a reasonable strategy, proceeding from the individual wage to the community averaged wage, and thus eliminating the idiosyncratic individual variation in preferences between working and fertility. Analyses of fertility can then include all women based on the regional wage, and not be restricted to a selected sample of women who are currently reported working for a wage. But another problem could still bias the estimated effect of women's regional wage opportunities on regional or individual fertility. Because an increase in the labor supplied by women in a region will tend to depress the market-clearing wage women receive locally, any omitted regional variables that contribute to greater female labor force participation are expected to also be correlated with lower wages, and hence be correlated with higher fertility. Consequently, these regional omitted labor supply variables would introduce a positive bias in the estimated effect of woman's regional wage on fertility, masking the theoretically expected negative impact of aggregate demand-induced variation in women's wages on fertility.

One estimation strategy to deal with this regional omitted variable problem is to specify a regional variable that shifts only the aggregate regional economy's demand for female labor (relative to the demand for male labor), and thereby affects the local wage available to women (relative to men). Variables of this form which shift the aggregate demand schedule for women's labor are candidates for being an 'instrumental variable' that can account for demand-induced variation in women wages, and can thus be used to obtain an unbiased estimate of the effect of women's wages on fertility. One such demand variable is the regional location of natural resources or the composition of industries, which influence the gender composition of employment opportunities and wages.

Coal mines, for example, employ mostly men, and communities dependent on coal mines for their livelihood have relatively low wages for women. Historically, these coal communities in the UK and the United States reported relatively high fertility levels, other things equal (Haines 1979). In the Northern provinces of Sweden where the price and quantity of timber increased at the end of the nineteenth century due to exports, men's wages increased relative to women's wages, and fertility remained high in these regions well into the twentieth century. By contrast, fertility in the Southern provinces of Sweden declined after the 1860s, as women's wages increased relative to

those of men, in response to higher output prices for exports of livestock, dairy, and food manufactured products, which employed relatively more women (Schultz 1985). Natural resource exports strengthen government finances by providing an inelastic source of taxation, notably in the case of oil exports, with a tendency to sustain customary social institutions that have been associated with relatively low levels of female education, low female labor force participation, and high levels of fertility, holding constant for other factors (Schultz 1994).

Labor economists have noted since the 1960s that in regions where the share of employment in certain industries, for example the services, is relatively large, female labor force participation rates tend to be higher. The importance of part-time, less-skilled, and physically less-demanding jobs may thus be associated with a larger share of women in the labor force, and a rise in the economic status of women relative to men. This form of 'female bias' in the industrial composition of local employment is found to predict increased women's wages relative to men's and lower fertility.

Changes in fertility over time can then be explained by changes in factors external to the household sector which govern the expansion of employment opportunities in industries that hire a disproportionate share of women (or men). The price of the industry's output when it is determined in international markets is one such factor. Terms of trade indexes linked to gender-specific employment and wages opportunities can predict women's wages relative to men's and provide a basis for estimating how demand-driven variation in women's employment opportunities influence fertility. However, these changes in relative prices and employment prospects must be perceived by couples as sufficiently long term in nature that they feel the need to adapt accordingly their reproductive goals.

6. Evidence from European Fertility Transitions

The decline in the price of food grains in Europe in the nineteenth century led to such a profound reallocation of labor and allied resources. With the opening of the Erie canal in 1825 and the reduction in ocean transportation costs, exports from the USA, Russia, and other world grain exporters depressed grain markets across Europe. Although restrictions of trade attempted to protect domestic agriculture, European farmers gradually adapted to their changing comparative advantage and left agriculture for urban jobs or emigrated, whereas those who remained in agriculture reallocated their effort from grain to livestock production and to the expansion of food and dairy processing industries. Because grain production traditionally employed more male labor, and livestock and dairy production used more female labor, these changing output prices boosted women's wages relative to men's. This reallocation of resources occurred more rapidly where economies were more open to

international trade in agricultural commodities. This transformation of composition of European agriculture or its consequences on the productive roles of women and men is not quantitatively studied in the Princeton European Fertility Project, although these changes could have influenced the diffusion of the fertility transition (Coale and Watkins 1986).

In Sweden, as noted earlier, these agricultural relative price changes were closely associated with the improvement in women's wages relative to men's, and with declines in fertility, by province over time, starting after 1860. The level of real wages for men was related to younger childbearing, but not to a change in total fertility rates. About one-third of the 25 percent decline in total fertility rates for Sweden in the period 1860 to 1910 can be attributed to these externally driven increases of women's wage opportunities, whereas the rest of the decline in Swedish fertility in this half century is associated with urbanization and the increase in child survival, under the assumption that these are exogenous developments (Schultz 1985). A similar demographic pattern unfolded in Denmark, which was also relatively open to international agricultural trade, while its demographic transition was only slightly less rapid than in Sweden.

The German fertility transitions has also been analyzed from 1880 to 1910. When regional persistent or fixed-effects are introduced in the analysis of times series of cross sections, the evidence of strong partial effects of industrialization and urbanization emerge (Richards 1977). Smaller regional units were examined in Prussia from 1875 to 1910, with the same regional fixed-effect specification for fertility (Galloway et al. 1994). However, the female labor force participation rates are used to explain fertility in a reduced form specification, as though the labor force participation of women was a fixed constraint on fertility decisions. Not surprisingly, this choice variable reflecting women's time allocation accounts for the largest fraction of the fertility decline, and if it is jointly determined by women with their fertility, as seems likely, the reported estimates are subject to simultaneous equation bias and are difficult to interpret as evidence for any causal model.

7. Advancement in Women's Schooling

Another widespread development in the world, which has contributed to increasing the cost of children relative to most other forms of consumption, is the advance in women's schooling. In the USA, by the start of the twentieth century, the gender gap in schooling was modest, except for college education. But this gap remained substantial in most countries in Southern and Eastern Europe until after the World War I. Moreover, women's schooling attainment began to gain relative to that of men in low income countries only in the last few decades. This progress has been particularly sluggish in South Asia where the

fertility transition has also been most gradual. Given the empirical tendency for wages to increase for women by at least the same percentage as they do for men when they obtain an additional year of schooling, the closure in the gender gap in schooling implies that women's wages are likely to continue to increase in most parts of the low income world for some time, and indeed increase at a more rapid rate than will the wages of men (Schultz 1995). The factors that have triggered these differential trends in the schooling of women and men have not been thoroughly studied, but the expansion of women's schooling closely parallels the decline in fertility across high and low income countries since 1960. Indeed, changes in women's schooling accounts for the largest share of the changes in total fertility rates observed in low income countries since 1960, and in Africa since 1980 (Schultz 1994). Even in an environment where economic progress has been minimal since the 1960s—Kinshasa City in Congo—the increasing rate of female education is the key factor explaining different levels of fertility across the population, and accounting for the decline in fertility in the 1980s and 1990s (Shapiro and Tambashe 2000).

However, educated women could have lower fertility for many reasons, in addition to the greater opportunity cost of their time in child rearing. The social and intellectual advantages that educated women enjoy help them in deciphering, adopting, and using effectively, new and old forms of birth control, and thereby avoiding unwanted births.

Female schooling may also affect fertility through its impact on the risks of child mortality. Censuses and surveys after the World War II have documented for dozens of countries that child mortality rates tend to be 5 to 10 percent lower for mothers who have completed an additional year of schooling (Schultz 1981, 1997). However, the proportionate decline in fertility associated with women's education is larger than the proportionate increase in their child survival rates. Therefore, better educated women have smaller numbers of surviving children, which implies they contribute less to the overall rate of population growth than their less educated peers (Schultz 1994).

Education of women is also closely related to their labor force participation outside of their family, holding constant for their husband's income or education (Schultz 1981). Household models of production and consumption generally assume that family labor supply choices are jointly determined, and women's education is expected to affect not only lifetime fertility, but also the timing of marriage and the matching of the productive characteristics between husband and wife in the marriage 'market.' Within such a framework of family coordinated decision making, it is clearly difficult to assess how one of these jointly determined life-cycle choices made by women affects another of their choices, as stressed earlier. To decompose the variation in fertility into that which is

due to the timing of marriage, marital fertility rates, and non-marital fertility rates is a suggestive arithmetic exercise, but one that can misguide statistical analysis because the three components are likely to be stochastically interdependent. Consequently, when analyses of fertility differentials during the demographic transition focus only on marital fertility differentials, correlations can be causally understood only if marriage behavior and fertility demands are behaviorally independent of each other, a working assumption that few social scientists would adopt (Coale and Watkins 1986, Cleland and Wilson 1987).

8. Conclusions

Economic explanations for the fertility transition recognize the catalytic contribution of increasing returns to schooling, especially for women, which has encouraged women's education relative to men's, and fostered the rise in women's wages. These attributes of development are not equally evident in all countries. Declines in fertility have therefore proceeded quite unevenly, first across the high income countries, and more recently across the low income countries, but following a pattern of economic developments that has been widely quantified in household surveys and suggestively followed in cross-country comparisons. At an aggregate level, states have simultaneously legislated socialized support systems to provide for the consumption requirements of the elderly, and for the school and health investment requirements of the young, which may have also on balance, reduced the private demands of parents for children.

Fertility Transition: Latin America and the Caribbean

In the second half of the twentieth century Latin America experienced a remarkable demographic transformation, with fertility declining from a regional

average of more than six children per woman in 1950 to less than three children per woman by the year 2000. In this article we describe the nature of the decline, assess the role played by the proximate determinants of fertility, and discuss the ultimate causes and consequences of this profound transformation.

1. Fertility Levels and Trends

CELADE (1999) has published estimates and projections of the total fertility rate (TFR) for 20 countries in Latin America and the Caribbean for the period 1950–2000. These estimates update Chackiel and Schkolnik's (1996) excellent overview of the transition. The estimates are based on population censuses and vital statistics analyzed using direct and indirect techniques, and are generally consistent with alternative estimates based on survey data, such as the World Fertility Survey (WFS) and the Demographic and Health Surveys (DHS). Figure 1 plots the TFRs for a subset of 10 countries that represent the types of transitions observed in the region.

Back in 1950 most countries in Latin America and the Caribbean had TFRs in excess of six children per woman. Notable exceptions (the last four solid lines in Fig. 1) were Argentina and Uruguay, with rates around three; and Cuba and Chile, which hovered around four and five, respectively, but dropped below three in the mid- to late 1970s. Cuba then went on to have the lowest fertility in the region, 1.6 children per woman by the year 2000. A second group of 10 countries experienced declines from much higher fertility to cross the four-child level in the 1970s and 1980s. These include Panama, Brazil, El Salvador, and the Dominican Republic (the dashed lines in Fig. 1), as well as Colombia, Costa Rica, Ecuador, Mexico, Peru, and Venezuela (not shown, but their trajectories are bracketed at both ends by the countries shown). By the end of the twentieth century only six countries still had TFRs above three, but they all had experienced substantial fertility declines for 20 years or longer. This third group includes Guatemala and Paraguay (the top two solid lines in Fig. 1, representing the highest and lowest TFRs in this group in 2000), as well as Bolivia, Haiti, Honduras, and Nicaragua (not shown).

While there are substantial differences among countries, age-specific fertility has fallen more rapidly at older than at younger ages, as one would expect of a transition driven primarily by a desire to limit fertility rather than space births (Chackiel and Schkolnik 1996). This notion is confirmed by birth-interval analyses that show a substantial decline in parity progression ratios (the proportion of women proceeding from one parity to the next), particularly at high parities, with little if any change in average birth intervals (Juárez and Llera 1996).

Figure 1
Total fertility rates, Latin America and the Caribbean, 1950–2000

The national averages conceal substantial variation across social groups in each country. Not surprisingly, fertility in Latin America has been substantially lower in urban than in rural areas; it decreases with increasing education of women, and with increasing status in occupation of the husband as one moves from agricultural workers through manual laborers to white-collar strata. The fertility decline started in the higher strata, but it soon spread to other groups, eventually reaching rural areas and women with no education married to agricultural workers. As a result, differentials increased at the start of the transition but

became narrower as fertility levels declined (Rodríguez 1996, Chackiel and Schkolnik 1996).

2. *The Proximate Determinants*

Following Davis and Blake's classic framework, changes in fertility can be traced to changes in intermediate variables affecting exposure to the risk of pregnancy, to conception, and to gestation. Most analyses focus on three key factors: marriage, contraception, and postpartum infecundity. A fourth important factor, abortion, is often omitted for lack of

reliable data. Moreno and Singh (1996), in a thorough analysis of these variables using WFS and DHS data, apply Bongaarts' model as well as an alternative model by Moreno to show that the bulk of the fertility decline in Latin America can be attributed to increases in contraceptive use, with changes in nuptiality and breastfeeding making only modest contributions.

Rosero-Bixby (1996) has examined the role of nuptiality in more detail. Using census and survey data he finds a slight increase in the time spent in union between 1950 and 1960 (consistent with isolated fertility increases in this period) followed by a flat trend. The proportion of consensual unions exceeds 50 percent in several countries, particularly in Central America and the Caribbean, and has increased over time. More remarkably, he finds no systematic trend in age at marriage. These results suggest that nuptiality trends could hardly contribute to the reduction in fertility in the region after 1960, and a more formal analysis shows only modest effects in selected countries.

Weinberger (1996) analyzed the role of contraception. She estimates a prevalence rate for the region during 1990 of 56 percent of couples where the wife is in the reproductive ages, with country-specific rates ranging from 7 percent in Haiti to around 70 percent in Costa Rica. The earliest national-level surveys measuring contraceptive practice go back to the 1970s and document a rapid and continuing spread of contraceptive use that is consistent with the observed decline in fertility. A distinctive characteristic of contraceptive use in the region is the high prevalence of female sterilization (20 percent of couples) and oral contraception (16 percent), which together account for about two-thirds of all contraceptive use. Other methods used by at least 5 percent of couples are periodic abstinence or rhythm, and intra-uterine devices. In contrast, male sterilization is rare (around 1 percent of users). In general, changes in the method mix over time have tended towards increased effectiveness, a trend largely due to increased reliance on female sterilization.

The role of induced abortion is hard to determine because of a dearth of reliable data. Frejka and Atkin (1996) argue convincingly that induced abortion is used widely in the region, but can provide only indirect evidence in most cases. Exceptions include Cuba, where abortion has been available on request since 1960, and Chile, where abortion is illegal but reasonable estimates are available from health statistics and surveys; both countries had total abortion rates in excess of two in the 1960s, coinciding with periods of steep fertility decline. (Interestingly, the early surveys in Chile helped motivate the medical profession to provide family planning services as an alternative to abortion.) Singh and Sedgh (1997) use indirect estimates based on hospitalizations for the treatment of complications related to induced abortions to show that, in addition to helping determine fertility levels,

abortion has played a significant role in the fertility decline in Brazil (where fertility in the 1990s would have been about 13 percent higher had abortion not increased from its level in the late 1970s), and more moderate roles in Colombia and Mexico.

Finally, postpartum infecundity appears to be the least important of the proximate determinants in terms of its role in the fertility transition in the region. The duration of breastfeeding in Latin America and the Caribbean is relatively short (with the exception of Haiti and Peru) and has not changed much over time.

3. Ultimate Causes and Consequences of the Decline

Traditional explanations of fertility decline have focused on socioeconomic changes that reduce the demand for children, but more recently there has been a resurgence of interest in theories that emphasize ideational changes and the diffusion of new ideas and forms of behavior. Several features of the Latin American transition suggest that the process represents more an innovation than adaptation to changing economic conditions.

Starting in the 1960s, Latin America underwent a process of modernization that resulted in remarkable improvements in educational levels, a shift away from agricultural work, greater participation of women in the labor force, and a doubling of per capita income between 1955 and 1980. Impressive as these achievements are, the changing socioeconomic composition of the population explains only a small part of the overall decline in fertility, which was driven largely by changes within social strata (Rodríguez 1996). Moreover, the economic situation changed drastically in the 1980s, as the region experienced a profound crisis (the 'lost decade') that eroded standards of living and reduced upward mobility; yet had little if any perceptible effect on the pace of the decline.

More direct evidence on the demand for children comes from data on fertility preferences. Starting in the 1960s, a number of surveys found preferences for small families in high-fertility regimes where women were not using contraception—the so-called 'KAP gap'—that evolved later into more sophisticated measures of unmet need for contraception and decompositions of fertility into its wanted and unwanted components (Westoff and Moreno 1996.) In countries like Costa Rica the transition seems to have occurred, at least initially, without a corresponding reduction in ideal family size (Rosero-Bixby 1999). Once the decline is established, however, preferences may well be reduced further. In Peru, for example, the TFR in 1977 to 1978 was 5.3 and its wanted component was only three. Ten years later the TFR had declined to four, but by then wanted fertility had further declined to two children per woman (Bongaarts and Lightbourne

1996). Still, back in the 1960s demand was already low and there was ample room for fertility reduction by better implementing existing preferences.

The gap persisted because the means to reduce fertility were not widely available at the time, but the situation was soon to change. Family planning programs were introduced in Latin America starting in the 1960s, largely as the result of private initiatives organized with help from the International Planned Parenthood Federation (IPPF) and, in some cases, the United States Agency for International Development (USAID). A leading private program is Profamilia, which was established in Colombia in 1965 and was a pioneer in the development of distribution networks and the use of radio to promote family planning. In the 1970s a number of governments started to provide services as well: a leader in this area was Mexico, where government clinics opened in 1974. Today most countries have a mixture of private- and public-sector programs, the latter often integrated with maternal and child health services. While estimates of the demographic impact of these programs vary, there is little doubt that they facilitated the transition by increasing the acceptability and availability of contraception (Mundigo 1996, Bongaarts et al 1990).

Once modern contraceptive methods became generally available, all that remained was for women to adopt them. It is here that diffusion or social contagion enters the picture, with friends and relatives playing a key role in terms of information flow and demonstration effects, at least in the early stages of the transition. A multivariate analysis of the spacing and limiting components of fertility shows that once the transition starts in a social stratum, it follows a broad but well-defined path that is consistent with a basic diffusion process (Rodríguez 1996). In a detailed case study of Costa Rica, quantitative spatial analysis combined with qualitative focus group research provides strong evidence of diffusion effects (Rosero-Bixby 1999). There is also a growing body of evidence that the mass media, particularly radio and television, can play a significant role. Perhaps the best documented example comes from northeast Brazil, where the fertility decline tracks the spread of television and the extremely popular *telenovelas*, nightly soap operas that often deal with life-styles, family values, sexuality, and reproductive behavior, and which can have strong if unintended influences on attitudes and values (Faria and Potter 1999).

Assessment of the consequences of the fertility transition is difficult because these changes occurred in times of economic crisis and turmoil (Potter 1996). There is, however, clear evidence that the decline resulted in lower infant mortality rates (Taucher 1996). Perhaps of more enduring consequence, the status of women has changed as a result of improved education and reduced fertility. In the words of a *New York Times* editorial on the subject, 'For all the machismo in Latin America, women there have gained sub-

stantially more rights and better treatment than women in the rest of the developing world.'

Fertility Transition: Middle East and North Africa

1. Introduction

Countries in the Middle East and North Africa (MENA) region provide a complex and rich experience on fertility transition. During the second half of the twentieth century, fertility trends took more

divergent courses than ever before. Several forces influenced fertility in conflicting directions. On the one side the forces of modernization, development, modern family planning technology and women's education, among others, have worked toward rapid fertility decline. On the other side, political, religious, cultural and institutional forces have supported early marriage and high procreation. The balance of these two sets of conflicting forces has, over time, influenced the onset and magnitude of fertility transition in the region.

2. Fertility Transition During the Period 1950–70

Throughout this period fertility was high in a group of 22 predominantly Arab and Muslim MENA countries (henceforth these countries will be referred to by the acronym AMENA). The total fertility rates (TFR) were five or more live births per woman (see Table 1 and Fig. 1) and the crude birth rates (CBR) were above 40 births per 1,000 persons. Some of these countries experienced a slight fertility increase. For instance, fertility increased from 5.74 to 6.36 in Lebanon and from 6.93 to 7.25 in Tunisia. Similar increases occurred in Egypt, Bahrain, Jordan and Libya. An odd country among this group is the former Soviet Union of Azerbaijan where fertility was relatively lower (TFR = 5.49; see Fig. 1).

A second group of four MENA countries experienced low and declining fertility ($3 \leq \text{TFR} \leq 4.9$; see Table 1 and Fig. 1). Between 1950 and 1970, fertility declined, albeit slowly, from 4.49 to 3.45 and from 3.0 to 2.61 in the Soviet republics of Armenia and Georgia, respectively. Cyprus experienced a similar slow decline from 3.71 to 2.79 during the same period. Also, fertility declined from 4.16 to 3.79 in Israel, which represents a special case because of its large immigrant population from Europe, the Arab States and Africa (Okun 1997, Goldscheider 1992). Henceforth, this group of countries will be referred to by the acronym (NAMENA), as a separate group in the MENA region.

Table 1
Distribution of MENA countries by categories of total fertility rates (TFR) 1950–2000

TFR	1950–55	1960–65	1970–75	1980–85	1990–95	1995–2000

Figure 1
Average total fertility rates in the MENA countries

Fertility trends in the above mentioned two groups of MENA countries (AMENA and NAMENA) reflect considerable differences in reproductive behavior during this period. High fertility in the AMENA countries was due to political, religious, cultural, and institutional factors, and to the supremacy of patriarchal and extended family norms (Yousif et al. 1996, Courbage 1999). Moreover, public policies were against family planning interventions to regulate fertility (Obermeyer 1992). By contrast, culture and public policies in the NAMENA countries were in support of small family size, women's education and the use of modern contraceptive methods (Okun 1997).

3. Fertility Transition During the Period 1970–2000

The onset and magnitude of the fertility transition during this period varied considerably (see Table 1 and Fig. 1). The slow fertility decline mentioned before in Cyprus, Georgia, and Armenia continued unabated and reached replacement level ($TFR = 2.1$) during this period. However, the traditional high fertility in the AMENA countries gradually declined. Fertility continued to decline in Azerbaijan and it reached below replacement level by the year 2000 (see Fig. 1).

It also declined to 2.2–2.9 live births per woman in six countries (Lebanon, Tunisia, Turkey, Iran, Kuwait, and Bahrain) and to 3.0–4.9 in ten others (Jordan, Sudan, Syria, Algeria, Libya, Qatar, United Arab Emirates, Egypt, Morocco, and Western Sahara; see Fig. 1). Fertility remained high ($TFR \geq 5.0$) in only five AMENA countries (Yemen, Saudi Arabia, Oman, Iraq, and the Gaza Strip).

Tunisia, a pioneer country in the AMENA group, provides a good example of a sharp fertility decline from 6.21 in 1970 to 2.55 in 2000—a drop of 3.66 children in 30 years. The total fertility rate declined in Egypt from 5.6 in 1976 to 4.1 in 1991 and to 3.9 in 1992; a drop of 30 percent in 17 years. Kuwait provides a third example with a TFR decline from 5.9 in 1980 to 2.89 in 2000; a drop of three children in 20 years. Fertility declined in the Maghrib countries too, by 2.8 children in Algeria (1977–92) and 2.9 children in Morocco (1971–92).

By contrast, fertility remained high in Iraq, Saudi Arabia, Oman, and the Gaza Strip where the TFR ranged between 5.3 to 8 children per woman (see Fig. 1) and the CBR stayed above 40 throughout the second half of the twentieth century. A slight fertility decline finally occurred in a couple of these countries during the 1990s. Fertility declined from 6.8 to 5.8 in Saudi Arabia, and from 6.2 to 5.2 in Iraq. By contrast, fertility in Yemen and the Gaza Strip remained at a

Figure 2
Population distribution by age in the AMENA 2 countries

high level of seven or more children per woman throughout the 1950–2000 period.

TFR declined to 3.6 in urban areas and it remained high at a level of 6.3 children in the rural areas of Egypt.

4. Urban vs. Rural Fertility

Place of residence (urban–rural) has a pervasive influence on fertility transition in the AMENA countries. It encapsulates many differences in opportunities available to women. Urban women have better access to the media and information technology, education, health, modern jobs, and family planning methods than their rural counterparts, most of whom are still under the grip of traditional beliefs and values (Yousif et al. 1996). The fertility decline is considerably higher and its onset earlier in urban than in rural areas. For instance the total fertility rate had dropped to below replacement level in Beirut by 1999, while in North Lebanon it averaged four live births (Kulczycki and Saxena 1999). In some AMENA countries a fertility decline occurred in the urban areas only. In Sudan, for example, fertility has declined to 3.7 in Khartoum and has remained high at above six children per woman in rural areas (Yousif et al. 1996). The

5. Women's Education

Women's educational attainment has contributed significantly to the fertility transition in the MENA countries. However, countries have differed from each other with regard to the level of education (or years of schooling) at which fertility declined. In several countries fertility declined in response to a few-years increase in women's education (Yousif et al. 1996). The rapid spread of women's education during the period 1970–2000 reduced the influence of traditional values, attitudes and norms and strengthened women's social status within households and communities. It facilitated their employment in modern activities outside the home as well. Consequently, the mean age at marriage for girls has increased to 25 or more years in several AMENA countries. Moreover, generations of educated girls have acquired modern aspirations and family desires.

Figure 3
Population distribution by age in the AMENA 1 countries

6. Impact of the Fertility Transition on Age Composition

The impact of past high fertility, which often is associated with a high population momentum, on the age composition of the population is universal in the AMENA countries. This is reflected in increasing absolute and relative numbers of children below the age of 15 and in a precipitous increase in the working age population (15 to 64 years of age). The high population momentum is so pervasive that the impact of the recent fertility decline in these countries has not yet taken its full swing (see Figs. 2 and 3).

However, the impact is clear in the AMENA countries that have experienced fertility decline earlier than the others (see Fig. 3). In Azerbaijan and Tunisia, for example, the percentage of children below age 15 is declining, and it reached 30.3 percent and 28.6 percent, respectively, in 2000. In Lebanon and Kuwait this proportion is also declining (to 33.7 percent and 32.7 percent by 2000). In countries like Yemen, the Gaza Strip, Saudi Arabia, Iraq, Jordan, and Syria, children still make up more than 40 percent of the total population. However, in all AMENA countries, the

percentage of the population at working age is increasing, which implies a high demand for social services, particularly family planning, health, and education, as well as jobs.

By contrast, continuous fertility decline in the NAMENA has led to a relatively stable absolute and relative number of children below age 15 (see Fig. 4). The working age population is growing rapidly and its proportion of the total population exceeded 62 percent in all of these countries. The relative and absolute numbers of elderly have increased too and it has reached 12.6 percent in Georgia and 9.8 percent in Israel. This process will continue in the future, with profound implications for health and old age security schemes in these countries. These changes reflect an older age structure compared with the AMENA countries.

7. Impacts of Public Policies on the Fertility Transition

Public policies in the MENA countries provided the ideological and operational context for the fertility

Figure 4
Population distribution by age in the NAMENA countries

transition. During the period 1950–70, population issues in the AMENA countries were seen as long-term problems of secondary importance, neither pressing nor urgent (Yousif et al. 1996). The reproductive role of women was regarded more important than their education and participation in modern employment. This public policy stand was evident during the International Population Conference in Bucharest in 1974. Delegates from the AMENA countries invariably argued in support of development, as opposed to family planning, as the best method for resolving population problems. Ten years later, by 1984, the political stand of these governments had changed, and in 1994 several AMENA countries reached an advanced stage on issues of population policy and development. Also, government support to population policies and programs gained importance, albeit at different times, in the AMENA countries.

Public policy in some countries changed direction several times. In Egypt, for instance, the government was against the use of modern contraceptive methods during the 1960s and 1970s. Starting in 1980, the government has changed its stand to support family

planning to regulate fertility and address population issues in the country. Its main challenge is in the rural areas, particularly in Upper Egypt, where fertility is highest and the potential for decline greatest.

Sudan and Iran provide other examples of countries with contradictory or vacillating public policies on population issues. The Sudan family planning program, which was progressing well during the 1970s and 1980s, has recently come to a standstill due to lack of government support. In Iran, the government's opposition to family planning after the Islamic revolution in 1979 has now changed completely to the opposite (Courbage 1999). In the Gulf States public policies on population issues and family planning are in their infancy.

8. Conclusions

Fertility transition mirrors divergences in culture and development of the MENA countries. Family values and traditions, social institutions, norms, ethnic divisions, religious beliefs, and all the various forces of

modernization and development are reflected in the fertility trends of the populations in this region. The downward trend in fertility in many countries and in urban areas is irreversible in view of ongoing social development, improving educational attainment, and increasing use of contraceptive methods. The potential for further fertility decline in the future is high, particularly in rural areas and in the AMENA countries where fertility is currently high.

Fertility Transition: South Asia

South Asia is defined here as the countries of former British India (India, Pakistan, and Bangladesh) plus Nepal and Sri Lanka. Their combined population was estimated to be 1.34 billion in the year 2000, equivalent to 22 percent of the global total. Fertility trends in this

region are thus a crucially important determinant of future global population size. In this article the course of fertility over the past 50 years will be described, attempts to explain changes in reproductive behavior will be reviewed, and prospects for future fertility decline assessed.

1. Data Sources

Though only Sri Lanka possesses a vital registration system with high coverage of births, there is nevertheless a relative abundance of demographic data sources in South Asia, including decennial censuses and large-scale single-round demographic surveys. In terms of regular demographic monitoring, the outstanding achievement of the region is India's Sample Registration System (SRS). The SRS has yielded annual demographic estimates for most states in India since the early 1970s.

The collection of accurate demographic data in South Asia is extremely difficult and all national datasets are flawed to some extent. This has generated considerable controversy over the timing and magnitude of reproductive change in South Asia. Genuine uncertainty still exists over the details, particularly in Pakistan, where the quality of data is especially poor, but the broad contours of demographic change are well established.

2. Fertility Trends

The historic level of fertility in South Asia was probably similar to that of Europe and China, namely an average of 5.5 to 6.0 live births per woman, with fluctuations in the range of 4.5 to 6.5. Natality rose during the 1950s and 1960s in some parts of the region, a reflection of declines in widowhood and changes in breastfeeding patterns and sexual behavior within marriage. Fertility peaked at around seven births per woman in Bangladesh and Pakistan in the 1970s but remained about one birth lower in the other three countries.

Sri Lanka was the forerunner of fertility transition (see Fig. 1). The onset of decline dates back to the 1950s, and began largely in response to a rising age at marriage (Fernando 1975). The first appreciable fall in national fertility in India occurred in the 1970s, in Pakistan and Bangladesh in the 1980s, and in Nepal in the early 1990s. Comparing the highest post-1950 fertility level with estimated levels between 1995 and 2000, childbearing has fallen most steeply in Sri Lanka (63 percent), moderately in India and Bangladesh (about 50 percent), and least in Pakistan and Nepal (about 28 percent). Undoubtedly the most remarkable development has been the steep fall in fertility in Bangladesh. Between 1980 and 1995 fertility fell from 6.5 to 3.2 births per woman. This is among the most

Figure 1
Past and projected trends in total fertility rates in South Asian countries
Source: United Nations 1999 *World Population Prospects: The 1998 Revision*. Population Division, New York

abrupt and pronounced changes in reproduction ever recorded in a developing nation.

These national trends mask geographical, ethnic, and socioeconomic variations in the timing of the onset and speed of reproductive change. In Bangladesh, fertility is lowest in the Rajshahi Division (in the north), characterized by relative poverty and landlessness, and highest in the Chittagong Division, generally considered to be the most conservative part of the country. In Nepal, fertility transition is more advanced in the Hill Zone than in the Terai (adjacent to India) or in the high-altitude Mountain Zone. The highest fertility in Pakistan is recorded in the least developed province, Baluchistan.

The diversity of reproductive trends in India is much greater (see Fig. 2). In the four northern states of Bihar, Madhya Pradesh, Rajasthan, and Uttar Pradesh, which comprise nearly 40 percent of the total population, demographic modernization has lagged far behind the rest of the country. Women's literacy, age at marriage, and life expectancy are all low; fertility has declined moderately but the level of childbearing was still above four births per woman in the mid-

Figure 2

1990s. By contrast, in the southern states of Kerala and Tamil Nadu fertility transition began early, probably in the late 1950s (Zachariah and Rajan 1997). According to the SRS the level of childbearing had already fallen to about four births per woman by the early 1970s. Kerala reached replacement level fertility (i.e., the level required to maintain stability of population size in the long term) of a little above two births by 1988, eventually stabilizing at 1.8 births per woman. Replacement level was reached in Tamil Nadu in 1993.

3. Determinants of Transition

3.1 Direct Causes

South Asian transitions to lower fertility have been driven by two direct causes: a rise in marriage ages, thus reducing teenage childbearing; and increased family size limitation by contraception and abortion. There is little evidence of postponement of live births following marriage, or of changes in birth spacing. Contraception and abortion have been used to limit family size but not to delay first births, nor for birth spacing. Reproduction is increasingly compressed within the age span of 20 to 30 years.

Throughout most of South Asia, early and universal marriage for women—with a wide gap of five to eight years in the ages of brides and grooms—has been the historic norm. Apart from Sri Lanka and parts of India (e.g., Kerala), the singulate mean age at marriage for women at the start of the twentieth century was about 13 years. (The singulate mean age is calculated from census or survey data on proportions single by current age: for details see Hajnal 1953 and also Ní Bhrolcháin.) Marriage has remained universal but women's age at marriage has steadily increased. By the 1980s, the singulate mean ages were: Bangladesh 16.6, India 18.3, Nepal 18.9, Pakistan 20.7, Sri Lanka 24.4.

Marriage postponement probably accounts for 20 to 30 percent of the decline in total fertility in Pakistan and Sri Lanka but rather less in the other three countries. However, delayed marriage is not consciously motivated by a desire for smaller family sizes. The fundamental cause is a change in the marriage market. In a rapidly growing population, each age group is larger than the preceding older one and, in societies where females traditionally marry older men, this creates a surplus of marriageable women. It thus becomes more difficult and expensive for parents to find suitable bridegrooms for their daughters. Increasing secondary schooling for girls accentuates this upward pressure on marriage ages.

The major direct cause of the South Asia fertility transition is increased use of contraception and abortion. Abortion is believed to be commonly practiced in all five countries but its precise contribution to fertility decline is impossible to gauge with any

confidence because in Nepal, Sri Lanka, and Pakistan it is illegal, and in Bangladesh and India most terminations are unrecorded.

In contrast, trends in contraceptive practice have been monitored reliably. A very pronounced link exists between reported contraception and fertility. In the 1990s, contraceptive prevalence (i.e., the percentage of married women in the reproductive age span who report current use of any contraceptive method) was highest in Sri Lanka (66 percent), and lowest in Pakistan (24 percent). Highly effective modern methods are dominant. In India and Nepal there is a heavy reliance on sterilization, mainly of women. In 1992 and 1993, sterilization accounted for 76 percent of contraceptive protection in India, and the median age of sterilization of women was 27 years. In contrast, the great surge in contraceptive practice in Bangladesh in the late 1980s and 1990s was dominated by increased use of hormonal methods.

3.2 Socioeconomic, Cultural, and Policy Influences

During the past 50 years, a fertility transition has spread across South Asia despite the variation in material, social, and cultural circumstances. Presumably some common underlying factor, or interrelated cluster of factors, accounts for the onset of transition over the same relatively short timescale. Such factors might include preceding mortality declines that have increased numbers of surviving children, or monetization of economies and growing aspirations for educating children and for material goods, all of which increase the cost of childbearing. The variations in the timing and speed of transition demand more context-specific explanations.

Population scientists disagree about the causes of change (see *Fertility Transition: Cultural Explanations* and *Fertility Transition: Economic Explanations*), and rather few widely-accepted generalizations can be made. One of the few is that the fertility transition in the region is not primarily a response to rising living standards. Bangladesh remains one of the poorest countries in the world and the southern states of India have income levels that are below the national average. Indeed, some commentators have proposed that reproductive change has been driven by poverty rather than prosperity, though the micro-level evidence does not support this view: poorer families have more children than richer families.

Progressive social policies, resulting in universal schooling, high life expectancy, relative equality of incomes, and state welfare provision, offer a compelling explanation for the early transitions in Sri Lanka and Kerala. But this thesis applies less obviously to Tamil Nadu, where literacy and life expectancy are not exceptionally high, and is implausible in the case of Bangladesh.

Gender inequality has been a major explanatory theme (see *Reproductive Rights in Developing Nations*).

In an influential paper, Dyson and Moore (1983) interpreted the north-south gradient in Indian fertility in terms of the kinship structure. North India, Pakistan, and the Indo-Aryan majority in Nepal are part of a wider West Asian kinship system dominated by patrilineage. Its key characteristics include early exogamous marriage for women, a joint family structure, and an emphasis on purdah, which result in very limited autonomy for young wives and considerable pressure to produce sons.

In contrast, southern India and Sri Lanka are part of a South and East Asian kinship system, where endogenous marriage and nuclear family are more prevalent, women's lives are less rigidly controlled, and preference for sons over daughters is less pronounced. According to Dyson and Moore this system, with its greater autonomy for women, is more amenable to demographic innovation, including the adoption of modern birth control. Bhat (1996) concluded that these elements of social structure and kinship account for some 30 to 50 percent of the north-south fertility difference in India. Possibly even more important is exposure to mass media, a result interpreted by Bhat as testimony to the powerful influence of Western ideas on reproductive behavior.

Considerable stress has also been laid on the role of education, particularly for women, as a facilitator of fertility transition. At the individual level the reproductive behavior of unschooled women and those who have received primary schooling differs little, whereas those with secondary schooling invariably have fewer children. Yet the contextual influence of schooling may be more important than the impact of individual attainment. Women in Kerala and Tamil Nadu have lower fertility than those in Bihar and Uttar Pradesh, regardless of their length of schooling (see Fig. 2). While it is widely accepted that high adult literacy has been conducive to reproductive change, it is also clearly not a precondition. In 1991, when Bangladesh was in the midst of rapid fertility transition, only 23 percent of adult women and 36 percent of men were literate.

The contribution of state family planning policies to the fertility transition is also controversial (see *Family Planning Programs: Development and Outcomes*). All five countries have population control policies with explicit demographic goals. All have offered financial incentives (or compensation payments) to individuals who agree to sterilization, and all have been criticized for coercive elements. In Sri Lanka, India, and Nepal, vigorous government promotion of family planning has probably accelerated fertility decline (see, for example, Caldwell et al. 1982). In Bangladesh it may have been even more important. A well-known experiment in the Matlab district demonstrated that the appropriate provision of services could reduce fertility (Phillips et al. 1988) and it has been claimed that, while a preceding mortality decline was the underlying cause of the fertility transition, the family planning program

was largely responsible for the timing and speed of change (Cleland et al. 1994). In Pakistan, the program has been largely ineffective because of weak political support.

4. Prospects for the Future
