Conventionalized construals are of course partly arbitrary (see below); but the semantic regularity of both conventional and novel construals has led cognitive linguists to argue that even grammatical categories such as 'noun' and 'subject' are susceptible to a cognitive semantic explanation. That is, a grammatical category such as 'noun' encodes a construal of an entity in a certain way, which can be discerned by the occurrence of particular word roots directly as nouns, and in the semantic changes that occur when a non-noun root is used as a noun, or can be morphologically derived as a noun.

Finally, cognitive linguistics has developed a model of categorization which has in turn been exploited by functionalist linguists. A classical view of meaning is that the meaning of a word, inflection or grammatical category must be a single definition that will cover all and only the appropriate uses of the word or category. Cognitive linguists have argued that many word and category meanings can be described in terms of polysemy, that is, distinct but semantically related meanings. For example, the meaning of *over* in *The bird flew over the hill* (path of motion) is distinct from its meaning in *The house is over the hill* (location), but they are related systematically. More specifically, cognitive linguists (drawing on research by psychologists) have suggested that many polysemous categories have one meaning that can be considered central or basic, called the category's prototype. Cognitive and other functionally oriented linguists have argued that many if not all grammatical categories are in fact polysemous, and many of these categories have a semantic/discourse-functional prototype which is found to be valid across languages (see *Linguistics: Prototype Theory*).

3.6 More Radically Functionalist Schools

Grammatical structure is commonly assumed to exist in speakers' minds. However, grammatical structure is also directly involved in social interaction in language use, and language use is central to accounting for language acquisition, language variation and language change. In the more dynamic process of language acquisition and language change, functional factors have been argued to play a role. In both language acquisition and language change, it has been argued that competing motivations among functional principles play a major role.

The concept of competing motivations is that (functional) principles may come into conflict such that there is no grammatical system that satisfies all of

the functional principles. As a result, change occurs over time in acquisition and in the history of a language, and the languages of the world exhibit structural diversity even though their speakers' linguistic behavior conforms to the same functional principles. (Competing motivation models do not presuppose that the competing principles are functional, and in fact competing motivation models are now used by many formalists; see below).

The most general and commonly offered example of competing motivations is that between economy and iconicity (see *Linguistics: Iconicity*). *Economy* is the principle that a speaker uses the least effort necessary to express himself or herself. For example, English leaves the singular number of nouns unexpressed: *book-φ* vs. *book-s*. Economy is considered to be a speaker-oriented functional principle: its influence on language is for the benefit of the speaker. *Iconicity* is, in part, the principle that all of the relevant parts of the meaning conveyed are in fact conveyed by grammatical elements in the utterance (words, inflections, etc.). For example, in some languages, both the singular and the plural of a noun are expressed by overt suffixes. This aspect of iconicity is considered to be hearer-oriented: any aspect of meaning left out by the speaker may not be recoverable by the hearer. Economy and iconicity compete with each other: a linguistic expression that is economical will not be iconic (since it leaves some elements of meaning unexpressed), and an expression that is iconic will not be economical (since certain elements of meaning are not left unexpressed). Hence, across languages, there is diversity in the expression of the category of number, and languages change from one form of expression of number to another over time.

Perhaps the best known competing motivations model in language acquisition is the competition model of E. Bates and B. MacWhinney (1989). In language change, a number of linguists have put forward competing motivations models, in particular J. Haiman (1985).

More recently, some functionalist linguists (P. Hopper, J. Haiman, and J. Bybee) have emphasized the dynamic character of language in ordinary use, and have argued that a speaker's grammatical knowledge should not be considered to be as static and immutable as is usually believed. They argue that a speaker's grammatical knowledge is not a tightly integrated system, but rather a more loosely structured inventory of conventionalized routines that have emerged through language use. The empirical research of the functionalist linguists who advocate this view has focused on the role of frequency of use on the entrenchment of grammatical knowledge, and on inductive models of abstracting grammatical knowledge from exposure to language use, both in acquisition and in adult usage. There have been a number of studies of inflectional paradigms of words that support the hypothesis that frequency of use influences

grammatical representation; however, studies of syntactic construction in this approach are in their infancy.

4. *Directions and Prospects for Functional Approaches to Grammar*

Taken as a whole, functional approaches to grammar are widely practiced in linguistics. Nevertheless, there are important divisions between different schools of functionalist theory and between functionalists and formalists.

A common misunderstanding (among formalists in particular) is the belief that functionalists do not accept the existence of *arbitrariness* in language, that is, that not all aspects of grammatical knowledge are explainable by functional principles. There is no functionalist that holds that view. However, most functionalist theories have not developed a model of the representation of grammatical form, instead focusing their attention on the analysis of functional domains and their role in accounting for grammatical structure. There are significant exceptions to this observation, notably the mixed formal/functional theories of Dik and Van Valin, the model of lexical and morphological representation of Bybee, and construction grammar in cognitive linguistics. Construction grammar appears to be gaining a wider audience, and some functionalists are beginning to develop more detailed models of grammatical structure that are compatible with functionalist theories.

A significant split in functionalism is between those who are more cognitively oriented, focusing their attention on cognitive explanations, and those who are more discourse oriented. These two functionalist approaches have largely gone their own ways, developing models of language meaning (cognitive linguists) and language in use (the discourse functionalists). However, there is some functionalist work which draws on both cognitive and discourse models (see, for example, Givón (1979) and Chafe (1994)). Some functionalists have argued for a rapprochement between the two approaches, since they are compatible: language must be understood from both a psychological and a social-interactional perspective.

Functionalist approaches to language generally have also neglected research in sociolinguistics (see *Sociolinguistics*). Sociolinguistics begins with the hypothesis that language is a dynamic, variable phenomenon, and argues that factors outside linguistic form, namely social parameters, account for variation and change in language. In both of these respects, sociolinguistics shares theoretical assumptions in common with functionalism. The increase of research on social-interactional factors and on relative frequency of use in functionalist research may lead to an integration of social with other functional factors

in a social-functional theory of linguistic variation and change.

A rapprochement between functionalism and formalism is less likely, because the two differ in fundamental assumptions about the nature of language and the relation between form and function. There are some respects in which practical research is converging among formalists and functionalists, however. For instance, competing motivations as a mechanism of analysis is now widely used in formalist theories under the name of *Optimality Theory*. The rise of computer-aided corpus research has led to a convergence in interests on naturally occurring language and the role of usage in grammatical structure. Some formal semanticists have made reference to prototypes and polysemy, and some semanticists working in a generative grammar framework (Jackendoff 1983) also give conceptualization a major role in analysis.

Grammatical Agreement

Grammatical agreement is a phenomenon in which word forms co-occurring in a clause are sensitive to each other. Inflected forms often agree in their values of number, gender, or person, as can be seen from the contrasting examples in (1a, b) to (4a, b)

- (1) French a. *La^{fsg} fille^{fsg} est^{3sg} belle^{fsg}.*
'The girl is beautiful'
b. *Les^{pl} garçons^{mpl} sont^{3pl} beaux^{mpl}.*
'The boys are handsome'
- (2) French a. *Je^{1sg} les^{3pl} ai^{1sg} vues^{fp1}.*
'I have seen them'
b. *Tu^{2sg} l'^{3sg} as^{2sg} vu^{msg}.*
'You have seen him'
- (3) Finnish a. *Taina löysi minun^{1sg} kirja-ni^{1sgPoss}.*
'Taina found my book'
b. *Taina löysi heidän^{3pl} kirja-nsa^{3Poss}.*
'Taina found their book'
- (4) German a. *Ein kleines^{nsg} Mädchenⁿ saß^{3sg} auf der Treppe, und es^{3nsg} lachte.*
'A little girl sat on the stairs, and she laughed'
b. *Ein kleiner^{msg} Junge^{msg} stand^{3sg} daneben, und er^{3msg} heulte.*
'A little boy stood beside, and he cried'

In (1), the definite article agrees with the following noun, and both the copula verb and the predicative adjective agree with the whole subject phrase. If any item of (1a) is exchanged with the corresponding item of (1b), the sentence becomes ungrammatical (e.g., **la fille est beaux*). Example (2) shows two agreement relations intertwined: the auxiliary agrees with the subject pronoun, while the participle agrees with the object clitic. Sentence (3) is an example of a possessed noun agreeing with the possessor in the genitive. In (4)

it is the pronoun in the second clause that agrees with the antecedent noun phrase in the first clause. Notice that *Mädchen* 'girl' is a neuter noun, triggering a neuter pronoun even though it refers to a female being; in contrast, the English pronouns in the translation are selected solely on semantic grounds.

Grammatical agreement can be seen as an interplay of morphological, syntactic and semantic aspects (Anderson 1988, Lapointe 1988, Corbett 1994, 1995, 1998, Pollard and Sag 1994). Morphosyntactically, agreement is a relation between syntactic constituents in virtue of the fact that the word forms they consist of bear similar information, either inherently or by means of morphological affixation (inflection). Semantically, agreement serves to keep record of discourse referents: only constituents that relate to the same referent may overtly agree with each other (Lehmann 1982). The sentences in (1) are about one referent (a single person or a group of persons), while those in (2) are about two referents in a seeing-relation.

Generally, agreement relations are found among the following elements:

- (a) NP- (or DP-) internally: determiner and noun, attribute and noun, possessor and possessed noun;
- (b) a predicate and its arguments: verb–subject, verb–object, preposition–object, predicative noun/adjective–argument; and
- (c) a pronoun or anaphor and its antecedent.

The categories that may appear in these relations are gender (e.g., feminine f, masculine m, animate, or neuter n), number (e.g., dual, plural pl, and singular sg), and person (1st, 2nd, and 3rd, or inclusive 1 + 2).

Nouns and pronouns (or pronominal affixes/clitics) function as the controller (or source) of an agreement relation in virtue of their features. Nouns are classified inherently for gender (or noun class), and sometimes also for number (cf. *scissors*, *trousers*, *brethren*), whereas pronouns are classified inherently for person and number, and sometimes also for gender. In some instances, this inherent classification is semantically based: as a default, female beings are represented by feminine nouns, but male beings by masculine nouns; aggregates are represented by plural nouns; addressees are represented by second person pronouns, but speakers by first person pronouns. In most other cases feature assignment is purely grammatical (consider the distinct genders in French *lune^f*, *soleil^m* vs. German *Mond^m*, *Sonne^f*, 'moon,' 'sun') and may even override the default (cf. German *Mädchenⁿ* 'girl') (Corbett 1991).

The grammatical elements that agree with the noun or the pronoun are said to be the agreement targets (or controllees); in (1), the article *la* is the target of *fille*, which is f, and both the copula *est* and the adjective *belle* are targets of the DP *la fille*, which is fsg. The agreement features of controller and target do not have to be identical, but they must be compatible with each other, as in *la fille^{fsg}* and *est^{3sg}*. In order for a DP to be the controller of an agreement relation, the

Grammatical Gender

Gender is a remarkable category, pervasive in some languages, for instance in the Indo-European and Dravidian families, and lacking in others, as in the Uralic family. We start with a brief consideration of terms, then examine how the number of genders in a given language can be established. The number varies considerably: two and three genders are often found, four and five are not unusual, while Fula (a Niger-Kordofanian language) has around 20. Most attention will be given to the problem of how the speaker assigns nouns to genders. Gender systems may have sex as a component, as in languages with masculine and feminine genders; but equally sex may be irrelevant, as in the Algonquian languages where the distinction is between animate and inanimate. Finally we consider prospects for investigating the category further.

1. Terms

The defining characteristic of gender is agreement; a language has a gender system only if noun phrases headed by nouns of different types control different agreements. The evidence that nouns have gender in a given language thus lies outside the nouns themselves. There is no substantive difference between 'genders' and 'noun classes'; the different terms are merely the products of different linguistic traditions. For instance, we find systems with three genders, to which nouns are assigned by similar rules, in both Kannada (a Dravidian language) and in Godoberi (a Nakh-Daghestanian language). By tradition the first is said to have three genders, and the second three noun classes. We shall use the term 'gender' in both instances.

2. The Number of Genders

The approach to gender sketched in Sect. 1 is based on Zaliznjak's (1964) notion of 'agreement class.' Two nouns are in the same agreement class only if they take the same agreements under all conditions, that is if we control for other grammatical categories such as case and number. Conversely, if two nouns differ in their agreements when factors such as case and number are held constant, then they belong to two different agreement classes and it will normally be the case that they belong to two different genders. While in many languages there is no dispute as to the number of genders, there are other languages where the question is far from straightforward. In the case of Romanian there has been a lengthy debate. The analytical problem of determining the number of genders and the tests for deciding the gender of a given noun depends on separating out the classes into which nouns are divided (the controller genders) from the number of different genders marked on agreement targets (the

target genders). Frequently the two match up, but in several languages they do not. A full treatment of the subject is not possible here; for a detailed account and extensive references see Corbett (1991).

3. Gender Assignment

We now ask how nouns are distributed over the genders of a given language, in other words, how does a native speaker 'know' what gender a noun belong to? Models of the mechanisms by which nouns are allotted to genders are called 'assignment systems.' Assignment may involve two sorts of information about the noun: its meaning and its form. We shall consider semantic systems first.

3.1 Strict Semantic Assignment Systems

This type is found in Dravidian languages like Kannada, spoken in the state of Karnataka, southern India (Sridhar 1990, p. 198). Nouns denoting male humans are masculine, those denoting female humans are feminine. There are also deities, demons, and heavenly bodies in these genders. All remaining nouns, including those denoting infants and animals, are neuter. Thus *appa* 'father,' and *candra* 'moon' are masculine, *amma* 'mother' is feminine, and *na:yi* 'dog' is neuter. Certain other Dravidian languages like Kolami have only two genders: nouns denoting male humans are masculine and all others belong in the nonmasculine gender (Emeneau 1955, p. 73). Elsewhere we also find the reverse. Thus in Diyari, a language of South Australia, there is a gender for nouns with female referents (such as women, girls, doe kangaroos), and the other is for all remaining nouns (Austin 1981). In Alamlak, a Sepik Hill language of Papua New Guinea, the masculine gender includes nouns denoting males and those denoting things like crocodiles, pythons, and arrows, which are long and thin, while the feminine is for nouns denoting females or short, squat items like turtles, frogs, and chairs (Bruce 1984, pp. 96–8, Foley 1986, pp. 80–81). An interesting system with some similar features is found in Taiap (Kulick and Stroud 1992).

3.2 Predominantly Semantic Assignment Systems

Many languages have semantic assignment rules, which, however, lack the coverage of those seen in Kannada. An example of what we shall call predominantly semantic assignment is found in Tsakhur, which is a member of the Lezgic group of the Nakh-Daghestanian family. Its four genders are shown in Table 1.

Assignment to genders I and II is straightforward: I is for male humans (also gods, angels, and so on) while II is for female humans (and female mythical beings). Most remaining animates are assigned to gender III,

Table 1
Gender assignment in Tsakhur

Criterion	Gender	Examples	Glosses
male rational	I (masculine)	dak _j gade	father boy
female rational	II (feminine)	jed _j sos	mother bride
animate (also some inanimates)	III (animate)	balkan	horse
other (including a few animates)	IV (neuter)	dadal (qow)	cock (nose)
		t'et'	flower
		nise (kabaj)	cheese (butterfly)

though a few belong to gender IV, along with some mythical beings. Inanimates are found in genders III and IV (Melnikov and Kurbanov 1964, Ibragimov 1990, pp. 54–6, and references therein, Kibrik 1999, pp. 48–9).

Languages of this general type are widespread. For some of them, researchers have proposed that abstract semantic criteria partly miss the point, and that if we can gain a better grasp of the world view of the speakers, we can then understand the assignment system. The most discussed case is that of Dyirbal, a language of North Queensland (Dixon 1972), which has four genders, primarily for: male humans and non-human animates (I), female humans (II), non-flesh food (III) and the residue (IV). There are numerous apparent exceptions: the moon is in the first, masculine gender and the sun is the second, feminine gender. However, in Dyirbal mythology, as indeed in much of Australia, the moon is the husband of the sun; in Dyirbal the mythological significance of referents is a key factor in assignment. Dixon's data and analysis continue to provoke debate, as shown by the recent paper by Polinsky (1998). There is similar debate as the role of world view in the gender assignment system of Ojibwa (and in other Algonquian language of southern Canada and northern USA).

In all the languages discussed so far, the meaning of the noun determines gender. In the strict assignment systems, the rules are immediately obvious; in the predominantly semantic systems, there may be a minority of exceptions, but these exceptions have been claimed to be largely apparent in some languages, once the cultural setting of the language is taken into account. If we ask which are the semantic criteria on which semantic systems can be based, we see recurring patterns. Quite often we find animate ~ inanimate, human ~ nonhuman, and male ~ female. Sometimes there is a gender for diminutives, as in various Bantu languages. There are also less usual genders, such as that for nonflesh food (Dyirbal) and the gender for insects (found in the Rikvani dialect of the Nakh-

Daghestanian language Andi). A criterion which is sufficient to define a gender in one language may be just one factor in the assignment to a gender in another. Thus the Bantu language Chichewa has a gender for diminutives, while in Dizi, diminutives together with nouns denoting females form a gender.

3.3 Formal Assignment Systems

In many languages, assignment by semantic rules would fail to assign many nouns to a gender. While in languages like Kannada the nouns not assigned by the semantic rules (the 'remainder' or 'semantic residue'), all belong to a single gender, in many languages they are spread over more than one gender. In such languages we find additional rules for assigning nouns to genders according to their form. Note the asymmetry: languages may use semantic rules, or semantic *and* formal rules, but not just formal assignment rules. In no language are nouns assigned to genders, as defined earlier, by purely formal rules. An example would be a language in which there were two agreement classes, and the nouns in the first all ended in a consonant cluster, and those in the second did not, and there was no semantic regularity for the distribution of nouns. I claim that this hypothetical type does not exist. Formal assignment rules may appeal to two types of information: phonological and morphological.

3.3.1 Phonological. A clear example of assignment depending on phonological information is provided by Qafar (Afar), an East Cushitic language spoken in north-eastern Ethiopia and in Djibouti (data from Parker and Hayward 1985). Qafar has rather standard semantic assignment rules, namely that for sex-differentiable nouns, those denoting males are masculine and those denoting females are feminine. It is the nouns which fall outside these rules, the residue,

Table 2
Russian nouns belonging to the semantic residue

Masculine	Feminine	Neuter
žurnal 'magazine'	gazeta 'newspaper'	pis'mo 'letter'
dom 'house'	izba 'hut'	zdanie 'building'
čaj 'tea'	voda 'water'	pivo 'beer'
dub 'oak'	sosna 'pine'	derevo 'tree'
ogon' 'fire'	peč' 'stove'	plamja 'flame'
avtomobil' 'car'	mašina 'car'	taksi 'taxi'
stul 'chair'	taburetko 'stool'	kreslo 'armchair'
den' 'day'	noč' 'night'	utro 'morning'
čas 'hour'	minuta 'minute'	vremja 'time'
nerv 'nerve'	kost' 'bone'	serdce 'heart'
nos 'nose'	ščeka 'check'	uxo 'ear'
lokot' 'elbow'	lodyžka 'ankle'	koleno 'knee'
flag 'flag'	emblema 'emblem'	znamja 'banner'

Table 3
Inflectional classes in Russian

	I	II	III	IV
NOMINATIVE	žurnal	gazeta	kost'	pis'mo
ACCUSATIVE	žurnal	gazetu	kost'	pis'mo
GENITIVE	žurnala	gazety	kosti	pis'ma
DATIVE	žurnalu	gazete	kosti	pis'mu
INSTRUMENTAL	žurnalom	gazetoj	kost'ju	pis'mom
LOCATIVE	žurnale	gazete	kosti	pis'me
gloss	'magazine'	'newspaper'	'bone'	'letter'

which are of interest. For them the phonological rules apply: nouns whose citation form ends in an accented vowel are feminine (for example, *karmà* 'autumn') while all others are masculine (for example, *gilàl* 'winter,' which does not end in a vowel, and *tàmu* 'taste,' which does end in a vowel, but not an accented one). These rules operate with few exceptions. Moreover, nouns denoting males and females typically fit them too (for example *bàqla* 'husband' and *barrà* 'woman, wife'). It might seem that we could dispense with semantic rules for Qafar, and treat it as being of a quite different type. However, while the phonological rule works for the vast majority of cases, we find the crucial example *abbà* 'father,' which is masculine, even though it ends in an accented vowel, which 'should' be an indicator of feminine gender. Conversely, *gabbixeèra* 'slender-waisted female' is feminine, though the accent is non-final. Qafar is remarkably for the simplicity of its phonological assignment rules, and for the fact that when the semantic and phonological rules are both applicable, they almost always give the same result. However, in cases of conflict, the semantic rules take precedence (as is the normal situation in gender assignment systems).

Other examples can occur in various parts of the world. Even French, often claimed to have no system to its gender assignment, has been demonstrated to have a phonological system, though not as simple as

that of Qafar. For example, of 938 nouns ending in *ê*, 99 percent are masculine (like *le pain* [pɛ̃] 'the bread'). And of 1,453 nouns in /ɔ/, 94.2 percent are masculine (like *le ménage* [mena:ʒ] 'the household' (for details see Tucker et al. 1977).

3.3.2 Morphological. In Russian, which is typical of many other Indo-European languages, nouns denoting male humans are masculine and those denoting female humans are feminine. But unlike the situation in languages like Kannada, it is not the case that the semantic residue is assigned to the neuter gender; in Russian the residue is shared between the three genders, with the neuter gender not even receiving the majority. Searching for additional semantic criteria is not at all promising, as the following data suggests (Table 2).

If we look instead at the morphology of the nouns, then we can make progress. There are four main inflectional classes in Russian, each with several thousands of nouns (for justification of this not uncontroversial view see Corbett 1982, pp. 202–11). There are six cases and two numbers (though no paradigm has 12 distinct forms because of various syncretisms). We give just the singular forms in Table 3.

The native speaker needs to know how a noun inflects, in order to produce grammatical utterances.

On the basis of that information, the assignment rules are straightforward. Nouns in class I are masculine, those in classes II and III are feminine, and those in IV are neuter. At first we might think that the semantic assignment rules are superfluous, since *mal'čik* 'boy' is in class I, while *devuška* 'girl' is in class II, and *mat'* 'mother' is in class III. In other words, many of the sex-differentiable nouns would be assigned to the appropriate gender by the morphological assignment rules. But there are also instances where this is not so, for instance, *djadja* 'uncle,' which denotes a male but is in class II, whose nouns are typically feminine. *Djadja* 'uncle' is masculine. Nouns like this show, once again, that we do not find languages where formal assignment rules are sufficient. Further rules are required in Russian for indeclinable nouns (like *taksi* 'taxi,' which is indeclinable and neuter). Morphological assignment systems are found in various other Indo-European languages. Looking further afield, in Arabic too, gender is assignable in the main according to morphology (Cowell 1964, pp. 372–5).

The different types of assignment criteria may overlap in ways which make it difficult to establish their relative weight in a given language. Thus there may be small clusters of nouns which can be accounted for by semantic criteria (apart from those covered by the main semantic rules) even within systems where formal rules have a major role (as shown for German by Zubin and Köpcke 1986, Köpcke and Zubin (1996). However, whenever gender languages are analyzed in sufficient detail, the gender of the vast majority of nouns turns out to be predictable.

4. Prospects

Studies on grammatical gender continue to appear regularly, including valuable studies of previously unresearched languages. Here we highlight two main areas where we can expect substantial new developments: lexicology and modeling.

4.1 Lexicology

Gender is a key category for lexicology, since it is crucial for understanding the nature of lexical entries. In a gender language the gender of a noun must be available. On the other hand, as we have seen, it does not normally need to be specified, since the information can be derived, by assignment rules, from other information which must be stored. We still do not know the full range of information which may be relevant (for instance, the possible semantic features which may determine gender assignment).

There are further surprises: it is possible too for certain nouns to be of different genders according to the sex of the speaker; this is found in Garifuna, a member of the Arawak family spoken in Belize, Honduras, Nicaragua, and Guatemala (Taylor 1977,

p. 60, Munro 1998). These two points raise interesting questions as to the shape of lexical entries, a general question which is of concern to lexicologists and increasingly to psycholinguists (see, for instance, Berkum (1995).

4.2 Modeling

When discussing some types of assignment system, the evidence is so clear-cut that alternative analyses are hard to imagine. However, with morphological assignment systems, particularly when the number of genders and the number of inflectional classes is similar in a given language, there are other possible analyses, in particular some would specify gender in the lexical entry and derive inflectional information from it. Arguments in favour of the approach taken in Sect. 3.3.2 include the following; first, and primarily, it is claimed that in languages like Russian the internal evidence shows that the gender from inflectional class approach is preferable (it proves impossible to predict inflectional class from gender but it is possible to predict gender from inflectional class); and second, there is the typological claim that one or other of the possible types of assignment system (or some combination) will always be in play in a gender language such that gender is predictable for the vast majority of nouns and so if the Russian type system were treated differently this would create an anomaly.

However, there is a further step which we can take, of a rather different nature. Since the Russian type languages are crucial, it worth investing additional time in clarifying them. Hence in Fraser and Corbett (1995) we give an account of the Russian gender and inflectional class relations in the Network Morphology framework. The analysis is implemented in the lexical knowledge representation language DATR (Evans and Gazdar (1996, Gazdar forthcoming), which means that the analyses can be verified by computer. Given minimal lexical entries for nouns our account does indeed predict the right genders for a wide range of nouns. An account like this which is both explicit and testable is not available for the alternative approach.

A more complex type is that in which gender is again assigned according to morphological class, but where the morphological class is itself predictable. One such case is Arapesh; a language of the Torricelli family, spoken on the north coast of Papua New Guinea. Genders and morphological classes form a substantial part of Fortune's (1942) grammar, which led to work based on it by Aronoff (1992, 1994, pp. 89–114). Once again, there are semantic assignment rules based on sex. But then there are morphological assignments rules, which determine 13 genders on the basis of 22 morphological classes (which are in turn predictable largely from phonological information). Again we have demonstrated how this system can be analyzed within the Network Morphology framework and have provided an implementation to demonstrate that our

claims are indeed valid (Fraser and Corbett (1997). There is a complex interaction of assignment to gender and to morphological class in Mayali, a non-Pama-Nyungan language of north Australia, which has four genders and five morphological classes for nouns. For the essential data see Evans (1997) and for details of a formal model of this system see Evans et al. (2001). Finally, there is interesting work on the development of assignment systems over time, including some modelling: see Comrie and Polinsky (1998), Polinsky and Everbroeck (1998), Polinsky and Jackson (1999).

5. Conclusion

Gender remains a puzzling category, apparently deeply embedded into the structure of some languages, and missing in other. This is found even in related languages: thus several Indo-Aryan languages have two or three genders, with substantial agreement, while another, Bengali, has no gender even in the personal pronouns. Where we find gender, the assignment rules can be simple, as in Kannada and Qafar, or complex as in French and German. It is an area in which gradual progress is being made and one in which there is still much to learn.

G. G. Corbett

Grammatical Number

Number is often taken to be a relatively straightforward category. It is often used as the textbook illustration of an inflectional category, and the situation in languages like English is believed by many to be the normal if not the only one. English makes a semantic distinction, and a formal distinction between, for instance, *cat* and *cats*, *child* and *children*. In fact the number category reveals many surprises, and the system found in English is a rather extreme one, when seen within the space of possibilities established from a survey of the languages of the world. We shall consider characteristics of the English system in turn, showing some of the ways in which it is typical or atypical. We shall give greatest prominence to the question of number values.

1. Nominal and Verbal Number

In English number is a nominal category, it involves the distinction between instances such as *cat* and *cats*. When it appears on verbs, this is by agreement with a subject noun phrase, as in *the children were playing happily*. The plural verb still indicates the number of children, and not the number of playing events. There are many languages which have verbal number, that is, where the number of the verb indicates the number of events (see Durie 1986 for examples).

2. Number as an Obligatory Category

Number is an obligatory category in English. If someone says, *there's a visitor waiting to see you*, when there are several, this is misleading and inappropriate. In many languages, however, the use of the plural is not obligatory, but is used when it is important to mark number. One example is the Cushitic language Bayso:

- (1) Bayso (Dick Hayward, personal communications, Corbett and Hayward 1987)
- liban* *foofe*
lion.GENERAL watched.1SG
'I watched lion' (it could be one, or more than that)

Another language, from many examples, is the Arawak family language Bare of Venezuela and Brazil (Aikhenvald 1995, pp. 18–19).

3. The Nominals Involved in the Number System

In English the majority of nominals can mark number, from the personal pronouns and nouns denoting persons (like *woman*) down to those denoting inanimate objects like *door*, and even to some denoting abstracts like *hour*. Many languages restrict the number opposition to fewer nominals, namely those which are high in animacy (Smith-Stark 1974). Thus in Slave (an Athapaskan language spoken in parts of the Northwest Territories, British Columbia, and Alberta, Canada) number may be marked on the noun phrase provided the noun denotes a human or a dog (Rice 1989, p. 247).

4. The Semantics of Number

As long as we stay with innocent examples like English *cat* and *cats*, the semantics of number look clear, since *cats* is appropriate for more than one instance of *cat*. In fact there are many concealed difficulties: a concise overview of work on number within formal semantics can be found in Link (1998), who shows how the study of plurals relates to different movements in linguistic semantics, and provides a substantial bibliography.

If we move from ordinary plurals to consider *I* vs. *we*, it becomes clear that here we have an 'associative' use of the plural; *we* is most often used for 'I and other(s) associated with me.' At the other end of the Animacy Hierarchy, nouns like *coffee* have a plural, provided they are recategorized: if *coffee* denotes a type, or a typical quantity of coffee, then there is an available plural, as in: *she always keeps three different coffees*, and *we've ordered two teas and three coffees*.

5. Number Values

A striking way in which English is limited in its number system is in terms of the number values. In English we can distinguish only between singular and plural. Many languages have more distinctions, and it is these on which we shall concentrate.

5.1 The Dual

A common system is one in which singular and plural are supplemented by a dual, to refer to two distinct

Table 1
Emphatic pronouns in Sursurunga

	<i>singular</i>	<i>dual</i>	<i>'trial'</i>	<i>'quadral'</i>	<i>plural</i>
1 exclusive	iau	giur	gimtul	gimhat	gim
1 inclusive	—	gitar	gittul	githat	git
2	iáu	gaur	gamtul	gamhat	gam
3	-i/on/ái	diar	ditul	dihat	di

Source: Hutchisson 1986 and personal communications
Note: á is used to indicate schwa (ə)

real world entities. Examples are widespread. We will take Central Alaskan Yup'ik, as spoken in the south-western Alaska (Corbett and Mithun 1996); the number forms are: singular *qayaq* 'kayak,' dual *qayak* 'two kayaks,' and plural *qayat* 'three or more kayaks.' The addition of the dual has an effect on the plural, which is now used for three or more real world entities, and more generally a change in system gives the plural a different meaning

5.2 The Trial

While the dual refers to two distinct real world entities, the trial is for three, and it occurs in systems with the number values: singular, dual, trial, and plural. This system is found in Larike, a Central Moluccan language spoken on the western tip of Ambon Island, Central Maluku, Indonesia. (Central Moluccan forms part of the Central Malayo-Polynesian subgroup of Austronesian.) This example is from Laidig and Laidig (1990, p. 7):

- (2) *Kalu iridu-ta-peu au-na-wela*
if 2.TRIAL-NEG-go 1.SG-IRR-go.home
'If you three don't want to go, I'm going home.'

In this language the dual and trial forms can be traced back to the numerals 'two' and 'three,' and the plural comes historically from 'four.' Such developments are fairly common in Austronesian languages. Sometimes the term 'trial' is used according to the form of the inflections (derived historically from the numeral three), even when the forms are used currently for small groups including those greater than three (and so are paucals) and sometimes the term is used according to meaning (for genuine trials). The Larike trial is a genuine trial, used for exactly three (Laidig and Laidig 1990, p. 92).

5.3 The Paucal

Paucals are used to refer to a small number of distinct real world entities, somewhat akin to the English quantifier 'a few' in meaning. There is no specific upper bound on the use of paucals (their lower bound will vary according to the system in which they are found). Let us return to the Cushitic language Bayso. Besides the general number forms (as in (1), where

number is not specified), there are also singular, paucal, and plural. Here is the paucal:

- (3) Bayso (Dick Hayward, personal communications, Corbett and Hayward 1987)
luban-jaa foofe
lion-PAUCAL watched.1.SG
'I watched a few lions'

The paucal is used in Bayso for reference to a small number of individuals, from two to about six. (Bayso has this system in nouns but not in pronouns.) The Bayso system is rare; normally the paucal is found together with a dual, so that the number values are singular, dual, paucal, and plural. This widespread system is found, for example, in Yimas, a Lower Sepik language spoken in the Sepik Basin of Papua New Guinea (Foley 1991, p. 216).

5.4 The Largest Systems

It is worth asking what is the largest system of number values. There are claims in the literature for languages with a quadral, for four distinct real world entities, thus giving a system of five number values. It is established that five number values can indeed be found, but the evidence specifically for a quadral is less clear. All the claims come from within the Austronesian family and the best documented case is Sursurunga (Hutchisson 1986, and personal communications), spoken in southern New Ireland. The forms labeled quadral are restricted to the personal pronouns, but are found with all of them, the first person (inclusive and exclusive), the second, and third (Table 1).

Here is an example of a quadral form in use (we will retain the traditional label 'quadral,' until we have justified replacing the term for Sursurunga):

- (4) Sursurunga (Hutchisson 1986 and personal communications)
gim-hat káwán
1.EXCL-QUADRAL maternal.uncle:nephew/
niece
'we four who are in an uncle-nephew/niece relationship'

The 'quadral' has two additional uses. First, in Sursurunga plural pronouns are never used with terms for dyads (kinship pairings like uncle-nephew/niece). Here the 'quadral' is used, for a minimum of four, and

not just for exactly four (Hutchisson 1986, p. 10). Second, in hortatory discourse, the speaker may use the first person inclusive 'quadral' in order to suggest joint action including the speaker, even though more than four persons are involved. These two special uses of the 'quadral' account for the majority of instances of its use. According to its meaning, the term 'quadral' is not appropriate. Rather the forms would be better designated 'paucal.'

Let us now consider the rest of the system of Sursurunga (data and judgments from Don Hutchisson, personal communications). The dual is used quite strictly for two people. It is also used for the singular when the referent is in a taboo relationship to the speaker. This is a special use; the dual's main use is as a regular dual. The trial will be used for three. However, it is also used for small groups, typically around three or four, and for nuclear families of any size. It is therefore not strictly a trial, rather it could be labeled a paucal (an appropriate gloss would be 'a few'). We noted earlier that this is a frequent development for the trial. The 'quadral,' as we have just seen, is used primarily in different ways with larger groups, of four or more (an appropriate gloss would be 'several'). This too would qualify as a paucal; we therefore have two paucals in Sursurunga, a paucal (traditionally 'trial') and a greater paucal (traditionally 'quadral'). The plural, as we would expect, is for numbers of entities larger than what is covered by the greater paucal, however, there is no strict dividing line (certainly not at the number five). Using semantic labels, we might represent the system in Sursurunga as having: singular, dual, paucal, greater paucal, and plural. Sursurunga has a well-documented five-value number category. There are certainly other languages with five number values; we do not have such detailed information as for Sursurunga and there is no certain case of a quadral: it seems that in all cases the highest value other than plural in such systems can be used as a paucal. Besides the split in the paucal, we may also find a split in the plural, with 'greater plurals' of different types, as for instance in Mokilese (Harrison 1976). Greater plurals may imply an excessive number or else all possible instances of the referent. They are as yet poorly researched, except in a few languages.

6. Conclusion

Number is indeed a much more complex category than is generally recognized, and the English system, though a common one, is at one extreme of the typological space. We noted that number may be a verbal category as well as a nominal one (but the possibilities are rather more restricted for verbal number). We also saw that number need not be obligatory, that the range of items which distinguish number varies dramatically from language to language, that the semantics of number are affected by

the particular item involved, and that the values of the number category can be just two or, in various combinations, up to five. More complex issues, which we have not been able to address here, include various interactions, notably between the forms of marking of number, the particular nominals which distinguish number in a given language, and the systems of number values. For these issues see Corbett (2000).

G. G. Corbett

Grammatical Relations

The linguistic concept 'grammatical relation' with its equivalents 'syntactic relation,' 'syntactic function' belongs to the most important concepts of traditional syntactic theory. By grammatical relations are understood structurally expressed characteristic syntactic relations between sentence constituents (see *Constituent Structure: Syntactic*), in particular between the

predicate and noun phrases (NPs). Thus, in the sentences (1) *Peter sent a message to Mary*, (2) *My friend sent a congratulatory telegram to his boss*, in addition to the predicate *sent* one can identify three NPs linked to the predicate by specific grammatical relations. One of the NPs (*Peter/my friend*) is the subject, the second (*a message/a congratulatory telegram*) is the direct object, while the third (*Mary/his boss*) is the indirect object. (Noun phrases that realize the same grammatical relation occupy the like-named position in the clause. Thus, the NP *Peter* in (1) occupies the subject position.) Each of the NPs in these sentences is structurally distinct from the other two and makes unique reference to a concrete participant in the events denoted by the given sentences. The subject and the direct object of this particular example are expressed positionally—the subject precedes the verb, the direct object follows the verb immediately—while the indirect object contains the preposition *to*.

Grammatical relations fulfill *distinguishing* and *characterizing* functions. First, they permit identification of the various participants in the event (what was sent, to whom and by whom it was sent), secondly they classify the NPs in the given sentence in terms of a restricted set of characteristic properties, allowing the identification of NPs in different sentences. Thus, in (3) *A message was sent to Mary (by Peter)*, (4) *Mary was sent a message (by Peter)*, both semantically related to sentence (1), the subjects will be, respectively, the noun phrases *a message* and *Mary*; in (5) *That he won is fine*, there is a clausal subject *that he won*; while in (6) *It is fine that he won* and (7) *It is dark*, the subject is the pronoun *it* (the so-called dummy subject). The concept ‘subject’ as a homogeneous syntactic relation unites different kinds of specific constituents. Each grammatical relation has a specific function (see *Grammar: Functional Approaches*) and specific linguistic means for its expression.

1. What Do Grammatical Relations Mean?

Despite the widespread use and obvious necessity of the terms subject and object, traditional grammar did not succeed in defining their meaning adequately. Definitions for ‘subject’ of the type ‘what the sentence is about’ are at first sight suitable for sentences (1)–(4), but they are dubious for (5), while the subjects in (6) and (7) clearly do not fall under a definition of this type.

In a series of investigations of the last decades (cf., for instance, the pioneering work of Keenan 1976) it has been established that in the most elementary sentences subject NPs correlate statistically with the meanings of various autonomous semantic domains.

First, subjects are linked to the semantic role properties of participants in the given situation. The subject usually encodes the agent, if there is one in the

sentence. If there is no agent in the sentence, then the prime candidate for subject position is the patient. In the presence of an agent the patient is the prime candidate for the position of direct object. Sentences with an agent and patient constitute the prototypical transitive clause with a Subject and direct object. Sentences with participants in other roles are assimilated to varying extents to the structure of transitive or intransitive clauses, or use the position oblique object. The participant with the role of recipient/beneficiary usually occupies the position of indirect object.

Second, there are statistical correlations with the discourse (communicative) domain (see *Linguistics: Information Structure*). Thus, subjects often communicate known (given) information, while objects communicate new information; subjects often coincide with the focus of empathy, i.e., with that participant from whose point of view the situation is described, and with the topic (theme), while objects often coincide with the comment (rheme).

Third, the ontological domain, connected with the properties of referents, influences the subject or object position of NPs. Nps denoting animate, and especially human participants tend towards the subject position, inanimates towards the object position (*Grammatical Gender*). Within the set of humans the greatest tendency towards subject position is shown by the speech act participants (concepts from the deictic domain, see *Deixis*).

In addition, concepts from the referential domain, which classify kinds of referents denoted by NPs and facilitate their correct identification by the addressee, also correlate with grammatical relations. Thus, the subject has a presumption of existence, usually has autonomous reference, and is definite and specific, while the direct object is often nonspecific.

However, it is not possible to assign any of the above-mentioned meanings as obligatory for the subject or direct object; in each given sentence these grammatical relations satisfy only some of these meanings.

What, then, is the invariant meaning of grammatical relations, if indeed one exists? There is no generally accepted answer to this question. However, the following can be offered as the most plausible answer. Grammatical relations order NPs in the sentence by rank in accordance with their overall communicative value in a concrete utterance. The ordering takes place by means of a system of rules which takes into account the concrete meanings of NPs according to all the relevant semantic domains, so that the first rank is assigned to the subject, the second to the direct object, then the indirect object and oblique objects, as shown in the so-called ‘relational hierarchy’:

$$\text{Su} > \text{DO} > \text{IO} > \text{OO}$$

where Su represents ‘subject,’ DO ‘direct object,’ IO ‘indirect object,’ and OO ‘oblique object.’ The subject

occupies a special position in this hierarchy. The subject is the most essential component of the sentence, and in some languages it is structurally necessary, in contrast to all other grammatical relations. The other grammatical relations are ranked primarily according to their degree of difference from the subject. In this way, grammatical relations have not an absolute, but rather a relative syntactic value in the sentence, and the relation of this value to meanings of various kinds is indirect in nature.

Grammatical relations are a means of cumulative expression of permitted combinations of more elementary meanings, primarily from the role and discourse domains. Given this, then, first, the same grammatical relation in different sentences of the same language can have a different set of meanings; and second, in different languages grammatical relations can be organized differently, since different combinations of these meanings may be grammaticalized (see *Grammaticalization*) into different grammatical relations.

It can easily be seen that the subject and direct object are furthest removed from the semantic role of a NP and that their basic characteristic is their rank position in the hierarchy. Together with the predicate they form the nucleus of the predicate–argument structure. Oblique objects, in contrast to subject and direct object, have a specific semantic role (e.g., place, time, cause, manner), and in a clause there can be more than one oblique object. The indirect object has an intermediate status. On the one hand, it is considerably more loaded, in terms of semantic role and ontological semantics, than are the subject and direct object, and in this it is like oblique objects, but on the other hand it is the easiest to incorporate into the nucleus, compare (1) and (8) *Peter sent Mary a message*. In (8), in contrast to (1), *Mary* occupies the position of direct object.

2. How are Grammatical Relations Encoded?

Languages use different means to encode grammatical relations. The best known morphological category specifically designated to encode grammatical relations is case (see *Morphological Case in Linguistics*). Case marking is present in many languages, e.g., in Latin and Greek, in the Slavic and Dravidian languages, and in the languages of Australia. Under case marking the grammatical relation is expressed by the morphological form of the head of the NP (i.e., of the noun, as in Latin and Russian) or by the forms of other structural constituents of the NP (e.g., forms of the article and noun in German). Alongside inflectional morphology many languages make use of grammatical words or particles (usually prepositions or postpositions), which combine with a NP to give analytical constructions that indicate the kind of grammatical relation (e.g., the combination of pre-

position *to* and NP, such as *to Mary* in (1), encodes the indirect object). The linear order of NPs in the sentence is the positional equivalent of inflectional or analytical marking (see *Word Order*) and is calculated according to the position of the NP relative to the verb, relative to the beginning or end of the sentence, or relative to other NPs. Morphological marking may be indicated not on NPs, but on the verb by means of agreement (see *Grammatical Agreement*): the form of the verb expresses information about the grammatical properties of that NP which stands in a particular grammatical relation to the verb. An example in English is agreement of the verb with a third-person subject in number, combining with the indication of grammatical relations through linear order. Some languages have polypersonal agreement of the verb with two or more NPs. Thus, in Abkhaz the verb has three agreement positions indicating agreement with specific syntactic types of NPs.

3. The Syntactic Functions of Grammatical Relations

The question of which grammatical relation a particular NP occupies in the sentence can by no means always be decided on the basis of the coding technique. The same means may be used to encode different grammatical relations and the same grammatical relation may use different coding techniques. Thus, in English an immediately postverbal prepositionless NP is not always a direct object: (9a) *He was sleeping all night*, cf. the equivalent Russian sentence with a time adverbial in the accusative: (9b) *On spal vsju noč'*, where the accusative is the typical case of the direct object. Conversely, in Russian the direct object can stand in the genitive case in the context of negation, e.g., (10a) *On kupil knig-u* (acc.) 'He bought a book' vs. (10b) *On ne kupil knig-i* (gen.) 'He didn't buy a book.' For this reason the question often arises of the criteria by which one can assign different grammatical relations to identically marked constituents or assign the same grammatical relation to differently marked constituents.

The decisive diagnostic role in identifying grammatical relations is played not by coding means, but by syntactic tests. The point is that the coding technique is merely the outer packaging that helps identify grammatical relations in the sentence, whereas the grammatical relations are really components of the syntactic structure of the sentence; their identity or nonidentity is determined in the last analysis on the syntactic level (see *Syntax*). In many languages the system of rules of syntactic organization operates to a considerable extent on the basis of units characterized in terms of grammatical relations, and thus the identity of syntactic behavior of constituents differing in form is an important criterion for uniting them as a single grammatical relation.

Within the clause, voice transformations are oriented to grammatical relations (see *Grammatical Voice*). Thus, the difference between active and passive voices is that different grammatical relations adhere to the same NPs in active and passive versions. Passivization is usually characterized as the promotion of the syntactic status of the direct object to that of subject and/or demotion of the syntactic status of the subject. In English both processes occur in passivization, cf. (1) and (2). The subject NP of the active loses its subject status (it is expressed by the prepositional phrase *by Peter*), while the direct object NP (*a message*) becomes subject (promotional passive). There are also languages in which passivization involves only the demotion of the status of the subject NP (demotional passive). However, in all cases passivization is defined in terms of grammatical relations, irrespective of the coding techniques used in the particular language.

Among nearly universal properties are constraints on reflexivization, operating in cases of coreference between two NPs in the same clause, e.g., (11) *Mary hates herself*, (12) *Mary does not think about herself*. Here, one of the NPs (*Mary*) must be in subject position and is a full identification of the referent (the controller of reflexivization). The other, nonsubject, coreferential NP is replaced by the reflexive pronoun (the target of reflexivization).

Under coordination there are also constraints on grammatical relations. Thus, in English coordination reduction is possible only with coreferential subjects. The second coreferential subject is omitted, e.g., (13) *John washed his hands and—[= John] began to eat*. Another construction formulated in terms of subjects is switch reference, attested in various languages: clauses are expressed differently according to whether their subjects coincide or not (usually by marking the verb of one of the clauses).

As a syntactic test one can use constructions with sentential complements with verbs like ‘want,’ ‘must,’ ‘begin.’ Sentential complements are usually expressed differently depending on the coreference versus non-coreference of the subject of the sentential complement and the subject of the main clause, cf. (14a) *Peter wants to congratulate Mary*, but (14b) *Peter wants Mary to congratulate him*. In (14a) the subject of the sentential complement is coreferential with the subject of the verb *want*, and is therefore not expressed overtly in the subordinate clause. In (14b) the coreferential NP is the direct object, therefore it cannot be omitted, but must be expressed by means of a pronoun.

The formation of relative clauses (see *Relative Clauses*) is constrained, in many languages, by the grammatical relation of the target of relativization. For instance, reduced (participial) relative clauses in English are restricted to subject targets of relatives: (15a) *the student buying a book*, (15b) *the book bought by the student*. In (15a) the target of relativization is in subject position (*The student buys a book*), therefore

the relative clause is formed directly from this structure. In (15b) the target of relativization is the direct object (*The student bought the book*), therefore in order to construct the participial version it is necessary first to passivize the relative clause, promoting the status of the target of relativization to subject position (*The book was bought by the student*). In some languages relativization is constrained also by the grammatical relation of the controller of relativization.

Not infrequently constraints on the formation of adverbial clauses (see *Adverbial Clauses*) also rely on grammatical relations. In Russian there is a set of subordinate clauses expressing background activity, the so-called converbal (gerundive) clauses. The subject of the converbal clause must be coreferential with that of the main clause (and is omitted in the converbal clause): (16) *Pokupaja ètu knigu, student potratil na poiski massu vremeni* ‘Buying this book, the student spent a lot of time in searching.’ In (16) the omitted subject of the converbal clause and the subject of the main clause is the NP *student*. Sentence (17) is ungrammatical: (17) **Pokupaja ètu knigu, u studenta propal košelek* ‘Buying this book, the student’s purse got lost,’ since *u studenta*, the NP in the main clause coreferential with the subject of the converbal clause, is not the subject (the subject of the main clause is *košelek* ‘purse’).

To the extent that many syntactic rules are operations in terms of grammatical relations, these rules can be used as tests to determine the syntactic status of a NP in morphologically ambivalent instances.

4. Initial vs. Derived (Primary vs. Secondary) Grammatical Relations

Certain syntactic processes change the grammatical relation of a particular NP or delete it. Such processes change the valency of a sentence (see *Valency and Argument Structure in Syntax*). In such instances it is important to distinguish initial and derived grammatical relations of NPs. Thus, in the passive the initial subject loses this grammatical relation, while the initial direct object becomes the subject of the passive sentence. It follows from this that syntactic processes are often formulated in terms of initial syntactic relations which are not present in the observable, derived syntactic structure. Their existence can nonetheless be reconstructed on the basis of the syntactic process that conditions the observed structure. In a series of instances properties of the initial grammatical relation of a NP are partially retained. For instance, in the examples (18a) *Uncle Tom built this hut for himself* and (18b) *This hut was built by Uncle Tom for himself*, the controller of the reflexive is in both instances the initial subject *Uncle Tom*, even

though in (18b) the derived, observable subject is *this hut*.

5. Nonuniversality of Grammatical Relations

In linguistics the aprioristic assumption of the universality of grammatical relations was long dominant. Many current syntactic theories derive from this assumption, in particular generative grammar (see *Linguistics: Incorporation*) and the theory of Relational Grammar. In the last decades, however, as a result of considerable progress in studying the nature of grammatical relations and thanks to the considerable broadening of empirical linguistic material this assumption is no longer self-apparent.

First of all, the functional and formal properties of grammatical relations characterized above (poly-functionality of content and cumulative expression) testify to their specific semiotic nature. Why should such a technique of identification and characterization of noun phrases be an obligatory property of natural language? Conversely, it is natural to allow that different languages might grammaticalize various concepts of different semantic domains and package them differently in linguistic form. What we identify as grammatical relations might be filled with different content in different languages and, moreover, one might find not a cumulative, but a separative technique of packaging elementary concepts. Finally, there is no *a priori* basis to assume that the concepts of some or even all the relevant domains should be grammaticalized in each language, given that so far not a single semantic domain has been found that would be grammaticalized in all languages (be it the category of gender, number, tense, aspect, mood etc., see *Grammatical Gender; Grammatical Number; Tense, Aspect, and Mood, Linguistics of*). Even as apparently as indispensable ontological category as part of speech (see *Word Classes and Parts of Speech*) has recently increasingly lost the assumption of universality.

Second, uncritical attempts to use relational concepts with respect to different languages often encounter serious empirical difficulties. One may start with the observation that the morphosyntactic means of encoding NPs in some languages is not only different from, but sometimes not even comparable with the encoding characteristic of Standard Average European languages. If one uses the widespread notation for the nuclear arguments with the symbols S, A, P (or O), where S is the nuclear argument of an intransitive clause, and A and P the agent-like and patient-like arguments, respectively, of a transitive clause, then in European languages the S/A arguments have identical encoding, grouping them together as the grammatical relation of subject, in opposition to the encoding of the P argument. Such a system is called accusative alignment. Alongside this possibility, many languages found in various continents have the ergative pattern, uniting the S/P arguments in opposition to the A argument. Here the S/P arguments are

usually morphologically unmarked, while the A argument is marked (ergative case or its analog). The ergative alignment of the nuclear arguments creates an empirical problem for the establishment of grammatical relations.

In the languages of the world other patterns are also found. One possibility is a pattern that distinguishes agent-like and patient-like arguments of both transitive and intransitive clauses (active alignment). Under active alignment one finds different expression of the single argument of verbs like 'run' and verbs like 'fall.' There is even the tripartite scheme, distinguishing all three arguments, S, A, and P. Finally, there is the neutral pattern, which fails to differentiate the S/A/P arguments by means of coding.

Languages characterized by 'unusual' non-accusative patterns are quite varied from a syntactic point of view. For instance, languages with ergative alignment may behave as syntactically accusative, i.e., in defiance of the coding technique S and A arguments are united in a single grammatical relation subject. Much more interesting is the situation where ergative alignment is also realized at the syntactic level: S and P arguments are united syntactically in the highest ranking grammatical relation, equivalent to the subject under accusative alignment. The A argument is also a nuclear argument, i.e., it occupies the second position in the Relational Hierarchy. Finally, there are ergative languages in which it is impossible to rank S, A, and P at the syntactic level. In languages of this type it is justifiable to speak of the absence of grammatical relations.

Among languages with active alignment are also found languages behaving accusatively at the syntactic level, as well as languages lacking syntactic relations. So far there is extremely little information available on languages with tripartite or neutral alignment. It is, however, quite clear that they too are quite varied. They may have or not have grammaticalized grammatical relations. In particular, there is evidence for the existence of languages with neutral alignment lacking grammatical relations. But one can assume the existence of a neutral alignment language opposing nuclear and nonnuclear arguments. In such a language the nuclear arguments would be equivalent to subject, and the nonnuclear arguments to oblique objects. If such a language is attested, then the thesis of the uniqueness of the subject will have been overturned.

Thus, grammatical relations both have a narrower sphere of use and are considerably more varied than is usually assumed.

It should be kept in mind that the thesis of the nonuniversality of syntactic relations is not universally held, and is even ignored in many works. However, the assumption of nonuniversality is preferable by far in empirical research of little-studied languages, since it does not impose an aprioristic standard on the description and helps to see the real state of affairs in each language under discussion.

6. Grammatical Relations and the Functional Approach to Language

The concept of grammatical relation has been known in linguistics since the time of the grammarians of antiquity. However, significant progress in understanding the nature of grammatical relations has been achieved only in the last decades thanks to the orientation towards the functional explanation of grammar (see *Grammar: Functional Approaches*), which has permitted establishing the polyfunctional character of the elementary categories which form the clusters known as grammatical relations. The majority of these categories were themselves discovered and investigated in the framework of the functional approach.

In this connection the question of the existence of different patterns of encoding S, A, and P arguments merits special attention. Proceeding from the now widely established assumption of the iconicity of the linguistic sign (see *Linguistics: Iconicity*), replacing the Saussurean assumption of the arbitrariness of the sign, one can allow for the existence of a functional motivation for the various coding patterns. These patterns unite arguments with different elementary roles in different ways. The basic prototype of all these groupings (see *Linguistics: Prototype Theory*) is given by the agent and patient of the transitive construction. From this viewpoint active alignment is a natural metonymic extension of the elementary roles of agent and patient, generalizing them to the hyperroles (macroroles) of actor (the participant in the event which performs, effects, instigates, or controls it) and undergoer (the participant in the event which does not perform, effect, instigate, or control it, but rather is affected by it in some way). Arguments with different elementary roles can be interpreted in terms of these hyperroles.

Accusative alignment is also motivated essentially not by grammatical relations, but by the hyperroles principal and patientive. The principal indicates the main participant, the 'hero' of the situation, who is primarily responsible for the fact that this situation takes place. In the transitive clause the principal is, of course, the agent-like argument, while in the intransitive clause the single nuclear argument has no competitors for the role of principal. The patientive is the most patient-like participant of a multi-participant event. This role unites, in addition to the patient, arguments of other types.

Ergative alignment articulates the S, A, P arguments by means of other hyperroles, absolutive and agentive. The absolutive is the metonymic extension of the patient to intransitive verbs, it is the immediate, nearest, most involved or affected participant in the situation. In the transitive clause the patient is most involved in the situation. In the intransitive clause there is no competition for the role of closest and most involved participant in the situation. The absolutive in

the transitive clause is in opposition to the agentive, the most agent-like participant of the multi-participant event.

Tripartite alignment distinguishes agentive and patientive of the transitive clause, distinguishing them from the single nuclear argument of the intransitive clause.

All these means of generalizing the elementary roles are in principle motivated, but a language has the option of grammaticalizing just one of them as its basic pattern. In addition, a language may have different patterns in different contexts, and examples of this kind have been attested.

7. Grammatical Relations and the Cognitive Approach to Language

The 'statistical' correlations between concepts of different semantic domains noted above and which are grammaticalized in grammatical relations and the means of their encoding are not chance, rather they have a cognitive nature, reflecting the human capacity for categorizing reality. Behind the limitless variety of whole grammatical systems lie the same stable cognitive structures of human thought and the pragmatic strategies (see *Pragmatics: Linguistic*) for their verbalization. The reconstruction of these structures and strategies on the basis of data from different languages is the task of cognitive typology (see *Linguistic Typology*).

Grammatical Voice

1. Introduction

A typical sentence (clause) of a natural language consists of the predicate and its arguments. Each argument is associated with a certain participant role and is expressed by a certain grammatical function in a clause. Voice is the grammatical category that relates the participant roles associated with arguments on the one hand and the grammatical functions of the noun phrases (NPs) expressing these arguments on the other.

Predicates can be characterized by the number of arguments they take; a one-place predicate is intransitive, a predicate with two arguments is transitive. The ability of a predicate to subcategorize for semantic arguments does not necessarily mean that all these arguments are overtly expressed by NPs; some arguments may be omitted and some arguments may be understood (implicit) but never expressed.

In terms of semantic arguments, the description of grammatical voices relies crucially on the recognition of two types of core arguments of a predicate, agent (logical subject) and theme (logical object). An agent is a participant that has some or all of the following properties: it exists independently of the event named by the predicate, can cause a change of state in another participant, is capable of movement, is volitional and capable of intention (Gruber 1965, Fillmore 1968, Dowty 1991). A theme is a participant that has some or all of the following properties: it may not exist independently of the event, undergoes a change of state in the event, is causally affected by an agent.

Turning now to the grammatical functions subject and object, these functions can be manifested in all or some of the following formal properties: case-marking, linear position in a sentence, agreement, and ability to determine the form and/or linear position of other constituents (for example, the form of reflexives).

Based on how agent and theme are mapped into grammatical functions, linguistic theory recognizes the following main voices: active, passive, middle, and antipassive.

In the active voice, agent is mapped into the syntactic subject of a clause, while theme is mapped

into the syntactic object, as in the English example (1).

- (1) *Invisible God* [agent, subject]
created a visible world [theme, direct object]

In the passive voice, agent is mapped into an oblique phrase or adjunct, whereas theme may be mapped into the syntactic subject, as in (2).

- (2) *The visible world* [theme, subject]
was created by invisible God [agent, adjunct]

In the middle voice, the event denoted by the predicate is construed as developing without external causation; the main participant is both the source and the recipient (beneficiary) of the event. Thus, the main argument of the middle voice is construed as combining features of agent and theme. The contrast between the middle voice and the passive voice can be illustrated by the English (3) and (4); in (3), the ability to wash well is perceived as the property of cotton, and no external agent is permitted:

- (3) *Cotton* [theme, subject]
washes well (*by consumers)
(4) *Cotton* [theme, subject]
is washed (well) (by consumers)

In the antipassive voice, agent is mapped into subject and theme is mapped into an adjunct. Although English does not have a regular antipassive, the contrast between (5) and (6) is illustrative of the contrast between the active voice (theme = direct object) and antipassive (theme = adjunct):

- (5) *The soldiers* [agent, subject]
shot the pirates [theme, object]
(6) *The soldiers* [agent, subject]
shot at the pirates [theme, adjunct]

Alternations in grammatical voice that operate on the same argument structure consistently show information-structural differences. The major distinction in information structure is between topic ('what the utterance is about') and focus (the constituent that, given a well-formed question-answer pair, is the part of the answer that corresponds to the wh-word in the question). Topic-focus differences can be used to motivate the choice of one voice over another. It is erroneous however, to think that each and every language has voice alternations; for a given argument structure, some languages have just one way of mapping arguments to grammatical functions.

2. Active Voice

A verb in the active is often unmarked for any morphological indication of voice; however, this is not a universal characteristic. A number of languages, for instance, many Austronesian languages, mark active voice on the verb with a special morpheme. For

example, in Malagasy, a significant number of verbs form the active by prefixation on the verb stem (7a); for some of these verbs, the passive form is morphologically simplex (7b) (Keenan and Polinsky 1998):

- (7a) *sasa-* ‘wash’ (root)—*manasa* ‘wash’ (active, present)
 (7b) *hita* ‘see’ (passive)—*mihita* ‘see’ (active, present)

A common active voice structure is the one where the agent or most agent-like argument of the predicate is subject, while the theme, if there is one, is direct object. Agent appears in the subject case which, depending on a particular language, could be nominative, as in (8a, b), (11), absolutive (9a), ergative (9b), or dative (10). If the verb is transitive and has a theme argument, the case marking of this argument is typically that of direct object (accusative in an accusative language, absolutive in an ergative language); however, theme objects of some verbs can also be marked by a special case, inherent to a given verb, e.g., as in Russian (11).

- (8) Latin
 (a) *rex* *dēcessit*
 king.NOMINATIVE died
 (b) *rex* *omnes*
 king.NOMINATIVE (all
cōpias *castrīs* *ēducit*
 troops).ACCUSATIVE of.camp led
 ‘The king led all the troops out of the camp.’
 (9) Chukchi
 (a) *ətlʔa* *wiri-gʔi*
 mother.ABSOLUTIVE descend-AORIST:3sg
 ‘The mother came down.’
 (b) *ətlʔa-ta* *məčək-w-ən*
 mother-ERGATIVE shirt-ABSOLUTIVE
təni-nin
 sew-AORIST:3SG:3SG
 ‘The mother sewed the shirt.’
 (10) Hindi
mujʰ-e tum-se pyaar he
 I-DATIVE you-INSTRUMENTAL love AUXILIARY
 ‘I love you.’
 (11) Russian
Korolʹ upravljaet
 king. NOMINATIVE rules
stran-oj
 country-INSTRUMENTAL
 ‘The king rules the country.’

The determination of grammatical functions associated with agent and theme depends on language-internal factors and cannot be done on the basis of isolated examples from a given language.

If the verb in the active voice is intransitive, its single argument may correspond to either topic or focus; focused subjects of intransitives often serve to introduce new information. In a transitive active sentence, the subject/agent argument is more typically associated with topic than the object/theme, as shown

by a number of text counts (Mallinson and Blake 1981). However, this information-structural preference can be overridden by a number of contextual factors, and an argument other than agent or even an adjunct can be construed as topic.

3. Passive Voice

Natural languages use passives extensively and show a wide range of variation in the expression of passives. The variation can be captured by the following parameters: (a) difference in overt marking between the active and the passive predicate; (b) expression of the subject of the passive; (c) accessibility of arguments to passivization; (d) expression of the passive agent.

In terms of the encoding of the predicate in the passive construction, passives can be morphological (synthetic) or periphrastic (analytical). In English, the formation of the passive always requires an auxiliary (‘be’ or ‘get,’ with slight semantic differences depending on the choice of the auxiliary), thus the passive is periphrastic. In some languages, passives are always formed morphologically, for example, in Swahili, where the passive is marked by the suffix *-w-* (12b):

- (12) Swahili
 (a) *Juma a-li-vunj-a* *dirisha*
 Juma he-PAST-break-ASPECT window
 ‘Juma broke the window.’
 (b) *dirisha li-li-vunj-w-a* *(na Juma)*
 windowit-PAST-break-PASSIVE-ASPECT by Juma
 ‘The window was broken (by Juma)’

Although it is common for passives to be morphologically more complex than actives, this is not always the case; in a number of Austronesian languages, morphological passives are simpler than actives, for instance, for subsets of verbs in Toba Batak, Indonesian, or Malagasy; it is also possible for both active and passive to be formed by affixation from a verbal root (stem), as in Malagasy.

Some languages combine morphological and periphrastic passives, depending on the verb categories. For instance, in Latin or Russian, imperfective verbs form morphological passives, and perfectives use periphrastic passives (Latin *capio* ‘take’ (active), *capitur* ‘is taken’ (passive imperfect), *captus est* ‘was/has been taken’ (passive perfect). In addition to passives proper, some languages use the so-called reflexive passive, in which the active form of the verb combines with a reflexive clitic such as Romance *se*, *si*, German *sich*, Slavic *-sja*. Finally, some languages do not use any verb marking to distinguish active and passive predicates; for example, in Acehnese and in Mandarin, the only overt marking of the passive construction comes from the marking of the agent phrase and, optionally, from word order (Perlmutter and Postal 1983).

In terms of argument expression, the mapping of agent into an adjunct is the necessary and sufficient characteristic of passive. It is therefore possible that agent is ‘demoted’ to an adjunct and the subject position is filled by an ‘expletive’ (‘dummy’)—a meaningless element similar to the English ‘it’ in ‘It rains’ or ‘there’ in ‘There was a riot.’ Passives whose subject is an expletive are known as impersonal passives. Impersonal passives can be formed from intransitive verbs, (13b), or transitive verbs (14b). In the latter case, theme remains in the object position, and the subject of the sentence is expressed by an expletive; in languages where pronominal subjects are typically deleted, the expletive of an impersonal passive is a 3-person null pronoun (*pro*), whose presence is signaled by the agreement features on the verb (14b).

13 German

- (a) *Alle Kinder tanzen*
all children dance
(b) *Es wird (von allen Kindern)*
it is by all children
getanzt
danced.PERF.PARTICIPLE
‘There is dancing (as performed by all children).’

(14) Lithuanian

- (a) *čia lankutojai klausosi muzikos*
here visitors.NOMINATIVE listen music.ACCUSATIVE
‘Visitors listen to music here.’
(b) *čia pro lankutoju klausoma muzika*
here visitors.GENITIVE listen-PASSIVE-3 music.ACCUSATIVE
‘There occurs listening to the music by visitors here.’

In a personal passive, the subject position is occupied by a meaningful argument (as in English). In some languages, arguments other than direct object can also become subject of the passive. In some dialects of English, passivization is equally possible for both objects of the verbs ‘give’ or ‘send’:

- (15a) *The doctor gave the child new medicine*
(15b) *New medicine was given the child (by the doctor)*
(15c) *The child was given new medicine (by the doctor)*

In Kinyarwanda (Bantu), any prepositionless object can become subject of a passive (Kimenyi 1988, p. 365), thus:

- (16a) *umugóre aréerekeesha imashiini ábáana amashusho*
woman is showing machine children pictures
‘The woman is showing pictures to the children with a machine.’ (Active)

- (16b) *amashusho are’érekeeshwa imashiini ábáana*
pictures are being shown machine children (n’umugóre)
by woman
‘Pictures are shown to the children with machine (by the woman).’ (Theme passive)
(16c) *ábáana baréerekeeshwa imashiini amashusho*
children are being shown machine pictures (n’umugóre)
by woman
‘The children are shown pictures with a machine (by the woman).’ (Goal passive)
(16d) *imashiini iréerekeeshwa ábáana amashusho*
machine is being shown children pictures (n’umugóre)
by woman
‘The machine is being used to show pictures to the children (by the woman).’ (Instrument passive)

In languages that allow the passivization of multiple arguments, the accessibility to passivization is determined by the following principle: if a lower (more oblique) object can be passivized, then all objects higher than it should be able to passivize as well. This predicts that there should be no languages where a passive as in (16d) is possible whereas passives as in (16b, c) are ungrammatical.

In terms of the expressions of the agent, no language seems to require that the passive agent be expressed; however, there are languages where an overt by-phrase in the passive is ungrammatical (Arabic, Latvian, Seri).

There are several functional motivations for the use of passives, and although they do not need to co-occur within a single language, these motivations are cross-linguistically consistent. In terms of information structure, passive allows a speaker to indicate that theme, not agent is the main topic of an utterance. Concomitantly, passive may serve to indicate that the passive agent is focus or part of focus. Syntactically, passive is needed if a language has rules that operate only on subjects; in such a case, passive is a ‘way-station’ for an argument that needs to be made accessible to a given rule. For example, English uses passive in embedded infinitival clauses to put theme in the position of the silent subject argument of the infinitive (PRO), as in (17b), where John is subjected to the interview:

- (17a) *We persuaded John_i [PRO_i to interview the lawyer]*
(17b) *We persuaded John_i [PRO_i to be interviewed by the lawyer]*

Passive may differ from active in pragmatic connotation, for example, politeness or indirectness. Such pragmatic differences are often invoked as the main reason for the prevalence of passives in certain narrative styles and in requests (passive imperatives) in Austronesian languages. A recurrent interpretive

difference between the active and the passive is in that the passive emphasizes the change of state incurred by the referent of the theme. Because of this semantics of change of state and the attendant semantics of the resultant state, passive constructions are more common in the past and perfect; the coalescence of passive and perfect in the history of Indo-European languages is well documented (Benveniste 1960, Kuryłowicz 1964).

Linguistic theories differ in terms of whether the alternation between voices should be accounted for in syntax, in the lexicon or in both modules; for a good overview of grammatical approaches to passive, see Spencer (1991, Chap. 7).

4. Middle Voice

The description of the middle voice, based on the Greek grammatical tradition, is that of an event initiated within/by the main participant and having a principle effect on the same participant. For example, in Sanskrit:

- (18) Sanskrit
 (a) *so namati daṇḍam*
 he.NOMINATIVE bends.ACTIVE stick.ACCUSATIVE
 'He bends a stick.'
 (b) *daṇḍaḥ namate*
 stick.NOMINATIVE bend.MIDDLE
 'The stick bends.'

A common extension of that meaning is that the volitional and sentient main participant is acting in his own interests. For example in Sanskrit:

- (19) Sanskrit
 (a) *so kamaṁ karoti*
 he.NOMINATIVE mat.ACCUSATIVE makes.ACTIVE
 'He makes a mat.'
 (b) *so kamaṁ kurute*
 he.NOMINATIVE mat.ACCUSATIVE makes.MIDDLE
 'He makes a mat for himself.'

The middle voice typically appears in clauses referring to body actions, grooming, speech acts, cognition, emotive events, and meteorological or spontaneous events (Kemmer 1993). Since middles often refer to properties, not events, verbs in the middle voice commonly have a stative meaning, but this is not a necessary characterization of the middle voice. Cross-linguistically, middle voice often coincides or partially overlaps with the passive (hence such terms as medio-passive, e.g., in the history of Indo-European languages), as well as with the reflexive and reciprocal. This conflation can be explained by the commonality of semantics—in the middle, reflexive, and reciprocal, the same participant is perceived as both the cause (source) of an event and as its recipient, thus as agent and theme.

5. Antipassive Voice

The antipassive voice is less common than the passive; in those languages where it is found, variation is observed in the following ways: (a) the marking of the antipassive voice on the verb; (b) the encoding of the subject (in contrast with the subject of the active); and (c) the expression of the theme.

The verb marking, as in the other voices, can be analytical or synthetic. Analytical antipassives (formed with an auxiliary verb) are found in some languages of the Caucasus, for instance in Lak (20b); synthetic antipassives appear to be more common, for example, (21b) (in (21a), where the verb is active, it agrees with both ergative subject and absolutive object; in (21b), the verb in the antipassive form agrees only with the absolutive subject):

- (20) Lak
 (a) *ga-nal uṣṛcu*
 he-ERGATIVE children.ABSOLUTIVE
buvcu-n-i
 carry-AORIST-3SG
 'He has carried the children.'
 (b) *ga (uṣṛcu)*
 he.ABSOLUTIVE children.ABSOLUTIVE
buclej ur
 carrying is.3SG
 'He is carrying children; he is doing the carrying.'
 (21) Chukchi
 (a) *əlpa-ta məčək-w-ən*
 mother-ERGATIVE shirt-ABSOLUTIVE
təni-nin
 sew-AORIST:3SG:3SG
 'The mother sewed the shirt.'
 (b) *əlpa (məčək-w-ək)*
 mother.ABSOLUTIVE shirt.LOCATIVE
ine-nni-gʔi
 ANTIPASSIVE-sew-AOR:3SG
 'The mother sewed (at the shirt).'

As the contrast between (21a) and (21b) shows, in an ergative language, the subject in the active and the subject in the antipassive may appear in different cases; however, this is not a necessary condition on the antipassive, and ergative languages are attested where the subject of the antipassive remains in the ergative case (Australian languages Djarru, Walbiri, Kuniyanti). The theme in the antipassive construction is syntactically optional, thus it is an adjunct. It can be expressed by any of the oblique cases or adpositional phrases available in a given language (for example, in Chukchi, it can appear in the dative, locative, or instrumental case), and it can be freely omitted. However, as (20b) shows, in some languages the case marking of the theme does not have to change; what is crucial though is that the theme be an adjunct syntactically, which may be manifested though 'behavioral' properties of an NP, not case marking. Finally, in

some languages, antipassives require that the theme not be expressed (for example, in Tzotzil), in ‘mirror image’ to the non-expression of the passive agent in passives of some languages.

The sources of functional motivation of the antipassive are similar to the sources observed for the passive. Syntactically, the antipassive is used when a language has rules that refer to absolutes. For example, in Chukchi only absolute arguments are accessible to relativization, thus, when an ergative subject has to be relativized, the antipassive is used as a ‘way-station’ for relativization:

- (22) Chukchi
- (a) *ətlʃa-ta məčəkʷ-ən*
 mother-ERGATIVE shirt-ABSOLUTIVE
təni-nin
 sew-AORIST:3SG:3SG
 ‘The mother sewed the shirt.’
- (b) *[*məčəkʷ-ən təni-lʔən*] *ətlʔa*
 shirt-ABSOLUTIVE sew-PARTICIPLE mother
 (c) [*məčəkʷ-ək ine-nni-lʔən*]
 shirt-LOCATIVE ANTIPASSIVE-sew-PARTICIPLE
ətlʔa
 mother
 ‘the mother that sewed the shirt’

Interpretive differences between the active and the antipassive construction derive from the presence of an affected participant (theme) in the former and its absence in the latter. A common inference in the antipassive construction is that the theme is not affected or affected just partially. Since the theme participant does not even have to be specified, the event denoted by the antipassive predicate is often construed as generic or habitual, taking scope over a set of possible objects. This in turn explains why the antipassive is more commonly found in the imperfective aspect and in non-past tenses which do not limit an event or limit it indefinitely. In terms of information structure, the antipassive shares with the active that agent is the most likely topic; unlike the active construction, the antipassive makes it more likely that sentential focus takes scope over the predicate and adjunct (if any) or just the adjunct.

Unlike passive, antipassive is less common across languages, and even in those languages that have an antipassive, it is often considered to be a lexical, not a syntactic process, because of its restricted productivity. A syntactic account of the antipassive has been offered by Baker (1988) in terms of incorporation: the object position in the antipassive construction is occupied by an NP which is morphologically realized as a bound affix (including null allomorphs), and this affix incorporated into the verb stem.

6. Phenomena Related to Voice

A number of phenomena overlap with voice or are encoded by some of the same markers as are used for

marking voice, in particular the passive. These phenomena include reflexives (predicates whose two main arguments have the same referent, acting upon itself), reciprocals (predicates whose two main arguments refer to participants acting upon each other), inchoatives or anticausatives (intransitive counterparts of ‘cause X to P’, as in the English *burn*, *melt*) which receive the same marking as regular or reflexive passives (for example, in Romance languages). Inchoatives are sometimes assimilated to middle voice forms. Discussions of impersonal passives sometimes include active impersonal passives to these constructions is problematic.

- (23) French
on discipline ces enfants
 ‘One disciplines these children.’

The active-passive alternation is sometimes extended to include the so-called inverse systems attested mainly in Native American languages. In an inverse system, there are two constructions differing in whether Agent or Theme is higher on the hierarchy Human > Animate > Inanimate (or such similar hierarchy). If Agent outranks Theme on the hierarchy pertinent to a given language, the direct form of the verb is used (24a); if Agent is lower, the inverse form is used (24b).

- (24) Navaho
- (a) *hastin líí yi-z-tal*
 man horse 3SG + DIRECT-3SG-kicked
 ‘The man kicked the horse.’
- (b) *hastin líí yi-z-tal*
 man horse 3SG + INVERSE-3SG-kicked
 ‘The horse kicked the man.’

Aside from the presence of an actual alternation, there is no structural similarity between a voice system and an inverse system.

Early descriptions of ergative case-marking systems (see (9) above) assimilated the ergative to the passive. Although historically some ergative systems can be shown to go back to passives (e.g., in Indo-Iranian or Polynesian languages), synchronically the ergative construction is active, not passive.

Finally, most languages have classes of verbs whose morphology is indicative of one voice but whose syntactic behaviour does not support the morphological appearance. Such verbs are typically described as deponent verbs, a name rooted in the Latin grammatical tradition where the term was applied to verbs with passive morphology (*vox passiva*) which functioned as active verbs (*vis activa*), for example, *loquor* ‘speak’, where the inflection *-or* is that of 1 person singular passive.

Grammaticalization

1. Definition of Grammaticalization

Many definitions of grammaticalization have been suggested according to various theoretical approaches. One of the most diffused and clearest is Kurylowicz' definition: 'Grammaticalization consists in the increase of the range of a morpheme advancing from a lexical to a grammatical or from a less grammatical to a more grammatical status', Kurylowicz (1975). Some examples of grammaticalization are: Latin *habere* from a full verb meaning 'to grasp, seize' developed to an auxiliary in periphrastic verbal constructions for the expression of the future (*dicere habet* 'he/she has to say > shall say') or the past (*dictum habet* 'he/she has said'). The prepositional + relative phrase of the Old English *þa hwile þe* 'at the time that' evolved to the adversative and even concessive meaning of the Modern English conjunction *while* (see Traugott and König 1991). The Latin demonstrative *ille* 'that,' with strong deictic function (*ille homo* 'that man,' *homo ille* 'that notorious, famous man') gave rise to the obligatory article of the Romance languages (French *l'homme*, Spanish *el hombre*), where its function is simply to mark the noun phrase. Grammaticalization is thus a process leading from lexemes to grammatical formatives: 'a sign is grammaticalized to

Table 1

Six aspects of grammaticalization

	Paradigmatic level	Syntagmatic level
Weight	Integrity	Scope
Cohesion	Paradigmaticity	Bondedness
Variability	Paradigmatic variability	Syntagmatic variability

the extent that it is devoid of concrete lexical meaning and takes part in obligatory grammatical rules.' (Lehmann 1995, p. 6). Sometimes the terms 'grammaticization' or 'grammatization' have been used instead of grammaticalization without any substantial difference.

As is shown by the example of Latin *ille*, grammaticalization may lead to the emergence of new grammatical categories (in the case in point, the article which did not exist in Latin). In all the adduced examples the grammatical output of the process has passed through a syntactic use of the lexeme—though this need not always be the case.

Lehmann (1995, p. 123) has suggested three relevant aspects of grammaticalization, which realize six parameters both at the paradigmatic and syntagmatic level (see Table 1).

While grammaticalization is a process, the six parameters are not processes but properties that linguistic forms possess in increasing or decreasing measure. A linguistic form shows integrity inasmuch as it maintains its phonological and semantic identity. Phonological erosion and semantic bleaching reduce the integrity of a form (Latin *ille* > Italian *il*, Spanish *el*, etc.). The scope is the structural size of a construction: when a full verb is grammaticalized as auxiliary it makes up one phrase with the main verb and thereby reduces its scope to just the main verb (see the example of *habeo cultellum inventum* 'I have found a knife' in Sect. 3.1). By paradigmatic cohesion is meant the formal and semantic integration of a form into a paradigm: the suppletive forms *better*, *best* are less paradigm integrated than *longer*, *longest*. Bondedness refers to the syntagmatic cohesion: the more a form is grammaticalized the more it will be syntagmatically constrained; French *le*, Spanish *el*, etc., are fully grammaticalized noun determiners which cannot appear in isolation. Paradigmatic variability refers, according to Lehmann, to the freedom with which the language user chooses a sign—and, again, variability decreases with increasing grammaticalization, if cases are weakly grammaticalized the case suffixes may vary with relative freedom:

(1) Hungarian

a gyerek az asztal-on *játsz-ik*
The child the table-SUPERESSIVE CASE plays
'the child is playing on the table'

but *asztal-nál* (adessive) and *asztallal* (< *asztal-val*, instrumental-comitative) would also be possible.

Another example of paradigmatic variability is: the use of Latin *ille* was not compulsory in pre- or postnominal position and was semantically governed, but in Romance languages it is in most cases impossible to have a noun without the article. Finally, the syntagmatic variability is the ease with which a form may be shifted in the linear order of a sentence: the more a form has undergone a grammaticalization process the less variable it will be; **I have a knife found* or **I have a found knife* are impossible in Modern English.

It has to be noticed that the processes alluded to under the three labels of weight, cohesion, and variability cut across different levels of language structure; therefore the same items (e.g., *ille*) turn out to be appropriate examples of different parameters (integrity, scope, etc.). Grammaticalization is a pervasive phenomenon whose effects may be seen at all linguistic levels. Consequently, 'There is a growing interest in integrating grammaticalization with theoretical work in descriptive and historical linguistics' (Giacalone Ramat and Hopper 1998, p. 1).

2. A Historical Sketch of the Research

The classical examples of *dicere habet* and *l'homme* go back to Antoine Meillet (1916), who probably used first the term grammaticalization—though the concept is implicitly referred to by some previous linguists such as Wilhelm von Humboldt (*Über das Entstehen der grammatischen Formen und ihren Einfluß auf die Ideenentwicklung*, 1825), William Dwight Whitney (*The Life and Growth of Language: An Outline of Linguistic Science*, 1875), Georg von der Gabelentz (*Die Sprachwissenschaft: Ihre Aufgaben, Methoden und bisherigen Ergebnisse*, 1901) and others (see Lehmann 1995, Chap. 1, Heine et al. 1991, pp. 5–11).

As can be seen from the titles just quoted, grammaticalization has from the very beginning been considered in a large theoretical frame as one of the most characteristic developments languages may undergo. This holds also for the linguists of the next generations. Edward Sapir (1921, p. 102), for one, observed that 'it is possible for a concrete concept, represented by a simple word, to lose its material significance entirely and pass over directly into the relational sphere [i.e., the expression of abstract morphosyntactic relations, PR] without at the same time losing its independence as a word': forms live longer than their own conceptual content, which may be bleached and eventually fade completely. Sapir's examples are the Chinese and Cambodian verbs for 'give' used in a very abstract sense to express the 'indirect object' relation (see also Sect. 3).

Though not using the term grammaticalization, the French linguist Emile Benveniste (1968) took up again the case of *habere*, and called it a conservative mutation whereby a new (periphrastic) form takes

over the function of an older one in the grammatical paradigm (e.g., *habeo dictum* 'I have said' instead of *dixi* 'I said').

3. The Present State of the Discussion about Grammaticalization

3.1 The Continuum of the Grammaticalization Process

Already Whitney and Benveniste have underlined the fact that linguistic changes do not happen abruptly: 'Present possession often implies past action: *habeo cultellum inventum*, (...) *habeo digitum vulneratum* 'I possess my knife (recovered after loss) [> 'I have found the/my/a knife,' PR], (...) 'I have a wounded finger' [> 'I have wounded my finger,' PR].' Thus, *I have found the knife* became the indicator of 'a peculiar variety of past action contemplated as completed,' (Whitney 1875, p. 91, cf. Heine et al. 1991, p. 7f, Benveniste gives an insightful philological description of how the periphrastic forms with *habere* came first to be used and later spread out.

As a matter of fact, grammaticalization, like all terms ending in *-ization*, alludes to a gradual process, not a state. Grammaticalization is different from grammar. Even what has recently been alluded to as 'synchronic grammaticalization' implies a process whose final stage cannot be simultaneous with the beginning moment. This is not in keeping with the assumption by generative transformational grammar of rigidly separated grammatical categories. Actually, the 'new trend' of grammaticalization studies which has flourished in linguistics since the 1980s is basically oriented toward a functionalist approach, with very few exceptions. Grammatical categories are not seen as waterproof boxes; they permit, on the contrary, the gradual leaking of forms from one category to another.

Being functionally oriented means that attention is paid to the internal mechanisms, which govern linguistic structures, and the external psychological/cognitive causes of grammaticalization. Several linguists have hinted at the fact that grammaticalization very often originates in discourse strategies (i.e., in pragmatics), evolving to syntactic structures and later obligatory morphological markers (up to a possible total erosion of the markers):

Discourse < Syntax < Morphology < Morphophonemics < Zero (see Givón 1979, p. 209, cf. Lehmann 1995, p. 13, Traugott and Heine 1991, p. 3, Bybee et al. 1994, p. 40f).

Habeo cultellum inventum originates at the discourse level: the speaker wants to underline that he does really possess (*habet*) a knife which has previously been found (*inventum*) and uses a construct where every word keeps its own value. This pragmatic, effect-

Table 2

The grammaticalization–degrammaticalization continuum; α represents the evolution towards grammar (grammaticalization) and β the opposite process of degrammaticalization

α . lexicon	→delexicalization	→morphologization	→morphology
full words:			full morphemes:
<i>habet</i>		<i>di(ce)re (h)a(be)t</i>	<i>dir-a</i>
β . lexicon	←lexicalization	←demorphologization	←morphology
full words:			full morphemes:
<i>ade</i>		<i>lemon-ade</i>	– <i>ade</i> (<i>lemon</i> + <i>ade</i>)
<i>perhaps</i>			<i>per</i> (+ <i>haps</i>)

loaded expression evolves to a standard analytic construction of the syntax (with inversion and no longer with syntagmatic variability (see Sect. 1 above): *habeo inventum cultellum*) and finally enters the morphological paradigm of the verb *invenire* ‘to find’ as its periphrastic (agglutinated) past form (note that at this stage of the Romance languages it is no longer possible to have the word order *habeo cultellum inventum* (**fai le couteau trouvé*): the auxiliary has agglutinated to the main verb). As an example of morphophonemic evolution one can quote the French future *dirai*, *dir-a*, etc. ‘I shall say,’ ‘s/he shall say’ from periphrastic future forms with *habeo*: *dicere habeo*, *dicere habet*: the auxiliary has undergone phonetic attrition and has become an inflectional ending.

There is a continuum between the phases of the grammaticalization process: Heine et al. (1991, p. 1) quote the case of Èwe (Kwa branch of the Niger-Congo family):

- (2) *me-ná ga kofi*
1Sg-give money Kofi
‘I gave Kofi money.’
- (3) *me-ple βstrú ná kofi*
1Sg-buy door give Kofi
a ‘I bought a door and gave it to Kofi.’
b ‘I bought a door for Kofi.’
- (4) *me-wɔ dʒ vévié ná dodókɔ lá*
1SG-do work hard give exam DEF
‘I worked hard for the exam.’

In (2) *ná* has the function of a full verb, meaning ‘give’; in (4) *ná* can be interpreted only as a preposition (‘for’), whereas in (3) it is ambiguous and allows two different readings. Should one day the Èwe language admit for (3) only the second reading, then we would have a categorial shift (VERB > PREPOSITION), much in the sense of the evolution of Old English *hwil* ‘time’ (NOUN) to *while* (CONJUNCTION) (see above, Sect. 1). At the end of an uninterrupted process there is really a break and a category shift.

Shifts like VERB > PREPOSITION, NOUN > CONJUNCTION are examples of so-called *transcategorization*. Items belonging to a main (and open) category (VERB, NOUN) pass to a functional (and restricted) category (e.g., ADPOSITION PRE-OR PREPOSITION according to the structure of the language, concerned, CONJUNCTION):

these examples clearly hint at a move from a less grammatical to a more grammatical categorial status—it is however clear that the term *transcategorization* (or *recategorization*) is more appropriate than *decategor(ial)ization* used by Hopper (1991, p. 30f) and others.

3.2 The Dynamic of the Grammaticalization Processes

In such a dynamic typology of grammaticalization it is possible to account also for interrupted grammaticalization processes: in Old Italian it was possible to use movement verbs (*andare* ‘go’ and *venire* ‘come’) as auxiliaries in far more cases than in Modern Italian (cf. Giacalone Ramat and Hopper 1998, p. 2f, with further references). Further, Hopper has drawn attention to what he calls ‘emergent grammar,’ i.e., to the incipient stages of grammaticalization at the level of discourse (see above): the negative French adverb *pas* meant originally ‘step’; therefore it was used first with movement verbs (‘he doesn’t go a step’), but later it spread to verbs such as ‘eat,’ ‘see,’ etc. and became the general mark of negation, ousting other nouns that denoted a least quantity and were used, like *pas*, to reinforce the negation (e.g., *mie* ‘crumb,’ *gote* ‘drop,’ etc.): specialization principle. Thereby the original meaning of *pas* was completely lost (bleaching process).

As noted by Hopper himself, the principles he suggests (specialization, persistence, divergence, etc.) characterize linguistic change in general and are not distinctive for grammaticalization (Hopper 1991, p. 21). This has raised the problem of defining the limits of grammaticalization vs. other dynamic linguistic processes (cf. Giacalone Ramat and Hopper 1998).

3.3 Unidirectionality of Grammaticalization?

Unidirectionality is a much debated question in the literature on grammaticalization. Many linguists maintain that the evolution towards grammar cannot

be reversed (Lehmann 1995, p. 19, Traugott and Heine 1991, p. 4f, Heine et al. 1991, p. 31f). This is true if by this it is meant that once a lexeme has entered the grammar, it will hardly come back and assume again a lexical value. But there are many instances of items or morphemes leaving the realm of grammar and assuming an autonomous value as lexical entries: Hungarian, Spanish, and Italian have a large number of present participles used as nouns, e.g., Hungarian *költő* 'poet' (< *költ* 'to compose'), Spanish and Italian *cantante* 'singer' (< *cantar(e)* 'to sing'); nobody can fail to recognize in French *seigneur* (> English *sir*) the comparative of the Latin adjective *senex* 'old' or in English *elder* 'official in the Presbyterian church' a comparative from Old English *ald* 'old.' Both were originally forms belonging to the grammatical paradigm of the adjectives, but later they developed an autonomous lexical meaning. Even syntactic constructs may develop to new lexemes: Dutch *misschien* 'perhaps,' (< (*het*) *mach schien* literally 'it may happen'), Italian *forse* 'perhaps' (< Latin *Fors sit (an)* literally 'be the case'), English *perhaps* literally 'per chances (plural).' Grammaticalization and lexicalization are two complementary processes (Moreno Cabrera 1998, Ramat 1992).

Degrammaticalization processes are certainly less frequent than grammaticalization processes, but they exist and have to be explained. The causes for their existence are to be sought in the overall tendency to use labels as economic symbols: e.g., suffix morphemes like *-ade* (from *orangeade*, *lemonade*, or even *gatorade*) can be separately manipulated and become autonomous lexemes: the label *ade* with the general meaning of 'fruit juice' is more economic than the phrase *fruit juice*, though not as transparent (see *bus*, in *schoolbus*, *autobus*, etc., as hyperonym for 'public transportation vehicle'). Economic symbolism and noneconomic iconism are conflicting forces which are at work in every natural human language (cf. Ramat 1992, p. 557, Newmeyer 1994, p. 69). If we had just unidirectional evolution toward grammar we would expect that languages become more and more grammaticalized, which by all evidence is not the case (see Moreno Cabrera 1998, p. 224). On the contrary, we have a double evolution towards grammar as well as towards lexicon (see Kurylowicz 1975).

Phonogenesis is also a process which shows that loss of grammatical function may give rise to new lexemes (cf. Hopper 1990, 1992). As the German grammatical prefix *ge-*, used to indicate collectives (see *Ge-beine* 'limbs,' plural, *Ge-dränge* 'crowd'), was no longer felt as a prefix, it underwent phonetic erosion to *g-* and gave rise to nouns such as *Glück* 'luck,' *Glied* 'limb,' *Gnade* 'grace' which synchronically are no longer analyzable: phonetic junk, no longer recognizable as a functional morpheme, produced new lexemes. In the same vein of reasoning we have to consider also remnants of disappeared paradigms: this applies to dual forms which survived the loss of the dual

declension: cf. Latin *ambo* 'both' (perhaps also *octo* 'eight') with the old dual marker *-o*.

Summing up, we may represent (see Table 2) the grammaticalization and degrammaticalization processes along a continuum which moves into two opposite directions. At both poles of the scale we have either clear lexemes (full words like *habet*, *perhaps*) or morphemes (inflectional *-a* or derivational *-ade*), while it is difficult to state when *habet* was delexicalized and the construct *dicere habet* became the norm to express the future, or *ade* was reanalyzed as a second member of a compound: that is why *di(ce)re (h)a(be)t* and *lemon-ade* appear in the previous scheme midway between (de)lexicalization and (de)morphologization. Transcategorization is a gradual process along a continuum; its final output represents a break in the categorial status of the input (see Sect. 3.1).

P. Ramat

Gramsci, Antonio (1891–1937)

Antonio Gramsci (born in Ales, Sardinia on January 22, 1891 and died on April 27, 1937) started out as a freelance journalist writing assiduously for *Il Grido del Popolo* and *Avanti!*, newspapers of the Italian Socialist Party in whose ranks he had been active since 1914. In 1919 he founded *L'Ordine Nuovo* which became the daily paper of the Turin Communists, of whom Gramsci was to become undisputed leader. In 1921 he joined the Communist Party of Italy, created from the walkout during the XVIII Socialist Congress in Livorno. The following year he was in Moscow representing the Italian Communists in the Third International. Returning to Italy in 1924 he founded the newspaper *L'Unità*. Two years later he participated in the III Congress of the Italian Communists, held in Lyon, where he opposed Amadeo Bordiga and obtained an overwhelming majority. The same year, despite his parliamentary immunity, he was arrested by the Fascists. Given a summary trial, he was sentenced to 20 years of imprisonment by the special Court for the Defence of the State.

Taken to the prison of Turi in the province of Bari, he remained there until 1933 when he was moved to Formia due to poor health. Obtaining a conditional discharge, in 1935 he was admitted to the Quisisana hospital in Rome, where he died following a stroke. Thanks to his sister-in-law Tatiana, his *Quaderni del carcere* ('Prison Notebooks'), written between 1930 and 1935, were sent underground to Moscow and delivered to Palmiro Togliatti. Published after the collapse of the Fascist dictatorship, they revealed a leading theoretician who, albeit following the path of Marxist–Leninist tradition, had elaborated an original concept of society and history underpinned by the theory of hegemony.

Gramsci's political thinking was deeply influenced by the October Revolution. He immediately saw it as confirming his activist and voluntaristic reading of Marxism, induced by Giovanni Gentile's neo-idealism. For Gramsci, Marxism was something more than a simple, empirical interpretation of history, as Benedetto Croce had defined it; it was a complete philosophy containing, in nuce, a new civilization to be constructed over a long and dramatic process. The industrial proletariat or, more specifically, its conscious vanguard, the Communist party, would be its protagonists. So Gramsci enthusiastically greeted the Bolshevik October as 'the revolution against the

Capital.' The revolution against the positivistic and deterministic interpretation of Marxism which the parties of the Second International had adopted while awaiting the inevitable, catastrophic collapse of capitalism. Gramsci also considered that Lenin had been able to grasp the systematic link between Marxism and German classical philosophy, of which Hegelianism had been the speculative summit. Thus Gramsci was prompted to see Lenin not only as the greatest strategist of the international workers' movement but also its greatest theoretician. In his deeds, even before his thoughts, he had expressed a higher degree of consciousness. Therefore, the unity of the theory and practice incarnated by Lenin and by the movement he had created had to be emphasized. Cultural work was thus a priority, to demonstrate that Communism was the positive response to the world crisis of capitalism and the moral dissolution of the bourgeois civilization, precisely because it had, thanks to Marxism, reached a higher degree of theoretical awareness. It was no coincidence that Bolshevism arose from the claim that the workers' consciousness should prevail over their spontaneity and that without a revolutionary theory no really revolutionary action was even conceivable. For Gramsci, the Communist revolution had to be seen as a philosophy which was being put into practice or, more precisely, as an ethical-political will enlightened by a theory whose aim was the reconstruction of the world.

Up to the end of 1923, Gramsci's thinking, expressed in a myriad of short articles on the political situation, was nothing else but an intelligent adaptation of Leninism to the Italian situation. All the typical elements of the Bolshevik model were to be found in it: the supremacy of theory over spontaneity, the concept of the party as a nucleus of activists devoted heart and soul to the revolution and submitted to iron discipline, the intransigent defense of orthodoxy against any form of revisionism, the military vision of the class war, the revolution as a declaration of war on the existing, the regime of transition focused on the dictatorship of the proletariat exercised by its conscious vanguard, the edification of Socialism as a substitution of the anarchy of the market with a single production and distribution plan; one can even find the idea, already expressed by Lenin to justify the red terror, that the Communists' historic mission was to 'purify the social environment with iron and fire,' exterminating the lower and middle bourgeoisie, 'corrupt, dissolute and putrescent humanity.' But, drafting his program-letter of February 1924, Gramsci started to work out the revolutionary theory that, in his *Quaderni del carcere*, was to be called the 'war of position' in opposition to the 'war of movement.'

Gramsci was the first Communist leader to realize that the Bolshevik strategy had few possibilities of success in Western Europe, with its robust civil society, rich in counter-powers and institutions relatively independent of the state. The Third International was

founded on the hypothesis that the world capitalist system had entered a phase of rapid and uncontrollable disintegration and that, therefore, the Communists' task would be that of accelerating this disintegration, mobilizing the proletarian masses against the bourgeois state, and enabling the Bolsheviks to take power. But the Comintern leaders had underestimated the vitality of capitalism that, despite the great postwar crisis, had shown it was strong enough to suffocate any revolutionary attempt before it was born. The 'war of position' was Gramsci's idea for rescuing the Communist movement from the blind alley down which it had gone. He had realized that the dominance of the bourgeoisie was based more on the consensus of the masses than on control of the coercive machinery. The celebrated theory of hegemony, developed in his *Quaderni del carcere*, says that the 'supremacy of a social group is shown in two ways, as dominance and as intellectual and moral leadership.'

Which is like saying that a class is hegemonic only insofar as it is capable of increasing the material and spiritual patrimony of society and obtaining the consensus of the working classes. Therefore there is no hegemony that is not founded on a 'historical bloc,' that is on an organized system of social alliances cemented by a common ideology. The historic bloc is the social basis of hegemony. It is not only a political phenomenon, it is also, and in a certain sense above all, a cultural phenomenon. This led Gramsci to claim that the superiority of a hegemonic class lasts insofar as it is able to keep its system of alliances united and bring in other social groups by satisfying, albeit within precise limits, their material and moral interests. Then, and only then, will it become the 'driving force of a universal expansion, of a development of all the national energies.' Gramsci's approach to the problem of social order was typical of the sociologies of consensus, stamped by a certain Marxism as interesting ideological distortions of reality, and he grafted their fundamental theorems on the trunk of historical materialism. He also took over Vilfredo Pareto and Gaetano Mosca's elitist theories of the late nineteenth and early twentieth centuries. His central premise was that the historical existence of a society is, always and necessarily, concentrated on the minorities–masses dialectic.

In *Quaderni del carcere*, society is conceived along Marxist lines as a hierarchical structure of classes, differing according to their position and function in organizing the production and reproduction of material life. But, for a class to make history, it must distinguish itself and become independent; it has to acquire a critical knowledge of itself. This happens gradually, transforming a class, an immediately corporate reality, into an ethical–political force with a national character that imposes its leadership on society. This is precisely the stage in which ideologies confront each other and enter into battle until one of them, or a combination of them, takes the upper hand

and unites not only the economic and political, but also the intellectual and moral, aims of society. Vice versa, a dominant class starts to decline when it gradually loses its ability to interpret the needs of the dominated classes and to mobilize national energies. It is true that a dominant class can keep its power even when it has lost its ability to rule, thanks to its control of the state's coercive machinery; but in the long run it is destined to be replaced by a new ruling class.

This led Gramsci to a conclusion which is, basically, the reformulation of Pareto's famous theory of revolution as a violent and traumatic substitution of an old aristocracy with a new aristocracy. But where Pareto only saw ideologies as rhetorical stratagems through which an elite justified its desire to dominate, Gramsci ascribed an enormously important function to them. Ideologies are not mere derivations, as Pareto called them; they are global visions of reality, essential for constructing a civilization. There is no civilization without an ideology, and without this ideology being absorbed by the lower classes and transformed into popular culture. So it can be said that history is dominated by the clash between ideologies, between hegemonic principles competing for the consensus of the masses. And the theatre of this clash is civil society. Gramsci saw this differently from Marx, that is as the society of industry and general competition, material base of the state and the ideological superstructures. For Gramsci, civil society is the theatre of intellectual and moral relations, where a social group that aspires to dominance constructs its own hegemony by soliciting the consensus of the dominated classes. Civil society, therefore, is a cultural rather than an economic reality: it is where rival hegemonic principles confront each other until one of them eliminates the others and becomes the impersonal engine of historical development.

Now, if what is decisive in history is not economic but spiritual power, then to move the middle classes out of the city of command, you first of all and above all have to earn the active consensus of the lower classes. That is, you have to incite a critical attitude to the existing order and persuade the workers to support the new type of society implicit in Marxist philosophy. The second consequence drawn from Gramsci's theory of hegemony was that the Bolsheviks' Jacobin strategy was not applicable to the type of war that had to be waged in Western societies. It presumed the power vacuum which had effectively occurred in Russia in 1917; in other words, it presumed the disintegration of the ruling class and the general collapse of the political system. Lenin and Trotsky's Blitzkrieg tactics had not, therefore, any possibility of success if there was a sufficiently cohesive historic bloc to repel frontal assault by the armies of the revolutionary movement. It was necessary to change the line of action, to work out a long-term strategy for gaining power.

The Italian Communist leader's answer to this problem is to be found in his *Quaderni del carcere*.

Studying the history of Western civilisation, Gramsci found a perfect model in the victory of Christianity over the Greco-Roman culture. Christianity had been, in its way, a revolutionary movement that had introduced a spiritual scission in ancient society and had triumphed thanks to its intellectual and moral superiority, to the indefatigable teaching of its apologists and to its organization. If it was impossible to conquer the bourgeois citadel *manu militati*, it was possible, as the history of the expansion of Christianity indicated, to conquer it by wearing away the ideological defenses of the middle classes. Thus the Communists had to imitate the early Christians by eroding from within, by a methodical, silent and all-embracing conquest of the ideological superstructures and the existing order until the working classes stopped supporting the ruling class. One of the fundamental theorems of Gramsci's sociological theory was that a class which wants to win power has first of all to be hegemonic. That is, it has to be able to exercise a firm and united, intellectual and moral leadership over the working masses and then to dominate them. It has methodically to take possession of the 'fortresses' and 'casemates' of civil society and transform them into the operational bases of its march towards the city of command. Thus, whereas Leninism had theorized the occupation of society through the violent conquest of the state, Gramsci proposes an inverse procedure: the conquest of the state through the cultural occupation of society. To this end, it was all-important to penetrate the mass-media, schools, universities and publishing houses and convert them into agencies for the socialization of Marxism.

In Gramsci's model for the conquest of power, violence was relegated to the background. Nonetheless, the strategic goal remained that of the Bolshevik Revolution: the institutionalization of the mono-party dictatorship as an indispensable condition for totally remodeling the social body. On this point Gramsci remained faithful to Lenin's teaching. The party, and only the party, had to be the leading light of the intellectual and moral reform for creating the new civilization whose institutional foundations had been laid in the Soviet Union. So that Gramsci, after having indicated the Communist party as the only institution which could be compared to the Catholic church, did not hesitate to define Marxism as the 'religion which could kill Christianity' by building the City of Man. And he saw the modern prince (the party of the professional revolutionaries, conscious vanguard of the working classes) as the historical agent. He who, overthrowing the entire intellectual and moral system of liberal civilization with his impassioned teaching, would have 'to take, in people's minds, the place of the divinity and the categorical imperative' (*Quaderni del carcere*).

Gramsci's is a rigorous theorization of the charismatic nature of the revolutionary party, not unlike Gyorgy Lukacs' in *Geschichte und Klassenbewusstsein*, where the Communist party is described as the

cosmic-historic agent which, in virtue of its superior theoretical knowledge, will have to achieve the 'salvation of humanity.' Gramsci defines the modern prince as the 'focus of the faith' and the 'custodian of the doctrine of Socialism' destined to introduce an epochal caesura in universal history. This prince has to ensure that he becomes the source of all the satisfaction his militants had previously found in a multiplicity of organizations. He must also destroy all these other organizations or incorporate them into a system in which this modern prince will be the 'only regulator.' Hence the distinction, spelt out in *Quaderni del carcere*, between two types of totalitarianism: the regressive kind, with a party opposing the drive of history, and the progressive one, which is precisely that of the modern prince bringing a new and superior culture.

This led Gramsci to affirm peremptorily that 'everything is politics,' and that, consequently, it is not possible to separate politics from philosophy, since the latter is the driving force of history in the making. A history that is always 'between two hegemonic principles, between two religions,' each of which aspires to regulate human life in all its material and spiritual manifestations. The idea of a competitive coexistence between a plurality of social forces and cultural models, so typical of liberal civilization, is not only entirely extraneous to Gramsci's political philosophy but even explicitly rejected. The final aim of his philosophy is the construction of the future city, conceived by Marxism as a 'harmonious society.'

The role of the intellectuals is of fundamental importance within this vision of the Communist revolution. They are the protagonists of history, since history is nothing else but the dramatic process through which a determinate philosophy takes over the world. Gramsci sees the revolutionary party as a 'collective intellectual' and gives the 'organized intellectuals' framed within the rigid discipline of Leninist centralism the function of 'permanent persuaders.' This explains why Gramsci's philosophy, in the decades following the publication of the Khrushchev Report (1956), had such a powerful influence on the Communist intelligentsia. The latter found in the *Quaderni del carcere* what they needed to liberate Marxism from Stalinist dogmatism and to conceive the fight for socialism as a magnificent pedagogical operation to conquer spiritual hegemony by changing how the subordinate classes felt and thought. But after the crisis of Marxism in the 1980s, Gramsci's theory of the peaceful conquest of power rapidly lost its fascination, despite the fact that some basic concepts of this theory—and first of all the concept of hegemony—have entered the lexicon of contemporary sociology.

Graphical Methods: Analysis

1. Introduction

Everyone is accustomed to seeing graphical displays used for presentation purposes: in scientific articles, newspapers, and magazines. Yet graphical displays may be used for exploratory purposes too, for investigating datasets and for uncovering the information hidden in them. Exploratory graphics are different. The aim is not to present information, but to use the graphics to uncover information. Static printed graphics can be useful for exploratory work, but the real gain lies in using interactive graphics on a computer.

In all the following examples it is assumed that exploratory analyses are being carried out, that each graphic is part of a broader analysis, and that they are drawn to aid the analyst, not to present the information to others. This is why there are few scales given. The analyst will know the approximate scaling and can always query the graphic on screen to get exact values, not only along axes, but for any point or object. In general a single presentation graphic is drawn to convey information to a potentially large

Figure 1

Bar chart of gender of car insurance policyholders

and varied audience, whereas a large and varied collection of exploratory graphics are drawn to extract information for a single person, the analyst.

Graphics are useful for checking basic assumptions and for getting a feel for data. Figure 1 shows a bar chart of gender from an insurance data set. Unusually there are seven codes for gender! Three made sense (firms are neither male nor female) and the rest were errors.

The histogram for policyholders' birth dates for the same data set was also revealing (Fig. 2). The tall white column to the left represents missing values for the variable (mainly firms again). There is a small isolated column at 1,900 (missings originally coded as '00?') and there are some very recent dates of birth, surely errors for car-driver insurance data. This is a large dataset (over 50,000 cases) and some errors may be expected, but it is extraordinary how often datasets which have been purportedly quality checked still have errors in them. Incidentally, the dip in the histogram is due to low birth rates during the war.

Assuming major errors have been corrected or removed, graphics are valuable both for checking old ideas and for generating new ones. After the historic 1990 Irish Presidential election it was hypothesized that Mary Robinson had won because she got the women's vote. Data from the last MRBI survey before the election suggests otherwise. Figure 3 shows a bar chart for the preferences for the three candidates linked to a spine plot for gender (in a spine plot all column heights are the same and column widths represent the counts so that highlighted proportions are directly comparable). The proportion of women intending to vote for Mary Robinson was only slightly higher than the proportion of men. Linking to another spine plot shows that urban voters were more important for Mary Robinson's win.

2. Background

Presentation graphics (see *Graphical Methods: Presentation*) have been used for a long time. Exploratory

Figure 2
Histogram of years of birth of car insurance policyholders

Figure 3
Barchart of candidates' support linked to spineplots for gender and location. (Results from the last MRBI survey before the 1990 Irish Presidential Election. Thanks to Jack Jones and the Market Research Bureau of Ireland for permission to use the data)

graphics are newer, not because people did not appreciate their value, but because without a computer it was not efficient to draw many variations of many different displays. John Tukey led the way with his innovative and provocative book, *Exploratory Data Analysis* (Tukey 1977; see *Exploratory Data Analysis: Univariate Methods*) although, curiously enough, the book was written slightly too early, before personal computers were becoming commonplace. Thus he emphasizes pencil and paper methods like stem and leaf plots for continuous data. These are like histograms laid on their side with each bin having a width of a power of 10. The advantages are the simple construction by hand, and the listing of each value individually. The disadvantages are the dependence on a very limited range of bin sizes, and the unsuitability

of the method for anything other than small datasets. Imagine a stem and leaf plot for the car insurance data set of Fig. 2.

More recent computer-oriented references include Cleveland and McGill (1988), Eick and Wills (1995), and Unwin (1999). There has also been much related work outside statistics for which Spence (2001) is a good source. In none of these works is a substantial formalization of exploratory graphics attempted. Considering that presentation graphics have been around much longer and yet Wilkinson's groundbreaking work (Wilkinson 1999) only appeared in 1999, this is not surprising. Furthermore, exploratory analyses are by their nature interactive and dynamic and so the process is difficult to explain on the printed page. Some of the best sources of information and examples

Figure 4

Direct querying of a bar. How many women supported Mary Robinson?

can be found on the web using keywords in this article and/or author names as search parameters.

3. Interacting with Displays

3.1 Interactive Features

Graphics may mislead. For instance, bar charts will look similar whether they are based on 50 or on 5,000 cases. (The survey in Figs. 3 and 4 was based on 1,000 interviews.) It is important to be able to check any impressions gained. Sometimes this might mean carrying out the corresponding statistical test (e.g., a chi-square test for comparing bar chart proportions), but a first step is to directly query the graphic, as in Fig. 4.

Direct querying is useful in all displays, especially when it is context sensitive. The same action may be used for each part of each plot and yet provide different information according to which part of which plot is queried. Other steps that may be carried out to gain more insight are to rescale the graphic (e.g., change the bin size in a histogram), to reformat the display (e.g., switch the axes of a scatter plot), to reorder the display (e.g., order the categories in a bar chart by count), to zoom in (e.g., concentrate on an outlying cluster of points in a scatter plot), or to select various groups of points and link them to their representation in other displays (see Unwin 1999).

Histogram bin sizes which are small pick out gaps and identify preferred values, while large bin sizes

emphasize overall trends. Figure 5 shows two histograms of maths marks for 126 Irish schoolchildren. Notice how one version picks out the typical gap below the pass mark of 40 and the other does not.

Scatter plots can be extremely informative tools for revealing the relationship between two variables, but the scales, the aspect ratio of the axes, the size and color of the points can all affect how they look. For large datasets with extensive overplotting (i.e., many points are drawn at the same location on the plot), some form of density estimation (see *Probability Density Estimation*) is necessary or there is a risk the dataset may be misunderstood. Figure 6 shows a scatter plot of the birth weights of 4,000 babies plotted against the estimated duration of pregnancy. A coarse density estimation has been used whereby black dots represent single cases and the brightest white ones at least 30 cases. It is clear where the majority of the data is concentrated.

Neither drawing sunflowers at each point with the numbers of petals representing the numbers of points nor jittering the data (adding small random components to each point to reduce the overlapping) are serious solutions for large datasets like this (although both suggestions are to be found in the literature). Sounder solutions have been suggested by several authors including Carr et al. (1987) and Hyndman (1996), but should be implemented interactively. Single displays optimized on a particular criterion cannot reveal all the structure in the data. An interesting problem for interactive scatter plots is how to display both highlighted and unhighlighted distributions informatively.

Variations of scatter plots may be used to display subgroup distributions in parallel, e.g., income of those surveyed by job category. The resulting parallel dot plots are a valuable initial exploration tool for smaller datasets, but parallel box plots are more effective for large datasets as in Fig. 7.

Bar charts are good for comparing absolute numbers, but are not good for displaying proportions. Simple pie charts are good for emphasizing shares, though it is difficult to compare the sizes of individual sectors and too often they are drawn with irrelevant three-dimensional features and other distracting distortions. Spine plots are best for comparing proportions based on selections, but can only deal with one

Figure 5

Histograms of maths marks out of 100 for a group of Irish schoolchildren

Figure 6
Babies' birthweights plotted against duration of pregnancy

selection at a time (see Fig. 3). Switching between bar chart and spine plot representations interactively is one solution.

3.2 Linking

Linking means that points selected in one display are highlighted in all other displays. Selecting a subgroup

Figure 7
Boxplots of salaries by job category in a bank

may identify an outlier within the group in another plot. There may be patterns within subgroups which mask each other when the data for all groups are shown together. Highlighting area-based plots is straightforward; an area corresponding to the size of the selected group is colored. Highlighting point displays is complicated by overplotting, as mentioned above in relation to scatter plots. The best solution for box plots seems to be the idea due to Wills of drawing a box plot for all the data in the background and a box

Figure 8
A parallel coordinate plot of the points by event for the mens' decathlon at the Sydney Olympics 2000. The medal winners have been highlighted

plot for the highlighted data on top (Eick and Wills 1995).

Linking is central to successful interactive graphics in the way it provides insight into multidimensional structure. Not just points in graphics may be linked, but cases, scales, orderings, and colors may be linked in any kind of window. In this sense querying is just a form of linking.

3.3 Interfaces

All of these tools are exploratory in nature and only work effectively when they are interactive. If you have to wait for the screen to clear and a graph to redraw, you will have forgotten why you wanted the change in the first place. Interactivity implies an intuitive interface, flexible commands, and a fast response. Command-line interfaces are valuable for the precise control they offer and the ease with which they can be recorded. For exploratory work it is direct manipulation of the objects on screen which is important and it is rarely of interest to know how a conclusion was first discovered, as it is common to find much better ways of showing results after you have first discovered them. All components of a graphic display (bars, axes, points, legend, etc.) may ideally be queried, moved, rescaled, and reformatted. To avoid clutter on screen, it is helpful to use cues to hint at what is possible rather than to fill the screen with visible controls. To protect the user from possible unwanted side effects of their actions, warnings, and undos are beneficial.

3.4 Dynamic Graphics

The term 'dynamic graphics' refers to graphical displays that move such as rotating plots, grand tour displays, or animations controlled by sliders. (A slider is a control which allows the user to change the value of a parameter of a model in real time and see the affected displays update continuously (see Data Desk or Tierney 1990). While the resulting dynamic displays may be informative, it is the interactive control in the hands of the user which is most useful and in this sense they are a specialist subset of interactive exploratory graphics.

4. Multivariate Displays

4.1 Continuous Variables

Modern graphical tools are very good for exploring many variables at once. Scatter plot matrices (a matrix display of scatter plots of all possible pairs of variables) have often been suggested for continuous variables, though they are inefficient in their use of space. For up to about eight variables (the number depending on the

screen's resolution and the analyst's eyesight) they can be used for exploratory purposes with linking.

Parallel coordinate displays are primarily for large numbers of continuous variables. Each variable is represented by a vertical axis and individual cases are joined by lines. There is an attractive geometric duality, pointed out by Inselberg (1998), that a point in a scatter plot is represented by a line in a parallel coordinate display and vice versa. Interactive tools are essential for these plots for two reasons: (a) the order of the axes affects what can be seen, so it has to be possible to change the order easily; (b) the large numbers of lines for a dataset of even moderate size makes it essential to be able to temporarily hide points and lines. Categorical variables can also be displayed on their own axes and Wills has suggested using circles whose areas reflect the numbers in a category. Since there is no natural order of categories for most such variables, being able to reorder categories interactively is also valuable. While there is in principle no limit to the number of axes which may be displayed in a scrollable window, it is clear that these displays provide only limited insight to the full multidimensional structure.

4.2 Categorical Variables

Interest in investigating multivariate categorical variables has grown with the rise of data mining. The large datasets which banks, retailers, and other commercial organizations want to study often include many categorical variables. Survey datasets commonly do too, but it is rare to find visualizations of such data. Mosaic plots are one way of uncovering the multivariate structures. Although first discussed in general by Hartigan and Kleiner in 1981, it is only in the late 1990s with the addition of interactive features that they have revealed their true potential (Hofmann 2000). A mosaic plot in its original form is constructed by dividing up the horizontal and vertical axes in turn by each new variable. Figure 9 shows a diagram for the Titanic data set (Dawson 1995). Initially the horizontal axis was divided up according to the numbers in each class, then the individual columns were divided vertically by age, then the resulting cells were each divided horizontally by gender. Finally, the numbers surviving in each group have been highlighted.

This mosaic plot allows the comparison of survival rates by gender within class and age group. The higher survival rates of the female adults compared to the males are obvious. Redrawing with a different order of variables (gender, age, class) permits direct comparisons of survival rates by class within each gender and age group. There are gaps drawn between the cells for two reasons: the display is easier to interpret, and empty cells can be shown (for instance, there were no children in the crew of the Titanic).

Alternative versions of mosaic plots include: (a) the same bin size display, where each cell has the same size;

Figure 9

Mosaic plot of the Titanic data in the order class, age, gender with survivors highlighted

this is good for identifying patterns of empty combinations and for comparing highlighted rates for all combinations; (b) fluctuation diagrams, where each cell's size is proportional to the count of the combinations which it represents, but the cell is drawn at a fixed position on the grid. Fluctuation diagrams have the advantage of maintaining a clearer structure, but can be very inefficient in their use of space in comparison to the original format. The alternating of horizontal and vertical axes is an arbitrary restriction and Hofmann has introduced double-decker plots, where only the horizontal axis is divided, as a particularly insightful way of looking at association rules.

One of the most useful approaches for analyzing multivariate data, especially with large datasets, is to study subsets of the data in parallel as in Fig. 7. Trellis displays (Becker et al. 1996) are a more sophisticated version and draw individual displays for each subset in a structured panel display. As in a mosaic plot, the panels are defined by a hierarchical succession of variable splits. Unlike mosaic plots the panels are all of the same size. Each panel may display any one of a number of basic statistical graphics, for example, a box plot or a scatter plot. The art in a successful trellis display lies in the choices of panel plot and of how to split the data set into subgroups. For this reason it would be useful for them to be interactive, but at the time of writing trellis displays are only available in a static form.

4.3 Multivariate Projective Displays

The multivariate displays mentioned thus far show all the raw data. An alternative is to concentrate on projections of the data onto specially chosen lower dimensional spaces. Good projections reveal almost

Figure 10

A biplot of the 13 variables and 178 cases of the UCI Wine data set

all the information in the data, albeit in the transformed space. Biplots are so called because they show both the projected points and also the axes of the variables (for continuous variables) or the category level points (for categorical variables) in the projection space (Gower and Hand 1996). Figure 10 shows the UCI wine dataset with the second group highlighted. This projection separates the groups fairly well. Long axes show that the corresponding variables are well represented in the projection space. Biplots have many

attractive properties, but remain two-dimensional representations. The larger the number of variables, the less likely it is that a biplot can reveal the major features of a dataset, but the addition of interactive tools enhances the capabilities of biplots substantially (Hofmann 1998).

The first major innovation in exploratory graphics was none of these tools: it was the rotating plot (Fisher et al. 1974 in Cleveland and McGill 1988), in which a succession of two-dimensional images gives the impression of rotation in three dimensions. This is a natural extension of a scatter plot, is excellent for three-dimensional continuous data, and is fun to use, but for higher-dimensional datasets it is not so practical. In that case it can be used in a different way, displaying three-dimensional projections of the data. Many methods of identifying 'interesting' projections have been discussed and the most effective implementation seems to be a directed grand tour. The grand tour was designed to rotate through all possible three-dimensional projections of a dataset of continuous variables and the analyst would decide which of the resulting projections gave him or her insight into the data. Directed grand tours make use of projection pursuit indices to guide the user towards revealing projections (Swayne et al. 1998).

5. Specialist Displays

5.1 Missing Values

In the histogram in Fig. 2 there was a special column for recording the numbers of cases with no values for that variable. Missing values are a problem for large datasets and any initial overview of the data needs to check for numbers of missings and for any structure among them. Some statistical methods cannot handle cases with missings. A simple approach is the missing value plot as in Fig. 11. There is a bar for each variable. The solid part of the bar on the left represents the cases with values and the blank section on the right the missing values. Bars can be queried and selected to give a rough idea of associations. In the figure it is clear that many cases are missing on a large number of variables.

This kind of display cannot reveal more complex structures and one idea is to use a fluctuation diagram of the corresponding binary variables (missing: yes/no), concentrating on the 10 variables which still have noticeable numbers missing.

5.2 Weighted Displays

In datasets arising from surveys or based on geographic areas, it can often be the case that individual

Figure 11

A missing value plot for variables from a patient survival study. A subgroup missing on only two variables is highlighted

data points are of differing importance: the unemployment rate in London should have a greater weight than the unemployment rate in Stratford-upon-Avon. Some authors have suggested using bubbles instead of points in dot plots and scatter plots, where the size of the bubble is proportional to the weighting variable. This can be effective for small numbers of cases, but generally leads to overplotting problems. Area-based displays such as histograms, bar charts, or mosaic plots have no such problems and counts are simply replaced by sums of weights. This can lead to very striking and informative differences in displays. The

Figure 12

Histograms of black population percentage by US MidWest county, unweighted (left) and weighted by black population (right)

left-hand histogram in Fig. 12 just about shows a single county with the highest percentage of blacks among the over 400 counties in the five US mid-west States. Most counties have low percentages of blacks. The right-hand histogram has the same horizontal scaling, but the height of the bins is now proportional not to the number of counties but to the aggregate black population in the bins. Most blacks live in counties with relatively higher percentages of blacks. It is, of course, necessary that the weighting variable is additive! Population is fine, population density is not (see Unwin and Hofmann 1998).

6. Statistical Tools and Plots

Surprisingly, and disappointingly, statistical graphics rarely make use of statistical tools. There are a few exceptions. Some packages offer the option of displaying box plots with confidence intervals around the medians. Some packages offer the chance of plotting error bars round means. SAS have software (*JMP*) where circles are drawn round subgroups as a means to enable graphical detection of whether differences are significant or not. However, the last example illustrates one of the problems. *JMP* offers several different options because there is no agreed optimal way of comparing several means simultaneously. The same

problem would arise with bar charts and more seriously with mosaic plots; there are so many possible statistical tests that it is not easy to specify a universally acceptable default. The solution will be to offer the various options interactively.

7. The Future

Advances in statistical graphics have not been due to improvements in screen resolution. The best exploratory graphics are simple displays. What makes them powerful is the speed and flexibility with which they can be manipulated and combined. It is the increase in computing power which has been crucial for modern interactive graphics. More powerful computing has also led to the development of computer-intensive analytic procedures and these have sometimes been combined successfully with graphics. Evaluation of projection pursuit indices and rotating plots is one example. Smoothing methods such as Lowess are another.

A major requirement for all statistical methods is that they can be scaled up to deal with huge datasets. Area-based graphical tools such as histograms and bar charts can in principle be used for datasets of any size, but interaction is necessary to catch details and explore links between variables. Much more needs to be done to cope with displays for large numbers

of variables, and interactive capabilities will be essential.

Statistical graphics has grown in fits and starts. There are many attractive ideas, some general principles, but little theory. Real progress will only come with a successful formalization, so that the future can build on the successes of the past. This is something to look forward to in all senses of the phrase.

8. Software

The displays in this article have been taken from screenshots. There has been no attempt to pretty them up; they illustrate exploratory analyses in progress. Most are from MANET (Unwin et al. 1996 and www1.math.uni-augsburg.de/Manet/), a couple are from Data Desk (www.datadesk.com). Other software also offers interactive capabilities, but the degree of interactivity varies considerably. For up-to-date information on software, check statistical websites.

Graphical Methods: Presentation

Figure 1 shows a graphic of death rates against birth rates for 27 selected countries in a 1990 UN databank (Wilkinson 1999b). The contours in Fig. 1 show two concentrations of countries. One, to the left, has relatively lower death rates and small-to-moderate birth rates. The second, toward the upper right, has high death rates and extraordinarily high birth rates. The curve in the middle of the contours shows that the overall relation between death and birth rates is curvilinear.

The single plot in Fig. 1 contains three graphs: (a) a point graph (collection of points) whose labels show country names; (b) a set of contours based on a kernel density estimate (Silverman 1986) that represents the concentration of the countries; and (c) a LOESS smoother (Cleveland and Devlin 1988). The graphic also includes three guides for our understanding. The first is a general geometric object called a form that is, in this instance, a line delineating zero population growth. Countries to the left of this line tend to lose population, and countries to the right tend to gain. The other two are guides that demarcate axes for the represented space. Other examples of guides are legends and titles.

Each of the constituent graphical elements in Fig. 1 has a long lineage in the history of statistical charts. Scatterplots of points and contours are several centuries old, and regression smoothers are at least a century old. The use of a rectangular coordinate system to locate graphs within a frame demarcated by axes predates by centuries Descartes’ eponymous Cartesian coordinate system. We shall review briefly the history of statistical graphics and charts.

Figure 1
Plot of 1990 death rates against birth rates for selected countries

The lines, colors, typography, proportions, and other aspects of Fig. 1 have been chosen to facilitate communication of the ideas and models underlying the chart. We do not need to resort to platitudes such as, 'A picture is worth a thousand words' to understand that this graphic comprises a relatively substantial analysis of the data. We shall review briefly the topic of graphics principles which can help us devise effective ways to display analyzed data.

The world of charts is enormous. Principles can guide us through that world, but there are many alternatives for representing one or more variables in a graphic. In the final section, we shall present some of these choices and use them to derive additional guidelines for developing effective presentations.

1. History

The contours, or level curves, in Fig. 1 represent a map. This representation is based on a statistical function that maps birth rate and death rate onto a density. Any value on this density can be derived from a corresponding pair of birth rate and death rate values taken from the domain of values within the frame bounded by the two displayed scales. The geometric space in which this mapping is embedded is three-dimensional. The first two dimensions are birth rate and death rate, and the third dimension is density.

The technical mathematical terms in the previous paragraph (contours, level curves, map, function, onto, density, value, domain, frame, bounded, scales, geometric space, and dimensions) are derived from ordinary language, often ancient, describing the physical world. This correspondence between the world of charts and the physical world is not coincidental. Charts are maps of abstract worlds. The word chart and the word cartography have the same root (Latin *charta*, a piece of paper or papyrus). The Greek word for geometry means 'land measurement'. A scale (in Latin) is a ladder. We map in order to organize our world in our mind. However, our world is larger than the domain of geography. As Pinker (1997) has argued, abstract reasoning is built on metaphors for reality. We manipulate abstractions by making them analogous to concrete objects.

Statistical charts are maps, but it does not suffice to simply describe them as abstract geography. The history of statistical charts contains remarkable leaps from a world of continuous rectangular (or spherical) space to other worlds that are categorical (worlds with gaps), multidimensional (worlds beyond three dimensions), and topological (worlds in abstract coordinate systems). Funkhouser (1937), Tilling (1975), Beniger and Robyn (1978), Fienberg (1979), Robinson (1982), Stigler (1983), Tufte (1983, 1990, 1997), Collins (1993), Wainer (1997), and Wainer and Velleman (2001) document these leaps. These references also contain numerous examples of graphics, ancient and modern,

that represent significant landmarks in this history. The remainder of this section will highlight a few.

Physical coordinates were used by Egyptian surveyors as early as the third millennium BCE for locating points on land (Beniger and Robyn 1978). By the beginning of the second millennium CE coordinates were used to locate nongeographic entities. Funkhouser (1936) shows an example of a line graphic of planetary movements on a space-time grid produced by an unknown astronomer in the tenth or eleventh century. Not surprisingly, one of the 'planets' is the Sun.

Cartesian coordinates were devised by Descartes for locating points in abstract space, particularly for representing equations underlying his analytic geometry (Funkhouser 1937). However, relatively few seventeenth or eighteenth century embeddings of observed data points in Cartesian coordinates have been found. (Funkhouser 1937, Tilling 1975). Scientists of the Enlightenment sometimes regarded graphics as dilettantish, and if they used them at all, it was for geometrical diagrams or maps of algebraic functions rather than for plots of raw data (Beniger and Robyn 1978). Social scientists of this period focused on collecting tables of state statistics that could be perused in detail without resorting to graphical approximation (Beniger and Robyn 1978, although see Stigler 1983). (Beniger and Robyn (1978) and Wainer and Velleman (2001) discuss notable exceptions to these observations (graphics by Wren, Halley, Huygens, Plot, Lister, Priestley) but conclude that the important varieties of what we now call the statistical chart did not arise until the work of Playfair in the late eighteenth century.

Playfair graphed the data of the state, the root of the word statistics. He invented the pie chart, the circle chart, the categorical bar chart, the area chart, and he adapted other geometric forms in novel ways to graph data over time and space. Wainer and Spence (1997) provide a brief biography of Playfair's fascinating life and the charts he created.

Other widely used graphical forms were developed in the nineteenth and early twentieth centuries. Beniger and Robyn (1978) and Stigler (1983) summarize a number of these. Density bars were used by Guerry in 1833 to display crime by age groupings. Pearson adopted this form for representing a frequency distribution and named it a histogram. Minard developed a number of schematic maps overlaying statistical data on geography. Florence Nightingale introduced polar area charts. The age-sex pyramid (a dual histogram) was introduced by F. A. Walker, Superintendent of the US Census in 1874. The sample cumulative distribution plot was introduced by Galton in 1875.

If charts are maps of abstract worlds, we might conclude that guiding principles for graphics usage could be derived from the psychology of perception and cognition in the physical world. Indeed, recent

psychological research has tended to support the simple statement that the more graphics adhere to the rules of the physical world, the more likely we are to extract and process the information in them, reliably and accurately. Section 3 covers this area.

2. Principles

Over the centuries of their history, various charts have emphasized communication (e.g., Snow's map of cholera deaths in London, reproduced in Tufte 1983), persuasion (Fletcher's map of the distribution of ignorance in nineteenth century England and Wales, reproduced in Wainer 1997), and graphic design (e.g., Playfair's chart of imports and exports of England to and from North America, reproduced in Tufte 1983). These criteria are, of course, not exclusive. Some charts incorporate all three (e.g., Minard's compound chart of Napoleon's troop losses in the Russian campaign, reproduced in Tufte (1983).

Not surprisingly, modern critics of charts have tended to align themselves along these same dimensions. Communicators (e.g., Cleveland, Kosslyn) have conducted experiments to determine rules that improve the transfer of information from chart-maker to chart-viewer. Persuaders (e.g., Holmes 1991) have evaluated charts on the basis of their psychological impact. Designers (e.g., Herdeg 1981) have applied aesthetic criteria. Others (e.g., Tufte 1983) have adopted the criteria of the communicator, and the methods of the designer. None of these approaches can claim exclusive validity. Since scientists are more interested in rules that foster accurate communication of replicable results, however, this section will focus on communication.

Evaluating graphical communication has been the province of psychology, in the subdisciplines of human factors, ergonomics, and applied cognitive science. For almost a century, human factor psychologists have developed methods and criteria for evaluating graphics. Military psychologists, for example, have conducted randomized experiments to test the effectiveness of aircraft cockpit displays.

Psychologists gave much less attention to the perception of statistical graphics until a statistician, William Cleveland, published a series of experiments designed to identify aspects of charts that helped or hindered accurate decoding of quantitative data (Cleveland and McGill 1984). (Beniger and Robyn 1978, cite a number of statisticians' informal studies of the effectiveness of popular charts in the 1920s, but these did not induce many psychologists to study the topic more formally.)

Cleveland used paper-and-pencil tests containing simple graphical elements—points, lines, angles, areas, colors—generated randomly by a computer. His subjects gave magnitude estimates of the values generating the instances of each element. From these estimates, he

Figure 2

Cleveland (1994) graphical features hierarchy

derived and analyzed error rates. Figure 2 summarizes the main result of these experiments. The top of the figure (BEST) represents elements that resulted in fewer errors and the bottom (WORST) represents those with more.

Cleveland's hierarchy gives us a start in designing effective displays. All other things being equal, we might choose to use a bar chart instead of a pie chart because judgments of position on a common scale and judgments of length are both more accurate than judgments of angle. There are exceptions to these rules, however (see the following discussion of Fig. 3b). A chart is more than the sum of its parts; elements interact in the context of a chart to suppress or enhance errors. Kosslyn (1994) summarizes relevant psychological studies in the extensive notes at the end of his book.

Others have provided numerous general rules for effective graphical communication. The following guidelines are derived from Bertin (1981), Tufte (1983), Cleveland (1994), and Kosslyn (1994).

Avoid clutter. Especially, do not clutter the data region inside the plotting frame demarcated by axes. Tufte constructs a data/ink ratio and urges us to maximize it by removing irrelevant detail. This exhortation has value as long as we do not remove redundant features that can reinforce an accurate perception. Most writers agree that one should avoid jazzy textures (especially stripes), gratuitous colors, excessive tick marks and grid lines, ornate fonts, and unnecessary embellishment. Avoid visual illusions due to pseudo-3D and other gratuitous use of color, angles, area, or volume in a 2D plotting world.

Seek simple geometric forms—straight lines, circles, triangles, squares. When it helps to simplify a relationship, use transformations (logs, square roots) to convert curves to straight lines, for example. Use polar coordinates when variables are cyclical (astronomical perceptual, directional).

Sort and organize. This is especially important for complex graphics. Usually, one should sort the values

Figure 3
Reported number of sexual partners (General Social Survey, 1993)

of a dependent variable (the range of the graph), but other sorts can help viewers navigate and perceive structure. Bertin (1981) has numerous examples showing the value of simple and multivariate data sorts. Figure 12 shows an example.

Annotate extensively. Make legends comprehensive and informative. Figure captions should describe the source of the data and explain the relation of the data to the graphic. Note exceptions (see Fig. 6).

3. Choices

Rules guide, but examples instruct. We need to consider specific choices for specific problems to understand exceptions to rules. The graphic representation problem is often expressed as one of choosing the proper chart type for a given set of data. This is an unhelpful way to express the problem, however. As Wilkinson (1999c) shows, different chart types with their own popular names are often mirror images or simple transformations of each other. Instead, we will examine several basic problems confronting the designer of a scientific graphic: geometry (choosing the type of graphical element for a chart), coordinates (choosing a coordinate system for the chart), and uncertainty (representing random error).

3.1 Geometry

The following examples were selected to illustrate principles, not exhaust possibilities. It is organized by the configuration and number of variables, categorical and continuous, that we wish to graph.

3.1.1 One variable. Figure 3 shows five different ways of representing values on one categorical variable. The data are from 1606 respondents to the 1993 General Social Survey (Davis et al. 1993). Respondents were asked, 'How many sex partners have you had in the last 12 months?' Those reporting more than four partners (some reported up to 100) were consolidated into the last category. There were 1,466 responses in the resulting six categories.

The upper left graphic is a bar chart of the frequencies of occurrence of each category. Bars are most suited for displaying either magnitudes referenced against zero (anchored bars, as in this figure) or a range of values on a continuous scale (range bars, as in Fig. 7).

Anchoring bars at zero can sacrifice resolution when no data values exist near zero; this creates substantial white space in the plotting area (Cleveland 1994). In

Figure 4
Consumption of spirits in gallons per capita, by US state, 1986

these cases, dots are preferable to bars because we do not need to include zero on the scale. The upper right graphic shows a dot plot of the same variable. In this

case, we would prefer the bar version because there are several values near zero and it is easier to anchor the bars visually on the partner categories. The locations of both the dots and the tops of the bars are easily decoded on the vertical scale.

The third graphic in Fig. 3 is a pie chart of the proportions of total category frequencies. The general antipathy statisticians have toward pie charts is misinformed. Pie charts are not always bad, although the issues on when to use them are complex. In general, bar charts are more suited to absolute judgments and pie charts are more suited to judging proportions (Simkin and Hastie 1987). Pie sectors near a fourth or half of a pie in size are judged especially accurately. When there are many sectors, however, pies are not usually appropriate. In this example, the bar chart would be more suitable.

The fourth graphic is a divided bar chart, which is nothing more than a pie chart in rectangular coordinates. Divided bars do worse than pies in studies of graphical perception (e.g., Simkin and Hastie 1987). Cleveland (1994) provides several examples to show why they are generally a bad choice.

The fifth graphic is a 3D pie chart. This is probably the worst of the popular ways to represent proportions. Three-dimensional graphics are not in themselves harmful. What creates the problem with the 3D pie chart is the distortion of angles that the perspective projection produces. In the 3D pie, the single partner category seems to cover almost 75 percent; the actual coverage is 68 percent.

Some users and computer programs apply line or area elements (see Fig. 7) to categorical variables. Popular examples are line graphics of means in analysis of variance, or area graphics of profiles across categories. These elements should generally be avoided with categorical data. Spacings between categories (even ordered categories) are not fixed, so slopes of line segments or profiles between categories are meaningless.

Figure 4 shows five ways of representing one continuous variable. The data are per-capita consumption of spirits for each of the 50 US states (Bureau of the Census 1986). The top graphic is a classic histogram overlaid with a kernel density estimate (Silverman 1986). Histogram bars look like ordinary bars, but they measure areas rather than intervals and they rest on a continuous scale rather than on a set of categories. Histograms are more useful than kernels when we are interested in displaying frequencies within intervals, especially when the intervals themselves are bounded by meaningful, round units. Kernels are more useful than histograms when we are looking for a smooth estimate of a continuous distribution.

The next graphic down is a dot histogram (Chambers et al. 1983, Wilkinson 1999a). This display represents each observation with a dot located at its scale value. If several values coincide on the scale, the

Figure 5

Number of reported sexual partners during previous year by reported level of happiness among 1,462 respondents to 1993 General Social Survey. Third variable is proportion of respondents in each sexual partner category

dots are stacked vertically. This display is most suited for small samples, when every value is to be displayed.

The graphic below that is a stripe plot (Chambers et al. 1983). A vertical stripe occurs at each data value. This display can handle more cases than the dot plot, although it is not suitable for large datasets.

The graphic following is a jittered density (Chambers et al. 1983). Random error is added to each value so that the plotting symbols do not overlap. This display is designed to handle roughly the same conditions as the stripe plot.

The last graphic in Fig. 4 is a box plot, or schematic plot (Tukey 1977). As Tufte (1983) notes, Tukey's plot is based on an earlier display that represents the quartiles of a distribution. In that earlier plot, the whiskers cover the range and the box covers the midrange. Tukey improved on this design by scaling the whiskers to allow for outliers. The display in Fig. 4 shows how important this feature can be. Two states (Nevada and New Hampshire) have unusually large values (see Fig. 6), possibly due to gambling and cheap liquor, respectively. The box plot is a clean representation of the summary values we usually want to see—the median, the twenty-fifth and seventy-fifth

Figure 6

Consumption of spirits in gallons per capita by US state vs. number of deaths from chronic liver disease and cirrhosis per 100,000 by US state, 1986

centiles (hinges), the extreme values (usually bounding the range), and possible outliers (outside values).

3.1.2 Two variables. Figure 5 shows four ways of representing two categorical variables crossed. The data are from the 1993 General Social Survey used in Fig. 3. The additional variable is general happiness, as measured by the response to the question, "Taken all together, how would you say things are these days—would you say that you are very happy, pretty happy, or not too happy?"

The upper left plot shows a 3D bar chart of happiness against number of sexual partners. The vertical scale is the proportion of respondents within each partner category. This graphic has the disadvantage that short bars tend to be hidden by long ones. Generally it should be avoided.

The graphic to the right is a tiled bar chart. This graphic uses color or gray scale to indicate the relative frequency of each category combination. However, as Cleveland's research has shown, the use of color or gray scale to encode continuous values is problematic (Cleveland 1994).

The next graphic below shows a paneled categorical plot. Instead of using an extra dimension in 3D, we use an extra categorical dimension in 2D to panel the plot. This is probably the most effective method for handling the extra dimensionality required for representing the frequencies, plus the two categories. The bottom panel shows a multiple divided bar chart. This layout has the same problems as the single divided bar chart (see Fig. 3). Cleveland (1985) shows an example of this graphic and offers a more effective dot plot alternative.

Figure 6 shows the most popular way of representing two continuous variables crossed with each other—the scatterplot. The data are per capita consumption of spirits for each of the 50 US states, used in

Figure 7

US patents issued from 1880 to 1980

Fig. 4 (Bureau of the Census 1986). The additional variable is number of deaths from chronic liver disease and cirrhosis per 100,000 people, by state. This scatterplot has been enhanced in a number of ways. The bordering box plots help us to assess the marginal distributions of the variables and highlight the Nevada and New Hampshire outliers. The smoother shows the conditional mode of deaths (estimated mode of deaths given consumption). This was computed through kernel regression (Scott 1992). This particular smoother limits itself to areas where there are relatively more data values, so it provides a conservative estimate of trend.

Time series data require special treatment. Figure 7 shows four examples. The data are number of US patents issued in the century from 1880 to 1980 (Wilkinson et al. 1996). The top panel shows a line element representing the series. Lines are most useful when a series is relatively smooth. The next panel shows a point element with a superimposed LOESS smoother. Points are best when we supplement them with a smoother; they tend to obscure time order if used alone, unless the series is especially smooth. The third panel shows spikes. These are vertical lines best used to reveal deviation from a constant level. This panel displays the residuals from the LOESS smooth. The lowest panel shows an area chart for the raw series. This highlights trend but prevents the use of

Figure 8

Advanced Psychology Graduate Record Examination (GRE) scores for 80 students taken from 10 years of a graduate psychology program. Students are grouped by whether or not they were awarded a Ph.D.

confidence intervals and other enhancements to the plot. Generally, it should be avoided. Cleveland (1994) discusses other graphical representations for time series data.

Figure 8 shows three ways of representing a categorical variable crossed with a continuous variable.

Figure 9

The number of reported sexual partners during last year by reported level of happiness among 1,462 respondents to 1993 General Social Survey. The third variable is the proportion of respondents in each sexual partner category

The data are based on 80 graduate students over a 10-year period in a US psychology department (Wilkinson et al. 1996). Graduate Record Examination Advanced Psychology Test scores are plotted against whether or not the students eventually received their PhD.

The first graphic employs a dot for the mean and a range bar to represent a 95 percent confidence interval on the mean. The bars do not overlap, which suggests that the advanced test can help identify those who achieve a PhD. (Interestingly, neither the Verbal nor

the Quantitative test scores predicted graduation in this sample.)

The second graphic is a notched box plot (McGill et al. 1978). This is a variation on the box plot that not only conveys more of the important data landmarks than the classic confidence interval plot but also provides an approximate confidence interval of its own. If the data are independent samples from identically distributed populations that are lumpy in the middle (approximately normal in their midrange), then comparing the notches yields an approximate 95 percent test of the null hypothesis that the true medians in the population are equal. In this example, the notches do not overlap, reinforcing what we concluded from the confidence intervals on the means. Because it relies on the median instead of the mean, the notched box plot procedure is more robust against outliers.

The third graphic is a dot plot (Wilkinson 1999a). Used frequently in the medical literature, this plot shows every data point. In a small sample (e.g., clinical case study), a dot plot can be useful for readers who wish to consider every data value. However, it is of little use in making informal graphical inferences concerning group differences. It is best to think of grouped dot plots as unadorned one-dimensional scatterplots within categories.

3.1.3 Three variables. Figure 9 shows a triple crossing of categorical variables. The data are from the 1993 General Social Survey used in Figs. 3 and 5. The additional variable is gender (observed by the interviewer, not reported by the respondent). We ask whether the relationship between reported happiness and number of sexual partners differs by gender.

The top plot in the figure shows a paneled graphic. The format is similar to a Trellis display (Becker et al. 1996), but the labeling of the paneling variables (happiness and gender) is placed outside the plotting area to improve readability.

The middle plot collapses happiness into a legend in order to reduce the number of panels. This is a popular method for saving space, particularly when representing factorial layouts in ANOVA and other designs. It has several problems. First, the line segments used to highlight trends have slopes that depend on the particular spacing and arrangement of partner categories. Unless we employ an external scaling procedure to determine the spacing of the partners categories, we have scant justification for using these lines. Second, the collapsing introduces a symbol choice problem. It is difficult to find symbols that are easily distinguishable for more than a few categories. The symbols collide, as well, at the upper end of the horizontal scales.

The lower plot introduces an even less appealing alternative. Clustered bar charts are used widely but they have several defects. First, it is difficult to discern

Figure 10
Birth rate and death rate vs. literacy for selected countries

Figure 11
Difference between death month and birthday by occupational category

separate patterns for the categories. One needs to focus on one set of bars to do this, but there is visual interference from the other bars in each cluster. Second, these bars can become quite thin with more than a few categories. Decoding this graphic is problematic.

Figure 12
Percentage per-capita spending on education, military, and health

Figure 13
Sex partners vs. feelings about the Bible (GSS survey responses)

Figure 10 shows a triple crossing of continuous variables. The data are from the UN databank used in Fig. 1. The additional variable is literacy (percentage of the population that can read). We ask whether literacy is related to birth and death rates taken together.

The upper plot is a 3D frame that includes a contoured regression surface and a scatterplot. The

Figure 14
Bootstrapped data from Gonnelli et al. (1996)

contours (as opposed to a wire-frame or rendered surface) help viewers discern literacy levels in different elevations of the plot and keep the surface from hiding the data. Coloring the contours improves the coherence of the surface.

The lower plot is a 2D frame that includes the same contoured surface plus a scatterplot of symbols whose size is proportional to literacy. This plot makes it easier to decode specific xyz triplets.

Some critics tend to eschew 3D surface plots, but they have their uses. As Wilkinson (1999c) argues, surfaces elicit a holistic impression of a function. They are less useful for decoding individual values, however. Perhaps the best compromise is to present both displays simultaneously to provide different structural

views. Another alternative is to categorize one or more of the variables and display the results in a paneled plot such as those in Fig. 9.

3.2 Coordinates

We do not ordinarily think of charts being embedded in different coordinate systems, except for certain scientific graphics such as polar plots. Some chart types, such as radar charts, pie charts, and horizontal bar charts are nothing more than popular charts in unusual coordinate systems. Wilkinson (1999c) provides numerous examples.

Figure 11 shows two different graphics in different coordinate systems, based on data from Andrews and

Herzberg (1985), contributed by C. O'Brien. The data are months since their last birthday during which members of different social groups died. The upper plot shows a paneled horizontal area chart produced by rotating a vertical area chart 90 degrees (exchanging x and y coordinates in this case). This graphic reminds us that horizontal bar charts are a coordinate transformation of a vertical bar chart, not a new chart type.

If it makes sense to consider a death one month before a birthday as being more similar to a death one month after, than to one six months after, then we might want to plot these variables in polar coordinates. The lower plot shows a profile plot of the same results.

Figure 12 contains a triangular coordinate plot. Mosteller and Tukey (1968), Bishop et al. (1975), and Wainer (1997) show examples of this type of plot. The data are from the UN dataset used in Fig. 1. The variables represent expenditures in US dollars per person for health, education, and the military.

The outside tick marks signify how to read the scales. Grid lines collinear with ticks demarcate values on the three scales. Iraq and Pakistan, for example, allocated most to military spending and least to education and health. Costa Rica spent more than 40 percent on education, almost 50 percent on health, and less than 10 percent on the military. While triangular coordinates may be used most frequently in analysis of mixture models in industrial experiments, they can also be useful for social science models involving tradeoffs or compensatory mechanisms.

3.3 Uncertainty

There are two chief methods for representing error in a graphic. The first is sharp: error bounds are represented by clear edges, points, or lines. The second is fuzzy: error is represented by blurring an estimate.

Figure 13 shows two sharp ways of representing error in a graphic. The data are from the 1993 General Social Survey used in Fig. 3. The additional variable is feelings about the Bible, as measured by the response to the question, "Which of these statements comes closest to describing your feelings about the Bible?" The responses coded are 1 (Word of God), 2 (Inspired word), and 3 (Book of fables). We assume that the dependent variable is continuous (biblical absolutism vs. relativism?) even though the responses are integers.

The upper plot shows error bars representing 95 percent confidence intervals on the means by category. Error bars are also used to represent one standard deviation or one standard error. It is important to make clear in accompanying titles or notes, which type is used. If the spacing of values on the independent variable is meaningful, then we can fit a linear regression model to our data. We shall further assume the number of sex partners to represent values of a continuous variable (promiscuity?). Assuming the

assumptions for inference using a t distribution are appropriate, we can fit continuous confidence bounds on the regression line as in the lower panel of the figure. This plot uses jittering to reveal the concentration of data points where they are tied.

Figure 14 shows one way to represent error by fuzziness. The data are from Gonnelli et al. (1996). They represent concentration of bone alkaline phosphatase (BAP) in a sample of women of different ages. The authors fit a linear regression (shown in the upper left panel) to argue that BAP levels increase with age.

A modal regression in the upper right panel indicates that there is a discontinuity in this relationship at age 45 years or so, corresponding most likely to the onset of menopause. Accordingly, we fit separate linear regressions to the two subgroups split at age 45 years (third panel). These regressions appear to be sensitive to outliers, however, so we fit linear models using robust regression with t weighting (fourth panel). This fit indicates that a plausible model for predicting BAP from age involves level differences but no slope differences.

It is not easy to compute confidence intervals on the robust linear fits, so we resort to bootstrapping to provide an estimate of error. The bottom panel shows the result of 20 bootstrap robust fits displayed as faint dashed lines. The non-overlapping envelopes of the fits indicates that our level-change model is reasonable.

4. Conclusion

Figure 15 shows the principal result of a survey by Cleveland (1984) on the use of graphics in scientific articles. The horizontal axis represents the percentage of total page area devoted to graphs in 47 articles sampled from the 1980–81 volumes of selected journals. As Cleveland noted, the substantial differences among disciplines remain when one examines number of graphs per article instead of page area.

In Cleveland's survey, social science journals ranked lowest in the use of graphics. We might speculate that this is a legacy of the aversion toward graphics among

Figure 15

Use of graphics in journal articles (data from Cleveland 1984)

eighteenth century social scientists that Beniger and Robyn (1978) describe. Whatever the reason, there is little justification for this to continue. Software packages such as S-Plus, SAS, SPSS, and SYSTAT (used for the graphics in this article) now offer statistical graphics and publishing standards such as Adobe PDF format now make it possible to display graphics as easily as text.

Graphical Models: Overview

1. Some General and Historical Remarks

Graphical models aim to describe concisely the possibly complex interrelationships between a set of variables. Moreover, from the description key, proper-

**Figure 1**

Initial partial ordering of variables in chronic pain study for a multivariate regression chain. Variables in the same box are treated on an equal footing. Variables in any one box are considered conditionally given all variables in boxes listed to their right. Associations among background variables in the double-lined box are not analyzed but taken as given

ties can be read directly. The central idea is that each variable is represented by a node in a graph. Any pair of nodes may be joined by an edge. For most types of graph a missing edge represents some form of independency between the pair of variables. Because the independency may be either marginal or conditional on some or all of the other variables, a variety of types of graph are needed.

A particularly important distinction is between directed and undirected edges. In the former an arrow indicates the direction of dependency from an explanatory variable to a response. If, however, the two variables are to be interpreted on an equal footing then an edge between them is undirected, or cyclic dependencies are permitted. For instance, systolic and diastolic blood pressure would typically be treated on an equal footing because they are two aspects of a single phenomenon, namely the blood pressure wave.

Graphical models started to be developed by Darroch et al. (1980) and Wermuth (1976) as special subclasses of loglinear models for contingency tables and of multivariate Gaussian distributions which are interpretable in terms of conditional independencies and can be represented by undirected graphs. See *Multivariate Analysis: Overview; Multivariate Analysis: Discrete Variables (Loglinear Models)*.

The first extension was to problems in which the variables can be arranged in sequence so that each variable is regarded as a response to all variables to the right of it in the sequence. This leads to representation by a directed acyclic graph. Then there are joint response models with graphs having blocks of undirected components, the blocks being again connected in a directed and acyclic way. Much recent and ongoing research is for more specialized situations such as

models for confounded dependencies, for event history data, for time series data, and for simultaneous dependencies in multivariate Gaussian distributions. The latter correspond, for instance, to independence graphs having directed cyclic components.

As an example of some of the above ideas we report here on a study concerning chronic pain. One main research question is: when investigating the development of this illness, is it necessary to include information on the patient's site of main pain? Figure 1 shows a first partial ordering of a set of variables within boxes. It reflects some of the prior knowledge on the development of chronic pain and its treatment. It also determines important aspects of the types of analysis to be carried out: relations among several background variables are taken jointly as given, univariate conditional distributions are studied when there is a single variable within a box, and joint conditional distributions are studied when there are several variables within a box. We return to a graph resulting from such statistical analyses in Sect. 6

We concentrate in this article on the use of models for the analysis and interpretation of empirical data, and mention some of their other uses in Sect. 7 on suggested further reading. The more recent statistical work quoted here by authors only is referenced in Edwards (2000), Studený and Bouckaert (1998), Richardson (1998), or Wermuth (1998).

2. Models for Contingency Tables and the Need for Extensions

For a q -dimensional contingency table, i.e., for counts on q categorical variables, the most complex undirected graph model has no constraints. It is called the saturated model and is represented by a graph in q vertices or nodes, with each node pair having exactly one edge, i.e., being connected by a full line. Each full line represents the conditional association of the connected variable pair given all remaining $q-2$ variables. Removing a line from the graph introduces a particular independence constraint for the corresponding variable pair: the pair are to be conditionally independent given all remaining variables. In a log-linear model formulation this is achieved by setting the two-factor and all higher-order interaction terms involving this variable pair to zero. If all full lines are removed, the graph of q disconnected nodes results. It represents the simplest model in the class, the one of mutual independence of all q variables.

This development built on previous work (quoted in monographs on graphical models) by M. S. Bartlett, M. W. Birch, L. A. Goodman, Y. Y. Bishop, S. E. Fienberg and P. Holland and much earlier work by A. A. Markov, who used the notion of conditional independence around 1900 to formulate simple multivariate models, now called Markov chains. A Markov

chain for q categorical variables can be represented by an undirected graph which is a single path of full lines, i.e., a sequence of nodes $i_1, i_2, \dots, i_q$ where just each consecutive pair is connected by a full line.

Compared to the larger class of loglinear models the graphical models are attractive for three main reasons: (a) the interpretation of a model can be much simpler if independencies are taken into account compared to only loglinear interactions; (b) parameter estimation can be strengthened by basing it on a sequence of possible small contingency tables which depends on the unique decomposition of a given graph into its prime graphs, i.e., into graphs which in a graphical sense cannot be split any further; and (c) a powerful separation criterion permits one to read all independence statements implied by a model directly off the graph.

This separation criterion for undirected graphs takes any three nonoverlapping subsets a, b, c of nodes in the graph of which the set c may be empty. Then the corresponding variables X_a are conditionally independent of X_b given X_c if every path from a to b has a node in c . This holds provided two conditions are satisfied: all pairwise independence statements specified with the missing edges of the undirected graph hold, and a technical positivity condition is fulfilled. One sufficient condition for checking the latter from an observed contingency table is that there are no zero frequencies.

In graphical models represented by undirected graphs all variables are treated on an equal footing, i.e., response variables and possible explanatory variables are not distinguished. This is appropriate for various different types of data, for instance for symptoms of a given disease, for items which are to measure slightly varying aspects of a particular attitude or of a behavior of persons, or for several aspects which all might contribute to a specific risk factor. However, for much multivariate research some response variables are of primary interest. There is in addition a set of background or context variables, and there are possibly sequences of intermediate variables which play the role of potential response variables to some and of potential explanatory variables to other variables under investigation. Typically, not all variables are only categorical; some are nominal, some are ordinally scaled, and still others are quantitative measurements. Subsets of variables may have to be considered as joint responses instead of univariate responses.

3. Questions Regarding Applications and Statistical Research

The original formulation of graphical models has already been extended in various directions to accommodate the need posed by different substantive research questions, to describe properties of different classes of independence models, and to prove corresponding results.

For research in different substantive fields such as genetics, economics, social, and life sciences, some important questions arising in applying graphical Markov models are:

(a) How do graphical Markov models relate to techniques applied traditionally in the given field? What additional possibilities do they offer to gain better insight into any given research question?

(b) How can a given graphical Markov model be best fitted to data? Is software available which permits fast application as well as comparison and integration into existing techniques and strategies of data analysis?

(c) Which of the associated new results in statistical theory are most useful for the substantive research at hand? Are case studies available in which graphical Markov models have been used fruitfully?

(d) Are criteria available to decide among alternative types of model to be considered for a given set of data?

The answers must depend partly on the specific substantive research questions. Also, the kinds of research questions which may be analyzed in the context of graphical Markov models widen as more theoretical results become available, and as new classes of model are developed. But many positive answers have become available, especially since, as described in Sect. 2 for general loglinear models, representations interpretable in terms of conditional independencies often result as a subclass of widely used tools for data analysis.

The following are some of the associated research questions in statistical theory.

(a) Which sets of independence statements can be specified within different classes of independence graphs? In particular, what are the defining independencies, i.e., what are (possibly alternative) sets of independence statements by which a given graph can be characterized? Which independence statements are implied in addition to those in a defining set?

(b) Under what conditions are two different graphs independence-equivalent; that is, when do they characterize the same independence structure, so that they imply an identical list of independence statements?

(c) Under what distributional assumptions do all models in a given class of independence graphs exist? When are they not only independence-equivalent but when are they also distribution-equivalent; that is, when do they define the same joint distribution?

(d) For which graphical Markov models do unique maximum-likelihood estimates exist? With which types of algorithm can maximum-likelihood estimates or parameter estimates in posterior distributions be obtained? When can large estimation problems be decomposed into smaller, simpler ones? When can complicated estimation problems be embedded in larger, simpler ones?

(e) Can the implied independence structure be predicted that results, for instance, after marginalizing over some of the variables and after conditioning on

other variables? When can even the strength and direction of implied conditional associations be derived explicitly?

(f) How can deterministic transformations of variables be utilized systematically in model building? Should definitions of variables, i.e., measurement questions, be integrated into the formulation of a graphical Markov model, or should they be introduced and studied separately?

While the last set of questions involve ongoing research, at least partial answers are available to all the others for most subclasses of graphical Markov models known until now. Here we give only examples of results, and point to the researchers who developed them.

4. Types of Independence Graph and Corresponding Markov Models

As mentioned before, there are a number of different types of graph which differ with respect to their defining sets of independencies. To describe them we denote by Y_v a random vector variable of d_v individual components. A graph for the node set V captures an independence structure for the joint distribution of all d_v components. For nonoverlapping subsets S and C of V , with S having at least two nodes, a graph for the node set S gives an independence structure for the joint conditional distribution of Y_S , given Y_C . When C is empty the graph is for the joint marginal distribution of Y_S . Conditional independence of Y_i and Y_j , given Y_C , is written more compactly as $i \perp\!\!\!\perp j \mid C$.

For each member of the following types of graph, there exists the corresponding independence structure for mixtures of discrete and continuous variables in some exponential family distribution, defined either locally for conditional Gaussian regressions, or globally for a general conditional Gaussian distribution or for one having no higher than two-factor interactions. For simplicity we illustrate here the different types of model only for a mean-centered vector variable Y_v having a joint Gaussian distribution and being partitioned into at most three components $V = (a, b, c)$. The overall covariance matrix as well as its inverse, the overall concentration matrix, are written accordingly, partitioned as

$$\Sigma = \begin{pmatrix} \Sigma_{aa} & \Sigma_{ab} & \Sigma_{ac} \\ \cdot & \Sigma_{bb} & \Sigma_{bc} \\ \cdot & \cdot & \Sigma_{cc} \end{pmatrix}, \quad \Sigma^{-1} = \begin{pmatrix} \Sigma^{aa} & \Sigma^{ab} & \Sigma^{ac} \\ \cdot & \Sigma^{bb} & \Sigma^{bc} \\ \cdot & \cdot & \Sigma^{cc} \end{pmatrix} \quad (1)$$

where the dots denote symmetric entries.

The concentration matrix in the marginal distribution of Y_c is denoted by $\Sigma^{cc \cdot ab}$, and the one in the joint marginal distribution of Y_b and Y_c has components $\Sigma^{bb \cdot a}$, $\Sigma^{bc \cdot a}$, $\Sigma^{cc \cdot a}$. In the latter, the notation

reminds one that marginalizing is over a . Similarly, the conditional covariance matrix of Y_a is denoted by $\Sigma_{aa \cdot bc}$, and the conditional covariance matrix of Y_a and Y_b given Y_c has components $\Sigma_{aa \cdot c}$, $\Sigma_{ab \cdot c}$, $\Sigma_{bb \cdot c}$. Here the notation reminds one that conditioning is on c . Finally, the matrix of regression coefficients of Y_c when regressing Y_b on Y_c is $\Pi_{b|c}$, while in the regression of Y_a on both Y_b and Y_c the regression coefficient matrix is in partitioned as $(\Pi_{a|b \cdot c}, \Pi_{a|c \cdot b})$. For example, $\Pi_{a|b \cdot c}$ are the coefficients of Y_b . The notation reminds one that regression is also on c .

4.1 Directed Acyclic Graph

A *directed acyclic graph* of Y_v is a graph of arrows in d_v nodes without directed cycles, i.e., starting from any one node it is impossible to return to this node by following any path in the direction of the arrows. The (i, j) arrow is missing in it if

$$i \perp\!\!\!\perp j \mid \text{parents of } i. \quad (2)$$

Nodes from which an arrow points directly to node i are called the parents of i .

For a Gaussian distribution, the independencies show as zero coefficients in recursive linear equations having independent residuals. More precisely, we have equations $AY_v = \varepsilon$, with residuals ε having zero mean and covariance matrix, $\text{cov}(\varepsilon)$, being a diagonal matrix T . Further, A is upper triangular with ones along the diagonal, giving $\Sigma^{-1} = A^T T^{-1} A$. Therefore (A, T^{-1}) is a triangular decomposition of the concentration matrix and off-diagonal elements in row i and A are negative values of regression coefficients when regressing Y_i on all its potentially explanatory variables, i.e., variables ordered to have indices larger than i . Thus, the independencies show as zeros in A . If only a directed acyclic graph is given, typically more than one set of recursive equations is compatible with it, i.e., with several different orderings of the variables, an upper triangular matrix can result which reflects the same independence structure as the given graph.

However, often a unique full ordering is provided from substantive knowledge about how the data could have been generated. This was how the geneticist S. Wright introduced and used path diagrams for recursive linear relations. For other than linear relations, a generating process in terms of univariate conditional distributions still determines uniquely the edge matrix in a directed acyclic graph and a corresponding factorization of the joint density. Separation criteria for directed acyclic graphs apply therefore to any joint distribution generated in this way over a directed acyclic graph. A first path criterion was given by J. Pearl, who called it d-separation (for separation in directed graphs). Two other equivalent criteria are due to S. L. Lauritzen and coworkers, and D. R. Cox and N. Wermuth.

4.2 Types of Undirected Graph

A *conditional concentration graph* of Y_s , given Y_c , is an undirected graph of full lines in d_s nodes. The full (i, j) line is defined to be missing in it if

$$i \perp\!\!\!\perp j \mid C, S \text{ excluding } i, j. \quad (3)$$

For a Gaussian distribution, the independencies show as zeros in the conditional concentration matrix $\Sigma_{ss|c}^{-1}$. Such models have been introduced by A. P. Dempster under the name of covariance selection. The name concentration graph model for Gaussian variables is more common now. It records that for Gaussian distributions the above independence statement is equivalent to the vanishing of a concentration, which is a multiple of the partial correlation of Y_i and Y_j given all remaining variables in S and C .

The name concentration graph model does not imply that for general distributions concentrations vanish, but only that the distribution satisfies a set of independence statements of the above type. The separation criterion in Sect. 2 holds for such general concentration graph models and was given by J. Darroch, S. L. Lauritzen and T. P. Speed.

A *conditional covariance graph* of Y_s , given Y_c , is an undirected graph of dashed lines in d_s nodes. The dashed (i, j) line is missing in it if

$$i \perp\!\!\!\perp j \mid C. \quad (4)$$

For a Gaussian distribution, the independencies show as zeros in the conditional covariance matrix $\Sigma_{ss|c}$. The models are a special case of T. W. Anderson's linear in covariance models. They may not have a unique maximum likelihood estimate.

In general a covariance graph structure can capture all independencies in a joint distribution only if it has, just as a Gaussian distribution, no higher than two-factor interactions. For binary variables this holds, for instance, for the quadratic binary exponential distribution. For mixed variables it can be achieved for the conditional Gaussian distribution with all three and higher-order interactions being zero. Separation criteria were given by G. Kauermann and by Richardson (2001).

4.3 Types of Chain Graph

A *chain graph* of Y_v is a graph in d_v nodes which may be arranged in a sequence of ordered boxes $(1, \dots, k, k+1, \dots, K)$ such that there are undirected edges within boxes and arrows between boxes all pointing in one direction, e.g., from k to $1, \dots, k-1$; the arrows form no directed cycle, i.e., starting from any one box it is impossible to return to this box by following the direction of the arrows.

A *chain graph of block regressions* contains full lines within boxes and full arrows between boxes. The full

(i, j) line is missing within box k or the full (i, j) arrow pointing from a node in one of the boxes $k+1, \dots, K$ to a node in box k is missing if

$$i \perp\!\!\!\perp j \mid \text{all nodes in boxes } k, \dots, K \text{ excluding } i, j. \quad (5)$$

For three chain components in a Gaussian distribution, each independence statement corresponds to a zero entry (possibly symmetric) in one of the following concentration matrices: Σ^{aa} , Σ^{ab} , Σ^{ac} , $\Sigma^{bb|a}$, $\Sigma^{bc|a}$, $\Sigma^{cc|ab}$. The name block regression arises in spite of this concentration matrix representation since dividing all elements in row i of, say $(\Sigma^{bb|a}, \Sigma^{bc|a})$, by the element in position (i, i) , a transformation into corresponding block-regression coefficients results. Two different equivalent separation criteria were given by M. Frydenberg and by M. Studený.

Models of this type for the special kind of model for mixtures of continuous and discrete variables called CG-regressions are known to have unique maximum likelihood estimates, but it took more than 20 years before an algorithm was made available by D. Edwards and S. L. Lauritzen that converges in reasonable time.

A *chain graph of multivariate regressions* contains dashed lines within boxes and dashed arrows between boxes. The dashed (i, j) line is missing within box k if

$$i \perp\!\!\!\perp j \mid \text{all nodes in boxes } k+1, \dots, K \quad (6)$$

the full (i, j) arrow pointing from a node in one of the boxes $k+1, \dots, K$ to a node in box k is missing if

$$i \perp\!\!\!\perp j \mid \text{all nodes in boxes } k+1, \dots, K \text{ excluding } j. \quad (7)$$

For three chain components in a Gaussian distribution each independence statement corresponds to a zero entry (possibly symmetric) in one of the following matrices of covariances or of regression coefficients: $\Sigma^{aa|bc}$, $\Pi_{a|b|c}$, $\Pi_{a|c|b}$, $\Sigma^{bb|c}$, $\Pi_{b|c}$, Σ^{ca} . A separation criterion was given by N. Wermuth and D. R. Cox and by T. S. Richardson.

A *chain graph of concentration regressions* is a mixture of a concentration graph and a multivariate regression graph. It contains full lines within boxes and dashed arrows between boxes. The full (i, j) line is missing within box k if

$$i \perp\!\!\!\perp j \mid \text{all nodes in boxes, } k, \dots, K \text{ excluding } i, j \quad (8)$$

the dashed (i, j) arrow pointing to box k is missing if

$$i \perp\!\!\!\perp j \mid \text{all nodes in boxes } k+1, \dots, K \text{ excluding } j. \quad (9)$$

For three chain components in a Gaussian distribution, each independence statement corresponds to a zero entry (possibly symmetric) in one of the following matrices of concentrations or of regression coefficients: Σ^{aa} , $\Pi_{a|b|c}$, $\Pi_{a|c|b}$, $\Sigma^{bb|a}$, $\Pi_{b|c}$, $\Sigma^{cc|ab}$. For

Figure 2

Simple examples of the four types of joint response graphs in Sects. 4.3 and 4.4. In each the joint responses are Y and X , and the explanatory variables are marginally independent: $V \perp\!\!\!\perp W$. The only additional independencies represented by each graph are in the (a) chain graph of block regressions: $Y \perp\!\!\!\perp W | (X, V)$ and $X \perp\!\!\!\perp V | (Y, W)$, (b) chain graph of multivariate regressions: $Y \perp\!\!\!\perp W | V$ and $X \perp\!\!\!\perp V | W$, (c) chain graph of concentration-regressions: $Y \perp\!\!\!\perp W | V$ and $X \perp\!\!\!\perp V | W$; and (d) cyclic graph: $V \perp\!\!\!\perp W | (Y, X)$.

Graphs (b) and (c) are examples of two independence equivalent graphs. In fact a distinction in independencies would emerge only with a third response Z in the left-hand box. Then a missing edge between, say X and Z , in (c) would refer to independency conditional on Y, V, W , and in (b) conditional only on V, W .

exponential families the concentration graph components refer to canonical parameters and the arrows correspond to (conditional) mean parameters. One intensively studied special case is for categorical data in which joint responses are modeled by loglinear interactions and dependencies via so-called marginal models. A separation criterion was given by S. A. Andersson, D. Madigan and M. Perlman.

Of these three types of chain graph only the second class, the graph of multivariate regressions, contains the general linear models in which every regression is of each component of the response separately on the same set of explanatory variables and the residual covariance matrix contains the remaining parameters. The class also contains seemingly unrelated regressions.

4.4 Cyclic Independence Graphs

Some fully directed graphs may contain directed cycles among a set of different variables and even for the same pair of variables. It has been shown by P. Spirtes and by J. Koster that the d-separation criterion can be applied to these graphs in unchanged form. Graphs of

traditional structural equation models may be slightly modified (Koster 1999) to have in our notation dashed lines, arrows, or combinations of both, as well as cyclic dependencies. Then a slightly extended version of the d-separation criterion can be applied to them as well. However, missing edges in these graphs need not point to any independence statement for the variable pair involved, and the meaning of edges in terms of distributional properties may have to be derived from scratch for a given graph.

Figure 2 shows examples of graphs for all four types of joint response models of Sects. 4.3 and 4.4. They have in common two connected joint responses, two marginally independent explanatory variables, and missing edges for two further pairs: (X, V) and (Y, W) .

5. Independence Graphs and Generating Processes

As mentioned above, multivariate models which have a univariate recursive generating process can be expressed in a stepwise fashion in terms of univariate conditional distributions. They are sometimes called association models generated over a directed acyclic graph. Because they can be compatible with causal interpretations they are attractive for much substantive research driven by causal hypotheses. See *Causal Inference and Statistical Fallacies*.

Multivariate regression chains are closest to a recursive generating process, since residual association may be regarded as a secondary feature. Also, after replacing each dashed line separately by two arrows starting from a common additional node, called a synthetic common source node, a directed acyclic graph results which implies the correct independence structure for the variables, in the given multivariate regression chain. It also implies covariance graph components which do not have interactions involving more than two variables.

In general, no similar simple generating processes are available for the other two types of chain graph containing chordless undirected cycles. The reasons were that (a) it is not possible to order the nodes in a chordless cycle of a concentration graph to generate it recursively in the given variables and (b) it is also not possible to enlarge the graphs by synthetic common sake nodes to generate undirected chordless cycles. At present the only ways known to generate such cycles are by conditioning on synthetic common responses or by postulating a dynamic process observed cross-sectionally in statistical equilibrium.

Experience suggests that multivariate regression chain structures fit well data from panel studies in several waves. Also, they permit prediction of individual responses without involving response variables considered on an equal footing, but only variables prior to all the joint responses. For many applications in medicine and social science this is an explicit goal of the investigation.

6. A Chain Graph as Partial Summary of Data Analysis

We now return to the variables in Fig. 1. The multivariate regression chain in Fig. 3 is derived by statistical analyses based on data provided by Judith Kappesser of the Department of Psychology at the University of Mainz. The data are for 201 chronic pain patients who have been given a three-week stationary treatment at a chronic pain clinic.

The response of primary interest in Fig. 1 is self-reported success of treatment. It is measured three months after discharge by a score which comprises several aspects of successful treatment. The background or context variables are age, gender, marital status, years of formal schooling, number of previous other illnesses, and duration of pain. There are a number of intermediate variables. Before and directly after treatment, questionnaire scores are available of depression and of self-reported type of pain, ranging from 'no pain' to 'pain as strong as imaginable.' The chronification index is a score incorporating different aspects of time, spreading of pain, use of pain relievers, and the patient's pain treatment history. The main site of pain has two categories: 'back pain' and pain on the 'head, face, or neck.'

The chain graph of Fig. 3 summarizes some important aspects of the results of analysis. It shows, in particular, which of the variables are needed for each response such that adding one more of the potentially explanatory variables does not improve prediction. Site of pain is an important intermediate variable and information on it should therefore be included in studies of chronic pain.

Some of the directions and types of dependency which cannot be read off the graph are as follows. Patients with many years of formal schooling (13 years or more) are more likely to be headache patients, while the others are more likely to be backache patients, while possibly because more of them have jobs involving physical work, and they are more likely to reach higher stages of intensity of pain before treatment. Backache patients reach higher stages of chronifi-

Figure 3

Multivariate regression chain of significant relations, well compatible with the data. Discrete variables are drawn as full circles, continuous ones as open circles

Figure 4

Form of dependence of primary response Y on Z_a

cation and report higher intensity of pain after treatment. Figure 4 shows that treatment is more successful the lower the intensity of pain, but for scores of intensity of pain of about six or higher this dependence vanishes. One path of development is that patients with shorter periods of formal schooling may get chronic backache, and patients with chronic backache get help too late and respond less well to the type of treatment offered.

Screening for nonlinear relations and interactive effects did not point to important other relations. The model is said to fit the data well because for each response taken separately no indication was found that adding a further variable would improve prediction. Had there been no nonlinear relations and no categorical variables as responses the overall model fit could have been tested within the context of available software for models of linear structural relations.

7. Suggested Further Reading

We have described some of the statistical aspects of graphical Markov models. Statistical monographs documenting the development are by Wermuth (1978), Whittaker (1990), Edwards (2000), Lauritzen (1996), Cox and Wermuth (1996). For an exposition of important different types of independence structure present in small data sets containing only linear relations, see Cox and Wermuth (1993). Models for single and joint response chain graphs can be viewed as a generalization of Sewall Wright's path analysis different from the generalization to models of linear structural relations (Bollen 1989). The two model classes have some subclasses in common, for instance linear systems represented by directed acyclic graphs and linear multivariate regression chains.

Monographs treating the use of graphical Markov models as a basis for probabilistic calculations in expert systems and for artificial intelligence applications are by Pearl (1988) and by Cowell et al. (1999). For their use in a specifically decision-making context, see Oliver and Smith (1990). For discussions in relation to causal reasoning, see the monographs by Spirtes et al. (1993) and by Pearl (2000).

Green Parties

Green parties have become established political players in most industrialized democracies and are emerging in several industrializing ones. The electoral strides of green parties, especially in Western Europe, have resulted in a situation unimaginable a decade ago: green parties in many national parliaments, green ministers sharing power in several European national governments, greens in the European Parliament forming one of the largest party groups, as well as sustained green representation at subnational levels of government. Yet greens' electoral fortunes are decidedly uneven: electoral success in northern countries contrasts with near invisibility in the South. Moreover, electoral success has brought new strategic dilemmas for the greens as they struggle to maintain their alternative 'green' credentials while joining parliaments and supporting, if not forming, national governments.

1. Emergence

The emergence of green parties needs to be understood in the context of a broader shift from industrial to 'postindustrial' politics. For younger, better-educated citizens in particular, the prosperity and rise in living standards enjoyed in the postwar era formed the backdrop for a change from materialist to 'post-materialist' values, or from 'old politics' to 'new politics' (see Inglehart 1977, Poguntke 1993). As the basic material needs (food, shelter, etc.) of a far higher share of the population were being satisfied, political attention shifted from materialist concerns to 'quality of life' issues, such as enhanced political participation, gender and racial equality, and, perhaps above all, environmental protection.

Growing environmental concern among the public was heightened by the continued degradation of the environment and increased media attention of environmental issues. Toxic chemical spills in major rivers, air pollution alerts in cities, and oil slicks in pristine coastal waters further increased public anxiety, especially in Europe and the USA. Meanwhile, the accelerated construction of nuclear plants in the wake of the energy crisis, as well as the increased deployment of nuclear weapons, awakened or reinforced fears about the safety of nuclear power, the problems of disposing nuclear waste, and fears of nuclear annihilation.

To many citizens in advanced democracies, none of these concerns was adequately addressed by existing parliamentary structures. A proliferation of extra-parliamentary, nonpartisan citizens' movements emerged in the 1960s and 1970s to protest issues of peace, ecology, and women's rights. These new social movements served as the antecedents for a new type of

'green' party, ideologically focused on new politics issues and an alternative paradigm of politics. Vowing to be different from mainstream parties in beliefs and practice, these new parties embraced a 'green' ideology which profoundly challenged conventional politics.

2. Green Party Ideology

The core green values forming this ideology (see *Environmentalism*) encompass a wholesale critique of advanced industrial society and advocate instead a 'sustainable society' (Dobson 1995) based on decentralization and reduced consumption of resources and material goods. For greens, the postindustrial 'good life,' revolving around economic growth and globalization, sophisticated technology, expanding services, and material goods needs to be replaced by a simpler lifestyle offering a cleaner planet, less resource depletion, social equality, a nature-centered spirituality, and local action to solve global problems.

Green parties are characterized not only by their values and beliefs, but by the way they express and pursue these beliefs. Above all, greens emphasize 'grassroots democracy': a decentralized, direct democracy within a radically participatory society. Policy decisions should be made at the lowest possible level and matched with varying local requirements. Diversity is not only tolerated, but celebrated. The organizational structure of most green parties thus tends to be decentralized and nonhierarchical, offering a wide range participatory channels to members, gender equality, and significant autonomy to local branches (Müller-Rommel 1998).

Green party values and practices do not represent a coherent or consistent ideology. Demands for grassroots direct democracy do not always mesh with the need for a sustainable society and the imposition of regulations such a society may require. Structures imposed to deter party hierarchy (e.g., midterm rotation of posts, refusal to appoint party leaders) have proved unworkable. Nor are greens a coherent or monolithic set of thinkers or actors. In particular, several ideological and strategic divisions characterize green parties.

3. Typology of Green Parties

The primary ideological distinction separating green parties is between 'purist' and 'rainbow/leftist' parties (Müller-Rommel 1993). Some refer to this divide as 'green-green' vs. 'red-green' parties. Green-green parties, such as *De Groenen* in The Netherlands, adopt radical environmental policies, reject leftist ideology as too proindustrial, and seek to create a clear distance between their views and views of mainstream parties, left or right. Red-green, or 'rainbow' parties, include the German Greens and the Dutch Green-Left. These

parties link ecological issues with leftist concerns of social equality and a critique of capitalism. The predominance of the latter parties has led some writers (Kitschelt 1989) to view green parties merely as an extension of a broader New Left ideology, in which environmental themes are adopted as one theme of many. This view neglects the existence of purist parties or purist elements within green parties. More importantly, it neglects the central role of green ideology and practice which defines green parties and separates them from their leftist counterparts. Green parties are best understood not merely as New Left parties, but as manifestations of an 'ecological cleavage' (Franklin and Rüdiger 1995). Despite their differences in emphasis, all green parties have broadly similar core ecological concerns and demands which serve as a pivotal part of their agenda and political identity.

Another broad distinction between green parties is their strategic orientation: the extent to which they embrace parliamentary, mainstream tactics, or favor instead more radical unconventional means to achieve their aims. All green parties pride themselves on alternative strategies, but the intensity of 'radicality' differs across parties. Generally, 'purer' parties eschew traditional forms of political activity such as party alliances, coalitions, or deals with mainstream parties. The small Dutch *De Groenen* party fits this bill. Other parties do not. For example, the French Greens (*Les Verts*) while originally adopting a 'purist' or 'green-green' ideology, were willing to engage in traditional forms of political activity such as participation in presidential elections. The strategic divide applies not only between but also within parties, as illustrated by the tension between German *Realos* (pragmatists) and *Fundis* (fundamentalists). These cleavages are damaging but not debilitating. Despite the obvious difficulties in pulling together different strands and types of green parties, the Green Group in the European Parliament has managed to exercise significant policy influence on issues such as auto emissions and biotechnology controls (see Bomberg 1998).

4. Electoral Fortunes

The varied electoral fortunes of green parties can be explained as a product of the wider political and economic climates, as well as more specific opportunity structures in which these parties operate. Examining the macroeconomic environment in which parties develop is a good starting point for explaining green party success. It is widely recognized that green parties fare better in 'postmaterialist' countries with higher levels of economic development and lower unemployment. Contrast green party emergence and development in the industrialized north with green parties' struggle to emerge and survive elsewhere. But these features are less able to explain differences among developed industrialized states (e.g., why do

green parties fare better in Ireland than in the USA?). More specific opportunity structures better account for such variation.

Electoral laws are often cited (especially by green parties themselves) as a major factor in determining electoral success. Certainly proportional representation (PR) has facilitated the development of new parties in several countries (e.g., Belgium and The Netherlands) while the first past the post electoral system as operates in the USA or British national elections has made it difficult for any small party to succeed unless they are regionally concentrated. But unsuccessful green parties also exist in countries with PR systems (Denmark, Greece) and other factors may be more important in explaining green success. A federal structure offers parties the opportunity first to articulate their demand at subnational level where they can gain experience, publicity, and often funds before launching a nationwide campaign (Müller-Rommel 1998). Green parties have been more successful in federal states (Germany, Belgium Austria, Switzerland, Australia) than in unitary states, and the weak US Greens may be the exception that proves the rule.

To understand change in green party fortunes, other explanations are needed. Evolving party systems help explain the swings in green party support, which often has floundered when major established parties (British Labour Party, US Democrats, Australian Labor Party) or other smaller protest or radical parties (such as the PPR in The Netherlands) either share or poach the ideas of greens and adopt green policies in deed or at least in word. Similarly, green parties face competition from other green actors—environmental interest groups or protest movements—who absorb green demands without themselves seeking government office. To illustrate the point, environmental awareness in the UK and USA is not noticeably lower than in countries with strong green parties, but this support is reflected in swelling membership of environmental interest groups rather than green parties (Rootes 1995).

These various explanations may be supplemented by an examination of political culture (compare France's embrace of radical culture and parties with the UK's tradition of political mediation and compromise) and episodic factors (environmental disasters, rise of new controversies such as genetically modified foods). Finally, a focus on agency and structure is required. Whatever the structural constraints in which they must perform, green parties shape their own fortunes by their (in)ability to develop and articulate a coherent party platform, run a professional electoral campaign, and avoid internal combustion through infighting and personality squabbles.

Taken together these contending explanations provide a plausible if nuanced explanation of green party development and change. Certainly green parties have developed and changed dramatically since their emergence in the 1970s. By the early twenty-first century,

green parties were represented in 15 national parliaments (mainly in Western Europe but also in the East), as well as in supranational organizations and hundreds of subnational and local assemblies. Moreover, by the late 1990s greens held ministerial positions in several major European countries. Most successful by far have been the German Greens (*die Grünen*) who first entered federal parliament in 1983, formed a governing national coalition with Social Democrats in 1998 and took on federal ministerial posts, including that of German foreign minister (Joschka Fischer). In late 1999 German Green Michaela Schreyer was the first green to be appointed as a member of the European Commission, the European Union's powerful executive.

5. Conclusion

The greens' success has clear policy implications, especially on issues of nuclear power, ecological tax reform, and citizenship rights (see Collier and Golub 1997). But success also has implications for green parties themselves. Greens have always faced a unique 'strategic conundrum' (Bomberg 1998) arising from their unique beliefs and movement roots. Put simply, how can they reconcile their radical alternative politics with participation in mainstream or 'grey' parliamentary and government structures? Throughout the 1990s most green parties shed their radical cloth in an attempt to capture votes, even at the expense of green party unity and purity. Most were rewarded with electoral success well beyond what had been imaginable in the 1980s. The price to pay has been tortured internal debates about strategy, and new questions about green party identity and purpose. Today the key questions facing green parties revolve around not whether to embrace power, but what to do with it. More specifically, green parties face three new challenges in the new millennium: first, how to carve out a policy niche as established parties and governments become wiser to green demands, and as green concerns themselves appear more mainstream. Second, how to take green ideas beyond the confines of rich industrialized states into Eastern Europe and the developing world where green parties remain marginal and environmental problems acute. Third how to ensure that the broader role of green parties—as consciousness raisers, agitators, conscience of parliament and politics—is not sacrificed on the altar of electoral success.

Green parties have come a long way since their emergence and development in the 1970s and 1980s. They have become established players able to shape party competition, government formation, and government policy. But this very 'establishment' carries risks for a party whose core values and identities depend mightily on their ability to challenge the conventional order, to agitate and to annoy. For most green parties,

the greatest fear is not electoral decline so much as the prospect of becoming a party with parliamentary platform, ministerial voice, but nothing new to say.

Green Revolution

The term 'green revolution' was applied to land reform in Eastern Europe in the 1930s and recently to the attempts to persuade governments and business to adopt policies and practices that are not inimical to the environment. But the term is most commonly used in the social sciences to describe the changes that took place in farming in Asia after the introduction of semi-dwarf wheat and rice varieties in the mid-1960s. If planted on irrigated land with the use of chemical

fertilizers and pesticides these crop varieties gave higher yields and greater profits than traditional ones. These innovations led to a substantial increase in the yield of wheat and rice, which was sustained until the 1990s when the rate of increase of yield and output declined; there may be difficulty in keeping cereal output ahead of population growth in the twenty-first century.

1. Early History

The period immediately following World War II in South Asia was characterized by rapid population growth, food shortages, and poverty. A great variety of wheat and rice varieties were in use, each adapted to their local micro-environment; little chemical fertilizer was used and no pesticides, and yields were low. In 1966 a semi-dwarf variety of rice known as IR8, bred at the International Rice Research Institute in the Philippines, was distributed amongst farmers in parts of India, whilst a semi-dwarf wheat originally bred in Mexico was also introduced. Where these High Yielding Varieties (HYVs) were adopted, yields and output increased dramatically. This led W S Gaud to state in a lecture in the USA in 1968: 'this and other developments in the field of agriculture contain the makings of a new revolution. It is not a violent Red Revolution like that of the Soviets ... I call it the Green Revolution' (quoted in Dalrymple 1979). The importance of the Ford and Rockefeller foundations and of the US government in sponsoring the breeding programs in Mexico and the Philippines meant that much of the criticism of the new technology and its alleged consequences was ideological. The term 'revolution' was perhaps unfortunate. The breeding of higher-yielding or disease-resistant varieties had been going on in Europe, North America, and parts of Asia since the rediscovery of Mendel's work at the beginning of the twentieth century, whilst the use of chemical fertilizers and applications of pesticides had been practiced since the 1920s in Western Europe, although adopted at far greater rate after 1945. More relevant were the developments in Japan.

Much Japanese rice had long been irrigated, but the area irrigated was increased in the 1890s when the most successful existing rice varieties were selected and their seed distributed to farmers. Chemical fertilizers were also applied. By the 1930s, rice yields in Japan and its colonies Korea and Formosa were substantially above those elsewhere in Asia. Even in South Asia there had been advances in technology before 1966. Indian grain output increased by 62 percent before 1950 and 1964, and in Pakistan by 59 percent (Farmer 1981). Although rice yields in China in the 1950s were low compared with the rest of East Asia, semi-dwarf rices were bred there independently of the research in the Philippines and distributed to Chinese farmers before IR8 was released.

2. *The Nature of High Yielding Varieties (HYVs)*

The principal characteristic of the HYVs were their high response to chemical fertilizers. They were also short with a stiff straw, and so, unlike the tall traditional varieties, did not lodge with higher yields. They were insensitive to photoperiodicity and matured in about 110 days rather than 180 days; it was thus possible to grow two or even three crops in a year. The yield potential of these varieties was greater in the temperate regions of Asia and in the dry season in the monsoon region than in the humid tropics, because of the longer hours of sunshine and hence the greater potential photosynthesis available to the plant. The highest yields are achieved in areas of well-managed irrigation and with adequate amounts of chemical fertilizers. At first the new varieties were highly susceptible to disease, and pesticides were necessary to obtain the high yield potential, but later varieties have been bred with a greater resistance to pests. Breeding of new varieties of rice and wheat has continued since the 1960s, increasingly in research stations in the countries where they are to be grown. High yielding varieties of maize have also proved successful and to a lesser extent new varieties of sorghum. Since the 1970s Chinese farmers have used hybrid rice seed. The new varieties introduced since the first HYVs are now often referred to as MVs (modern varieties).

3. *The Diffusion of the Modern Varieties*

The inputs of the Green Revolution are divisible: seed, fertilizer, and pesticides can be bought in small amounts and so in theory could be obtained by farmers with only very small holdings. In practice however, the first adopters were generally occupiers of larger farms with better credit facilities and a greater awareness of the new technology. By the 1980s however, there was near universal adoption in irrigated areas with no differentiation of inputs by farm size or tenure. The principal incentive to adopt was the greater profit per hectare, in spite of the increased unit costs. At first the use of fertilizers and seeds were subsidized, and the improvement and extension of irrigation was undertaken by government. In the 1980s however, subsidies

began to be withdrawn, and the further extension of irrigation had become very expensive. The introduction of modern varieties began at different times in different countries and different regions. Rice was introduced into India, for example, in 1965 but not in South Korea until 1972. The rate of adoption also differed; by 1976 four-fifths of all the rice in China was sown with modern varieties, but only 7 percent in Burma, 11 percent in Thailand, 14 percent in Bangladesh. National differences persisted in the 1990s (see Table 1).

Within countries there have also been major regional differences in the rate of adoption; thus in India in 1990, 95 percent of the rice in Punjab and Tamilnad was sown with modern varieties, but only one-third in Bihar and Kerala (Singh 1997). By the 1990s some of the major international differences in the rate of adoption had been reduced, but a greater proportion of Asia and Latin America's wheat was sown with modern varieties than Africa or the Near East, whilst more of China's was in new varieties than the rest of Asia (see Table 1). But of course there is a difference in the proportion of each continent sown in wheat, rice, maize, and other crops. Little wheat or rice is grown in tropical Africa, so the proportion of these crops in modern varieties is of little significance. This distribution explains why, in the mid-1980s, modern varieties were planted on less than one-third of the total cereal area in the developing countries: only 1 percent in Africa, 22 percent in Latin America and 36 percent in Asia (Tangley 1987).

4. *The Consequences of the Green Revolution*

In the 1950s and 1960s it was feared that future population growth would outrun cereal output in Asia and increase malnutrition and hunger. This has not occurred. The rate of increase in output of both rice and wheat in Asia exceeded population growth rates between 1966 and 1995. Population increased 76 percent but rice output doubled; and the real price of rice has fallen steadily since the 1950s, halving between 1970 and 1990. Cereal consumption per capita has increased by 25 percent, imports have been greatly reduced, and grain reserves built-up. The increase has

varied between countries (Table 2), and has been greater in wheat than rice output, but there have been dramatic increases in cereal harvests throughout the region. In the 1950s and 1960s increases in cereal output were largely due to an extension of the cultivated area; since the 1960s, overwhelmingly due to the increases in crop yields following the adoption of the new high-yielding varieties (Table 3).

The shorter growing season for HYVs has also allowed more double cropping in some parts of Asia. Yields have stagnated in the 1990s, however, particularly in Japan and Korea, which have the highest rice yields. The yield potential of the original HYVs has not been increased since the 1960s; the many new varieties bred since then have had greater disease resistance or better quality grain, but not greater yield potential. Additionally, in the high-producing irrigated rice areas, waterlogging, salinization, and disease have led in some places to a decline in yields. The fall

in rice prices and the continued increase in import prices has squeezed cereal producers, and many have left farming or turned to more rewarding crops. In the last few years there have been renewed fears for the future of cereal output in Asia.

5. Criticisms of the Green Revolution

Initially the Green Revolution was greeted with extravagant praise and high expectations. These were excessive, for it was unlikely that many farmers could reach the yields obtained on experimental farms, or that all farmers could profitably use the new techniques. A barrage of criticism followed to the present, although with changing targets. Controversy remains over the social and economic effects of the Green Revolution, nor is this surprising. There are three technical reasons why interpretations may differ. First,

national and state statistics in India and other parts of Asia are not reliable and so different interpretations of changes are possible, particularly with reference to land tenure, farm size and labor. Second, it would be surprising if there were identical responses to new technology over such a vast area and population with greatly varying physical and socioeconomic environments. Third, research produces different results at different stages of the adoption cycle of agricultural innovations. It is unlikely that the consequences of technological change in the 1960s would be the same in the 1990s.

But there are other criticisms that are a result of the unequal distribution of farm sizes and land ownership. Early critics believed that the adoption of HYVs benefited the larger farmers most, often led small farmers to sell their land, increased landlessness, and forced down real wages. It was argued that while those with larger farms—and in most of Asia more than 20 acres is a large farm and most farmers have less than five acres—were able to rapidly adopt the new technology, and make considerable profits; smaller farmers were unable to do so and often sold their holdings to larger farmers, whilst many tenants were evicted to allow landowners to farm larger units. The number of landless households increased and so forced down real wages. In some areas the larger farmers adopted machinery to replace labor, and real incomes of the landless fell. Consequently income inequality increased.

These criticisms were made most fiercely in the early 1970s. At the time it was pointed out that many of these trends predated the 'green revolution,' or had alternative explanations. Machinery was being adopted before 1965, and rural population growth alone was sufficient to increase landlessness. Since then there have been more sample studies over longer periods (David and Otsuka 1994, Hazel and Ramasamy 1991). They have shown that small farmers have been able to adopt the new techniques, seed, and other inputs; that real wages have not fallen; and that the adoption of machinery has often been the result of farm laborers seeking higher paid jobs elsewhere. Other critics pointed out that the HYVs were only profitable in irrigated areas, and that improved varieties of only wheat and rice had been bred, yet in many parts of India farmers grew other cereal crops so that the benefits of the 'green revolution' occurred only in limited regions. This was true at that time, but subsequently modern varieties were bred that gave higher yields than traditional varieties in rainfed areas and with low amounts of fertilizer. Furthermore, high-yielding varieties of other crops have been bred: high-yielding maize were bred in Kenya and Rhodesia before 1965, and now occupy half the African maize acreage, whilst in India high-yielding varieties of sorghum and millet have been bred. The early HYV rices had an inferior taste, and although subsequent varieties were of higher quality, richer consumers still

prefer the taste of traditional varieties. Other critics were alarmed that the inputs for the new farms were imported, whilst some believed that that monoculture was replacing the diversity of cropping in traditional Asian farming, particularly the replacing of protein rich pulses with cereals.

By the 1990s new fears replaced these traditional concerns. Yields were—and still are—stagnating and even declining as a result of waterlogging and poor drainage in irrigated areas, whilst chemical pollution was becoming a problem. Falling cereal prices and rising costs are now threatening the future of cereal output, whilst Asia's population may increase by 53 percent by 2030. It may be that a new technological advance will be necessary to maintain Asia's freedom from famine that was the result of the 'green revolution' of the 1960s.

Greening of Technology and Ecotechnology

‘Greening of technology’ and ‘ecotechnology’ have similar meanings. Both terms define a perspective regarding the impact of technology as a mediator and/or cause of the environmental problems in modern societies. Both imply a move toward a different kind of technology that is environmentally friendly.

1. ‘Green’ and ‘Ecological’

‘Greening’ and the prefix ‘eco’ refer to technology’s association with environmental processes and to its role, and thus humankind’s, as a cause of environmental change, from pollution to global climate change. Greening of technology and ecotechnology call for more environmentally benign technology, including systems that operate with a minimum impact on species and habitat. So both terms define a vision for change and refer to a set of criteria to be taken into account when evaluating the qualities of given technologies in terms of their impact on the natural environment, ranging from wastes and emissions to the consumption of non-renewable resources. They call for intentional technological designs to achieve the goals in question. Also in other fields these terms are used to pinpoint intended changes and policy needs, as exemplified by ‘greening of industry,’ ‘ecotourism,’ ‘greening of consumption,’ ‘eco-efficiency,’ and ‘green accounting,’ each pointing to specific areas of socioeconomic activity.

Although the term ‘green’ is used as a synonym for nature and natural in a number of situations, the close link to environmental problems is rather new and follows from the systematic and public recognition of pollution impacts in the 1960s and subsequently. In this sense, the term differs from that used in, for example, the ‘green revolution’ and its emphasis on increasing crop production from improved varieties and petro-chemical inputs (see *Green Revolution*). Indeed, some of the impacts following from the green revolution and identified by Rachel Carson (1962) in *Silent Spring* are precisely those illustrative of the double-edged character of technology and the impetus for green technology. The origins of the new uses of ‘green’ and ‘eco-’ in regard to technology have not been adequately addressed. The linkages between technology and environmental damage, however, were highlighted in the Club of Rome report *Limits to Growth*: ‘For the first time, it has become vital to

inquire into the cost of unrestricted material growth and to consider alternatives to its continuation’ (1972, p. 191) and brought to the international policy discussions in 1972 at the United Nations’ first global environment conference in Stockholm.

2. ‘Technology’

Technology is at the same time the engine of economic growth and human well-being and the immediate cause of environmental degradation. Technologies as machine embedded or enacted processes are the basis for transforming materials using energy. Industrial mass production and transport technology extract and concentrate materials, increasing energy demands and amounts of waste, both from the industrial process and from the ‘throwaway culture’ it supports. This waste includes materials that cannot be reused or recycled but remain concentrated and combined in ways that cause health hazards and reduce the stock of raw materials accessible for future generations. Such resource consumption is accompanied by impacts on the structure and function of the biosphere, be it increasing atmospheric carbon dioxide or the extinction of species.

The definition of ‘technology’ is important for the scope of its impact on nature. Technology does not only cover machines and other artifacts, but also includes processes and procedures, like the methods used in rural agrarian production and in the structure of settlements (e.g., contemporary continued urbanization leading to mega-city societies). The question extends beyond the domains covered by the notion of ‘technology,’ however, to the sociology of its use and the organization of economic processes. These systemic uses of technology are registered in such terms as technological system, or socio-technical ensemble (see *History of Technology*). Through these broader uses of the term, technology addresses such human activities as the movement, transformation, and consumption of materials and energy. Many environmental impacts from technology are not only linked to the production of technology *per se* or its basic function, but also to how production and consumption are connected (see *Industrial Metabolism*).

3. Is ‘Green’ an Attribute or a Process?

The labels ‘ecotechnology’ and ‘green technology’ are commonly applied to environmentally friendly production technologies and/or products, such as wind turbines and solar cells for renewable energy, natural textiles, and organic farming reducing, for example, the use of inputs from petrochemical industries. This use has been contested on the grounds that, in absolute terms, no technology is truly green and, in some cases, green and technological risks (or perception of risks) are confused. This is the case for genetically modified crops, for example. They are usually labeled as ‘non-

green,' in public debate. But from a different perspective, it can be argued that such hybrid crops could produce more food on less land. It is, however, not questioned that specific technologies can be less polluting and greener than others, in relative terms.

What is identified as environmentally friendly, green, or ecological is dependent on how the environmental problems and risks are perceived and prioritized. Every technology has an impact on the environment, and the choice between technologies must be assessed in terms of these impacts and the risks involved when recognizing the limits to existing knowledge. This leads the decision in the direction of a political process that has to deal with uncertainties as well as conflicting interests in the outcome.

Consequently in more sophisticated uses of the notions of 'green' or 'ecological,' they are used to characterize the direction of change based on selected measures referring to environmental performance of technologies. The notions are thereby used to establish distinctions between the outcome of different change processes and their focus.

4. Promotions and Problems

While traditional environmental policies developed and installed in the 1970s focused on the discharge of pollutants from production, the growing awareness for a need to engage industry in a constructive way resulted in new policy strategies in the later part of the 1980s. Here the strategy was to engage companies in environmental protection measures by introducing the concept of cleaner technologies and industrial ecology (see *Industrial Ecology*). The cleaner technology (could also read 'greener') approach value materials and energy reductions based on improved design and production as the highest priority, followed by substitution of nonrenewable materials, recycling, and ending with filtering and waste handling as the absolute lowest priority.

These new policies were supported by the introduction of environmental management as a new subdiscipline and the implementation of new management standards like the international ISO 14000 series and EMAS in the EU together with economic fees on pollution and waste. By focusing their interest on waste and the inefficient use of materials and energy, many companies improved their environmental performance. Again the ambiguous character of technology is illustrated: cleaner is not a simple quality of technology, but a product of a specific direction in industrial transformation.

Following these insights, environmental regulation has also changed from a focus on industrial point sources as the object of regulation (e.g., smokestack emissions) to broader aspects of societal production and consumption, such as the impacts from product use and disposal (e.g., recycling). Product lifecycle and

eco-design approaches have begun to be implemented by companies and supported by government environmental policies, especially in the developed world. The lifecycle approach addresses environmental impacts from the perspective of the complete cycle of a product's life: the production of raw materials, the transport of materials and products, the production process, the use of the product, and the final recycling or disposal of the product as waste. Consequently it introduces a rather extended obligation for companies in managing not only their own pollution and resource consumption but in being responsible for the complete chain of supplies and for the minimization of environmental impacts and resource consumption through consumption and disposal. Procedures for eco-design have as their main focus the translation of environmental impacts within the design phase and the reorganization of innovative processes to include both environmental concerns but also user perspectives and new types of expertise (Mitch and Jørgensen 1989).

The problems from which green and ecotechnology have evolved are now also registered in the term 'sustainable development,' signifying the dual needs of providing improved human well being with less environmental impacts (see *Sustainability Transition: Human-Environment Relationship*). This idea was officially recognized in the World Commission on Environment and Development's report *Our Common Future* (The Brundtland Report), which stated that 'When the century began neither human numbers nor technology had the power to radically alter planetary systems. As the century closes, not only do vastly increased human numbers and their activities have that power, but major, unintended changes are occurring in the atmosphere, in soils, in waters, among plants and animals, and in the relationships among all of these' (1987, p. 343).

The introduction of cleaner technologies has in principle shown results in reducing waste and the discharge of pollutants in quite substantial ways. But voluntary actions in industry do not guarantee the introduction of these green technologies (Kemp 1997). And these results do not satisfy those needed for a future whose material and energy demands appear to be enormous. Rather radical reductions in materials and energy consumption and also the reduction of the 'ecological footprint' of individual consumers are required. Phrased as the 'factor 4' and 'factor 10' strategies for reductions in materials and energy use, a new agenda for technological change has been outlined, including also the need for increased global wealth. This agenda will influence product designs, work organization, transport, and culture in radical ways in order to reach the result: a radical reduction in the amount of materials and energy circulated and used per produced unit of good or service (Weizsäcker et al. 1997). Such changes cannot be reached in business and industry alone, but will have to include

behavioral changes of consumers as well (see *Consumption, Environmentally Significant*). This strategy is not seen as different from or in competition with strategies focusing on industrial performance and eco-design, but as supplementary to them (Fisher and Schot 1993).

5. Involved Actors

Such greening and ecological concerns engage a large part of industry. This engagement is partly a response fueled by industrial interests in promoting and marketing their green improvements, and partly a response to pressures from governments and consumers to reduce environmental impacts. During the 1980s a number of new national and international organizations and networks were established in response to these challenges. These included cooperating networks as the World Business Council for Sustainable Development, the European Roundtable for Cleaner Production, the American Coalition for Environmentally Responsible Economics, and many others established on both regional and global levels. Consumers and environmental grassroots movements also took part in the construction of new agendas for green technologies and greener products, some even becoming involved in innovations, for example, Greenpeace's development of a low-energy refrigerator and cooperation with an industrial company about its manufacture, and other organizations' contribution to innovation in the wind turbine. The 'green' impact is also seen in the commercial use of environmental qualities in marketing products, ironically termed 'green speak' and 'green wash' when not based on substantiated environmental performance improvements.

6. Academic and Disciplinary Context

The study of 'greening' and 'ecotechnology' is not the subject of one specialist discipline but involves a large number of academic disciplines, ranging from engineering and design to social perception and innovation management. Specific subfields in the technical sciences advance green or ecological technologies, including energy-efficient cars, urban ecology, ecotextiles, organic farming, and energy efficient household equipment. Special attention has been given to methodologies assessing the impact of a product during its complete lifecycle (in short: LCA for life cycle assessment) and in searching for tools to be used as a basis for environmental prioritization. Design procedures and ways of translating and integrating environmental concerns into design practices have escalated as research interest lately showing both in the design journals and in new design manuals (*Ecological Engineering* is an example). New inter-

disciplinary research centers have also been established.

Technology studies, drawing on the experiences from the STS (Science Technology Society) field, and the studies of innovation in both management and evolutionary economics also sometimes include studies of the environmental dimensions of technology. The technology studies field, in particular, has developed a special interest in studying green technologies. But in the mainstream academic social science disciplines, as in the mainstream technology design fields, environmental concerns are often not explicitly mentioned or even left aside. Researchers have therefore built their own networks and journals and organize special sessions within the meetings of other formal organizations. One example, however, of a cross- or interdisciplinary organization, is the 'Greening of Industry' Network, established in 1990.

Among the mainstream social sciences, political science and economics have been active in regard to environmental regulation and politics lately. The interest in 'green industrial policies,' 'greening of business activities,' and 'green tax reforms' has been growing. So has the support for 'environmental economics' focusing on how to make external impacts visible in the economic system (i.e., the costs and problems caused by the economic system, but not accounted for in the price and market mechanism). Although 'technology' is often referred to in this context, in most studies both the environmental problems and the technologies stay in the 'black box,' and are not analyzed in detail.

7. Future Directions of Research

The rather dispersed character of research in 'greening of technology' illustrates two fundamental problems: the need for an interdisciplinary approach to tackle the problems, and the need for an integration of environmental concerns into a number of technical and social science disciplines. The need for interdisciplinary approaches is obvious in design and in management, where the traditional focus has been on economic priorities and organization rather than environment matters. These priorities have less to do with the character of the field of research than with the tradition of disciplines. The need for integration among disciplines is obvious, given the range of linked issues, from specific technologies, to business management, to government policy.

The complexity of the problems and interested communities is confounded by the juxtaposition of policymakers' and managers' desire for simple solutions. Such solutions are problematic, of course, especially when they are not measured by assessments of knowledge limitations and uncertainty (see *Precautionary Principle*). More generally, in studies of innovation and technological design there is a need to

develop methodologies to cope with integrating environmental concerns into design and management of processes and to deal with the conditions for use and consumption.

The development of greener technologies is not simply a question of improvements and integrations in the technical sciences and in design practices, though we should not underestimate the importance of these areas. A change in the dominant priorities for technological development is dependent on priorities set in the business sector, and changes therefore must address both management practices and societal governance. Likewise, since business is not unresponsive to public pressures and consumer actions these concerns must be addressed as well. In short, the greening of technology is a multi-sectoral and multidisciplinary subject which is likely to increase in importance as future generations cope with increasing demands to meet human needs, needs that are being redefined to include environmental quality (IHDP 2000).

Grounded Theory: Methodology and Theory Construction

Grounded theory is an inductive methodology that provides systematic guidelines for gathering, synthesizing, analyzing, and conceptualizing qualitative data

for the purpose of theory construction. In addition, one of its creators, Barney G. Glaser (1978, 1992), has long proclaimed that grounded theory methods may be used with quantitative data. The term, 'grounded theory,' derives from its central premise: theory must be developed from systematic analysis of empirical data. This methodology consists of flexible strategies to guide qualitative data collection, and, particularly, data analysis. The strength of the grounded theory method lies in articulating: (a) logical steps for handling data collection and analysis, (b) a means of correcting errors and omissions and of refining analytic ideas, (c) tools for studying basic social and social psychological processes in natural settings, and (d) strategies for creating middle-range theories.

Prior to publication of Barney G. Glaser and Anselm L. Strauss's *The Discovery of Grounded Theory* (1967), training in qualitative research had largely occurred through an oral tradition of mentoring and immersion in a field setting. Thus, the grounded theory method represented a significant advance because it codified steps in analyzing qualitative data. The distinctive features of the grounded theory method include: (a) simultaneous data collection and analysis, (b) reliance on comparative methods, (c) early development of categories, (d) intermediate analytic writing between coding data and writing the first draft, (e) sampling for developing ideas, (f) delay of the literature review, and (g) a thrust toward developing theory.

1. The Intellectual Heritage of Grounded Theory

Grounded theory derives from the intellectual traditions of each of its founders. Strauss brought Chicago School pragmatism, symbolic interactionism, and field research to grounded theory (see also *Symbolic Interaction: Methodology; Field Observational Research in Anthropology and Sociology*). Hence, grounded theorists study processes in natural settings and invoke pragmatic criteria of usefulness to evaluate the completed study. Grounded theory methods themselves echo pragmatist and symbolic interactionist assumptions of social life as emergent and open-ended, and answer Herbert Blumer's (1969) call to study social action in natural settings. Glaser's training in survey research at Columbia University lent grounded theory its systematic approach, positivist proclivities, and procedural language. Glaser codified steps of analysis of qualitative data in an analogous way as quantitative research had been codified. His efforts culminated in an explicit statement of how to handle data analysis (Glaser 1978, Glaser and Strauss 1967). Glaser's approach assumed a knowable world waiting to be discovered, unbiased observers who are uninfluenced by preconceived logico-deductive theories of this world or by prior research about it, and a view of grounded theory

categories as arising from the data. As a result of its divergent origins, grounded theory contains elements of both positivism and constructivism.

Glaser and Strauss developed grounded theory methods at a time when quantification had gained hegemony throughout the social sciences. Theory and research had become separate pursuits. The quest for quantified research findings resulted in the waning of qualitative studies. Except for an occasional classic study, most quantitative methodologists ignored qualitative research and relegated it to disciplinary sidelines, or treated it only as a precursor to rigorous quantitative research. Qualitative research was deemed impressionistic and anecdotal, unfitting the scientific quest for quantified facts. In contrast, Glaser and Strauss (1967) argued that qualitative research could stand as science in its own right, demonstrate rigor, and generate theory.

Glaser and Strauss's arguments found receptive audiences. Their methods appealed to social scientists who wished to conduct qualitative research but lacked tools for doing it. In the late 1960s and throughout the 1970s, grounded theory methodological rationales contributed significantly to re-establishing the legitimacy of qualitative research. This method provided researchers with ready justifications for conducting qualitative studies and strong rationales that their research inquiry was systematic. Not surprisingly, diverse qualitative researchers still claim to use grounded theory to establish their credibility and the legitimacy of their research enterprise. However, their claims of using grounded theory may rest on having conducted some form of qualitative research or on only following the initial steps of the grounded theory method.

2. *Developments and Changes in the Method*

Although *The Discovery of Grounded Theory* called for conducting qualitative research and developing theory, it was less clear on details about using the method. Glaser's *Theoretical Sensitivity* (1978) set forth the most explicit statement of how to conduct grounded theory research, yet its abstract and dense writing made it resonate most with those who have had prior training in grounded theory. Since then, Glaser's position has remained consistent with his early formulations. For Glaser (1992), grounded theory builds on discovered data, avoids preconceiving interpretation of them through extant theories or categories, relies on comparative methods, and aims toward theory development. Thus, the grounded theorist compares data with data, data with concept, concept with concept, and theoretical category with theoretical category. For example, the grounded theorist compares one interview excerpt with another, an interview excerpt with a concept that may explain it, a concept with another concept and so forth.

Strauss with his co-author, Juliet Corbin (1990, 1998), took grounded theory in somewhat different directions than the early formulations. They introduce several new techniques, stress description, and include verification as part of grounded theory. They emphasize adherence to technical procedures which Glaser views as forcing data into preconceived categories rather than letting categories emerge through comparing data with data. Both Strauss and Corbin and Glaser's approaches remain objectivist because they each assume the reality of an external world, discovery of data within that world, a neutral observer of it, conceptual categories as emanating from the data, and representation of data and subjects as nonproblematic.

A constructivist grounded theory (Charmaz 1995, 2000) adopts methods of grounded theory without adhering to earlier objectivist, positivist assumptions (see *Constructivism/Constructionism: Methodology*). It places priority on the studied phenomenon rather than methods of studying it; hence, it adopts grounded theory strategies as useful tools, not as rigid prescriptions. Because these grounded theorists build reflexivity into the research process, they scrutinize their research experience, ways of knowing, and products of knowing (see *Reflexivity: Method and Evidence*). A constructivist grounded theory attends to data collection closely. It does not assume that data simply exist in an external world, awaiting discovery. Nor does it assume that an observer can enter the research scene as a *tabula rasa*. Rather, what observers see and hear depends upon their prior interpretative frames, biographies, and interests as well as the research context, their relationships with research participants, and modes of generating and recording data. The questions that observers ask of the empirical world shape data that they select from it. Similarly, constructivists view their conceptual categories as constructed through their interpretations of the data rather than emanating from them. Thus, they assume that their resulting theoretical analyses provide interpretive renderings of a reality rather than an objective reporting of the reality.

3. *Data in Grounded Theory Research*

Although grounded theorists have given priority to data analysis over data gathering, the quality of their gathered data affects the final analysis. Full, rich data provide a more thorough view of the studied topic. The kind of data obtained for a study should suit the research topic and research participants. Grounded theory methods have become closely associated with interview studies, however, they are suitable to use with varied forms of data such as ethnographic field notes, written personal accounts, and documents (Clarke 1998).

A hallmark of grounded theory studies is that data collection and analysis proceeds simultaneously. Each

provides a check on the other. Grounded theorists code and categorize data during the initial stages of data collection. This strategy helps them to shape further data collection to gather material that fits the topic and field setting. Hence, they are less likely to pursue their preconceptions about their topic and more likely to follow leads obtained through their early analysis to find new data.

Grounded theory methods are emergent; both the type and nature of data and analysis emerges throughout the research process. Before grounded theory methods were developed, researchers separated data analysis and collection phases of research. Often they discovered later that they had gathered extensive, but thin, data that contained gaps. Grounded theory strategies include returning to the field to gather more complete data that fills gaps and answers questions. Because grounded theory methods are aimed to further the theoretical power of the analysis, these methods tailor data gathering to the researcher's emerging analysis. Thus, adopting these methods makes data collection more efficient and, therefore, streamlines the research process.

4. Grounded Theory Strategies for Theory Construction

The purpose of grounded theory strategies is to develop middle-range theories. Each stage of grounded theory analysis moves the work toward theoretical formulations. The techniques involved in three major strategies of the grounded theory method, coding, memo-making, and theoretical sampling, serve to both build theory and to distinguish grounded theory from other kinds of qualitative analysis.

4.1 Coding Qualitative Data

Coding is the first phase of analysis. Rather than apply extant concepts to their data, grounded theorists create codes as they study their data and, in abbreviated terms, define what they see in it. Coding helps the researcher begin to conceptualize what basic processes occur in the research setting or situation. While coding, grounded theorists ask the essential question: 'What is happening here?' Objectivist grounded theorists believe that the most significant processes in the setting will be apparent and that research subjects will inform the researcher of them. Constructivist grounded theorists believe that the most significant processes may be liminal and taken for granted by research subjects.

Grounded theory coding includes the following characteristics: (a) a focus on action and process, (b) a practice of line by line initial coding, (c) a simultaneous involvement in coding and further data collection, (d) an emphasis on analytic development rather than description. In initial or open coding the researcher

proceeds to code line-by-line to begin breaking bits of data into specific types of action. After assessing which initial codes appear most frequently, grounded theorists then apply these codes to large amounts of data during a second stage of focused coding. Strauss and Corbin (1990, 1998) also recommend 'axial coding' which means coding for the dimensions of a category.

4.2 Memo-writing

Memo-writing constitutes the pivotal intermediate stage between coding data and drafting the theoretical analysis. Through memo-writing, grounded theorists fill out their codes and identify gaps in them. They define the code, delineate and analyze its properties, specify conditions under which it exists and changes, demonstrate its relationship to other codes, and weigh its significance for processes discovered in the field. An objectivist grounded theorist proceeds by emphasizing external characteristics of the code and the processes with which it is linked. Constructivist grounded theorists look for their own assumptions and implicit meanings, as well as those of their research subjects. Throughout data collection and analysis, constructivists remain more interpretive and less tied to overt behavior than their objectivist counterparts.

4.3 Theoretical Sampling

Theoretical sampling means sampling to develop or to refine emerging theoretical categories, not to describe populations chosen before the research begins. Thus, theoretical sampling occurs after the grounded theorist has defined and analyzed core theoretical categories through focused coding and memo-writing, but needs more data to develop, refine, and check the properties, boundaries, causes, and consequences of these theoretical categories. Thus, theoretical sampling builds precision, density, and complexity into the emerging theoretical statements and keeps them grounded in data.

When engaging in theoretical sampling, the researcher makes brief inquiries into fruitful areas for core categories of the emerging theory. Techniques of data gathering in theoretical sampling vary and are aimed to answer questions about the emerging theoretical categories. Theoretical sampling raises the conceptual level of the analysis and does so through systematic comparative analysis. The scope of the theory increases as the grounded theorist samples and compares different groups for their relevance to the theoretical category.

Gaps and questions may necessitate either returning to the same field setting or research problem or obtaining data in a different setting that possesses the characteristics the grounded theorist needs to test. Conducting comparative work across groups or field

settings allows the grounded theorist to build variation and complexity into the analysis. The emerging theory determines whether seemingly disparate groups make relevant sources to sample for theoretical comparison. For example, a study of establishing trust may sample such groups as mountaineering partners, con-men and women and their marks, and married couples. Theoretical sampling fosters a developing a full range of the properties of the category. Grounded theorists stop theoretical sampling when they have saturated their core categories and find no new data to shed light on them.

5. Current Emphases and Future Directions

The grounded theory method has significantly influenced the development of qualitative research in the social sciences and professions, particularly nursing and education. Strauss and his colleagues trained several generations of graduate students in sociology and nursing, whose students and colleagues have subsequently adopted the grounded theory method. In sociology, this method has, perhaps, had most influence in medical sociology and social studies of science (see Baszanger 1998, Clarke 1998, Star 1989). However, recent debates between Glaser and Strauss and Corbin, as well as larger epistemological debates about scientific inquiry, have intensified interest in examining and using the method. Although questions have been raised concerning objectivist premises within grounded theory, a constructivist revision of the method provides answers to them and points to new directions. In short, the grounded theory method can be expected to gain renewed support from those social scientists and professionals who value conceptual analysis of rigorous empirical qualitative research.

Group Decision Making, Cognitive Psychology of

A group is a set of three or more persons who engage in joint activity directed at a common goal. For many groups, the goal is to make a decision. For other groups, the goal is achievement of a political, social, educational, or recreational objective. Regardless of their overall purpose, every group must make decisions so that member's actions are coordinated, and directed toward the common objective. This article presents major developments in the understanding of the cognitive processes involved in group decision making. It begins with a description of the forces leading to the current importance of group decision making, and proceeds to explain how the cognitive processes in decision making groups can be understood with a social information processing model. Next, some of the conceptual and methodological problems surrounding group decision making theory and research are covered. The theme throughout this discussion concerns differences among group members in terms of their information, beliefs, and decision preferences. The significance of two recent advances in addressing differences among group members, the Judge Advisor System and Information Sharing paradigms, is explained.

1. Groups as Information Processors

Group decision making has become increasingly important in the world of work for many reasons. One is that a greater proportion of jobs now involve cognitive work, so just as individual workers shifted from physical to cognitive work, so did groups.

Another force promoting the use of groups is the effort to increase representation and participation in organizational and societal decision making. Decisions that might have once been dictated by an authority are now made by a group representing various levels and segments of the population. Much of the current group research occurs in the context of organizational theory and practice (Sanna and Parks 1997)

The growth in the practice of using groups for decision making has been accompanied by a similar growth in the study of cognition in groups. The benefits of this research extend to all groups because all groups, regardless of their purpose, are dependent on cognitive processes for functioning. Simply put, people must coordinate their individual processes of attention, reasoning, judgment, memory, etc. during interaction in order to achieve their common goal. Group decisions are essential to coordination, and occur at many points during interaction. A group must choose its goal and the nature of the process that will be used to achieve it, select information deemed relevant, and integrate information, beliefs, etc. to determine the group's course of action.

The influence of 'real-world' practice is evident by the efforts at realism in modern group decision making research. Whereas early group research used games, trivial and 'eureka' decision problems, research tasks now capture such essential features of real decisions as the inability to know, with certainty, the quality of the decision at the time it is made. Motivational issues are taken more seriously by, for example, using incentives for making good decisions to reflect better the consequences facing persons in decision making groups. Other advances in group decision making research are the use of ongoing groups, and the study of interactions using technology (email, videoconferencing, etc.).

Part of the current scientific activity pertaining to cognitive processes in groups can be traced to the recent growth of cognitive psychology and the birth of social cognition (Fiske 1992), a subdiscipline of psychology devoted to the study of cognition about social objects (see *Cognitive Psychology: History*). Advances in these areas, combined with the increased prevalence of groups engaged in decision-making tasks, led to the modern view of conceptualizing groups as information processors. As described by Hinsz et al. (1997), key leaders in this development, the information processing approach to groups emphasizes the social processing of information, thereby integrating the group decision making and social cognition research approaches. In the social information processing view, groups exchange ideas, information, resources, strategies, etc. in the service of a processing objective. Research is directed at understanding attention, encoding, processing, storage, retrieval, feedback, and response processes in groups. Although recent group research tends to be guided by an individual-level information processing model, group and individual

level processing are not assumed to be identical, and a pervasive research agenda is to understand the qualitative and quantitative differences between individual and group processing.

A primary difference between individual and group decision making arises from the greater complexity of group level processing of information, that is, group decision making requires coordination of individual members' cognitive processes and communication of the outputs of these processes. For example, consider how the memory problem in groups requires development of common strategies for transactive memory (Wegner 1987), a shared representation of the organization of information over members. It is through transactive memory that groups are able to identify and use the unique information that members previously knew or are able to recall from group interactions. Further, groups have more complex processes because they have a number of unique problems from which individual performers are free. At the start, group members face social uncertainty about the other group members. This refers to an inability to predict the behavior of other persons, making it difficult to know the extent to which they are willing or able to work toward the group goal. Group members may have different ideas about what the group goal is or should be. If so, it is necessary to negotiate them before purposeful interaction can occur. At any point in time, groups can have social goals that detract attention, time, and efforts from the task of making a decision. Even if all members are clearly focused on a single objective directly related to their decision problem, they are likely to have differences in information, beliefs, and preferences that need to be integrated in order to reach that objective.

2. Levels of Behavior in Groups

Despite the differences between individual and social information processing, it is sometimes possible to apply 'individual' cognitive constructs at the group level. Consider the case of human judgment. Judgment is the location of an object in an abstract representation such as a scale from one to nine, or a set of categories. An example of judgment in group decision making is a committee's recommendation for a salary offer. On occasion, group members' independent judgments may agree closely enough for the purpose at hand. But often, group members have cognitive conflict, that is, differences in beliefs. In some cases, groups may begin with varying judgments but end the task with a consensus group judgment of the amount. Yet, in other circumstances, members will adhere to discrepant judgments, and the judgment for the group must be a compromise such as the central tendency of the members' judgments. Then an accurate picture of the group's judgment needs to include some indicators of the variation in the members' judgments. The

Figure 1
Three types of relationships between individual, member, and group judgments

problem is similar for cognitive tasks with discrete outcomes, such as deciding to uphold or overturn a law. When all are in agreement, there can be a group determination; if not, there can be only majority and minority member opinions. In general, we can describe members' cognitions at the group level if observations of the members of a group are indistinguishable, that is, every group member provides a response identical to that of every other group member. Under such conditions, we can speak about group goals, group confidence, group memory, and so forth. Otherwise, it is necessary to represent the diversity of group members' cognitions, with or without information on the cognitive value for the average or majority.

Figure 1 illustrates the distinction between the application of the cognitive construct of judgment to individuals, group members, and the group. Prior to interaction, there are three independent individual judgments representing individual information processing. These are similar in the first case, but different in the bottom two cases. These individual judgments or the beliefs surrounding them may be discussed during group interaction. Group interaction allows for social influence processes to transform the initial individual judgments into revised member judgments. Thus, the term 'member' is used to refer to individual members' judgments during or following group interaction to distinguish these judgments from the

initial individual judgment, whether or not they have changed. In the first case, members learn that they are in agreement on a single judgment that becomes the consensus group judgment. Member judgments have become similar in the second case, but not the third. As in the first case, the integration of member judgments into a single group judgment is straightforward in the second case. But in the third case shown at the bottom of the figure, there is no consensus group judgment, only an average judgment for the group. There may be no alternative but to use this average judgment to represent the group judgment. But an accurate picture of the group's judgment must include the persistent differences among member judgments.

3. Problems in Conceptualizing Groups

The study of cognition in decision making groups extends to many aspects of the groups behavior. In practice, groups are comprised of individuals who can have considerable cognitive conflict in their processing of information relevant to their interactions and objectives, that is, the various persons in a group may have different schemas or frames for the problem at hand, attend to different problem features, or know or recall different information (see *Mental Models, Psychology of*). Due to such discrepant views within the group, one of the first problems encountered by group researchers is appropriately representing a group, that is, research needs to begin with a model of the group that describes features of its structure and function that are important to the research question. This is often difficult because the members themselves can differ with respect to their own mental representations of the group. They can lack agreement in their beliefs about who is in the group, what its goals are, and how the group should proceed to achieve them.

There are four ways in which group researchers can deal with the problem of group representation. The first is to use the researcher's model, with the implicit assumption that it represents not only the reality of the group, but also the members' mental models of the group. For example, a group may be characterized as egalitarian without any assessment of members' beliefs about status and authority within the group. Second, the researcher can elicit the perspectives of a representative of the group. Although it is often convenient to collect information from only one group member, that person may not accurately represent the entire group. A third approach to the problem of group representation is to identify and use members' cognitive representations of the group. Typically these are represented mentally by a few discrete structures or categories. A final solution is to impart a model to group members prior to group formation and interaction. This latter option is especially popular in the laboratory study of *ad hoc* groups. With this approach,

Figure 2
Illustrations of Judge Advisor Systems showing role differentiation in groups

group members may be informed that they were selected for the group because of their knowledge in a given domain, and instructed to discuss a problem until they reach a consensus on its solution. The advantage of this last approach is that data collection begins with a common understanding within the group—and between the group and the researcher—about the group's composition, task, and procedures.

One aspect of groups in natural settings that is not captured by most laboratory research is role differentiation (see *Decision Making (Naturalistic)*, *Psychology of*). What may appear to an outsider or the researcher as five persons sharing information and power to achieve their goal may be better represented as something else. Many groups are structured with a

leader who is authorized to act on behalf of the group, or with a single member who emerges to take on the role of leading the group to its goal. In many circumstances, information processing becomes social when an individual seeks advice from others. The traditional group model does not adequately describe either the group with a leader or the individual seeking advice from others. A recent paradigm that accounts for role differentiation reconceptualizes the group as a Judge Advisor System. The Judge Advisor System, illustrated in Fig. 2, is a model of social decision making that was designed to distinguish between the member responsible and accountable for making a decision, known as the Judge, and the other members, called Advisors, who provide input to the Judge (Sniezek and Buckley 1995, Sniezek and van Swol 2001). The top diagram shows a group where each member can interact with any other, but the Judge is the leader who is responsible for the goal. In the bottom diagram, the Judge is also responsible for the goal, but seeks and interacts with a number of independent Advisors to elicit resources needed for goal attainment. Whenever a decision maker interacts with another person in the course of making a decision, the process becomes social, and cannot be portrayed accurately by individual decision making theory and research.

A central cognitive activity according to this view is information search. The Judge must decide to solicit advice, whom to consult, and when to stop. Research on advising in decision making has become an international scientific activity (e.g., Harvey et al. 2000). Although similar to information search from non-social sources, this social information search differs in that the social sources are capable of strategic and reactive behavior in the process.

4. Cognitive Conflict in Groups

At this point the reader can reasonably wonder why cognitive tasks should be done by groups and not a single individual. With so many coordination costs groups must be much more inefficient than individuals. Nevertheless, there are many reasons for using groups for cognitive tasks even when the costs of coordinating members' difference are high. Some of these reasons are unrelated to the task itself; for example, democracy requires broad representation of views regardless of costs. In some situations, the task is simply not divisible; multiple persons are required. Yet, the primary motivation for using groups to make decisions is that the problem is important, and there is uncertainty about the quality of the various decision alternatives.

Ironically, the very same cognitive conflict in group inputs that creates challenges often provides the rationale for the use of groups. With a diversity of inputs, there is the potential for the group to follow the

one that best serves members' collective interest. Put simply, there are more ideas and strategies from which to choose. The best input in a group will, by definition, be superior to that of the average member, and superior to those of most members. For the most part, groups performing cognitive tasks have been found to produce outcomes that are better than those of the average member, though not as good as those of the best member. The extent to which the group outcome is better than that of the average individual input increases with the variation in group members' inputs. An important point is that this result has been obtained even when analyses control for the initial bias in group members' inputs. This assures us that the benefit of input variation cannot be attributed to groups simply discounting their poorest member.

In some cases, group outcomes can be even better than those of any group member (Sniezek and Henry 1989). Clearly the potential for such dramatic improvements in results can greatly outweigh the inefficiencies and other costs of group information processing. However, this potential benefit comes with the risk that groups can sometimes perform below the level of the poorest individual member. Therefore, a more realistic picture is that groups have the potential to be superior information processors compared to individuals working independently, but they simultaneously pose the risk of costly, inefficient, and seriously inferior performance.

Heterogeneity of inputs in a group is necessary but not sufficient for process gain. A second requirement is that those inputs be shared with other group members. One stream of research on information sharing in groups, originated by Stasser and co-workers, identifies some barriers to the sharing of information that is unique to individual group members (Stasser and Titus 1985). For starters, there is a sampling advantage for common information that means it will be more likely to be discussed in the group than unique information. Even if both common and unique information is discussed, groups tend to weight common information more than unique information. Unique information that is contributed to discussion is influential only on the judgment of the group member who contributed it. While the reduction of belief heterogeneity is necessary for group consensus, it is not always easy. This is especially true when disagreements go beyond differences in preferences to differences in preference structures. In the latter case, members have cognitive conflict, that is, differences concerning the interpretation or importance of information.

The picture that emerges from research on cognitive processes in groups shows a series of challenges unique to social information processing. Most of these problems arise from the fact that group members are not replications of an individual but varying individuals. We have seen that the persons comprising a group can vary in their beliefs about the nature of the group and its goals as well as their processing objective, focus of

attention, encoding format, and memory processes. The essence of the group challenge is to reconcile member differences so that coordinated action is possible.

Group Decision Making, Social Psychology of

People do many things in groups, of which one of the most significant is making decisions (see Baron et al. 1992, Brown 2000, Hogg and Tindale 2001, Levine and Moreland 1998, Moreland and Levine 1994). Indeed decision making is one of the most important functions of groups (see also *Group Processes, Social Psychology of*). Our lives are largely guided by decisions we make with others (e.g., groups of friends), or are made by groups of others (e.g., parliament), and many of us also spend a significant portion of our

working lives engaged in group decision making (e.g., committee meetings). Group decision making is also influenced in varying ways by the wider intergroup context in which the group exists—that is, by awareness of the existence of other groups (i.e. outgroups) with which one's own group may be in competition (see also *Intergroup Relations, Social Psychology of*). Finally, although group decision making usually involves people getting together to exchange information, it can also involve virtual groups making decisions via computer.

Social psychologists have long been interested in processes involved in group decision making, and whether groups make better or different decisions than do individuals—it is a field with significant applied relevance. There are many different ways to approach the study of group decision making (e.g., social communication approaches, social influence perspectives), there are many different facets of group decision making (e.g., persuasion, negotiation), and there are many different group decision making phenomena (e.g., juries, groupthink). Group decision making almost always involves psychological movement of group members from a relative diversity of positions to a more consensual position or to agreement on a group position. Group decision making reduces opinion differences within groups. Group decision-making can therefore be considered a social influence phenomenon (even a conformity phenomenon) that often also involves discussion, argument, persuasion, and leadership (see also *Group Processes, Social Psychology of*).

1. Social Combination Models

Social combination models relate the distribution of initial opinions in a decision making group to the final group decision (Stasser et al. 1989). These models, unlike social communication models, are not really concerned with interpersonal communication processes that transform individual positions into a group decision, but rather with the decision making rules that determine how group members combine their preferences (initial positions) into a group decision—the focus is on group preferences and their change over time. There is now an array of social combination models (Baron et al. 1992). Some are complex computer-simulation models, whereas others are more immediately related to real groups.

1.1 Social Decision Schemes

Social decision schemes are explicit or implicit decision-making rules that groups can adopt to decide how to combine information into a group decision (Davis 1973). Knowledge of the initial distribution of individual opinions in the group, and what rules the group is operating under allow reliable prediction of the final group decision. These rules include: (a)

unanimity—discussion pressurizes deviants to conform; (b) majority wins—discussion confirms the majority position, which is then adopted as the group position; (c) truth wins—discussion reveals the position that is demonstrably correct; (d) two-thirds majority—unless there is a two-thirds majority the group is unable to reach a decision; (e) first-shift—the group adopts a decision consistent with the direction of the first change in opinion by any member of the group. For intellectual tasks (where there is a demonstrably correct solution, as in, e.g., a mathematical puzzle) groups tend to adopt the truth wins rule, and for judgmental tasks (with no demonstrably correct solution, e.g., for aesthetic preference) the majority wins rule.

Rules vary in (a) strictness—i.e., the degree of agreement required by the rule (unanimity is very strict and majority less strict), and (b) distribution of power among members—i.e., authoritarian rules concentrate power in one member, whereas egalitarian rules spread power evenly. Generally, the stricter the rule the less the power concentration—unanimity is very strict but low in power concentration, whereas two-thirds majority is less strict but has greater power concentration. The type of rule adopted can, mainly due to its strictness, influence not only the group's decision but also members' preferences, their satisfaction with the group decision, the perception and nature of group discussion, and members' feelings for one another. For example, stricter decision rules can make the process of reaching final agreement exhaustive, slow, and difficult, but can enhance liking among members, and satisfaction with the quality of the decision.

1.2 Social Transition Schemes

Kerr's (Stasser et al. 1989) social transition scheme model focuses on the actual pattern of member positions that a group, operating under a particular decision rule, moves through *en route* to its final decision. To track opinion transitions, member opinions are monitored during the process of discussion, either by periodically asking the discussants, or by getting them to note any and every change in their opinion. These procedures can be intrusive, and therefore one issue concerns the extent to which they affect the natural ongoing process of discussion.

2. Jury Decision Making

Social combination models have often been tested with simulated juries, as the laboratory analogue has similar characteristics to an actual jury (e.g., *ad hoc* collection of people who initially do not know one another). Of course, juries are important decision making groups in their own right (Hastie et al. 1983), not only because they are held up as a symbol of all that is democratic, fair and just in a society, but also

because of the consequences of their decisions for defendants, victims, and the wider community (see also *Justice: Social Psychological Perspectives*). For instance, the 1992 Los Angeles riots were sparked by a 'not guilty' jury verdict, and the murder trial of O. J. Simpson in the mid-1990s became a national obsession in the USA. Juries are groups, and thus prey to all the consequences of group processes involved in group decision making.

Research on juries indicates that the initial majority position usually prevails in determining the final verdict. Close cases, which are associated with an even split of initial juror positions, tend to produce a hung jury. Hung juries, which are considered a relatively favorable outcome from the perspective of the defendant (the case is often dismissed), are less likely as jury size decreases from 12 to six persons, and if the decision rule changes from unanimity to some form of majority. Because jurors are instructed to presume the defendant innocent while reasonable doubt remains, juries have a leniency bias. This bias tends to surface (via acquittal) in close cases where there is an even split of opinions.

Juries are decision making groups that make a decision about a person. Thus, characteristics of the defendant and of the victim can affect the jury. Physically attractive defendants are more likely to be acquitted or to receive a lighter sentence, though biases can be reduced by furnishing sufficient factual evidence, presenting the jury with written rather than *in vivo* testimony, or explicitly directing the jury to consider the evidence alone. In the USA (and probably elsewhere) race can also affect the jury. Blacks are more likely to receive prison sentences, and people who murder a black are less likely than those who murder a white to receive the death penalty. Another issue is the influence of laws and penalties on the jury. Harsh laws with stiff penalties (e.g., the death penalty) tend to discourage juries from convicting. The jury foreman is important in guiding the jury to its verdict, because he/she occupies the role of leader. Research suggests that the foreman is likely to be someone of higher socioeconomic status, who has had previous experience as a juror, or simply initially occupies the seat at the head of the table.

3. Risky Shift and Group Polarization

Folk wisdom has it that people in groups make inherently more conservative decisions than they do on their own—individuals are likely to take risks, while group decision making is a tedious averaging process that errs towards caution. This is consistent with traditional social psychological perspectives on conformity and group influence processes—through mutual influence, people's attitudes tend to converge on the group mean (see also *Social Influence, Psychology of*, Turner 1991). However, under some circumstances groups can make more risky decisions than

individuals. Specifically, groups that already favor risk to some extent (i.e., the mean of the members' prediscussion opinions favors the risky pole of a decision making dimension) tend, through group discussion, to arrive at a group decision that is even more risky than the mean. This has been called risky shift. Later research showed that if the group initially favors caution then there is a cautious shift, and indeed that group decisions can be more extreme than the mean of the members' prediscussion opinions on a range of decision making dimensions that do not involve risk or caution, provided that the group initially tends towards one direction. Hence, the effect was renamed group polarization. It is defined as a tendency for groups, as a consequence of discussion, to make decisions that are more extreme than the mean of individual members' initial positions, in the direction already favored by that mean.

Since 1960, research has produced many different explanations of group polarization. They can be simplified to three major perspectives: persuasive arguments, social comparison/cultural values, and self-categorization.

(a) *Persuasive arguments theory*. Focuses on the persuasive impact of novel information. A group that leans in one direction will generate, during discussion, more novel arguments favoring that direction than the opposing direction, and, because novel arguments are persuasive, will cause members to become more committed to their original position and thus the group to shift more in that direction.

(b) *Social comparison/cultural values*. Focuses on people's motivation to avoid social censure and to seek social approval. Group discussion reveals the group's views, which are assumed by members to reflect what is socially desirable or culturally valued, and so group members publicly shift in the direction of the group in order to gain approval and avoid disapproval.

(c) *Self-categorization theory* (see also *Social Identity, Psychology of*). Argues that people in decision making groups psychologically identify with the group and use the group's position, which is cognitively represented as a prototype, to define themselves. The prototype is formed not only to capture similarities within the group but also to distance the group's position from outgroup or non-ingroup positions. Thus, extreme groups form polarized prototypes. The process of categorizing oneself as a group member (self-categorization) causes people to conform to this prototype and, thus, produces group polarization.

4. Groupthink

Groups sometimes employ defective decision-making procedures that produce poor decisions that can have disastrous consequences. Janis (Janis and Mann 1977) coined the term groupthink to define a style of thinking in cohesive groups in which the desire to reach

unanimous agreement overrides the motivation to adopt proper rational group decision-making procedures. The main cause of groupthink is excessive group cohesiveness, but there are other factors that relate to structural faults in the group (e.g., lack of impartial leadership) and to the immediate decision making context (e.g., high stress). Together, these factors generate a set of symptoms that are associated with defective decision making procedures. For example, there is inadequate and biased discussion and consideration of objectives and alternative solutions, and a failure to seek the advice of experts outside the group. A number of American foreign policy decisions with unfavorable outcomes (e.g., the 1961 Bay of Pigs fiasco, the unsuccessful defense of Pearl Harbor in 1941) have been attributed to groupthink in Presidential decision-making committees. Groupthink is probably a lot more common than one would like to think. It is a serious pitfall of group decision making, and groups need to be particularly vigilant in order to avoid it. A special decision making procedure, called the nominal group technique, is available to help groups avoid groupthink.

5. Group Remembering and Transactive Memory

Group decision making involves collective recall of information (see Clark and Stephenson 1995). Group remembering is not simply a retrieval activity in the pursuit of veridical recall, rather it is a constructive process where comparisons among group members shape the resultant group memory. Complex ideas can sometimes be transformed through group discussion into much simpler, and thus distorted, shared knowledge—a process called social representation, that is similar to rumor transmission. Group remembering may not be more accurate than individual remembering, but may be subject to implicit or even intentional bias.

Another feature of group remembering is transactive memory. Groups often need to bring a large amount of information to bear upon a decision, and thus they develop a differentiated memory structure where individuals or subgroups specialize in different memory domains. Where this occurs people not only have to remember their own part of the puzzle, but they also need to know who specializes in what memories—they develop a transactive memory structure. Research shows that group functioning and decision making is compromised where people have not acquired a transactive memory, or where such a system has not developed in the group.

6. Intergroup Decision Making

Decision making groups often contain factional rifts. In fact, many decision making groups can be considered interactive decision-making contexts where representatives from different groups are brought

together to reach a mutually satisfactory agreement (Brown 2000). In this sense, the group is actually a context for intergroup decision-making aimed at reducing intergroup conflict (see also *Intergroup Relations, Social Psychology of; Conflict and Conflict Resolution, Social Psychology of*). Examples of intergroup decision making include negotiations between nations, hostage crises, union/management confrontations, and parliament. The intergroup dimension introduces an additional dynamic to group decision making, because decision makers are charged with the responsibility to argue on behalf of their group, not themselves (Pruitt and Carnevale 1993).

When people are bargaining on behalf of groups to which they belong they tend to bargain more fiercely and uncompromisingly than if they were bargaining for themselves. The effect is enhanced when negotiators are aware that they are being observed by their constituents, either directly or through the media. This bullish strategy of intransigence is less likely to secure a satisfactory compromise than a more interpersonal orientation in which both parties make reciprocal concessions. Direct negotiation between group representatives is therefore likely to reach an impasse where neither group feels it can compromise without losing face.

To break the deadlock a third party can be recruited to mediate between the groups (Pruitt and Carnevale 1993). To be effective, mediators should have power, must be seen by both groups to be impartial, and the groups should already be fairly close in their positions. Biased mediators are ineffective because they are not trusted, and weak mediators are ineffective because there is little pressure for intransigent groups to be reasonable. Although mediators have no power to impose a settlement they can help in several important ways: (a) they can reduce the emotional heat associated with deadlock; (b) they can help reduce misperceptions, encourage understanding, and establish trust; (c) they can propose novel compromises that allow both groups to appear to win—i.e., change a zero-sum conflict (in which one group's gains are the other group's losses—the more one gains the more the other loses) into a nonzero-sum conflict (i.e., both groups can gain); (d) they can help both parties make a graceful retreat, without losing face, from untenable positions; (e) they can inhibit unreasonable claims and behaviors by threatening to publicly expose the group as being unreasonable; and (f) they can reduce intra-group conflict and thus help a group clarify its consensual position.

Where mediation fails, the last resort is arbitration, where a third party is invited to impose a mutually binding settlement. Arbitration can backfire because both groups adopt outrageous final positions in pursuit of a favorable compromise. One way to combat this is through 'final-offer arbitration,' where the third party chooses one of the final offers. This tends to encourage more reasonable final positions.

7. Motivation and Status

Group decision making is influenced by how hard members are prepared to work towards a group decision. Research on performance motivation suggests that people are often less motivated to work hard in groups than they are on their own—a phenomenon called social loafing (see also *Group Productivity, Social Psychology of* and Baron et al. 1992). A final aspect of group decision making is that some people have greater influence over the decision making process because they have higher status or occupy a leadership position. Research on status within groups shows that influence over group decisions and group action stems from possession of specific status characteristics, abilities and skills directly related to the group's function, and of diffuse status characteristics, membership of social categories that have high status in society at large (see Ridgeway 2001). Finally, leadership research suggests that effective leaders are people who can instill and inspire others with their own vision for the group, so called, transformational leaders who can transform a group so that its decisions reflect the leader's preferences (see also *Leadership, Psychology of*).

8. Future Directions

Due to its applied relevance the study of group decision making is always popular. However there are some key directions for future research. One such direction is the study of shared cognition—how groups create shared memories and representations and influence people to think in a collective manner. Another direction is the study of how intergroup relations impact decision making in groups. And finally, the study of computer-mediated decision making by virtual groups is a new area that is already attracting great attention.

Group Processes in Organizations

The success or failure of social and commercial organizations depends not only on specific individuals but also on the quality of the interaction and communication within groups (intragroup relationships) and between groups (intergroup relationships). Groups inside organizations influence individual performance, motivation, and work satisfaction as well as productivity, decision quality, learning, innovation, absenteeism, and fluctuation. Group processes are a central subject of social psychology as well as organizational psychology. During the 100-year history of group research, a substantial amount of literature has been amassed (for current reviews, see West 1996, Hinsz et al. 1997). In the following, we will concentrate on a selection of group research issues that we believe are of particular relevance to the understanding of group processes in organizations.

1. Definition and Structural Dimensions of Groups

Groups are defined as a number of people who are oriented toward the same or similar goals and who interact and communicate in order to achieve these goals. All groups share at least three structural principles: norms, cohesion, and role differentiation.

Norms. Norms can be defined as the shared expectations of the group members about how they should act or behave in certain situations. Norms make the behavior of group members more easily predictable and thus help to clarify social relationships.

Cohesion. When group membership is highly attractive—because goal achievement and need satisfaction are perceived to be achieved better in the group—group members are motivated to sustain the contact with the group. The sum of all the forces that increase group attractiveness is called ‘cohesion.’

Role and status. Role differentiation in groups is the social-psychological basis for work differentiation and organization. Role is defined as the expectation of the group members about the appropriate behavior in a certain position. Role-conformant behavior is regularly positively sanctioned, and deviations are sanctioned negatively. Status means that people differ in the hierarchy of prestige, power, influence, and privileges. High-status group members are allowed to deviate from group norms more strongly without being sanctioned than low status members (idiosyncrasy credit).

2. Conformity and Dissent

Conformity and dissent within groups are central aspects of group functioning. Behavior according to the group norm is necessary for relatively conflict-free interaction. Normally, group pressure brings the groups’ behavior and attitudes into line with the norms. This is important for group functioning and in order to achieve the relevant goals. However, normative behavior can also be dysfunctional, as has been shown by Asch’s studies (1951) in which group members expressed clearly wrong and irrational perceptions just because of the groups’ pressure towards conformity.

2.1 Groupthink: The Conformity of Groups

Groupthink describes the phenomenon by which existing information that is relevant to a certain decision is not processed by the group members in a rational and systematic way, but instead information processing is biased in the direction of a preferred decision alternative within the group. This reduces the quality of information processing within the group and increases the risk of faulty decisions. Analyzing historical political disasters following group decisions, such as, for example, Pearl Harbour, the American invasion of Cuba, or the Vietnam War, Janis (1982) has specified the symptoms of *groupthink*. These symptoms can be observed in the economical field too, such as, for example, in project teams, or on boards or committees. The risk of groupthink is amplified when groups are homogeneous (absence of minorities and

contradicting views), when the group structure is markedly hierarchical, and when there is a strong commitment to particular decision alternatives before group discussion begins.

The symptoms of groupthink include the following (cf. Janis 1982). (a) *Illusion of invulnerability*; that is, high conformity concerning the views of the group members and concerning their thinking styles makes them optimistic and overconfident. (b) *Willingness to take high risks* resulting in warnings, potential hazards, and other forms of negative feedback being ignored or not taken seriously. This behavioral tendency in groups serves the purpose of avoiding questioning one’s own basic beliefs and value systems when facing a challenging decision. (c) *Stereotyping of members with a different opinion* by labeling them as incompetent. (d) *Pressure towards conformity* exerted by the formal leader or the majority of the group in order to stabilize the group’s homogeneity. Conformity pressure helps members to neglect counter arguments more easily and supports self-censorship processes which makes group members (falsely) assume that silence means approval.

There is considerable empirical evidence regarding prevention and intervention strategies for counteracting groupthink. Some examples are (for a summary of these interventions, see Frey et al. 1996):

- (a) the group leader acts as an impartial coordinator,
- (b) systematically strengthening self-confident minority members,
- (c) bringing external experts into the group,
- (d) implementing artificial conflict in the group decision process (e.g., by devil’s advocacy or dialectical inquiry techniques),
- (e) holding each group member individually responsible for the decision process and the outcome,
- (f) creating different subgroups separately engaging in decision making.

2.2 Minority Influence

The problem of conformity and homogeneity in groups is that it may come at the expense of divergent thinking, which can be helpful when scrutinizing premature conclusions, and innovative thinking. Due to conformity pressure, the default information processing style in groups is consent oriented. Minority influence, however, often generates productive dissent.

According to Moscovici (1976), minority members are able to oppose the pressure towards conformity in groups under certain conditions—and are thereby able to influence the attitudes and behavior of the majority. To achieve this, minority members should present their point of view in a consistent behavioral style, though not rigidly (flexibility of negotiation and argumentation), while signaling a willingness to compromise.

Why can minorities exert an influence on majority members? According to Moscovici's Conversion Theory (cf. Moscovici 1980), minority members induce an internal cognitive conflict within members of the majority; majority members then ask themselves *What is in fact the right course?* This leads to an intensification of information processing, and is accompanied by divergent and more creative thinking styles, resulting in a less biased information search and greater openness for the minority position. In contrast to this, majorities exert a pressure to conform, producing social conflict between people or subgroups of people within the group rather than a cognitive conflict. Group members ask themselves *Which person is right now?* This leads to a more superficial processing of information, and is accompanied by conventional and conformist styles of thinking.

What is the relevance of the minority research for group processes in organizations? Very often minority groups or minority persons have the feeling that they *cannot* change a big organization. Taking minority research into account, the opposite is in fact true. Minority influence in organizations is a precondition for scrutinizing common patterns of thought and practice, and thus is an important ingredient for organizational learning, change, and innovation. The interesting thing is that a minority can be influential independently of the hierarchical structure.

3. Bringing Together Individual Contributions

How can individual contributions be brought together in an optimum way so that production losses (e.g., loss of motivation and coordination loss) can be minimized, and procedural gains or synergies (e.g., motivating each other, learning from each other, and sharing innovations) are maximized?

3.1 Activating or Impeding Individual Performance

Whether social inhibition or social facilitation occurs via the mere presence of other persons is a question of the complexity and newness of the task to be performed. If other persons are present, difficult or new tasks are carried out less satisfactorily, since these tasks will lead to uncertainty and fear of negative feedback ('social inhibition'). Simple or well-trained tasks, on the other hand, are usually carried out better in the presence of other people, as the active subject can expect success and a positive judgment from his/her colleagues ('social facilitation').

In the case of social inhibition, no matter whether the task performed is difficult or not, loss of motivation is involved. For example, if the individual contributions are not perceptible in the groups' overall output, or their importance for group productivity is not clearly seen, social loafing occurs. When group

members expect other people in their group to be 'free-riders,' they may be inclined to conclude that their own individual contribution might be too high compared with the contributions of other group members. Consequently, individual performance will be decreased since no one wants to be left to carry the can; this is called the 'sucker effect.' Additionally, if group members fear negative comments from others, or if they are not sure about the norms and standards of evaluation as a whole, they will also withhold optimal performance (for fear of a negative evaluation). These motivational impediments on optimum individual performance can be met by transparency of performance feedback, by conveying concrete individual as well as collective performance norms, by fostering intrinsic motivation (e.g., interesting and challenging tasks), by strengthening group cohesion in combination with a high achievement norm, and by pointing out how important each and every individual contribution is for the group's productivity (for an overview see Sheppard 1993).

On the other hand, when group cohesion is high and the group's task is highly important, one can observe that groups will increase individual performance via motivation gain. If the group members' capabilities do not differ very much, and if the success of the group as a whole is very important for all the members, very strong and competent persons often try to compensate for the weaknesses of their colleagues by trying even harder to do their best. The weaker group members then likewise try to increase their output, as they do not want to be the 'losers' bringing the whole team down. These gains in motivation are especially likely if group cohesion is high—that is in case of a very attractive group (cf. Brown 1992), in case of a high mutual sympathy (cf. Latané 1986), and if the group's task is highly important (cf. Williams and Karau 1991).

3.2 Task Structure and Social Combination of Individual Resources

According to a very well-known model of group performance in social psychology (i.e., Steiner 1972), the *de facto* group performance is a function of the potential group performance, minus procedural losses, plus procedural gains. In order to find out whether groups are working to their full potential, one needs to determine the potential level of group performance. For this, one needs to know the individual capabilities of the group members and the type of task at hand.

In general, the structure of work tasks may be *additive*, in which case the potential group performance is the sum of all the individual performances, for example in the case of brainstorming. If the task is structured in a *compensatory* way, then the potential group performance is the result of the mean of all individual performances, for example in the case of

guessing tasks or majority decisions). If work tasks are *disjunctive*, the group potential is the result of the best individual performance (for example in the case of problem-solving tasks or decision problems). Thus, determining a group's potential level of performance requires consideration of the group task. In order to further determine whether and to what extent a group is working below (or sometimes even above) its potential, the actual group performance is obtained and compared with the potential level of performance. The differences tell us to what extent group-induced procedural losses and procedural gains have occurred.

3.3 Synergy in Groups

Practitioners very often speak about 'group synergy.' This means that a group is more than the sum of all its parts, or more precisely: that a group generally does better than its aptest single member. However, synergy effects have only rarely been demonstrated in social-psychological group research (for an overview, see Hill 1982, Brown 1993). Stroebe et al. (1992) have argued that the common belief in group synergy may rest on an overestimation of one's own output in group contexts. For example, where brainstorming is concerned, single individuals usually believe they are better and more productive when they work in groups—probably because they feel 'enriched' by the ideas of the others and because many new perspectives emerge. However, Stroebe et al. (1992) have shown that individual group members are inclined to claim other group members' ideas as their own body of thought (and, hence, believe in 'having produced a lot'). Consequently, one feels being 'more productive' as a participant of a brainstorming group compared with working alone. Each group member extrapolates this impression onto the other persons, and in the end believes that the group is much more efficient than the sum of its components (i.e., members) working alone. This overestimation feeds the idea of 'group synergy.'

3.4 Top Performance of Work Teams

There is growing evidence that top performances in groups occur despite dominant forces such as conformity, groupthink, loss of motivation, and coordination loss (Levine and Moreland 1990, West 1996). A high decision quality and top performance of teams is likely under the following conditions.

(a) Homogeneity of values and rules exists, meaning that team members agree on rules for dealing with each other; they are able to communicate honestly and to respect each other, and show loyalty.

(b) A heterogeneity of talents, experiences, education, and backgrounds exists within the team.

(c) The team has a vivid commitment to excellent output and an ethos of achievement. All members take responsibility for team success.

(d) Team members fit together technically and personally.

(e) Team members are able to profit from their individual strengths.

(f) Orientation towards the best practice idea (benchmarking). This technique means comparing oneself with best practice in one's own branch or with the best in the world, but also with the best within the organization.

The team is able to use the tool of team reflection, meaning regular joint reflection on social and task issues. What is good and should be sustained, what is bad and should be improved (West 1996).

4. Group Dynamics

Group interaction may be viewed from three different theoretical perspectives. First, one can look at socio-emotional relations where cohesion, role-forming, open communication, the building of trust, and linear models concerning the development of groups are relevant (forming, storming, norming, performing; Tuckman and Jensen 1977). Second, one can look at the development of goal-directed and output-oriented groups, mainly to be found in work groups in organizations where goal finding, role differentiation, leadership, quality of decisions, coping with problems, and action-oriented models of group dynamics (cf. Pinto and Prescott 1988) are relevant. Third, one can look at the development of interpersonal and task-related structures within and between groups, in organizations where high-quality work, customer orientation, and innovation are sought to be improved. Scientific progress has been made in all these fields (cf. Brodbeck 1996, Hinsz et al. 1997). In the following we will discuss two subjects that are particularly related to the development of goal and task-oriented group dynamics: group learning and approaches to team development in practice.

4.1 Group Learning

Group learning in general has not been explored very well to date (Argote and Epple 1990). However, transactive knowledge systems have been researched quite thoroughly; in other words the way in which a group chooses to encode, store, and retrieve information systematically. Transactive knowledge systems make information accessible for team members, even if this information has been (physically) stored by other members of the group (Wegner 1987). According to Liang et al. (1995), teams that have been trained to do complex tasks together (i.e., who have been trained as a team) do better afterwards than groups where the members have been trained individually to solve the task. The authors hold that this lead in the output is due to the fact that teams who have been trained as a group have established transactive knowledge systems. These structures improve the group's performance, for

example by means of group processes such as feedback about weaknesses, helping each other out, sharing information that others need right now. A model of group learning as a multilevel phenomenon; that is, on the individual level, the group level, and respective interactions between these two levels; has been presented by Brodbeck and Greitemeyer (2000a, 2000b).

4.2 Team Development

Typical techniques of team development usually deal with the analysis and layout of group processes in order to increase work performance, personality development, team climate, and cooperation between departments. Four team development approaches can be distinguished. (a) The interpersonal approach tries to increase competence as well as cooperation by promoting self-reflection within groups. (b) The goal-oriented approach tries to increase motivation, performance, and subjective well-being by optimizing goal finding and goal negotiation, for example by way of participation, mutual feedback, and intelligent reward systems. (c) The role approach tries to reduce misunderstandings and conflicts (due to poor coordination or bad communication): underlying conflicts are to be made visible and a better role understanding achieved using techniques of role building and role reconstruction. (d) The process-oriented approach aims to obtain an increase in performance as well as achievement by restructuring collective work processes (such as problem solving and decision making) by way of well-established methods (e.g., Delphi Technique), to some extent assisted by computer technology (for example, group decision support systems (GDSS)).

Practitioners often combine these approaches. For example, it is common to combine the negotiation of new goals with role negotiation so that a corresponding new understanding of expectations and norms can be established. (For concrete techniques and measures of team development that can be utilized in this process, see West 1997.)

5. Social Identity: In-group–Out-group Processes

Until now we have discussed group processes and their consequences within groups. Of course, in organizations there are also group processes between groups. Here the most important theory which is relevant for these processes is Tajfel's social identity theory (SIT). Interestingly, it is a psychological theory about the social cognition of individuals (not a sociological one that directly addresses entire collectives such as organizations). The predictions made by SIT are among the best proven in social psychology.

Individuals identify with the groups they belong to and derogate others who do not belong to their group

(the in-group). Consequently, there is a high degree of identification with the in-group and the respective organization, but at the cost of respect for and cooperation with individuals perceived to belong to other groups (out-groups). Tajfel's theory is very important for understanding the in-/out-group processes underlying conflict and conflict resolution.

Social identity theory emphasizes that all individuals are motivated to shape a positive social identity. The underlying processes are: (a) categorization; that is, a basic cognitive mechanism for structuring the manifold stimuli from the environment in an orderly fashion—in particular, within their social environment, humans categorize on the basis of who belongs to the in-group and who does not (in-group/out-group distinction). (b) Social comparison; that is, a basic sociocognitive mechanism for gaining information about where one stands within the social context—in particular, humans compare their own in-group with other out-groups, preferably in such a way that the dimension on which the comparison is performed produces positive distinctiveness (i.e., a feeling of positive uniqueness). Having the choice of a dimension is important in that when the in-group compares badly (e.g., with a highly performing group), it can be argued that it is more important to have character than to have strong skills and success, thereby protecting the positive distinctiveness of the in-group. Thus, in summary, SIT describes the dynamics between groups on the basis of the individual's motivation to achieve social identity and positive distinctiveness—at the cost of derogating others because they are perceived to belong to an out-group.

Tajfel (1978) shows that even a minimal group context (minimal group paradigm) which may come about through a more or less arbitrary distinction between two groups (e.g., admirers of Vasily Kandinsky vs. admirers of Paul Klee), suffices to produce the in-group favoritism and out-group discrimination processes. People from the out-group are discriminated against more—for example concerning the evaluation of positive attributes, concerning judgments about liking, and concerning the distribution of material rewards (compared to persons from the 'in-group').

These processes are highly relevant for groups within organizations because very often subgroups within organizations think in terms of in-groups and out-groups instead of seeing the overall organization as an in-group. An organization is always in a conflict, on the one hand to increase the in-group feeling because a strong feeling of togetherness is positive, on the other hand the in-group feeling must not be too strong because this could mean shutting down borders so that there are not that many contacts between groups and departments. Therefore the question is what can be done in order to increase both. According to Tajfel's SIT, it is (a) good to have a common goal which can only be achieved by joint action and

cooperation of all groups, (b) important that groups have background information about what the tasks of the other groups are, (c) good to have a rotation of positions between heterogeneous groups, and (d) good to have a lot of informal activities and personal relationships between members of different groups. The important point is that a group must be open and have open borders.

6. Group Processes in Mergers, Acquisitions, and Change Management

When organizations are merged or taken over, or when organizational changes take place, group processes as described in SIT play a central role. In mergers and acquisitions, it is important that the norms and values of the distinct groups can be combined and are not too different from the start. Very often, these groups behave towards each other like an in-group towards an out-group. Very often with mergers or acquisitions, two actual competitors which merge as an in-group or out-group come together and have to continue as one group. Very often, an earlier empty competitor has to be integrated. Many intergroup conflicts can be reduced by taking into account certain psychological findings about the acceptance of change management processes, which are listed below.

(a) There is a cultural fit between the two merging companies and therefore an identification with the new emerging culture is possible (principle of identification and social identity).

(b) The change process is perceived to be definite, inevitable, and irreversible (principle of inevitability).

(c) The vision is clearly perceived and shared, and one understands the reasons why change is necessary (principle of explainability and sense).

(d) Participants have the impression that they can foresee and predict the processes to come (principle of predictability).

(e) There is a consensus about rules and responsibilities (principle of clarity).

(f) Participants feel they are an active part of the decision process (principle of participation).

(g) They feel they are being treated fairly; for example, there is perceived fairness about resources and positions (procedural fairness).

(h) Top managers are perceived as being trustworthy and are positive role models (principle of truthfulness).

Very often, groups and people who are responsible for change processes in organizations, who have to make the relevant decisions and who are responsible for the implementation of those decisions, have a poor understanding of how human beings and groups function in psychological terms. This is one reason why so many mergers, acquisitions, and change processes fail. Very often, the culture and the mentality

of groups do not fit with each other; when the above-mentioned aspects are neglected in the change process, it will fail.

It is the inability to judge employees' and groups' anxieties, hopes, and expectations correctly, and to communicate why and how and what changes are necessary (Hogan and Overmyer-Day 1994). Taking the above-mentioned conditions into account will help to make change processes more successful in the future.

7. Future Directions

Group processes in organizations are a typical example of good interdisciplinary cooperation between social psychologists and organizational psychologists. This research shows that nothing is as practical as a good theory. Of course, there are no integrating theories of groups but as we have shown there are different small group theories which can be applied for different heterogeneous phenomena. In the future, it is important to have an integration of these small group theories and in the empirical field it is also necessary to do more longitudinal studies within organizations.

Group Processes in the Classroom

Interest in group learning and group processes has a very long history and remains a key focus of current efforts to improve education. Group processes in the classroom occur when peers engage in a common task and can include a variety of both social and cognitive

processes. The focus of this entry is on cooperative or collaborative groups of peers and the various theoretical approaches that attempt to explain group processes in these kinds of group. These approaches propose varying mechanisms for the effectiveness of group learning. Comparisons of empirical findings across studies conducted from different theoretical perspectives are very difficult because of the wide variances in tasks used, duration of studies, roles of teachers and students, outcome measures, and other variables such as group composition. One consequence of the variance in theoretical approaches is the fact that these approaches require different decisions with regard to key variables such as group size or group composition. Group processes can best be understood within particular theoretical approaches. This entry will not address the influences of specific variables but will instead focus on the delineation of various theoretical perspectives and the linkage of research and practice.

1. Theoretical Approaches to Group Processes

Different theoretical approaches to peer learning propose different underlying mechanisms or processes that come into play when a group works together (O'Donnell and O'Kelly 1994). Slavin (1996) described two main classes of orientation toward peer learning: a social-behavioral orientation that includes motivational and social cohesion approaches, and a cognitive orientation that includes elaboration and developmental perspectives. There are two distinct developmental theories. Table 1 delineates key differences among these perspectives as they relate to instructional decisions and problems that may arise from such decisions.

1.1 Social-behavioral Perspectives

The concept of interdependence among group members is fundamental to the motivational and social cohesion perspectives on cooperative learning, although they differ in how interdependence is created and sustained. When group members are interdependent, the success of one member can occur only if other members are also successful. In competitive situations, one person's success requires that another person fail. In the social motivational approach, interdependence is created by the use of group rewards. In Student Teams Achievement Divisions (Slavin 1995), students work in small groups to master material that the teacher has presented. Each student takes an individual quiz on the material, and points are assigned to the group based on each individual's improvement score. Thus, students are accountable for improving over past performance and learners of varying abilities can contribute equally to the total group score. Group rewards are assigned based on the team's number of points. A key component of this

Table 1

Key considerations in cooperative learning from a variety of theoretical perspectives

Considerations	Theoretical perspectives				
	Social-behavioral			Cognitive	
	Motivation	Social cohesion	Elaboration	Developmental	
				Piagetian	Vygotskian
Goals/incentives	Rewards essential	Rewards nonessential	Rewards nonessential	Rewards nonessential	Rewards nonessential
Group size	Large (4–6)	Large (4–6)	Small (2–4)	Small	Dyads
Group composition	Heterogeneous	Heterogeneous	Heterogeneous	Homogeneous	Heterogeneous
Tasks	Rehearsal	Rehearsal/integrative	Rehearsal/integrative	Exploratory	Skills
Teacher role	Director	Facilitator	Facilitator	Facilitator	Model/guide
Potential problems	Use of reward	Poor social skills	Poor help-giving	Inactive	Poor help-giving
Averting problems	Group size	Social loafing	Unequal	No cognitive	Providing adequate
	Improvement scores	Cognitive loafing	participation	conflict	time/dialog
	Simpler tasks	Team building	Direct instruction in	Structuring	Direct instruction in
	Social cohesion	Conflict resolution strategies	help-giving	controversy	help-giving
		Discuss group process	Model help-giving		Modeling help-giving
			Scripting interaction

approach is the reliance on individual accountability. Evidence of the effectiveness of this approach comes from a large number of studies (Slavin 1996). The kinds of learning task used in this approach, however, tend to focus on basic skills or factual knowledge, and it is unclear whether this approach is effective in promoting higher-order skills.

1.2 Social Cohesion Perspectives

In the social cohesion approach, interdependence derives from a motive of care and concern. Group members help one another because they are concerned about their peers. Teaching social skills that will support this type of interdependence is an important emphasis in social cohesion approaches. The Johnsons's Learning Together technique (Johnson and Johnson 1994) illustrates the social cohesion approach. The empirical evidence supporting this orientation toward group learning as a means of enhancing academic achievement is much weaker than that supporting the motivational perspective. Slavin (1996) notes that cooperative learning methods that emphasize team building and group process, but do not provide group rewards, are not very effective but that when they are combined with the use of rewards or accountability, student achievement from group learning exceeds individualistic learning. Slavin concludes that individual accountability and group rewards are critical to the success of cooperative learning methods.

Not everyone subscribes to the idea that rewards are necessary to create cohesion or interdependence. Cohen (1994) believes that cooperative learning that uses group rewards may be useful for lower-level skills but may not be either necessary or helpful for promoting higher-order skills. Thus, decisions about whether to adopt a motivational or social cohesion approach to peer learning may depend on the desired outcomes from group interaction.

Cohen (1994) emphasizes a different source of social cohesion, suggesting that the interest value of the task in which students engage will create the kind of interdependence necessary for students to succeed. In such situations, difficulties associated with status differences among students are ameliorated. When students have low status in the group, they participate less and in ways that do not promote achievement. Explicit rewards in this context may only exacerbate the problems created by differential status in a group. Cohen and her colleagues have successfully promoted social cohesion in groups by reducing status differences among group members so that they are oriented to accept that all students *can* contribute to task accomplishment. Complex and interesting tasks are necessary for this level of inclusion to occur. Cohen and her colleagues have been very successful in promoting student achievement. Results from Cohen and her colleagues suggest that the nature of the task

may have important implications for the kind of accountability that is needed to promote effective group learning.

1.3 Cognitive/Elaborative Perspectives

The third perspective identified by Slavin is a cognitive/elaborative approach and is based on information processing theory. The role of the group interaction from this perspective is to increase active processing by providing opportunities for restructuring and elaborating knowledge. Group learning techniques influenced by this perspective tend to provide some structure to the interaction of students by emphasizing the cognitive processes in which students must engage. Examples of work influenced by this perspective include the use of scripted cooperation by O'Donnell, Dansereau, and colleagues (O'Donnell and Dansereau 1992), reciprocal peer questioning (King 1999), reciprocal teaching (Palinscar and Brown 1984), and the work of Noreen Webb (Webb 1992). The empirical evidence supporting the use of these techniques is strong.

The quality of discourse is critical from this perspective and will have an influence on the outcomes from group interaction. Webb (1992, Webb and Palinscar 1996) has shown that the quality of explanations that are provided in a group are linked to achievement. Giving explanations is more strongly associated with achievement than receiving explanations. King (1999) has also shown that instructional efforts to improve the quality of discourse by teaching students to ask questions that facilitate knowledge construction is very effective.

1.4 Developmental Perspectives

A fourth approach to understanding cooperative groups relies on two different theories of development. From a Piagetian perspective (De Lisi and Golbeck 1999), peers can learn from one another because they can provide opportunities for cognitive conflict and resolution. Groups that experience mutuality of influence and power are most likely to provide a context within which cognitive development can occur because they are more likely to include differences of viewpoint. Children who have not attained the principle of conservation often develop and maintain conservation concepts when they have worked with a child who has already developed this concept (De Lisi and Golbeck 1999). Much of the work on conceptual change in science education has been influenced by this perspective.

From a Vygotskian perspective (Hogan and Tudge 1999), children acquire knowledge and skills that are first modeled in the community and are subsequently internalized by an individual. When cooperative learning is anchored in Vygotskian theory, it is

concerned with the larger community of practice in which individual learning is accomplished. Key processes include the scaffolding of the learner's performance by a more expert individual. The difference between what an individual can accomplish alone and with the assistance of an adult guide or more capable peer is defined as the zone of proximal development.

1.5 Sociocultural and Combined Theoretical Perspectives

A fifth perspective that undergirds such group learning techniques such as Communities of Learners (Brown and Campione 1990) may be identified. It includes the developmental perspective of Vygotsky, with its emphasis on the sociocultural basis of learning, and a social cohesion approach in which such learning is motivated by care and concern. Other forms of cooperative learning borrow from multiple perspectives in making choices about the selection of tasks and the organization of learning (Van Meter and Stevens 2000).

2. Research and Practice

Despite the burgeoning research findings that might assist teachers in making choices about grouping for instructional purposes, teachers do not seem to rely on the empirical research for guidance when making such choices (Antil et al. 1998). However, few studies have examined teachers' beliefs about group processes in the classroom.

2.1 Teachers' Use of Cooperative Learning

The research findings from any of the perspectives previously described seem to have little systematic influence on teachers' choices about groups. Although Slavin (1996) is convinced that empirical evidence supports the use of group rewards, he notes that there is quite a reluctance on the part of classroom teachers to use them.

Antil and his colleagues (1998) conducted a study of elementary school teachers' conceptualization and utilization of cooperative learning. Eighty-five teachers responded to an initial survey, and 93 percent of them reported that they used cooperative learning for both academic and social reasons. In interviews with 21 of these teachers, Antil found that the majority structured tasks to create positive interdependence, and taught students skills for working in groups. Few, however, employed recognized forms of cooperative learning and, in particular, did not link individual accountability to group goals. No data were presented, however, that linked classroom practices in relation to cooperative learning and student achievement. It is clear from this study that teachers do not implement the particular practices of cooperative learning that

research has shown to be effective. However, when teachers receive extensive professional development, the effects on student achievement can be powerful (Schultz 2000).

2.2 Usable Models of Group Processes

The availability of multiple perspectives on peer learning and the proliferation of specific techniques may contribute to the disconnection between the available research findings and their use by classroom teachers. The kind of classification system represented in Table 1 is rarely presented to either pre-service or in-service teachers. Usable models of peer learning that can guide practical decisions are needed. Such models need clearly to link expected outcomes to classroom processes and teachers' actions or decisions.

Slavin (1996) proposed a model of effective peer learning with motivation at its core. Motivation is necessary in order for students to engage in the active processing (e.g., explanations) that is linked to achievement. The keys to motivating students are group rewards and individual accountability. Teachers can act to create and sustain children's motivation that will allow them to link will and skill in pursuit of achievement.

Van Meter and Stevens (2000) emphasize the quality of discourse in a group as the key variable in effective group learning. Other instructional choices should be such that the quality of discourse is enhanced. Thus, task instructions and group composition are only interesting insofar as they influence the quality of the discourse among peers.

These two models provide a simple set of goals for teachers using group learning. Coherence among classroom decisions about fundamental aspects of arranging instruction (e.g., group size, group composition, type of task) is more likely to occur if there is a clear goal in place (e.g., motivate students to engage in active learning). Teachers in the Antil et al. (1998) study reported that they did not subscribe to particular cooperative techniques because they wanted to maintain their decision-making autonomy. The two models that are briefly described here with their emphases on motivation and discourse provide a set of superordinate goals that can accommodate teachers' needs for autonomy, while preserving a principled approach to decision making about group processes.

3. Future Directions

Given that teachers seem reluctant to use group rewards (Slavin 1996), it is important to specify the conditions under which alternative methods of creating interdependence among group members can be effective. What are the kinds of tasks for which extrinsic reward are not necessary? Answers to this question lie in the analysis of the kinds of process in which students engage when they are engaged in

interesting and challenging tasks. A clearer understanding of effective processing of complex tasks may make it possible to find alternatives to rewards.

The tension between theories of group processes and classroom practices of group learning presents the richest source of future research questions. Teachers' beliefs about learning lie at the fulcrum of their abilities to implement effective group learning in the classroom. The relationships between teacher beliefs, implementation practices, and student achievement remain untouched as research questions. Research on this set of relationships would provide valuable insights that could inform teacher preparation and in-service professional development, and also improve classroom practice of group learning.

Group Processes, Social Psychology of

Group processes encompass such a wide range of phenomena that the social psychological study of group processes has many different focuses. It can focus on individual cognitive and motivational processes that produce group behaviors, interpersonal processes among more than two people, cognitive and social processes that cause people to conceive of themselves as group members and behave accordingly, intergroup relations that affect intragroup processes, the interrelationship of individual, interpersonal, and social processes, the behavior of specific groups or types of group, and so forth (e.g., Baron et al. 1992, Brown 2000, Hogg and Tindale 2001, Levine and Moreland 1998, Moreland and Levine 1994). What unites this diversity is a focus on the group as a social psychological entity.

1. What is a Group?

There is, however, little agreement on a social psychological definition of the group (see Hogg and Abrams 1988). The dominant view (since Floyd Allport in the early 1920s) is that a group is a collection of individuals, and that group processes are actually individual or interpersonal processes among a number of people. For instance, Latané's social impact theory attributes differences between interpersonal and group behavior to, among other things, the effects of increasing numbers of people. An alternative perspective (see Hogg and Abrams 1988) is that groups and group behavior are qualitatively distinct from individuals and interpersonal behavior, and that different or

additional concepts are needed to properly analyze groups—for example, groups produce norms that regulate members' behavior and people reconfigure their self-concept so that it is defined in terms of properties of the group as a collective. This perspective is represented by the early work of Wundt and Durkheim (late nineteenth century), and McDougall and Mead (early twentieth century), the more recent work of Sherif and Tajfel, and presently by social identity theory (see *Social Identity, Psychology of*) and intergroup approaches (see *Intergroup Relations, Social Psychology of*). It is argued that the analysis of groups in terms only of interpersonal processes is reductionist—it does not adequately address questions to do with group processes, but instead deals only with interpersonal processes among more than two people.

The issue of 'what is a group' continues to simmer as an important, and unresolved, metatheoretical debate in social psychology. Many researchers adhere to one view or the other, for example, perspectives that focus on the interdependence of individuals in small face-to-face aggregates vs. perspectives that focus on the collective self-concept that derives from membership of groups of all sizes. Others opt out of the formal controversy—this is particularly true of an increasing number of scholars who research group processes from more applied perspectives (e.g., sport psychology). In recent years, however, there have been promising attempts to integrate interactive small group perspectives, intergroup perspectives, and cognitive self-concept perspectives (see Brown 2000).

2. Studying Group Processes

Traditionally the study of group processes has lain at the heart of social psychology. It was in many ways the explosion in the late 1940s and early 1950s of research into what was then called group dynamics that set experimental social psychology off on its current expansion. Even at the beginning of the twenty-first century, early group dynamics researchers like Kurt Lewin and Leon Festinger have significant impact on the discipline. Group processes research thrived until about the mid-1960s when it suffered a fairly rapid decline in popularity (replaced by attribution theories, then social cognition), from which it is showing strong signs of recovery, mainly through cognitive and intergroup perspectives on group processes (Moreland et al. 1994). The apparent demise of traditional group processes research may be due to a variety of factors (Steiner 1974). For instance: (a) it is time consuming and costly to conduct research with interactive groups; (b) data from group research are rarely neat, tidy, and easily explained; (c) the computer revolution shifted social psychological interest from the study of groups to the development of theories of individual human behavior that resembled computer software; and (d)

the logical end-point of reductionist perspectives on group processes is to focus exclusively on individual psychology.

3. Group Formation, Commitment, and Identity

A central concept in the study of group processes is 'group cohesiveness,' which refers to the overall solidarity of groups, their 'groupness,' and the process that transforms an aggregate of unrelated individuals into a psychological group. Through cooperative interdependence in the pursuit of shared goals, people become attracted to one another, to the group, and to the group's goals. In this way a group forms, and its overall cohesiveness is an arithmetic combination of individual members' attraction to one another and the group. This attraction-to-group—or interpersonal attraction—analysis has not gone unchallenged, and recent perspectives place an emphasis on some form of commitment to group, or self-definition in terms of group membership (Hogg 1992). For instance, social identity theory does not consider attraction-to-group to be the basic process of group formation, but rather one of a range of consequences of a process of identification with the group (i.e., self-categorization in terms of the group's defining features—see *Social Identity, Psychology of*). Moreland and Levine (e.g. 1994) have developed a 'group socialization model' to address what they consider to be a lack of diachronic perspective in many models of group formation and development. Commitment is considered the most basic process. People become committed to a group, and a group to its members, through bilateral cost-benefit analyses of membership in this group relative to other groups. As mutual commitment rises or ebbs, members move in and out of different general roles within the group (e.g., new member, 'oldtimer')—a process characterized by role transitions that are quite marked, and which can involve public rites of passage.

4. Group Influence

Groups influence the attitudes and behaviors of their members in many different ways (e.g., Turner 1991—see *Social Influence, Psychology of; Attitude Change: Psychological*).

4.1 Direct Influence and Persuasion

Direct influence attempts involve individuals, subgroups, or the group as a whole trying to persuade members (e.g., deviants, dissenters) to go along with or come into line with the group. Persuasion attempts may range from relatively polite requests all the way to direct orders (see *Obedience: Social Psychological*

Perspectives) backed up by threats and ultimately force. Persuasion is generally more effective if the source of influence has a degree of legitimate authority and power within the group (see *Leadership, Psychology of*; Chemers 2001). Direct influence generally produces behavioral compliance which is not necessarily matched by underlying cognitive or attitudinal change—people go along with the group for instrumental reasons which may include a desire to be evaluated favorably or to avoid disapproval or punishment.

4.2 Indirect Influence and Group Norms

Groups can also influence members indirectly through the power of social norms that describe and prescribe appropriate behavior for group members in that context (Brown 2000, Turner 1991). In the absence of direct social pressure people conform to group norms. This may happen through ‘normative influence,’ in which people simply publicly comply in order to obtain social approval or avoid disapproval from others—there is no underlying cognitive change. Another process is ‘informational influence’ which produces true conformity—underlying cognitive change which may go along with behavioral change (see *Attitudes and Behavior*). Informational influence is effective where people are uncertain about the objective correctness of their beliefs, and in the absence of objective criteria they use group members’ behaviors as social criteria (Festinger 1954; see *Youth to Adulthood across Cultures, Transition from*). A third process is ‘referent informational influence’ (see *Social Identity, Psychology of*) in which people who identify with a group construct a contextually appropriate norm that defines the ingroup in contrast to relevant outgroups, and then enact the norm as an automatic consequence of self-categorization.

Although indirect group influence usually comes from the ingroup, there are at least two ways in which an outgroup can have influence: (a) outgroups influence the nature of the ingroup norm that people conform to, and (b) minority outgroups can adopt strategies to convert people to their viewpoint (e.g., by promulgating a consistent and consensual viewpoint, and by presenting themselves as actually part of the ingroup)—see *Social Movements: Psychological Perspectives*.

5. Group Structure

Whereas norms and social influence processes tend to produce uniformity within groups, other factors introduce unevenness and variability across the group that structures the group into different regions. Aspects of group structure can surface through intragroup patterns of who prefers or likes whom, known as ‘sociometric choice’ (see Hogg 1992).

5.1 Roles

Groups usually embrace a number of different roles that can be occupied by different people, or by subgroups of people. Roles prescribe behavior, and they emerge to assist the group to function better as an integrated entity. According to Moreland and Levine’s (1994) group socialization model, the group socialization process involves people moving in and out of quite distinct general roles within the group as a function of commitment to the group. Roles are rarely equal—some are more desirable than others, and have more power, prestige, and status attached to them. In this way, groups are often internally structured into role hierarchies. High status roles tend to be occupied by people who have specific status characteristics (abilities and skills directly related to the group’s function) and/or diffuse status characteristics (they are members of social categories that have high status in society at large)—see Ridgeway 2001.

5.2 Communication Structures

Another feature of group structure is the ease with which members or role occupants can communicate with one another (see *Communication and Social Psychology*; see Baron et al. 1992). Depending on the group’s task, different communication structures can emerge—highly centralized structures channel all communication through a single communication hub (often the leader), while less centralized networks allow freer communication among all members. The nature of the communication network affects group functioning, task performance, member satisfaction, and group solidarity. For instance, highly centralized networks can, under certain circumstances, reduce efficiency, cause peripheral members to feel excluded and dissatisfied, and even reduce group cohesion. Communication networks can be traced and described using Bales’s ‘interaction process analysis’ method, which documents who communicates what with whom, and how often.

5.3 Leadership

One of the most important, and certainly the highest status, role in a group is the role of leader (Chemers 2001, see *Leadership, Psychology of*). Research on leadership suggests that effective leadership (often defined in terms of the ability to motivate members to internalize and act on one’s own innovative vision for the group) is an interaction between leadership style and the type of leader that is needed in a particular situation. Another factor that may be important in some circumstances is that the leader is perceived to be a good group member who closely fits the defining features of membership. Because leadership is a role, leadership dynamics involve followers—if followers will not be led then the leader cannot lead.

Generally, followers tend to endorse leaders who have good leadership qualities, who have abilities that benefit and promote the group as a whole, and who are good group members or have been good group members in the past. These attributes encourage followers to endow the leader with status and to allow the leader to be innovative.

5.4 Deviance

Whereas leaders are at the pinnacle of the intragroup role hierarchy, deviants are at the bottom (see Hogg and Tindale 2001). Research suggests that groups try very hard to socialize marginal members by making them conform or by finding them useful and valued roles within the group. If these attempts fail, people evaluatively reject deviants, often pathologizing their behavior and attempting to classify them as outgroup members. Research on the 'black sheep effect' suggests that because marginal members pose a threat to the normative integrity of the group and thus threaten members' group membership-based self-concept, marginal ingroup members are actually disliked even more than an identical person who belongs to an outgroup.

6. Group Performance

Since groups often exist to perform specific tasks, an important question to ask is whether groups perform better or worse than individuals (see Baron et al. 1992). This is an extension of an even more fundamental question about how individual task performance is affected by the presence of others. Coactors or a passive audience tend to improve performance of a well-learned or easy task, but impede performance of a poorly learned or difficult task (see *Social Facilitation, Psychology of*). In general, however, groups are interactive entities, and the question becomes one of whether the task is better accomplished by interaction in a group, or simply by individuals working alone. The answer to this question is that it depends on the specific nature of the task—for instance, more cars can be produced by a group effort based on a coordinated division of labour, than by individuals building them from scratch (see *Group Productivity, Social Psychology of*).

6.1 Social Loafing, Free Riding, and Social Dilemmas

Groups often perform less well than would be suggested by the sum of the abilities or performances of individual members (see Moreland and Levine 1994). This can be because of coordination losses, that is, interference between individuals trying to coordinate their actions within the group. Coordination

losses may be one explanation of why group brainstorming is often a suboptimal way to generate novel ideas in a group. Groups can also perform less well because of motivation losses, that is, people in groups put in less effort because they are less motivated. This latter 'social loafing' effect seems to be partly due to a reduction in perceived personal identifiability and responsibility in the group (see *Deindividuation, Psychology of*), and can be explained in terms of 'social impact theory.' Social loafing can be reduced by, among other things, task importance, enjoyment, and relevance, and increased group cohesiveness and personal identifiability. Related to loafing is a tendency for individuals in a group confronted by a scarce resource to free ride, that is, maximize their own short-term gains with little regard for the group as a whole and thus their long-term gains (see *Social Dilemmas, Psychology of*). Many of the environmental problems faced by the world today are examples of social dilemmas. Social dilemmas can be (partly) avoided by having a leader manage a resource rather than letting the members compete directly, or by having members identify strongly with the group that accesses the resource.

7. Deindividuation, Collective Protest, and the Crowd

A common assumption about groups is that they cause people to lose their sense of individuality and that this leads to low motivation, lack of responsibility, and antisocial conduct—all captured by the notion of 'deindividuation' (Zimbardo 1970, see *Deindividuation, Psychology of*). Historically, this perspective, which has its critics (see Postmes and Spears 1998), is most evident in research on a particular type of group—the crowd. Starting with LeBon in the late nineteenth century, social psychologists have generally considered crowds to be irrational and antisocial because members of the crowd are deindividuated. A contrasting perspective is one that views crowd behavior as social protest (see *Social Movements: Psychological Perspectives*). Crowds have a purpose that is tied to a specific identity, and so crowd behavior has a logic to it because it is tightly regulated by the context relevant norms of the group. Where a crowd engages in antisocial acts, this is because the event is an expression of protest against a dominant group—the protest takes the form of violation of the dominant group's norms and rules.

8. Group Decision Making

One of the most common tasks that groups perform is decision making (Baron et al. 1992, see *Group Decision Making, Social Psychology of*). Group decision making is potentially superior to individual decision

making because in a group there is a larger pool of expertise, viewpoints, and so forth. Groups may come to decisions slowly, but this may be a good thing, particularly for complex issues, because it indicates proper consideration of all facets of the issue. However, groups are also subject to an array of group processes that may impair decision making, for example, factional conflict, biased leadership, and pressures to be obedient and compliant.

8.1 Groupthink and Group Polarization

One potential problem is the tendency for highly cohesive decision-making groups, that are under stress and do not have impartial leadership, to engage in 'groupthink,' a mode of thinking in which the desire to reach unanimous agreement overrides the motivation to adopt proper, rational group decision-making procedures. Groupthink involves defective decision-making procedures, which generally produce poor decisions that can have disastrous consequences. Many poor-quality crisis decisions made by governments have been attributed to groupthink, for example, the 1961 Bay of Pigs fiasco. Another potential bias in group decision making is 'group polarization' (see Turner 1991). This is a tendency for group discussion to cause groups to come to a decision that is more extreme than the mean of the individual members' prediscussion opinions. Polarization occurs only when the prediscussion mean already tends to favor one pole of the decision-making dimension—the group decision is then more extreme in this direction.

8.2 Social Combination Models

A major focus of research on group decision making concerns how one can predict a group decision from the initial distribution of members' views (Baron et al. 1992, Hogg and Tindale 2001). A number of social combination models have been derived to relate the distribution of initial opinions in a decision-making group to the final group decision. The most enduring of these is Davis's social decision schemes model (Davis 1973, which identifies at least five implicit (or explicit) decision rules that can exist in groups (e.g., unanimity, majority wins, truth wins). Different rules tend to prevail for tasks in which there is a demonstrably correct solution ('intellective tasks') as opposed to tasks which are more a matter of taste and preference ('judgemental tasks'). Rules also differ in terms of how strict they are (i.e., how much intragroup agreement is called for), and how much power concentration they have (i.e., how much power is located in one individual). Unanimity is very strict but low on power concentration, while two-thirds majority is less strict but has greater power concentration. Strictness and power concentration have effects on satisfaction

within the group, and on the speed with which a group makes a decision. Social combination models are often tested using a simulated jury paradigm.

8.3 Group Remembering

Group decision making usually involves collaborative recall of information, or group remembering (Baron et al. 1992, Hogg and Tindale 2001). Group remembering is not simply a retrieval activity in the pursuit of veridical recall, rather it is a constructive process where social comparisons among group members shape the resultant group memory. As such, group remembering may be subject to implicit or even intentional bias. Another feature of group remembering is 'transactive memory.' Groups often need to bring a large amount of information to bear upon a decision, and thus they develop a differentiated memory structure where individuals or subgroups specialize in different memory domains. Where this occurs people not only have to remember their own part of the puzzle, but they also need to know who specializes in what memories—they develop a transactive memory structure. Research shows that group functioning and decision making is compromised where people have not acquired a transactive memory, or where such a system has not developed in the group.

8.4 Intergroup Decision Making

Decision-making groups can contain factional rifts, or can be considered to be interactive decision-making contexts in which opposing groups or their representatives come together to reach an agreement. Under these circumstances the group provides a context for intergroup decision making (see *Intergroup Relations, Social Psychology of*). Because individuals are acting as group representatives rather than individuals, face-to-face intergroup bargaining has a relatively low probability of success—intransigence and stalemate is more likely. Third party mediation can help, and as a last resort, so can arbitration (in which a settlement is imposed by a third party).

9. The Intergroup Dimension

The study of group processes has tended to focus on what happens among members of small interactive groups (e.g., Levine and Moreland 1998, Moreland and Levine 1994), and does not fully consider how relations between groups may influence these processes. There are, however, indications that an intergroup perspective may be useful in helping to understand intragroup processes (Brown 2000, Hogg and Abrams 1988, see *Social Identity, Psychology of; Intergroup Relations, Social Psychology of*). For inst-

ance, group polarization may be an intergroup phenomenon in which a relatively extreme ingroup differentiates itself from a less extreme outgroup by becoming even more extreme. Group decision making may sometimes actually be intergroup decision making, and the commitment process that underlies group socialization involves an assessment not only of ingroup membership but also outgroup memberships. There is also an array of group behaviors that are more properly termed intergroup behaviors: these may include a more favorable evaluation of the ingroup, its members, and all it stands for, in relation to outgroups (i.e., ethnocentrism); discriminatory behavior against outgroups and in favor of the ingroup; and stereotypic perceptions and assumptions about ingroup and outgroup members (see *Stereotypes*). Also, the extreme forms of collective behavior that occur in crowds are sometimes best explained in intergroup terms—the crowd is a group with a passion that is guided and fuelled by the group's opposition to an outgroup (e.g., football supporter groups). Finally, group influence is not purely one-way, with the group bringing dissenters and deviates into line. It is often an intergroup affair with active minorities within the group trying to sway the majority to its own position.

10. Specific Groups

The study of group processes has tended to have numerically small, face-to-face, demographically homogenous, short-lived, task-oriented groups in mind (Steiner 1974). As such, a great deal of research has used four to six-person laboratory groups of university (often psychology) students. In many cases, experimental studies of group processes have used the dyad as the prototypical group. This is based on an assumption that group processes are merely aggregated interpersonal processes. More naturalistic studies have dealt with a great variety of groups—gangs, housing programs, sports teams, summer camps, scout troops, school classes, military groups, therapy groups, juries, government and organizational decision-making groups, and so forth. Studies in the intergroup tradition have tended to be interested in cognitive processes and so have often, though not exclusively, used rather abstract laboratory experiments where groups are often only nominal and there is no interaction.

11. Future Directions

There has been a marked revival of interest among social psychologists in group processes (Moreland et al. 1994). The key feature of this revival is an integration of intergroup, small group, and social cognitive perspectives in social psychology (see Brown

2000, Hogg and Tindale 2001) that sets a clear course for future developments. Recent developments have, however, tended to focus on generic group processes rather than the phenomenology of specific types of group. Although the study of larger, naturally occurring groups in more naturalistic contexts is time consuming, methodologically problematic, and involves weaker experimental control, future developments in group processes may be assisted by more of this type of research. Indeed there is evidence that although certain group processes may be common to all groups, a full understanding of groups also needs to recognize differences between small interactive groups and large social categories, between groups that vary in the degree to which they are a coherent entity, and between groups as diverse as a family, a sect, a therapy group, an army, a nation, a virtual group, and so forth (Deaux et al. 1995).

Group Productivity, Social Psychology of

Group productivity refers to the degree to which working in a group context either enhances or reduces individual motivation and performance. Group productivity is one of social psychology's cornerstones. The earliest documented studies in social psychology examined the effects of groups on individuals, and hundreds of laboratory and field studies have been conducted on this issue.

1. Historical Background

The earliest studies revealed two seemingly opposing consequences of group work. In the 1880s, Max Ringelmann observed that oxen yoked together did not pull plows as fast as would be expected from their individual efforts. In his laboratory, he asked male volunteers to pull on a rope as hard as they could, both alone and as members of groups ranging in size from two to six. He found that as group size increased, group performance was increasingly lower than would be expected from the simple addition of individual performances, suggesting that working in a group could reduce performance (see Kravitz and Martin 1986). In 1898, Norman Triplett noted that competitive cyclists were faster when racing against other cyclists than when racing against the clock. In his laboratory, he demonstrated that children worked harder on a physical task when they were in the presence of other children who were working on the same task compared to when they worked alone, suggesting that working in a group could enhance performance.

Triplett's work helped stimulate a flurry of studies on what came to be known as 'social facilitation,' revolving around the idea that the presence of others could facilitate individual performance. Meanwhile, Ringelmann's findings were essentially ignored, regarded with skepticism, or interpreted solely in terms of poor coordination of group members' activities. It was not until 1974 that Ringelmann's findings were

replicated, and not until even later that the motivational component of these findings was examined as an important and reliable phenomenon that came to be known as 'social loafing.'

2. Social Facilitation

Though Triplett's findings were replicated early and often, inconsistencies began to emerge across studies throughout the first half of the twentieth century. Specifically, the presence of others, either as an audience or as coactors (i.e., individuals who work on the same task in each other's presence but who do not combine their outputs into a group product), did not always enhance performance and sometimes reduced performance. Zajonc (1965) devised an elegant solution to this discrepancy. He suggested that the presence of other people increases generalized drive, thereby facilitating dominant responses. On simple or well-learned tasks, dominant responses are likely correct and the presence of others should enhance performance. On complex or unfamiliar tasks, dominant responses are likely to be in error and the presence of others should reduce performance.

Later research has largely supported Zajonc's view (for a review, see Bond and Titus 1983). Indeed, most researchers now define social facilitation as the tendency for the presence of others to facilitate performance on simple or well-learned tasks but to impair performance on complex or unfamiliar tasks. However, there is an active controversy among researchers and theorists as to why and when the presence of others facilitates dominant responses. The mere presence perspective of Zajonc (1965) and others focuses on arousal and assumes that the presence of other people introduces an element of uncertainty to a situation that leads people to become more aroused and alert, regardless of whether or not the other people present have any interest in what the individual is doing. Cottrell's (1972) evaluation apprehension theory states that mere presence is not sufficient to produce arousal, but rather that it is the ability of other people to create apprehension about being evaluated that leads to social facilitation. If others are present but are paying no attention to the individual and have no regard for how well the individual performs, performance should not be affected. Finally, distraction-conflict theory (Baron 1986) focuses on attention rather than arousal as the primary mediator of social facilitation. Research has documented repeatedly that the presence of others can be distracting and can divide an individual's attention between working on the task at hand and monitoring the behavior and reactions of the audience or coactors. Distraction-conflict theory suggests that individuals try to resolve this cognitive and attentional conflict by increasing their effort at the task to overcome the effects of distraction, thereby enhancing performance on simple tasks and reducing it on complex tasks.

Research has found some support for all of these theories. It appears as though mere presence, evaluation apprehension, and distraction are all capable of creating and contributing to social facilitation effects. Arousal levels have been documented to increase in the mere presence of others, and support has been found for social facilitation even when the others present are very unlikely to create any apprehension about evaluation. Arousal does become more pronounced, however, when observers are clearly evaluating the individual. Similarly, studies have shown that social facilitation effects can emerge from situations in which the presence of others creates distraction. Thus, arousal, evaluation apprehension, and distraction can all potentially contribute to social facilitation effects, both alone and in combination with one another (for a detailed discussion of these factors, see Geen 1991).

Research has also documented social facilitation effects across a wide array of settings, tasks, and subject populations. The effect also appears to hold for a wide variety of animals in addition to humans, including armadillos, chickens, monkeys, and rats. In one rather unusual study, the ability of cockroaches to run either a simple runway or a maze was examined either alone, in coacting pairs, or in the presence of other cockroaches who observed from behind a plastic barrier (Zajonc et al. 1969). When in the presence of coactors or observers, cockroaches ran the simple runway more rapidly but took longer to navigate the maze, replicating prior social facilitation research on humans and other animals. Social facilitation has also been widely documented in field settings. As just two examples, social facilitation effects have been documented for gymnastics performance and billiards playing in public settings.

However, although social facilitation effects are well-established, they appear to be somewhat small in magnitude in comparison with other prominent social psychological phenomena and the impact of facilitation on performance sometimes varies across performance measures. Based on their meta-analysis of 241 studies, Bond and Titus (1983) concluded that, on simple tasks, the presence of others increased the rate of productivity but did not improve performance quality. They also concluded that, on complex tasks, the presence of others reduced both the quantity and quality of performance. Finally, they noted that the productivity gains associated with simple tasks were weaker in magnitude than the productivity losses associated with complex tasks performed in the presence of others.

3. Social Loafing

Formally, social loafing is a reduction in motivation and effort when individuals work collectively compared with when they work individually or coactively.

In order to study the effects of group context on individual motivation while controlling for mere presence effects, social loafing researchers usually compare individual performance on collective tasks to individual performance on coactive tasks, while holding group size constant across these conditions. In addition, in order to separate motivation loss from mere coordination loss (i.e., poor coordination of group member's actions), social loafing researchers often employ pseudogroups in which individuals work alone or produce outputs that can be individually monitored by the researcher, but believe that their outputs are being combined with those of others into a group product.

These methodological features were prominent in a highly influential experiment by Latané et al. (1979). Participants shouted and clapped as loudly as they could both individually and with others. While blindfolded and wearing headphones to mask the noise, participants shouted both in actual groups, and in pseudogroups in which they shouted alone but believed they were shouting with others. Participants still reduced their efforts on the pseudogroup trials, even though they only thought they were working with others. Thus, Latané and colleagues (1979) demonstrated that a substantial proportion of the decreased performance of groups was attributable to reduced individual effort, as distinct from coordination loss. They also coined the term 'social loafing' for the demotivating effects of working collectively.

Since the late 1970s, more than 90 studies on social loafing have been conducted. Both laboratory experiments and field studies have been conducted, using a wide variety of tasks and examining a range of subject populations. The bulk of the available evidence suggests that social loafing is moderate in magnitude and consistently found across studies. A meta-analysis of 78 studies by Karau and Williams (1993) found that the magnitude of social loafing was comparable in size to that of a number of prominent social psychological effects. Social loafing has been found for a wide variety of tasks, including evaluative tasks such as rating the quality of editorials and poems, cognitive tasks such as navigating computer mazes and detecting visual signals, creative tasks such as song-writing and thought-listing, physical tasks such as pulling on a rope and swimming, and work-related tasks such as typing. Furthermore, although national differences are occasionally found in some studies, a number of studies have documented social loafing regardless of participants' gender, nationality, or age. Thus, social loafing is robust and generalizes across tasks, as well as across most subject populations (Karau and Williams 1993).

However, social loafing is not inevitable and a number of factors have been found to moderate the effect. Thus, studies have found that social loafing can be reduced or eliminated by making individual inputs identifiable, enhancing task meaningfulness or personal involvement with the task, providing individual

or group comparison standards, providing incentives for good performance, threatening punishment for poor performance, increasing personal perceptions of efficacy at the task, and increasing the uniqueness of individual contributions (Karau and Williams 1993). Finally, gender and culture both appear to moderate social loafing. In their meta-analysis, Karau and Williams (1993) found that the magnitude of social loafing across studies was lower for women and for people in Eastern cultures such as Japan, Taiwan, and China, than it was for men and for people in Western cultures such as the USA and Canada, although significant effort reductions were still found within each of these groups.

A number of theories have been offered to explain social loafing, of which four perspectives are most prominent in the literature. First, social impact theory (Latané 1981) views people as either sources or targets of social influence and states that the amount of social impact experienced in a situation is a function of the strength (status or power), immediacy (physical or psychological closeness), and number of sources and targets present. On collective tasks, the influence of the outside influence source (the manager or the experimenter) is diffused across all of the group members, making it less potent on collective tasks than on individual tasks.

Second, the arousal reduction viewpoint (Jackson and Williams 1985) builds on social impact theory to suggest that the presence of others actually reduces arousal when those others are co-workers rather than coactors. According to this view, social loafing is the flip side of social facilitation because the presence of other co-workers lead to reduced drive, and therefore to reduced performance on simple tasks but enhanced performance on complex tasks.

Third, the evaluation potential perspective (Harkins 1987) suggests that social loafing arises because individuals can often be evaluated when working coactively, but are harder to evaluate when working collectively. Thus, individuals can 'hide in the crowd' on groups tasks and avoid taking the blame for a poor group performance. Similarly, they may also feel 'lost in the crowd' and unable to take credit for a good group performance.

Fourth, expectancy-value perspectives (Karau and Williams 1993, Kerr 1983, Sheppard 1993) suggest that individuals work less hard on a collective task because they feel their efforts will not be instrumental in obtaining an outcome that they personally value. As delineated in detail in a model by Karau and Williams (1993), collective tasks pose unique barriers to motivation both because they create more obstacles to the perceptions of efficacy and instrumentality, and because they may undermine the value attached to the task. All of these theories appear to have some usefulness, with the expectancy-value approach representing a more comprehensive or integrative approach to understanding individual motivation in

groups, and the other viewpoints explaining specific mediators of social loafing quite well, albeit in a more restricted fashion.

4. The Relationship Between Social Facilitation and Social Loafing

Both social loafing and social facilitation are concerned with the effects of group contexts on motivation and performance and yet social loafing suggests that this presence decreases performance whereas social facilitation suggests that this presence increases performance for some tasks but decreases performance for other tasks. Indeed, the very first empirical studies of group productivity by Ringelmann and Triplett documented these seemingly contradictory effects of groups.

The key to resolving this discrepancy appears to be in specifying whether the other people present are co-workers or coactors. In social loafing studies, groups are composed of co-workers who pool their efforts together. In social facilitation studies, however, groups are composed of coactors who work in one another's presence but do not pool their efforts. Therefore, while both types of studies explore individual motivation in social contexts, they examine two very distinct aspects of group life. Taken together, they suggest that the impact that other people have on an individual's effort depends on whether or not the individual is actually working with those others on a collective task. Collective tasks have potentially demotivating properties, whereas coactive tasks tend to increase drive, thereby enhancing performance on simple tasks but reducing it on complex tasks. In other words, social loafing research is targeted to collective group work, whereas social facilitation research is targeted to the mere presence of coactors or observers.

5. Future Directions

Existing research on social facilitation and social loafing has revealed many important dynamics of group life, highlighted the conditions under which groups are likely to enhance or reduce individual performance, and provided a number of theoretical perspectives for understanding the dynamics of social motivation. Additional research is likely to provide an even richer understanding and greater guidance as to how groups can be designed and managed to bring out the best in individuals.

Group Psychotherapy, Clinical Psychology of

Group psychotherapy is the treatment of psychological, behavioral, emotional, and interpersonal problems in a group context. This article traces the development of group procedures in clinical psychology from its roots as a didactic technique to contemporary psychoanalytic, behavioral and cognitive-behavioral, and interpersonal treatment procedures. These approaches stress different therapeutic mechanisms and methods, but nearly all trace the health-promoting effects of groups to a common set of factors that instill a sense of hope, promote social learning, and induce self-disclosure, emotional ex-

pression, and self-insight. Research suggests that group psychotherapy, when properly administered, is as effective as individualized treatment techniques.

1. Approaches to Group Psychotherapy

Group psychotherapy emerged as a means of helping people deal with mental and emotional problems in the early years of the twentieth century. Psychotherapy itself was developing during this period, but most pioneering psychotherapists worked with individual patients only. Some innovators, however, applied their basic change principles in group settings, as did some therapists who turned to groups for didactic purposes or because their patient load demanded a massed approach to treatment. These group applications were often confined to a particular psychiatric facility or clinic, but in time they became more dispersed as other mental health professionals heard of and made use of the group methods. These early psychotherapy sessions involved treating individuals 'in groups, with the group itself constituting an important element in the therapeutic process' (Slavson 1950, p. 42).

Group psychotherapy is used currently to treat a variety of problems, including addiction, thought disorders, depression, eating disorders, and personality disorder. Group psychotherapists are usually credentialed mental health professionals and their patients tend to be suffering from diagnosed clinical conditions. The methods used by group psychotherapists are as varied as individual approaches to therapy. Psychoanalysis, psychodrama, systems-theory, object relations, existential, Gestalt, and humanistic are just a few of the general orientations adopted by group psychotherapists, who tend to be more eclectic than nongroup therapists in their approaches to treatment. Most approaches, however, fall into one of three basic categories: psychoanalytic, behavioral and cognitive-behavioral, and interpersonal (Forsyth and Corazzini 2000).

1.1 Psychoanalytic Group Psychotherapy

Psychoanalytic group psychotherapy draws on Freud's (1922) conceptualization of the causes of dysfunction and his recommendations regarding the most effective way to treat those dysfunctions (see *Psychoanalysis in Clinical Psychology*). The analyst, through such traditional analytic methods as free association, interpretation, and the dissection of transference processes, creates a powerful relationship with the client who then gains insight into unresolved conflicts. The psychoanalytic group psychotherapist, however, exploits the group situation to stimulate self-insight, transference, and the cathartic release of unconscious anxieties. In most cases the therapist acts

as the authority in the group and works with each patient in turn. This rotation gives each patient the opportunity to experience the benefits of one-on-one psychotherapy, but also gives them the opportunity to gain from the analysis of co-members' psychological and emotional difficulties. The group setting, as a recapitulation of a family grouping, also provides more opportunities to work through problems that result from early family conflicts. Just as individual therapy usually stimulates parental transference, group psychoanalysis stimulates sibling transference. Indeed, some experts suggest that Freud's Vienna Circle—ostensibly a study group formed by Freud and his students to discuss theories of adjustment—was a form of group psychotherapy (Roth 1993).

Psychoanalytic group psychotherapists diverge on one key aspect of the process. Some stress the importance of the individual in the group. This approach argues that the therapist should stress individual-level processes in treatment, and avoid spending valuable treatment time exploring the dynamics of the therapeutic group. Others, in contrast, integrate the treatment of the individual with the analysis of the group itself. The group-as-a-whole approach, which can be traced to Bion, Rickman, and Foulkes's work at the Northfield Military Hospital in England, is a sterling example of this approach. Although group-as-a-whole therapists embrace psychoanalytic assumptions of unconscious motivations, personality conflicts, and transference, they make use of the tension between the group and the individual to promote growth and development. Bion, for example, stressed the analysis of defense mechanisms used by groups to cope with ego threats, uncertainties, and anxieties. He believed that these strategies are rooted in dependence, for the group members engage in collective projective identification as they struggle to avoid blame for their problems by shifting responsibility from themselves to the therapist. Bion assumed that rapid and lasting adaptive change could be achieved by helping group members understand both individual and collective defensive processes that unfold in their group session, and his work provided the basis for the Tavistock Institute of Human Relations (Harrison 2000).

1.2 Cognitive–Behavioral Therapy Groups

Cognitive and cognitive–behavior psychotherapists, rather than searching for the cause of the problematic behavior in unseen unconscious conflicts or interpersonal transactions, base their interventions on principles derived from learning theories (Dobson et al. 2000) (see *Dialectical Behavior Therapy*; *Cognitive Therapy*). They identify and quantify desirable cognitions and behaviors that will be encouraged and undesirable cognitions and behaviors that will be extinguished, and then modify these behaviors thro-

ugh cognitive restructuring, self-instructional training, and problem-solving instruction. Cognitive–behavioral therapy groups use these principles with two or more individuals (Rose 1993). Cognitive–behavioral group therapy is generally both structured and problem-focused. Pretreatment assessments identify a patient's current level of functioning, and interventions are calibrated to fit the patient's level of functioning and targeted outcomes. The therapeutic interventions usually use a constellation of behavioral procedures, including modeling, rehearsal, and feedback.

1.3 Interpersonal Group Psychotherapy

Many group psychotherapists not only exploit the social processes that occur in groups during treatment, but they also trace psychological disturbances back to social sources—particularly interactions with friends, relatives, and acquaintances. Interpersonal theorists assume that behavior results from individuals' failures to take note of, and correct, cognitive and behavioral tendencies that disrupt their relationships with other people (see *Interpersonal Psychotherapy*).

Many group therapists, recognizing the interpersonal bases of psychological problems, use the group setting to help members examine their interpersonal behavior. Yalom's (1995) interpersonal group psychotherapy (also called interactive group psychotherapy), for example, stresses the 'here-and-now' of the group's interaction over the analysis of events and experiences that occur outside of the group (the 'then-and-there'). Members may spend some time, especially early in the group's life span, discussing problems they are facing at home or work, but Yalom feels that much of this discussion will be futile since members' characterize such events inaccurately. Yalom instead recommends that members focus on interactions within the group, with each member eventually responding to one another as they do to others in their lives. The group thus becomes a 'social microcosm,' giving members true insight into the causes of the personal problems.

2. Therapeutic Factors in Groups

Group psychotherapy is based on the Lewin's law of psychological change: 'It is easier to change individuals formed into a group than to change any of them separately' (Lewin 1951, p. 228). But what aspects of the group promote positive change? A common-factors perspective on group therapy suggests that various types of group psychotherapies, despite their many differences, share some common properties, and these commonalities may be responsible for their effectiveness. A psychodynamic therapist uses different techniques than a cognitive-

behavior or interpersonal therapist, but these various formats share mechanisms that promote change and sustain well-being. Yalom (1995) terms these shared qualities curative factors, and his list includes the installation of hope, universality, the imparting of information, altruism, the corrective recapitulation of the primary family group, the development of socializing techniques, imitative behavior, interpersonal learning, group cohesiveness, catharsis, and existential factors.

2.1 Social Motivation in Group Psychotherapy

Groups, by their very nature, satisfy a range of basic human social motives. Although individuals who are suffering from some behavioral or psychological problem may not find 'safety in numbers,' they can find 'reassurance in numbers.' When they assemble in a therapeutic group they quickly realize that the situation they face is shared by others. Yalom (1995) calls this realization universality, for patients realize that they have not been singled out to bear some extraordinary misfortune; rather, the problem they face is a universal one.

Therapeutic groups also capitalize on social comparison processes to stimulate growth and adjustment. Social comparison occurs when individuals spontaneously compare themselves to other people around them. This comparative process does not occur in individualistic therapies, for patients can only imagine how they are coping relative to others. In groups, in contrast, patients learn, both directly and indirectly, about one another's functioning. These comparative data yield two useful consequences. First, comparison provides patients with a baseline to calibrate their own level of functioning and determine where they stand along the 'coping vs. collapsing' continuum (Yalom 1995). They may learn, through downward social comparison—comparing themselves to those in the group who are performing poorly—that their own situation is not so bleak as they originally assumed. Second, this comparison can increase their sense of optimism about reaching an improved level of functioning. Yalom (1995) terms this process the installation of hope. Whereas individuals facing unpleasant circumstances alone may feel discouraged and pessimistic, when group members recognize that others are improving their motivational levels.

2.2 Interpersonal Learning

Much of the learning that occurs during psychotherapy is social in nature. Under the guidance of the therapist, patients explore and gain insight into sources of anxiety, they identify and practice behaviors that they can use to cope with sources of stress, and they acquire the skills they need to interact with others. The therapist models the behaviors they want

clients to adopt, and shape their behaviors through feedback and selective reinforcement. When therapy is delivered in a group context, however, the sources of social learning are multiplied. Group psychotherapy necessarily involves patients interacting with other patients, and so it sets up opportunities for interpersonal learning among patients. Some therapists purposely minimize the impact of the group on the individual patients, but most group therapists exploit these social processes to promote change.

Yalom (1995) argues that much of the curative power of a group springs from such social processes as imparting of information from one person to another (guidance), the development of socializing techniques, imitative behavior, and interpersonal learning. For example, the exchange of information among participants was one of the first purposes of groups, for the earliest group therapies were primarily didactic in nature, with psychotherapists lecturing to large groups of patients about mental and physical health. Interpersonal learning also occurs indirectly, as group members monitor their impact on the other people within their group, and the psychotherapist helps them draw conclusions about their maladaptive interpersonal tendencies. Group members also gain from simple observation of others. By watching others' emotional displays, problem-solving behaviors, coping strategies, and interpersonal maneuverings, patients acquire adaptive social skills.

2.3 Emotional Experiences and Group Development

Groups set the stage for strong emotional experiences for members. As therapeutic groups develop over time, members become closely connected to each other emotionally, developing bonds of friendship that are as strong as any they experience in nontherapeutic relationships. Members also report a strong level of identification with the group, with the result that they are more willing to accept the group's influence.

The range of emotions experienced depends on the group's stage of development. Early in the group interactions tend to be superficial, but in time conflicts tend to surface. In most groups, these conflicts between members and the group therapist give way to the development of cohesion. This progression of emotional experience, although characterized in a variety of ways, generally follows the forming, storming, norming, performing, and adjourning pattern identified by Tuckman (Tuckman and Jensen 1977). During the forming stage members are uncertain how to behave, and do not trust one another enough to disclose personal information or to admit they need help. During the storming stage group members often find themselves in conflict over the purpose of the group, and they may withdraw from the group and the therapist. In groups where the leader takes a non-directive orientation, this conflict stage focuses on the leader's failure to 'take charge' of the interactions.

During the next phase, norming, the group becomes more cohesive, as norms and standards emerge that dictate how each session will unfold. This stage makes the performing stage possible, where group members engage earnestly in the exchange of information that will help them achieve their therapeutic goals. In time, members must deal with issues of termination as the group adjourns. This movement from one stage to another is therapeutic, so much so that a group that does not move through these stages may not benefit its members (Yalom 1995).

2.4 Self Processes in Therapeutic Groups

All group psychotherapies stress the value of groups as vehicles of self-understanding and self-efficacy. Although group members may initially be reluctant to disclose any information about themselves in the relatively public group setting, as they develop stronger bonds of trust their disclosures change from superficial to substantial. Group members also report feeling gains in self-efficacy as they help others in their group with their problems.

Members particularly value the self-insights they achieve in groups. In interpersonal therapy, in particular, patients often act in the therapeutic group as they do in other social contexts, so much so that the behaviors that caused them interpersonal difficulties erode their relationships within the group. When their fellow group members and therapist call their attention to the parallel, patients experience greater insights into their own motives and emotions. In many cases, as Freud's analysis of groups suggests, these tendencies can be traced to early childhood experiences in the family of socialization.

3. The Effectiveness of Group Psychotherapy

When they were initially proposed, skeptics questioned the wisdom of putting people who are suffering from psychological problems together in one group. How, they asked, could troubled individuals be expected to cope in a group when they had failed individually? And how could the therapist guide the therapeutic process in a group, given the subtle nuances that pervade one-to-one therapies? In time, however, the method gained widespread acceptance as therapists added group sessions, either supplementing or completely replacing their individual sessions.

But do members leave the group better adjusted than when they entered? Meltzoff and Kornreich (1970) were guardedly optimistic about the utility of group therapies because 80 percent of the methodologically sound studies reported either major or minor benefits for clients, whereas nearly all of the studies that reported no benefit were methodologically flawed. Bednar and Kaul (1994) were guardedly

positive, although they questioned the quality of the outcome research in group psychotherapy. Meta-analytic reviews also suggest that group approaches are as effective as individual methods (e.g., Fuhrman and Burlingame 1994). Fuhrman and Burlingame (1994), for example, reviewed 700 group therapy studies and seven meta-analytic studies before concluding that group methods are effective treatments for a wide variety of psychological problems. Similarly, Faith et al. (1995), in a meta-analytic review of 63 studies of sensitivity training, concluded that these groups generally led to increases in self-actualization and self-esteem and improved interpersonal relations. They noted that these effects increased in larger groups, when the groups met for longer periods of time, and when the measures focused on behavioral outcomes rather than self-reported ones. McRoberts et al. (1998) found that group therapies were more effective with clients (a) who were not diagnosed clinically, (b) suffering from substance abuse problems and/or chemical dependencies, and (c) who attended 10 or fewer sessions. Older studies—those conducted prior to 1980—were more likely to favor group over individual approaches.

This positive conclusion, however, requires some qualification. First, the empirical evidence is not definitive. Whereas a number of reviews are positive, others conclude that group therapy is not as potent as individual therapy. Second, the changes brought about by group experiences may be more perceptual than behavioral. Group members frequently report achieving major insights into their behavior and are positive about the gains they have achieved, but objective indices of outcome are more contradictory. Self-reported insight is also related to actual improvements in adjustment. Third, as Bednar and Kaul (1994) note, a participant may decide to leave the group before they have benefited in any way, and in rare cases patients are significantly harmed by the group experience. Last, far more data of better quality are needed to settle the question of efficacy. As Forsyth and Corazzini (2000, p. 325) conclude, the 'use of varied and undocumented therapeutic methods, with different types of clients, by therapists who differ in skills and experiences, in studies that too frequently lack valid measures and adequate controls, make it difficult to draw firm conclusions.'

Group psychotherapy's empirically supported usefulness is reason enough for its continued growth, but the approach will also prosper as health maintenance organizations require, and patients increasingly seek, group-level treatment methods. Group psychotherapy is an efficient therapy, for a single therapist can treat more than one individual at a time—a characteristic that is considered very valuable in healthcare systems that seek to minimize costs without cutting quality. But group approaches may also become more popular as clients seek out supportive, stimulating environments for achieving personal change. Indeed, the

increasing popularity of self-help groups signals the need for treatments that take advantage of groups for promoting adjustment. Although the use of groups in business and educational settings was once considered innovative, individuals now expect to learn and work in group contexts. These experiences, combined with a growing collectivism in cultures that were once primarily individualistic, should heighten awareness of groups as a means of treatment.

Groups in Special Environments

1. Introduction

‘Special’ environments include those that require extraordinary facilities for human survival, as well as those that temporarily pose dangers because of disaster, accident, or violent conflict. Also known as ‘extreme and unusual environments’ (EUEs), they have always engaged high public interest. Since the 1950s, social scientists have begun the systematic study of how people react in and are affected by experiences in hazardous habitats. These include life-support capsules (under water, in space, near the Poles, on offshore oilrigs), natural and industrial cataclysms, combat zones, refugee and concentration camps.

To date, most of the research emphasis has been on the ways in which people react to their experience (Wilson et al. 1988), on methods for preventing, minimizing, or treating negative outcomes (Holland and Curtis 1998), and on how individuals are selected and trained for some special environments, such as space and submarine missions (e.g., Santy 1994). Methods used in these efforts have included some experiments; but the emphasis has been on simulation and analogue studies, questionnaires, interviews, and the content analysis of archival materials.

Although researchers have focused on the individual, the behavior of human beings in special environments is to a great extent the story of groups. Solitary individuals have found themselves in such situations, sometimes by accident (shipwrecked mariners, sole survivors of other disasters) and sometimes on purpose (aboriginal youths on spirit quests, solo mountaineers, hermits, single-handed sailors, early astronauts, and adventurers of various sorts); but the modal inhabitants of EUEs are not alone.

Many aspects of the environment itself strongly influence group relations and behavior. Some of these are: the dangers involved, life-support equipment, duration of the stay, deviation from accustomed physical parameters (temperature, humidity, air quality and pressure, gravity, noise, crowding, comfort, the availability of food and water, and shelter), remoteness from home, the possibility of communication with one’s family and the parent organization, medical care, and rescue if needed. Whether the group is caught up in an extreme environment unwillingly, by accident or superior force, or has volunteered, and its motives for volunteering (excitement, prestige, patriotism, curiosity, money, altruism) are also significant. Last, it is useful to distinguish between organized

groups (teams, crews, units) and random conglomerations of individuals who happen to be thrown together in an unusual environment.

Many issues apply only to a subset of EUE situations; for example, polar, space, undersea, and similar missions require a relatively small group to be chosen from a larger number of applicants. This is obviously less true of the recruitment of combat soldiers, and not at all of groups caught up in accident or disaster. Nevertheless, there are concerns that are common to many kinds of groups, in a range of extreme environments. It is these general aspects of group functioning in EUEs that will be covered in the subsequent examination of the existing literature.

2. Cohesiveness

One striking pattern is the deep interpersonal bonding that many groups experience, existing alongside other groups' very high levels of friction and hostility. In extreme situations, self-sacrifice is not unusual, from Captain Lawrence Oates of Scott's South Pole team who, when supplies were running too low to sustain the whole group, left their shelter and went off to certain death in a blizzard to the real-life hero of the World War II ballad, Rodger Young, who 'fought and died for the men he marched among.' Studies of combat soldiers show that their primary motivation for risking their own safety is identification with their leader and unit, and comradeship with their fellows. Soldiers who have not developed such ties—for example, recent replacements—are much more likely to fail the test of battle (Manning 1991). Even in less organized groups, such as civilians in cities undergoing aerial bombardment or a natural disaster, high levels of mutual helpfulness and feelings of solidarity are commonplace.

In capsule EUEs, being confined in a small space with the same people for a long time, under conditions of danger, discomfort, fatigue, lack of privacy, and other stressors, is a potential source of hostility. Admiral Byrd (1938), among others, reflected on the time when a colleague's 'pet ideas become a meaningless drool, and the way he blows out a pressure lamp or drops his boots on the floor or eats his food becomes a rasping annoyance.' Intimate disclosures, encouraged earlier by loneliness, proximity, and boredom, in retrospect seem embarrassing and regrettable. Violations of personal space or possessions seem contemptuous provocations, irritating habits are perceived as deliberate affronts, and minor disagreements can become infuriating. The results range from vehement arguments through ostracism and physical attacks, to murderous assaults (Suedfeld and Steel 2000).

One of the most pervasive findings in isolated groups is that of dislike and disrespect between subgroups, such as polar scientists and support personnel or people from different cultural or national backgrounds

(Kanas 1998). This is a growing problem, as many projects involving EUEs are becoming international and/or multicultural.

3. Workload

One important aspect of EUE groups is that they are often overworked as well as stressed. In many extreme environments, living and working space is limited, facilities are functional and Spartan, and duties are both important and demanding. Survival as well as mission success may depend on everyone's performance, so that there are superordinate goals—important to all, and unreachable without total effort and cooperation. Social loafing or shirking is, while certainly not unknown, relatively rare and easily detected. In fact, studies have shown that members of submarine, space, and polar crews spend much of their supposed recreational or resting time working, sometimes leading to severe fatigue. In other situations, such as disaster rescue and combat, exhaustion may be the result of extreme physical exertion and danger. Insomnia, which is endemic in many EUEs, exacerbates the problem, as do physical discomforts including noise and duties that interrupt sleep (Stuster 1996).

Even the most dedicated crews may come to resent the demands made on them by the situation or by the organization to which they belong. There have been minirebellions or simple refusals to comply with work schedules by groups in both the American and Soviet space programs, as well as in many other EUE settings (Harrison et al. 1991). Typically, these have been brief and moderate, consisting of a self-declared and temporary 'time out,' although in some more extreme cases in wartime and extended sailing voyages they became full-blown mutinies.

4. Boredom

There is a quite opposite situation as well: in many special environments, there may be long stretches of unstructured time when there is little if any important work to be done. This has been true of groups of prisoners of war, ships' crews on multiyear voyages or frozen into the polar ice, personnel in remote stations, civilians in air raid shelters and refugee camps, troops between active duty deployments, resource extraction workers waiting for equipment repairs, resupplies, or further exploration, emergency workers (firefighters, paramedics) between calls, and so on. Spacefarers spending a year or more en route to their destination and then again on the way back will experience this (in contrast to astronauts in short-term, overprogrammed missions such as those of the Space Shuttle) (Stuster 1996).

Under physical and social monotony, free time becomes a time of boredom, lassitude, and apathy.

The desire to explore and manipulate—play with—elements of the environment becomes important. The group may manufacture artificial challenges, sometimes taking unnecessary risks either unthinkingly or deliberately. As individuals lose interest and motivation, they may neglect personal hygiene and withdraw from the group. As a result, and because hostile exchanges at least break the monotony, interpersonal arguments and conflict may intensify.

Alert leaders of organized groups make sure that no one has too much free time: initiating systematic recreational activities, getting people to put in extra work on cleaning and maintenance, and introducing novel work assignments such as cross-training crew members. In Arctic whaling and exploring ships of the eighteenth and nineteenth centuries, sailors and officers put on elaborate theatrical and musical performances, making their own scenery and costumes; competed in athletic events; and published shipboard 'newspapers' filled mostly with stories and poetry, since there was very little real news (Johnson and Suedfeld 1996). In the ghettos of Nazi-dominated Europe, Jewish authorities arranged elaborate cultural, scientific, religious, and educational programs. Even in lifeboats drifting after shipwreck, officers have organized duty watches, group sing-songs, story-telling, and the like. In all of these environments, such strategies help to maintain morale, ensure that necessary work gets done, and divert group members from their danger, deprivation, and fear.

5. Group Culture

Group culture represents an identity, made up of the characteristics of the members and what emerges from their interactions, which identifies the in-group as distinct from all others. This phenomenon is particularly marked in EUE groups: nicknames, jargon, practical jokes, initiation rites, and so on, weld the group together and simultaneously express and improve its morale. So do adornments such as bizarre hair-styles or beards, and special symbols such as badges, patches, pins, special articles of clothing, and other unique identifiers.

This pattern of values, activities, norms, jokes, and general lifestyle characteristics becomes particularly meaningful to isolated groups and frequently incomprehensible to outsiders. Such groups have an awareness of shared hardships and triumphs, and feel removed from the outside. As an example, a group of aquanauts living in an undersea environment came to refer to the rest of humanity as 'Earth people' (Radloff and Helmreich 1968), and of course the designation 'the world' is widely used among polar personnel and foreign-service soldiers when referring to home. The use of in-group jargon is also a way to deliberately stigmatize newcomers and outsiders (Taylor 1987).

Rituals, special foods, and the celebration of major

occasions are important aspects of group culture. For centuries, these have been used to strengthen a feeling of solidarity and continuity, and to exercise everyone's ingenuity, have fun, and reduce boredom and they continue to do so in the Space Age.

6. Leadership

Leaders of EUE groups have a role that is in many ways more crucial to the group's success than those normally encountered in most modern organizations. They may be cut off from the parent organization, so that they can not receive advice or instructions from their superiors; even when communication is possible, it may be long delayed. In any case, because of the unique circumstances, supervisors or consultants 'back home' may not fully understand all of the relevant factors—or the group may think that they do not, and therefore may be reluctant to follow instructions or advice (Connors et al. 1985). In such cases, the leader on the spot must decide how to handle the uncertainty and conflict.

The leader's formal rank confers the power of reward and punishment; but the impact of these can be attenuated in long-duration remote work, where any material reinforcers may be trivial or far in the future, and in extremely dangerous environments where any 'punishment' may in fact increase the transgressor's safety (e.g., a court-martial that would involve a transfer to the rear echelon). Even worse, the leader may come to be seen as dictatorial, petty, and unfair, with consequences that can range from the unpleasant to the disastrous. The best EUE leaders are those who use formal authority sparingly but are admired, perceived as holding authority legitimately, seen as a role model to be emulated, and believed to be expert in solving the problems that the group faces (Stuster 1996).

Good interpersonal relations are made even more important by the fact that in EUEs the trappings that normally keep leaders remote and aloof—secretaries and aides, imposing offices, separate facilities, and so on—are drastically attenuated (Kanas 1998). Social leveling occurs even in traditionally hierarchical groups, such as military units. The leader is revealed as having human foibles and faults. If the crew dislikes or disrespects the leader, it has many opportunities to express its feelings. Conflict between the leader and a key subordinate or a clique of group members, is common under stress and requires wise strategies balancing tact and forcefulness. Excessive consciousness of rank differences may also lead to disaster for the group: social psychologists have identified a number of airline crashes that could have been avoided if a crew member who noticed that something was wrong had dared to assertively interrupt the captain while the latter was paying attention to something else (Helmreich 1984).

How the leader should function varies with the circumstances. EUE groups have indicated that on matters of a technical nature, like navigation or equipment repair, the leader is expected to make decisions in consultation with the relevant technical experts; on issues of routine policy, like work assignments and recreational schedules, the leader should consult with the entire group in an open way, even if the group's preferences are not followed exactly; and in emergencies, the leader's clear, unhesitating, and unilateral decision is appreciated even by those who otherwise resent direction (Stuster 1996, Suedfeld and Steel 2000).

The difficulties related to EUEs are especially severe for the leader: resolving other people's environmentally caused stresses while one is experiencing the same ones is a true challenge to leadership. One development that arises only too frequently is the leader's becoming a source of stress for the rest of the group. In an EUE, attributes that can be tolerated in a normal environment become unbearable. Some leaders are too unstable, demanding, threatening, perfectionistic, or inconsiderate—traits that may be part of their personality, or that emerge because they too are under stress. These traits lead to decreased leader influence, and to increased resistance on the part of other group members. In long-duration special environments, it is probably not a good idea to rely too much on a crew's ability to tolerate the commander (Kanas 1998).

7. Sex and Gender Issues

The presence of growing numbers of women in formerly all-male EUEs has affected morale and performance, and raises some interesting issues. Almost all Western military forces, national Antarctic programs, and space programs have by now included female members and some leaders. These developments have changed group dynamics, in as yet undetermined ways. If a recent all-female Antarctic traverse expedition is typical, a shift toward more emphasis on group cooperation and solidarity may be occurring, perhaps with some decrease in goal orientation, and it certainly seems that women in mostly male groups both provide and are offered more interpersonal support and nurturance than has been usual (Rothblum et al. 1998).

There is a lively controversy among military and polar officials as to whether sexual integration has resulted in additional or reduced sexual tension, and as to just how pair relationships affect the participants and the rest of the group. Some people are less sexually frustrated, but others are not; resentment, jealousy, and envy have surfaced. In at least one Antarctic case, there was a serious drop in station morale when the cook's romantic partner abandoned him and began a relationship with someone else, and meals became unappetizing. One can only speculate what would

happen on a long-duration EUE mission (or in an emergency) if, for example, the group leader were involved in this kind of triangle (Suedfeld and Steel 2000).

8. Selection and Training

This topic applies to only a subset of special environments, but is important in those. There are two phases of selection: selecting out (eliminating applicants below the threshold) and selecting in (picking the best possible crews). The former is done on an individual basis, using biodata, interviews, and tests; in the second stage, both individual and group selection become relevant. The interaction and performance of potential crewmates are observed in analogue or simulation situations (field and laboratory settings respectively, both incorporating some aspects similar to the eventual EUE). For example, candidates may go through a wilderness survival course or (in the ex-Soviet space program) undertake a long cross-country journey in a small automobile. Many programs choose and train crews as a unit; if for some reason one member must be struck from a mission, the entire crew is replaced (Santy 1994).

9. Future Directions

The number of people exposed to EUEs, fortuitously or deliberately, is not likely to diminish in the near future; and as the sheer technical and physical difficulties are solved, more attention will be paid to psychosocial issues. An emphasis on understanding group reactions, not only individual ones, is emerging. As the connections between EUEs and 'general' social science areas become clearer, research will become less atheoretical and applied; EUEs provide unique opportunities for both gathering new knowledge and having an impact on serious real-life problems, which may tempt more social scientists into the field (both literally and metaphorically).

P. Suedfeld

Groups, Sociology of

A group is a bounded collection of interacting individuals or a consensual social categorization. It is difficult to distinguish sociological and psychological studies of groups and, in the past, there has been a

considerable overlap. Still, one feature may help to make a reasonably accurate distinction. The sociological study of groups always involves attention to collective phenomena in addition to the concept of the group itself. The psychological study of groups sometimes does, but often does not, involve attention to these phenomena. In the work of sociologists, processes of interaction and of individual behavior in social contexts are seen as giving rise to durable or semidurable collective phenomena (such as cohesion; relational structures pertaining to status, communication, friendship, power, control; structural similarity; distribution of information; collective goods provision; social norms; collective representations; styles of conflict resolution; patterns of group decision-making).

These small-scale collective phenomena, in turn, influence the behavior of individuals and their interactions (see Fig. 1). Some sociological work concentrates on relation 1, some on relation 2, and some on 1 and 2, and other combinations. Relation 3b allows explicit feedback mechanisms involving both levels (as in expectation states theory, see below). Psychological studies often focus on the direct influence of interaction (or the presence of others) on attitude change, productivity, satisfaction, self-esteem, depression, etc., occasionally allowing for feedback mechanisms (3a and 3b). The extra arrows in Fig. 1(i) indicate exogeneous factors (such as genetic dispositions, rules, established categories, status differences).

1. Historical Background of Small Group Research

The scientifically serious investigation of groups in the sociological tradition started with anthropological studies of tribes, clans, and families in the nineteenth and early twentieth centuries. Sumner, Simmel, and Cooley were early codifiers of that kind of research. The most important turn in this development occurred

Figure 1
Schematic depiction of the explanation of groups

in the 1930s. Within the span of a few years, four great books appeared which had two very important messages in common: that groups are constituted by a cognitively mediated functional interdependence between individuals, i.e., people who are dependent on each other for achieving a goal interact, and something important happens to their minds and the way their minds operate when they interact. In addition, the actual situation in which their action is placed matters most for behavior (as opposed to traits or other cross-situational constants). In 1934 Mead's (then already posthumous) *Mind, Self and Society* appeared. Two years later, Lewin's *Principles of Topological Psychology* and Sherif's *The Psychology of Social Norms* came out. A year later, Parsons' *The Structure of Social Action* made its appearance. Merton's early work on reference groups was also quite influential.

From this time, group studies continued in two traditions—experimental and field studies—and both traditions bore the mark of this convergent conception of groups. Under the leadership of Lewin and Sherif, 'group dynamics' as the experimental study of groups was then called, achieved great heights. Field studies had Mayo's Hawthorne studies and Whyte's famous *Street Corner Society* as models. Both traditions owe their success to the simultaneous consideration of the three fundamental interdependencies in groups: *functional* (related to goal achievement), *cognitive* (related to common categorizations, beliefs, and knowledge) and *structural* (related to the configurations of social relations) (see Lindenberg 1997 for more detail on this and other aspects of this article).

However, the precise nature of the interdependencies was not yet well investigated and in the late 1950s and early 1960s, specialized groups of studies on each of these interdependencies became dominant, with interesting crossovers between psychology and sociology. Homans (1950, 1958), a sociologist, combined the field and the experimental traditions in the study of functional interdependencies in exchange relations. Inspired by Homans, two psychologists, Thibaut and Kelley (1959), worked out the study of small groups as the study of functional interdependencies. Their book is to this day one of the best on the subject. It influenced Homans' further work on the subject (Homans 1961). Cognitive interdependencies were elaborated by Sherif and turned into a major strand of group research called 'social identity theory' by Tajfel (1982) and Turner (1982), both psychologists but very influential among sociologists and in turn influenced by sociological symbolic interactionism. In a related development, Moscovici, a psychologist, elaborated Durkheim's theory of collective representations (see Flick 1998). Structural interdependencies were more formally elaborated by the psychologist Cartwright and the mathematician Harary and turned into a full-blown network approach by sociologist White and his followers (see White et al. 1976).

2. Bringing Different Kinds of Interdependencies Back Together Again

This section deals briefly with the field study approach and in some more detail with experimental studies. No attempt is made to be complete. Rather, the overview is selective. The selection criteria are first, that the studies should be substantively important. Second, they must mainly focus on group processes comprising small groups (i.e. face-to-face interaction with at least one common goal), small networks, and face-to-face encounters. Third, the studies must be seriously concerned with the integration of at least two of the three fundamental interdependencies. Fourth, they must cluster around a program of investigation with some continuity.

With regard to field studies, work inspired by Goffman was chosen. Goffman's studies provided a new integration for field studies in sociology (excluding Mayo-type studies). With regard to experimental (and simulation) studies, expectation states theories, various groupings of social exchange theories, and studies of friendship and cognitive networks were selected. Studies of social dilemmas are covered elsewhere (see *Cooperation: Sociological Aspects*). Helpful discussions of a broader scope can be found in Cook et al. (1995) and Foschi and Lawler (1994). Due to space restrictions, the reader will at times be referred to bibliographies and collections rather than individual works.

2.1 Fieldwork Studies

From the beginning of the 1960s, fieldwork studies on face-to-face groups have received their main theoretical guidance from Goffman (1961). He also put short-lived groups, or 'encounters', on the map. There is a relatively small but very productive circle of contributors to this kind of research (a few important examples are Anderson 1978, Cahill and Lofland 1994, Fine 1987, MacLeod 1995). These studies are concerned with conformity, status, group divisions, identities, and their combination in impression management. They are rich in descriptive detail. Aspects of functional and cognitive interdependencies are clearly present in Goffman's work.

2.2 Experimental Studies

2.2.1 Expectation states theories. Generic expectation states theory is concerned with the formation and maintenance of power and prestige structures in face-to-face task groups (see literature in Berger and Zelditch 1993). Following the tradition of Bales in the 1950s, power and prestige are conflated and their structure is conceived in terms of behavioral aspects

(opportunities and influence) rather than the distribution of scarce resources. People are higher on the power and prestige structure, the more opportunities to act they receive, the more often they take advantage of these opportunities, and the more often they win disagreements if and when they occur.

The basic mechanism that creates this structure is pairwise interaction (between, say, Ego and Alter) that is governed by performance expectations. It is the (unobservable) structure of these performance expectations which keeps generating the observable power and prestige structure. When Ego has positive performance expectations towards Alter, he or she will give more action opportunities to Alter and Alter will more likely take up each opportunity offered. Alter has influence over Ego. It is assumed that there is an evaluation bias. Ego is more likely to judge Alter's performance to be positive if the performance expectation was positive and vice versa. And if Ego nonetheless voices disagreement, he or she is more likely to eventually yield to Alter if the performance expectation was positive to begin with. Such evaluation biases greatly enhance the stability of the power and prestige structure (provided the task endures).

The theory is meant to apply to task groups. For this reason, functional interdependence is by definition the starting point. Here, a joint task and face-to-face interaction is what makes a collection of individuals into a group. Each group member's contribution influences a group score (mostly outcome interdependence, say, linking bonus to agreement in answers). There are also cognitive aspects. For the theory to apply, group task achievement must be a salient goal in the interaction with other members ('collective orientation'). The central cognitive element in the theory is a performance expectation. It presupposes other cognitive elements, such as goal criteria and causal beliefs about how likely a particular characteristic or behavior is to lead to success or to failure. Cognitive interdependence comes about when the performance expectations (and, prior to that, the goal criteria and causal beliefs) are being shared. Given the evaluation bias, the interdependence means that performance expectations of different group members interlock (see Moore 1985).

Functional and cognitive interdependencies are closely interlinked in this theory. This link is made even stronger through extensions of the theory to include external status characteristics (see Berger and Zelditch 1993) and the generation of status characteristics from nominal distinctions (see Webster and Hysom 1998). Task groups are embedded in a wider culture in which such status and competence beliefs exist (such as 'men are better at mathematics'). People seem to follow the maxim 'when in doubt, assume that a salient characteristic is task-relevant' (the so-called 'burden of proof principle'). With regard to gender, this favors men in general tasks as well as in 'masculine' tasks, and it favors women only in stereotypically

'feminine' tasks. Through the link of performance expectations with worthiness, there is also a link of expectation structures to conceptions of just rewards, which is worked out in the 'status value theory' of distributive justice (see Berger and Zelditch 1993).

Ridgeway has shown that, in turn, such cultural beliefs can be explained by the diffusion of *status-belief-generating mechanisms* in small groups. When interaction partners in task groups are doubly dissimilar in that they differ in valuable resources (say high pay level) and in a salient nominal distinction (such as race or gender), then a process of misattribution will causally link having the valuable resource with the nominal distinction and eventually with assumptions of competence, worthiness, and esteem. The group consensus on this attribution generalizes to the idea that 'most people' believe it to be so (Ridgeway et al. 1998). Group members are likely to transfer such beliefs to other group contexts, thereby spreading and reinforcing them across groups and turning them into cultural status beliefs. Similar mechanisms are now invoked to explain legitimation and delegitimation of power and prestige structures in groups (see Berger et al. 1998).

2.2.2 Theories of exchange in networks. Theories of social exchange by Blau (1964), Homans (1950), and Thibaut and Kelley (1959) have given rise to a number of theories on the influence of social structure on the distribution of exchange ratios or benefits within groups. The results of these theories are also relevant to the explanation of network effects on power advantages on a macro level (see, e.g., Burt 1992). Paradigmatic for these theories is Emerson's (1976) concept of 'network connection,' which points to externalities between exchange relations. Two exchange relations are connected if and only if the exchange in one relation affects the exchange in the other (in terms of frequency and value). Thus, in an exchange network, the specific distribution of ties can have a strong impact on the distribution of benefits, but this influence depends on the nature of the network connections. For example, if there is a rule that one may exchange only with one other partner then the network is negatively connected. Division of labor creates positively connected networks in which exchange with one stimulates exchange with the other(s). Negative connections are easiest to trace both theoretically and empirically, and thus the bulk of research in this area is on negatively connected networks (an important exception is Burke (1997), who has developed an interesting link between network exchange and identities).

One prominent version of such a theory is *exchange network theory* (Cook and Yamagishi 1992). The distribution of benefits (or rates of exchange) within a network is explained on the basis of power ('power/dependence'). In positively connected networks, the power process is determined by brokerage, i.e., by the

ability to connect resources of various actors, and by the value of the focal resource to the actors. In a negatively connected network, power is based on the value and degree of availability of a focal resource from alternative sources. The more value Ego gets from an exchange with Alter compared to the best available exchange alternative, the more dependent Ego is on Alter and the more power Alter has over Ego. With repeated exchange in such negatively connected networks, the exchange ratio is predicted to shift toward the point at which neither of them could improve his or her outcome by exchange with another partner. Power advantages are thus structurally induced, given the 'connectedness' of the network.

A variant of this theory for coercive power has been elaborated by Molm (1997). Interestingly, Molm predicts and finds that power based on the ability to inflict damage on others is not structurally but strategically induced in order to extract rewards from the other. This opens exchange theory to a more explicit consideration of rational strategies, especially with regard to the balance between incentive to coerce and fear of retaliation. Lawler's work is also relevant to this topic (see, e.g., Lawler 1992a).

Elementary theory (ET, sometimes also called 'network exchange theory') is also rooted in the Homans/Emerson tradition and it also explains exchange ratios on the basis of structurally induced power (see Berger and Zelditch 1993, pp. 323). The major difference with exchange network theory is twofold. First, in reference to Weber, ET considers resistance to the exercise of power more explicitly than exchange network theory. Second, ET uses experiments in which the degree of 'exclusion' (i.e., the degree of negative connectiveness) varies. This second possibility gives it more flexibility to approximate various real life phenomena. However, the way resistance and the representation of exchange are worked out imposes strong restrictions, which reduces real life application to some degree (see Van Assen 2001). More recently, interesting links of ET with expectation states theory (Willer et al. 1997) and with game theory (see Willer and Skvoretz 1997) have been developed.

An additional grouping of theories on exchange should be mentioned. It is also related to the Homans/Emerson tradition but uses different elaborations. There have been long-standing efforts to explain structural network effects on power and exchange rates by means of game theory (especially using the concept of the 'core') by Bonacich and co-workers (see, e.g., Bonacich 1998). See Friedkin (1995) for yet a different model and Fararo and Skvoretz (see Berger and Zelditch 1993, pp. 416) for a comparison of various models. There is also a productive development of models that use exchange in networks for the explanation of power processes in collective decision making, mostly in small groups (see Stokman et al. 2000). Because these models are not tied to a particular experimental paradigm, they are more open

to the consideration of other exchange models and strategies (such as Coleman's model; see Coleman 1990) and to an explicit consideration of strategies of persuasion and challenges that accompany exchange strategies.

2.2.3 Friendship and cognitive networks. In recent years, dynamic friendship networks have received an increasing amount of attention. A new line of research has opened up by taking relatively simple behavioral assumptions and tracing their structure-generating consequences through simulation and, at times, also empirical research. What is new is that the interdependence of simultaneous friendship choices is modeled. If choices go on simultaneously in a group of strangers, what structure will emerge from the interdependence of choices under various choice preferences and constraints? How does 'group' size affect the resulting structure(s)? How does heterogeneity of the choosing individuals affect the resulting structure(s)? Preferences have been made more complex by stepwise adding status preferences to similarity preferences, and by explicitly introducing friendship dissolution to friendship formation. As to influence, friends do not just have a preference for similarity, they also become more similar. Paradigmatic for this kind of work is Stokman and Zeggelink (1996) and work presented in Doreian and Stokman (1997). See Van der Bunt (1999) for empirical research. Work linking this kind of dynamic approach to issues of cooperation is exemplified by Flache and Macy (1996) and Flache and Hegselmann (1999).

Networks are also cognitively represented which, in turn, contributes to the generation of joint cognitive and social structures. Research dealing with these aspects of networks link explicitly cognitive and structural interdependencies (see Carley 1986, Freeman 1994, Krackhardt 1987, Pattison 1994). Related research deals with the effects of cognitive interdependencies on learning, search, and general problem-solving strategies in groups and organizations (see Carley 1995, Edmonds and Dautenhahn 1999). Here functional interdependencies in terms of joint production are added explicitly (see also Troyer and Silver 1999). In the future, one can expect innovative impulses from these lines of research for sociological group research in general.

3. Evaluation

Sociological research on groups is lively, productive and, in the experimental fields, also cumulative. There is also a slow tendency to open up across the narrow borders of the research paradigms. However, there are a number of important shortcomings (see Lindenberg 1997 for more detail and for suggestions for new directions). First, field and experimental studies generally ignore each other. This is not a

desirable state. Crossovers in the past have been very productive and should be encouraged. Second, the experimental paradigms carry such a strong weight that they hamper new theory formation. For example, in expectation states theories, the functional interdependence is experimentally restricted to outcome interdependence with regard to agreement. There is little or no task interdependence. In the exchange theories, exchanges are often limited to divisions of resource pools. Such exchanges lack many of the properties of the exchange of goods, information, and emotions. On the whole, there is little attention to the effects of joint production on expectations and exchange.

Third, functional interdependencies should have analytical primacy. This primacy derives from the fact that cognitive processes are strongly influenced by goals (see Gollwitzer and Moskowitz 1996) and structural effects only occur in interaction with goals (externalities) as has been seen in exchange network theory. Yet, in most exchange theories this primacy is lacking. Fourth, present research rarely includes 'groupishness' (i.e., categorization and framing effects) in its consideration of cognitive interdependencies (see Lawler 1992b as an exception). For example, in expectation states theory, 'collective orientation' is introduced as a scope condition, not as a variable. Related to this point is, fifth, that the distinction between small groups and small networks is non-existent or ad hoc. There is little or no theory on the influence of groups on networks or vice versa, or on networks nested in groups. Sixth, the study of inter-group relations for the explanation of what goes on inside the group needs much more attention. A positive example of what is needed is Coleman's classic study of the influence of interscholastic athletic competition on the local status structure in schools (see Coleman 1961).

Growth Curve Analysis

The phrase 'growth curve analysis' denotes the processes of describing, testing hypotheses and making scientific inferences about the growth and change patterns in a wide range of time-related phenomena. The term 'growth curve' was used originally to describe a graphic display of physical stature (e.g., the height or weight) of an individual over consecutive ages. In contrast to some longitudinal data, growth curves have unique features: (a) the same entities are repeatedly observed, (b) the same procedures of measurement and scaling of observations are used,

and (c) the timing of the observations is known. Formal models for the analysis of growth curves were developed in many different substantive domains with a common goal—to examine and uncover a fundamental set of regularity conditions or 'basic functions' responsible for the manifest growth and change. Techniques for the analysis of growth curves were initiated in the physical sciences, more fully developed in the biological sciences, and then used in studies of the size and health of plants, animals, and humans. In the behavioral sciences, growth curve analyses have been applied routinely to a wide range of phenomena—from experimental learning curves, to the growth and decline of intellectual abilities and academic achievements, and to changes in other psychological traits over the life span.

Growth curve analyses are among the most widely studied and well-developed mathematical and statistical techniques in all scientific research. These analyses have roots in the seventeenth- and eighteenth-century calculus of Newton and probability of Pascal, but this article is limited to more recent historical developments and other related techniques, such as time-series and dynamical systems analyses are not covered.

1. Growth Curve Data Collections

The first reported growth curve data were collected by the French Count de Montbeillard between 1759 and 1777. These data consist of semi-annual measurements on the growth of the height of his son over nearly 18

Figure 1

The initial 'growth curves' of human height data from Scammon (1927, p. 334). Note: The vertical (y) axis represents the height in centimeters and the horizontal (x) axis represents the age in years from birth

Figure 2

Alternative 'velocity curves' of physical stature from Tanner (1960, p. 22). Note: the left-hand graph shows the change in height as a function of the change in time (y) versus the age in years (x), while the right-hand graph shows the same curves (y) plotted around the time of maximum change in scores (x) for each individual

years. The data were plotted by Scammon (1927) and are presented here in the upper curve of Fig. 1. As Scammon reported

it will be noted that the curve shows the typical four phases which most modern students have observed in the postnatal growth in stature of man, and which are characteristic of the growth of so many parts of the body (p. 331).

The first analysis of these data was by the naturalist Buffon in 1799 and

should be given full credit for the discovery of seasonal differences in growth a full hundred years before the modern investigation of this work (p. 334).

The lower growth curve in Fig. 1 is based on group averages obtained by Variot in 1908 and

it is interesting to note that, while the absolute values of the two series are quite different, the general form of the curve is essentially the same in both instances (p. 335).

These early growth curves were the precursor to an enormous collection of biological data on growth and change. A more recent illustration comes from the important work of Tanner and his colleagues (see Tanner 1960). In the individual plots of height in Fig. 2: (a) the 'velocity' or rate-of-change is plotted at each

Figure 3

The 'learning curve' of a cat from Thorndike (1911) as reported by Garrett (1951, p. 44). Note: the response time (y) required for a cat to escape from a closed box by pulling on a wire as a function of consecutive number of trials (x)

age and (b) these curves are plotted against their own 'highest peak velocity.' This display demonstrated two interesting features of physical growth: (a) persons

Figure 4

Growth curves of intellectual abilities in selected boys and girls from Bayley (1956, p. 67). Note: Age 16 D scores (y) plotted as a function of age at measurement (x) for (a) five boys and (b) five girls

who start growth at the earliest ages also grow the most but (b) all individuals share a remarkably similar shape in their 'adolescent growth spurt.' Extensions of these basic findings on physical growth systems and the contrast of chronological time vs. biological time, are still used in contemporary research.

Experimental psychologists have routinely collected different kinds of growth curves. Among the first here were the classical 'forgetting' curves collected by Ebbinghaus in the 1880s, whose work introduced the use of quantitative methods in the study of learning and memory and stimulated many experimental data collections. Included here are the 'curves of improvement' in studies on telegraphic language by Bryan and Harter in 1897. These principles were also used in the animal learning curve experiments of Thorndike in 1911, and one example of such data appears in Fig. 3. This plot illustrates an example of 'trial and error' learning: learning was objectively defined by decreasing response time and the lack of smooth function over trials was considered as error. Thorndike used these growth curves to illustrate several classical principles of learning, including the 'law of exercise' and the 'law of effect' (see Garrett 1951).

Differential psychologists have also contributed growth data in many different substantive areas. One good example of this tradition is given in the plots of Fig. 4 from work of Bayley (1956). Individual growth

curves of mental abilities from birth to age 25 are plotted for a selected set of boys and girls from the well-known Berkeley Growth Study. Because mental ability was not easily measured in exactly the same way at each age, these individual curves were created by adjusting the means and standard deviations of different mental ability tests (i.e., Stanford-Binet, Terman-Merrill) at different ages into a common metric. As Bayley says

they are not in 'absolute' units, but they do give a general picture of growth relative to the status of this group at 16 years ... These curves, too, are less regular than the height curves, but perhaps no less regular than the weight curves. One gets the impression both of differences in rates of maturing and of differences in inherent capacity (1956, p. 66).

This use of 'linked' measurement scales created a novel set of growth data and permitted the use of growth analyses initially derived in other scientific areas.

2. Linear Models for Growth Curve Analyses

The simplest growth models are based on the simplest mathematical functions. The fitting of a straight-line to a set of measurements, a standard procedure in scientific research, was an initial model used by

Wishart (1938) in a classic paper on growth analysis. These linear models were quite practical because the calculations used standard statistical assumptions (e.g., independence and normality of the residuals), standard forms of estimation (e.g., Gauss-Markov least squares, maximum likelihood), and standard statistical tests of goodness-of-fit (F-tests, chi-square tests, and likelihood ratio tests).

Another key idea was also introduced by Wishart (1938) when he showed how power polynomials could be used to fit the nonlinear curvatures apparent in growth data. The individual growth curve (consisting of $t = 1, T$ occasions) is summarized into a small set of linear orthogonal polynomial coefficients based on a power-series of time ($t, t^2, t^3, \dots, t^p$) describing the general nonlinear shape of the growth curve. A model of growth data might require a second-order (quadratic), third-order (cubic), or even higher-order polynomial model fitted to the data, but the basic shape of each individual curve could be captured with a small number of parameters.

The organization of individual differences is an important consideration in any contemporary growth model. In the linear model, each individual is assumed to be following a straight line over time, describable by an intercept term and a slope term. The average of these individual scores can be used to describe the overall growth curve for the group, and the individual differences can be considered in the context of other substantive questions, e.g., do the groups under observation differ in intercepts or slopes? In the more complex polynomial models, Wishart suggested a second stage of analysis where these polynomial coefficients describing each individual curve were considered as the underlying scores that co-vary among different individuals. In a quadratic polynomial, for example, a person's trajectory over time could be summarized using an individual intercept, linear slope, acceleration, and a residual term, and secondary questions could be addressed, e.g., do the groups under observation also differ in acceleration?

This 'curve-fitting' or 'two-stage' approach was relatively easy to implement using a standard statistical basis for hypothesis testing (e.g., Bock 1975). The simplicity of this approach allowed linear growth models to enjoy widespread use in behavioral studies and become a useful starting point for understanding individual differences in change (e.g., Rogosa and Willett 1985). The persistent critiques of this polynomial approach include some key issues:

- (a) the individual parameters can be difficult to estimate, especially for higher-order terms and incomplete data,
- (b) even high-order polynomials (i.e., $p > 4$) cannot capture 'seasonality' or 'phase-shifts,'
- (c) the substantive meaning of these individual parameters is often in doubt, and
- (d) the individual level parameters can be transformed (i.e., rotated) to yield alternative meaning.

These standard critiques are appropriate, and they still apply to many other contemporary forms of growth curve analyses.

More complex linear models have been used to represent growth. A linear model applied to different age segments but with connected critical 'knot points' permitted a 'conjoined' or linear or polynomial 'spline' model (e.g., Bryk and Raudenbush 1992). This kind of spline model is not often used, partly because it is atheoretical, and partly because it may require a relatively large number of parameters to achieve adequate fit. A more parsimonious organization of individual differences was proposed in the form of 'latent curves,' independently defined by both Rao and Tucker in 1958 (cited in Meredith and Tisak 1990). Principal components of the repeated observations were used to reorganize these data into the sum of a small number of unspecified linear functions are fitted to growth data, the shape of the latent curves is determined by the component loadings, and the individual curve parameters are the component scores. The summation of latent curves has roots in classical nineteenth-century work of Fourier as now widely used. In a recent innovation, Meredith and Tisak (1990) showed how these 'Tuckerized curve' models could be represented using confirmatory common factor analysis models, used to represent a wide range of alternative models (including most of the models discussed herein), and fitted using structural equation modeling techniques (also see McArdle 1988, McArdle and Bell 2000, McArdle and Woodcock 1997).

3. Nonlinear Models for Growth Curve Analysis

The linear models can be used to describe a variety of nonlinear shapes, but many growth curve models for specific substantive problems have included nonlinear functions of the parameters. For example, Ebbinghaus in 1880 described his forgetting curves using a form of the classic 'exponential growth' model. Here the rate of change is a linear function of the percentage of initial size (e.g., compound interest), and individual trajectories rise or fall in nonlinear fashion towards some asymptotic values. In contrast, the nineteenth-century Velhurst curve of population growth, an S-shaped 'logistic curve,' was used in the early twentieth century by Pearl for many forms of growth. At about the same time Peters advocated an 'ogival' curve of growth in ideational learning, Thurstone found that a hyperbolic curve of learning best to fit the norms of many different tests, and both Ettlinger and Valentine demonstrated direct relationships among these functions (see Seber and Wild 1989, Bock and Thissen 1980).

More complex nonlinear models have been used extensively. In about 1825 Gompertz described the growth curve in terms of two exponential accumulations of different rates towards different asymptotes.

This flexible model was studied in the first half of the twentieth century by Winsor, used by Medwar to study the growth of chicken hearts, and by Deming for human physical growth, and in studies of learning curves (see Browne and du Toit 1991). Another popular nonlinear model, introduced around 1938 by von Bertalanffy, suggested that an individual's change in weight was the direct result of the difference in the forces of anabolism and catabolism, with the exact relationship specified by known empirical properties. In subsequent work, Richards challenged the empirical basis of this model, and formally showed how many prior models can be seen as specific solutions of a 'family' of deterministic differential equations; specific restrictions led to the exponential, logistic, Gompertz, and von Bertalanffy equations. This work was more recently extended by Nelder and Sandland and MacGhilcrest (1979). (See also Seber and Wild 1989, Zeger and Harlow 1987.)

Attempts to fit a single growth model to observations over a wide range of ages with a minimal set of parameters led researchers to combine aspects of other models. Jenss and Bayley in 1937 proposed a simple composite where a linear part was used to fit the early rapid growth phase and this was added to an exponential part to fit negative acceleration of the later slowing-down phase. A more complex composite model, the sum of multiple logistic curves, was suggested by Robertson in 1908 and Burt in 1937 but only made practical and fully developed by Bock and his colleagues (see Bock and Thissen 1980). In each segment the rate of growth (a) increases early, (b) reaches a maximum (peak growth velocity), (c) decreases towards the asymptote, and (d) the final value of one segment is used as the starting value of the next segment. A novel composite model based on multiple logistic functions was developed by Preece and Baines in 1978 and here the model parameters were supposed to be linearly related to meaningful biological parameters. Simple versions of this new family of curves have proven useful in contemporary work (see Hauspie et al. 1991).

The mathematical elegance of these nonlinear formulations often make it seem that the parameters estimated are related directly to the underlying phenomena and there is a tendency to treat these estimates with direct substantive interpretation. Prior research has shown this to be a difficult goal and now it is known that all models permit alternative formulations that may fit equally well. Another important property of growth curves comes when the fixed parameters of the nonlinear curves, the 'parameters of the means' also represents the 'means of the parameters' of the individual curves. However, classical research by Merrill in 1931, Estes in 1957, Tucker in 1966, and Keats in 1983 has shown this form of 'dynamic consistency' does not always hold, even for some of the most popular growth models (e.g., a group exponential). Contemporary statistical models are

now constructed carefully to clarify the unique substantive interpretation of nonlinear parameters (see Browne and du Toit 1991, Bock and Thissen 1980).

4. *Multivariate Growth Curve Analyses*

The collection of multiple variables at each occasion of measurement leads naturally to questions about relationships among growth processes and multivariate growth models. In biological research, early efforts were directed at characterizing the parallel properties of different growth variables. Models were developed originally to deal with the size of two different organs, and early nineteenth-century work was used by Huxley to form a classical 'allometric' model where two variables have a constant ratio of growth rates throughout the growth period. Many physical processes were subsequently found to grow in parallel, or in an ordered time-sequence (e.g., Tanner 1960). This work led to more sophisticated models based on systems of differential equations for the size of multiple variables. In one comprehensive multivariate model, Turner in 1978 extended the simple growth principles to more variables and permitted an examination of biologically important interactions based on the size and sign of the estimated parameters (see Griffiths and Sandland 1984).

Multivariate research in the behavioral sciences has relied on advanced versions of the linear growth models formalized by Rao, and Pothoff and Roy (see Bock 1975). The structural models developed within this framework have added measurement models and this includes work on multivariate models of latent curves (McArdle 1988). These structural models have proven useful in testing hypotheses about parallel growth processes across time in multiple psychological variables. In recent examples, McArdle and Woodcock (1997) showed how latent growth of a single common factor of intellectual abilities is a poor representation of multiple abilities data and McArdle (2000) showed how a multivariate dynamic sequence could be fitted using standard structural equations. Current research in this area is focused on an improved understanding of the time-sequences and interactions among multiple behavioral and biological variables.

5. *Recent Issues in Growth Curve Analysis*

The prior developments in growth curve analysis represent an important but limited class of longitudinal data analyses (e.g., Nesselroade and Baltes 1979, Bock 1975, Pinheiro and Bates 2000). These developments have been distinguished by features of the models themselves: (a) the degree of mathematical specification, (b) the way these statistical models are fitted, and (c) the clarity and substantive meaning of

the results. In future work, most of these problems are likely to remain under active investigation.

Most contemporary growth curve models can be written in a common symbolic form (Seber and Wild 1989). A general model for a change in the scores over time (often using derivatives dy/dt or differences $\Delta y/\Delta t$) can be based on some mathematical functional form ($f\{x\}$) with unobserved scores ($x[t]$) and with unknown parameters ($\beta[t]$) to be estimated. Additional statistical forms not discussed here can be included, including autoregressive residual error structures, Markov chains, and Poisson processes. The growth functions described here are not an exhaustive listing and future extensions to more generalized functions, and to dynamic and chaotic forms are likely.

Recent research in statistical model fitting is important here too. It is now clear that growth curve models of arbitrary complexity can be fitted to the observed trajectory over time (i.e., the integral) and the unknown parameters can be estimated to minimize some statistical function (e.g., weighted least squares, maximum likelihood), and parameter estimates obtained using nonlinear programming. This generic statistical approach avoids some problems in older techniques, such as fitting a model to a log-scale or directly to the velocity or the analysis of difference score data (Fig. 2). These new techniques make it possible to address the critical problems of forecasting future observations, and further research on Bayesian estimation is the focus of current research here (for details, see Seber and Wild 1989).

This generic model fitting approach also permits a wide range of new possibilities for dealing directly with unbalanced, incomplete or missing data. In early work, linear polynomials were used extensively to deal with these kinds of problems. But recent work on linear and nonlinear mixed and multilevel models have surfaced, making it possible to estimate growth curves and test hypotheses by collecting only small segments of data on each individual (Bryk and Raudenbush 1992, Pinherio and Bates 2000, Verbeke and Molenberghs 2000). These statistical models are being used in many longitudinal studies to deal with self-selection and subject attrition, multivariate changes in dynamic patterns of development, and the tradeoffs between statistical power and costs of person and variable sampling. The statistical power questions of the future are not 'how many occasions do we need?' but 'how few occasions are adequate?' and 'which persons should we measure at which occasions?' (McArdle and Woodcock 1997, McArdle and Bell 2000).

Some of the most difficult problems for future work on growth curves are related to the elusive meaning of the growth model parameters. Growth curve analyses also rely on basic measurement properties including (a) interval scaling, (b) age-and-time equivalence, and (c) substantively meaningful. These issues are key problems in the behavioral sciences and future

research is needed to address these fundamental concerns. Multivariate models may be useful here, especially as these models are further extended to a fully dynamic time-dependent form. In any case, empirical information and experimentation will be needed to judge the utility of any growth curve model.

Given the long history of elegant formulations from mathematics and statistics in this area, it is somewhat humbling to note that many of the most insightful growth curve analyses have come from careful visual inspection of the growth curves (e.g., in Figs. 1–4). The insight gained from visual inspection of a set of growth curves is not in dispute now and in fact obvious visual features should be highlighted and emphasized in future research (e.g., Pinherio and Bates 2000). As in the past, the best future growth curve analyses are likely to be the ones we can see most clearly.

Guilt

Guilt has a number of related but distinguishable meanings. The word generally signifies having committed or being responsible for a wrongdoing, sin, or offence. This definition easily translates into the legal use of the word which means having committed a crime or tort as indicated by the offender's plea or the court's decision. A third usage of the word describes the feelings or emotion connected with recognition of having done wrong. Guilt, in other words, has a descriptive sense, a legal sense, and an affective sense.

1. Descriptive and Legal Meanings of Guilt

The Oxford English Dictionary traces the word guilt back to Old Teutonic words such as *geld*, meaning to pay, and Old English words (*gylt*, *gielt*, etc.) meaning delinquency, the fact of having committed an offence, being legally liable to a penalty, and a penalty for a crime. Modern definitions, such as are found in the seventh edition of the *Concise Oxford Dictionary*,

focus more simply on having 'committed a specific or implied offence.' Thus, in its broadest sense guilt simply signals that someone is responsible for an action or omission that is considered wrong. Implicit to this is the assumption that the guilty person was causally involved, though it has been argued that the person's intentions were not considered important in many times and places (Wierzbicka 1999).

As is evident from the origin and definitions of guilt, the concept is strongly linked to legal, especially criminal frameworks. Within a legal setting, the word guilt is used either by the defendant in pleading to a charge, or by the jury in convicting (a guilty verdict), to indicate responsibility for having committed a crime or tort (see Lely 1902). It often also indicates, as a consequence, liability for some penalty (Walker 1980).

To be guilty of a crime, one needs to commit the *actus reus* (the wrongful act) and to have *mens rea* (a guilty mind). Intention to commit the *actus reus* is the paradigm guilty mind. But over the centuries a variety of defences against a finding of *mens rea* have been refined in the common law: coercion, duress, mistake, self defence, provocation, insanity, necessity, accident and automatism being the main ones. The most sweeping defence against criminal responsibility is infancy, even though the *actus reus* has been committed with intent. Children under eight in most nations cannot be found guilty of a crime and there are generally qualifications on the capacity to hold older children criminally responsible. This is a major distinction between legal guilt and descriptive and affective guilt (which children can experience or at least are learning to experience).

In some contexts, recklessness—a weaker standard than intention but a stronger one than negligence—will be found to justify criminal guilt. In others the criminal law will countenance strict liability—guilt without *mens rea*. Generally this is reserved for contexts in which proving a guilty mind is difficult or when public policy regards the act itself to be sufficiently dangerous. Proving beyond reasonable doubt that the possessor of the illicit item had any criminal intent in relation to it is difficult, so the law resorts to the expedient of the *actus reus* of possession as sufficient for guilt. A second set of circumstances where the criminal law sometimes allows guilt without *mens rea* is where the *actus reus* involves a very great danger to the community and where the criminal actor has a capacity to take extraordinary steps to protect the community from that danger. Manufacturing pharmaceutical products or operating nuclear power plants are examples of where such strict liability crimes are countenanced in many nations.

Increasingly the world's legal systems accept the idea that a collectivity, such as a corporation, can be guilty of a crime. The reading of corporate criminal guilt initially became more expansive in the US; it then spread throughout the common-law world and in the final decades of the twentieth century took hold in the

civil-law world. Corporate criminal guilt can be based on a notion of corporate intention, or it can be determined that the corporation is vicariously responsible for the guilty intention of one of its members. Or corporate guilt can be based on a combination of a harmful corporate act that was enabled by irresponsible corporate policies or procedures (the corporate equivalent of the individual mental element of recklessness) (Bucy 1991, French 1984, May 1987, Fisse and Braithwaite 1993). In some ways the law imposes higher standards on corporations which are able to implement corporate compliance systems than it does on individuals. Arguably this spectrum of expectations is necessary for a 'risk society' (Beck 1992) where large corporations can cause aircraft to crash and nuclear power plants to melt down. At some point during the twentieth century in all industrialized societies, most litigants in the higher courts were corporations, rather than individuals.

Prior to the Middle Ages, when the distinction between tort and crime evolved, guilt was routinely used in civil law. Whether one burnt down the house of another intentionally (arson) or accidentally, one would be guilty of the act. In most legal systems guilt came to be used almost exclusively to refer to criminal guilt. However, when a civil wrong involved some element of fault, it remained appropriate to refer to the defendant as guilty of that civil wrong. While guilt was decreasingly so used when the fault element was only negligence, in US law it remained more common than in other systems to use the term guilt when exemplary damages were set in civil cases. When treble damages are imposed in a tort case, the existence of a punitive as well as a compensatory element in the court order means that it is appropriate to speak of the wrongdoer as guilty of that wrong. In equity and contract, if the conduct of a defendant is 'unconscionable' or shows bad faith, we can refer to the person as being guilty of unconscionable conduct. Finally, in US regulatory law there is the widespread phenomenon, less common in other nations, of civil penalties which can be imposed on evidence of guilt on the balance of probabilities, as opposed to the criminal test of beyond reasonable doubt. Americans speak of such defendants as being guilty of a breach of the law, even though there may not be criminal intent and defendants may not be able to avail themselves of excuses which would be available to them were criminal charges to be laid. Today, in a world where most of the things that can be done for good or ill in the world are done by organizations, most such civil penalty defendants are corporations. (See *Remedies and Damages: Legal Aspects*.)

At an even more macro level than the corporation, international law debates about crimes against humanity, such as genocide, resonate today with concern about 'impunity' as the world moves to establish an International Criminal Court. In this literature collective guilt is often supplanted by the concept of

collective shame as something nations might transcend through a process such as the South African Truth and Reconciliation Commission.

At both the macro level of national reconciliation and in the most micro context of juvenile justice and child protection, part of the impact of the growing social movement for restorative justice has been to shift the emphasis in debates around legal institutions from debates about guilt to debates about shame (Braithwaite 1999). We now turn to the affective foundations of this contest.

2. Feelings of Guilt

In addition to communicating both general and legal responsibility for wrongdoing, guilt has also come to be discussed as a feeling or emotion. At its core, a guilty feeling simply refers to the knowledge of one's guilt. However, the concept assumes not just awareness of wrongdoing but also discomfort with it. Thus, acceptance of having done wrong seems to be an important precondition of feeling guilty, although it is not when someone accepts or is assigned guilt in a descriptive or legal sense. The feeling of guilt is characterized by negative affect and may include behavioural changes. So, for example, it is sometimes said that someone is acting guilty or even that someone was consumed by guilt. Indeed, much classical literature, such as Shakespeare's *Macbeth* and Dostoevsky's *Crime and Punishment*, has followed the deterioration of characters haunted by past deeds. In such examples of guilt or guiltiness, the emotion is usually endured in secret, as the individual tries to hide his or her transgressions from the view of others. In fact, as will be seen, guilt is described by some theoretical traditions as a distinctively private emotion, especially in contrast to other related emotions such as shame.

Perhaps the most influential, or at least the most widely recognised, use of guilt in the social sciences has occurred within psychoanalytic theory. Freud (1949) argues that a primitive basis for guilt is the fear of losing another's love. In this primitive form feelings of guilt occur when one's transgression is discovered by an authority figure, or when the individual fears its discovery. This, according to psychoanalytic theory, is the only form of guilt young children can feel. However, individuals become able to feel what might be called true guilt with the formation of a super-ego or conscience, which internalizes the values that might have otherwise been enforced by an external authority. In this way individuals come to punish themselves through feeling bad (guilty) for transgressions or, because of the internal nature of the superego, even for offensive thoughts. Within this framework, conscious feelings of guilt, which Freud suggests should be called remorse, occur after committing a transgression. However, Freud also suggests that unconscious feelings of guilt play a much more malevolent role and are

the underlying cause of neuroticism. This is because the superego is characterized as taking on the aggressive and punishing characteristics of the external authority as well as the individual's own feelings of aggression towards the external authority. Ultimately the superego redirects this aggressiveness towards the ego, or conscious self. Ignoring the complexities raised by Freud's analysis of neuroticism and unconscious forms of guilt, what is most significant about this psychoanalytic perspective is that it describes guilt as an internally generated sanction based upon the individual's recognition of wrongdoing. For further detail on Freud's conception of guilt see his *Civilisation and its Discontents* (1949).

Guilt is also assigned an important role in the comparison of cultures by anthropologists such as Benedict (1946) and Mead (1937). In comparing the way societies maintain social control, a distinction is drawn between those that rely more heavily on internalized feelings of guilt and those that rely to a greater extent on social mechanisms of shame and shaming to maintain conformity. In Benedict's famous comparison, United States society is classified as a guilt culture, while Japanese society is classified as a shame culture. This distinction reflects Freud's conception of guilt as an internally generated sanction which develops as a result of socialization practices. However, it also highlights the alternative emotion of shame, which is described as a reaction to others' criticism and is similar to Freud's conception of 'primitive guilt.' This contrasting of shame and guilt as social versus internal control has been an influential one, with much of the recent research on guilt and shame examining the social vs. non-social dimension (Cheek and Hogan 1983, Gibbons 1990, Wallbott and Scherer 1995, Tangney et al. 1996). Indeed, as will be seen, a growing interest in shame has meant that research on both emotions has been dominated by an interest in distinguishing them.

While the social distinction between shame and guilt has been influential, it has also been questioned by a number of perspectives. Piers and Singer (1953) argue that there is much evidence from everyday life that individuals experience shame in private and without others' intervention. Building on the psychoanalytic framework they argue that shame and guilt are distinguishable because they result from different psychological tensions. Whereas guilt arises from tension between the ego and superego (conscience), shame is the product of tension between the ego and what they call the ego ideal. The ego ideal might be described as the individual's perception of their ideal self, those attributes and characteristics to which he or she aspires. This structure implies a new distinction: shame is about failure, it represents a shortcoming, whereas guilt is about transgression, it represents breaking a rule. Lewis (1971) argues that a second distinction implied by this psychoanalytic structure concerns the object of the two emotions. When feeling

guilt the individual's attention is focused upon the act or omission itself, but because shame is about failure to achieve an ideal, it is focused upon a global evaluation of the whole self. Thus, in addition to the emphasis upon transgression evident in the legal, Freudian and early anthropological perspectives, this later work has argued that guilt is felt about specific actions rather than the self.

The distinctions between guilt and shame have become a significant focus of recent empirical research. While empirical studies show that subjects' memories of feeling guilt involve less self-conscious feelings than their memories of shame (Wicker et al. 1983, Tangney et al. 1996), evidence that guilt is less focused upon evaluation of the whole self is equivocal. While at least one study (Niedenthal et al. 1994) has suggested that guilt is more specific in focus, a number of other studies (Tangney et al. 1996, Wicker et al. 1983) have found no significant difference between the emotions on this dimension. Indeed, a recent study (Harris 1999) which clustered subjects' reports of feelings using factor analysis did not distinguish between shame and guilt in either dimension. These results suggest that shame and guilt may often be empirically indistinguishable.

The discussion highlights the importance that has been placed in recent time on distinguishing feelings of guilt and shame. It is equally apparent that the issue has not been resolved and continues to be an important focus of research. This is particularly evident in recent research which explores guilt proneness and shame proneness as personality dispositions that are related to individual coping mechanisms and psychopathologies such as depression (Tangney 1991, Harder 1995, Ferguson et al. 1999). Despite disagreement over the dimensionality of guilt, research has highlighted a number of characteristics of guilt: that it is felt as a result of the acceptance that one has committed a wrongdoing; that it is focused upon one's actions or omissions; and that it often involves the perception of having hurt others in some way (Kugler and Jones 1992).

Gynecological Health: Psychosocial Aspects

Most women do not experience menstrually related changes that interfere with their lives to any appreciable extent. Where such changes are identifiable, they do not have a simple biological basis but are embedded in a complex social and cultural context.

1. Menstrually Related Distress

A comprehensive review (Klebanov and Ruble 1994) indicated no relationship between subjective distress and any hormonal measure; there is no consensus on its definition, symptoms, prevalence, effects, or indeed the component of the menstrual cycle (premenstrual, menstrual, or intermenstrual) with which the distress is associated.

Although mood, physical symptoms, and coping with life are claimed to demonstrate menstrually related cyclicity, the empirical evidence is mixed and inconclusive. Decades of research provide evidence for no cyclic variation in any aspect of cognitive functioning, memory, or motor performance (Richardson 1992). Women's reports of symptoms and mood swings are no different from those experienced by men (McFarlane and Williams 1994), and menstrually-related fluctuations in mood are considerably less than those associated with days of the week.

Prevalence estimates of menstrually related distress range from 95 to 5 percent, illustrating a complete lack of definitional consensus. The main standardized self-report survey, the Moos Menstrual Distress Questionnaire, obtains prevalence rates between 55 and 70 percent for physical discomfort, and between 23 and 70 percent for negative affect, with the majority of symptoms extremely mild and causing negligible distress (Logue and Moos 1986).

The American Psychiatric Association included a preliminary definition of premenstrual dysphoric disorder (PDD) in DSM-IV. PDD involves 'symptoms such as markedly depressed mood, marked anxiety, marked affective lability, and decreased interest in activity ... during the last week of the luteal phase in most menstrual cycles during the last year. The symptoms begin to remit within a few days of the onset of menses and are always absent in the week following menses.' PDD is diagnosed if the condition is com-

parable in severity to a major depressive episode, involving marked impairment in either social or occupational functioning. PDD must be confirmed with prospective daily ratings over at least two cycles, since retrospective reports are unreliable and there is little consistency across consecutive cycles. Rivera-Tovar and Frank (1990), using a prospective, blind, study over 90 days, found that 5 percent of US students met criteria for PDD. This suggests that some women experience menstrually related distress, but that it is not the norm, and it should be noted that experiencing distress on a cyclic basis does not necessarily mean that it is hormonally mediated.

2. Postnatal Distress

It is often assumed that negative psychological outcomes of childbirth result from hormonal changes, but three main categories of childbirth-related psychological distress with different causes and prognoses need to be distinguished.

2.1 Baby Blues

Postpartum dysphoria, or 'baby blues,' tearfulness, mood swings, and irritability, occurs in a high proportion of mothers in the few days following childbirth, and normally resolves itself within 10 days. It is not related to any environmental, social, or cultural factor (Kumar 1994), and may be related to changes in estrogen levels, although individuals undergoing surgery experience similar symptoms, suggesting it may be a reaction to physical stress. Prevalence estimates vary from 26 to 85 percent of all mothers. The condition is distressing, especially if women are not expecting it, but resolves quickly and has little long-term impact.

2.2 Postpartum Psychosis

Postpartum psychosis, characterized by hallucinations, delusions, and other schizophrenia-like symptoms, occurs in all societies, at a relatively consistent rate of 0.01 to 0.02 percent of all births (Kumar 1994), and can result in suicide or infanticide. Previous psychotic illness is the strongest risk factor for postpartum psychosis; there is no link with life events, stress, or relationship difficulties, supporting the view that it arises, like other psychotic states, in biologically susceptible individuals as a reaction to substantial life change.

2.3 Postpartum Depression

Nonpsychotic postpartum depression is mainly influenced by psychosocial factors, and there is no

convincing evidence for hormonal causation (Kumar 1994). Postpartum depression is predicted by relationship difficulties, low social support, previous depression, and stress. It is identical in presentation to other major depression, and while DSM-IV allows the specifier 'with postpartum onset' to be applied to depression which occurs within four weeks of the delivery of a child, it has no separate diagnostic category for postpartum depression.

Rates of depression in new mothers, assessed by the Edinburgh Postnatal Depression Scale (Cox et al. 1987), are between 6 and 10 percent. Symptoms may begin at any time up to 12 months after the birth of the baby and may be preceded by normal adaptation. High rates of depression persist as long as the mother has young children at home, and fathers also experience postnatal depression. Looking after a baby is stressful and anxiety provoking, and fatigue and disturbed sleep add to the difficulty. Depression in the postpartum period is best treated as reactive depression, reflecting a need for social and practical support, rather than as unique to childbirth.

3. Fertility-related Problems

3.1 Infertility

Infertility is generally defined as the failure to achieve a pregnancy after 12 months of unprotected sexual intercourse. Research on failure to conceive focuses on women, even though the cause is equally likely to be a characteristic of the male partner (Rowland 1992). The main causes are biological, although stress and anxiety can exacerbate physical problems.

Infertility and its treatment are distressing, but neither is associated with major psychological disturbance. The long-term outcomes of successful *in vitro* fertilization for children and their families are positive, but most outcomes are less benign. Involvement in *in vitro* fertilization is disruptive, expensive, and stressful. The probability of bearing a living child is around 10 percent per treatment cycle, and the risk of gynecological and obstetric complications, malformations, and multiple births is significantly increased. Repeated cycles of treatment are associated with increasing levels of depression (Rowland 1992).

3.2 Fertility Control

Access to adequate contraception and to abortion is important to women's physical and psychological well being. Where abortions are legal, around 2 percent of women aged between 15 and 44 have an abortion in any year. The worldwide annual death rate from illegal abortions has been estimated at 100 000, while the death rate from legal abortions is 0.05 per 10 000, 25 times lower than the rate for childbirth. Provision

of safe abortions and adequate contraception would have a major impact on the well being of women and children in developing countries.

Women may need support in deciding whether to choose abortion, but the majority experience no significant psychological distress. Psychological distress following abortion is considerably lower than that associated with childbirth. Distress is highest during decision making before the abortion, and the most common postabortion reaction is a sense of relief.

Women who cope best with abortion are characterized by optimism, high self-esteem, and a sense of personal control. Social, cultural, and partner support, and confidence in the decision, assist in coping, while women with a history of psychiatric disorder are likely to react negatively (Adler et al. 1992).

3.3 Miscarriage

Miscarriages are relatively common; over 30 percent of 50-year-old women have had at least one miscarriage. Reactions to spontaneous abortion of a wanted pregnancy are generally characterized by short-term grief, anxiety, and depression, normally resolved successfully within a few months (Slade 1994). Reactions to medical abortions follow a similar pattern, with short-term distress which may be severe but which resolves rapidly. Serious negative consequences are rare, and associated with previous psychiatric illness or lack of social support.

4. Menopause

Menopause is a natural physiological process resulting from aging of the ovaries, leading to cessation of ovulation and of estrogen production. Natural menopause occurs over several years. During the perimenopause, estrogen levels decrease and menstruation becomes irregular and ceases. The postmenopause, defined after 12 months without menstruation, is reached at an average age of 50.4 years.

Menopausal symptoms are categorized as: vasomotor (e.g., hot flushes, night sweats), psychosomatic (e.g., headaches, dizziness), and psychological (e.g., tiredness, irritability). The most common symptoms, reported across most cultures, are hot flushes and night sweats, clearly the result of changes in estrogen. However, prevalence of symptoms varies between countries, suggesting that sociocultural factors play a role (Hunt 1994).

Hormone replacement therapy relieves hot flushes and night sweats, but does not influence psychological well being in mid-aged women. Stress, life events, history of depression, and expectations are the strong-

est predictors of psychological well being during menopause. Women in their middle years often experience major life events (McKinlay et al. 1987). Once life changes are accounted for, there is little evidence to suggest that menopausal women are particularly prone to negative psychological states.

5. Conclusion

Distress associated with gynecological events is better explained by poor social support and by negative expectations than by endocrine function. Future research might usefully examine the experiences of women in a wider range of situations, including women in same-sex relationships, women who choose childlessness, and women with disabilities. An exploration of the experiences of women in different ethnic groups would also provide a broader perspective on psychosocial aspects of gynecological health.

Gypsies and Travelers

The label *Gypsy* refers to diverse groups—each with its own history, culture, and name—who live in scattered communities throughout Europe and North America and in parts of Asia, Central and South America, and Africa. (In Europe, the label *Roma* is commonly used.) The English word ‘Gypsy’ is derived from ‘Egyptian,’ based on the false assumption that they had come from Egypt. From linguistic evidence, however, it is apparent that Gypsies originated in India. They began migrating westward in the tenth century, spreading across Europe and absorbing aspects (e.g., religion, language) of the host cultures they lived among. Eventually, they formed the groups found today. The Indic structure of the major dialects of *Romani* spoken by Gypsies has been heavily influenced by European languages, Greek, Armenian, Persian, and possibly Arabic.

Traveler is the term commonly used to refer to indigenous groups who share economic and structural features with Gypsies. They practice (or once practiced) similar peripatetic occupations and occupy a similar minority position vis-à-vis the majority populations of the countries in which they live. In Ireland and Scotland, for example, indigenous groups once known as ‘tinkers’ and ‘tinklers,’ but who refer to themselves as Travelers or Traveling People, have occupied a niche very similar to Gypsies for at least 300 years. Similar indigenous Travelers found in other European countries include the *Resande* in Sweden and *Woonwagenbewoners* in The Netherlands. Other indigenous groups are found in South Asia, they include the *Kanjar* in Pakistan and northern India and the *Ghorbat* in Afghanistan. Like Gypsies, members of some Traveler groups have since migrated to other countries. Irish and Scottish Travelers, for example, now also live in the United States, having first emigrated there in the mid-1800s. The designation Traveler is also sometimes used as a broad term to encompass both indigenous Travelers and Gypsy populations.

1. Identity

All Gypsies and Travelers see themselves in opposition to outsiders who they typically categorize with a single label. Many Gypsies, for example, use the term *gadje* (non-Roma in the Romani language); Irish Travelers call members of the majority Irish population *buffers*. Most Gypsies follow, to varying degrees, a system of purity rules which govern women’s behavior and how food, eating utensils, clothing, washing containers, and the body are handled. Most believe that the body is ritually unclean from the waist down and, consequently, that anything associated with the lower body is polluting. Individuals and groups who do not follow purity rules are by definition ‘polluted’ or ritually unclean, which is one factor reinforcing the boundaries between Gypsies and non-Gypsies. Of course, Gypsies and Travelers also distinguish their own group from similar groups, usually on the basis of kin ties (or lack thereof), differences in dialect, and other criteria such as socioeconomic status, occupation, and length of settlement (i.e., before 1945 or during the communist era for East European groups).

Language also acts as a marker of ethnic identity. While Gypsies speak the language of the majority population of the countries in which they live, most also speak a form of Romani. Most indigenous Travelers likewise have specialized argots which they typically use to disguise their communications in the presence of outsiders (e.g., during economic transactions). Other markers of group identity, such as items of material culture, skills, or traditions, are also used to create and reinforce a symbolic separation between themselves and outsiders. Roma in Hungary, for example, assert that it is their ‘Gypsy work’—their wit, speech, and ability to hustle—that allows them to survive, rather than the income they make from the wage labor the State forces them to engage in. Irish Travelers pride themselves in their ‘cleverness’—their ability to live by their wits—and see this as something which differentiates them from other Irish. It has been suggested that ‘disreputable’ behavior of Spanish Gitanos—their flaunting of accepted social norms about appropriate public comportment (e.g., loudness, violations of street etiquette)—is a deliberate strategy intended to offend non-Gypsies and keep them at a distance. Other groups use their involvement in horse trading or their distinctive music and celebrations to symbolically draw boundaries between themselves and outsiders.

When possible, Gypsies and Travelers limit their interaction with members of the majority population to economic transactions and brief, necessary encounters with institutional representatives such as legal, social service, or medical personnel. Most academics who have studied these groups have documented their antiestablishment attitudes and efforts to remain outside the direct supervision of the State. Socialization among Gypsies and Travelers instills in

most children a strong sense of ethnic pride, and few express a desire to abandon their identity or group. This pride is reflected in and reinforced by high rates of group endogamy. Nevertheless, attrition in the form of 'passing' into mainstream society as well as intermarriage with non-Gypsies or non-Travelers does occur. Some groups have been subjected to long-term state-sponsored assimilation programs, which have included forced settlement among non-Gypsies, wage labor, and education.

As the quintessential Other, Gypsies and Travelers have historically captured the imagination of artists and writers and figure prominently in the arts and literature of many countries. In Russia, for example, writers such as Pushkin, Tolstoy, and Blok included Roma in their works. Likewise, Travelers ('tinkers') have figured prominently in the work of such literary figures as Irish playwright J. M. Synge.

2. Economic Organization

The traditional economy of Gypsies and Travelers was based on petty trade and the provision of craft products, specialized services, and entertainment to customers and clients in the majority populations they lived among. In many countries, they serviced a scattered rural population, conveniently bringing goods and services to their customers' doors. Others provided services which had to be performed on site. Rom wipe-tinners, for example, traveled the United States retinning expensive mixing bowls and massive, relatively immobile counter tops, holding tanks, tubs, troughs, sinks, and separators used in institutional cafeterias, dairies, and commercial bakeries. Black-topping (or tarmac laying), a common occupation of Gypsies and Travelers in North America, Ireland, and Great Britain today, likewise must be done on site. Sometimes, Gypsies and Travelers provide unique products or services that cannot be acquired from anyone else. The Kanjar of Pakistan, for example, sold handmade terracotta toys, while the Qalandar entertained their clients with trained monkeys and bears. Fortune telling remains a profitable specialization for many American Rom. Because Gypsies and Travelers often accepted payment in kind (e.g., farm produce, fuel), the services they provided were especially attractive to poorer clients.

Occupational flexibility, the ability to do several income-earning activities at the same time, and to change occupations quickly as demand dictates, is a key aspect of the traditional economy. When the Ludar arrived in the United States from Bosnia, for example, they brought trained bears and monkeys, but they also peddled small goods, dealt in horses, told fortunes, and made rustic furniture. Since the 1950s, they have focused on laying blacktop, tarring roofs, and working carnival concessions. Irish Travelers

once swept chimneys, made tin containers, bought and sold donkeys and horses, peddled small goods (e.g., brushes, needles, boot polish, religious pictures), told fortunes, and performed agricultural labor. As these rural-based occupations became obsolete, they moved to urban areas and began laying tarmac, selling carpeting from door-to-door, collecting and recycling scrap metal, and selling second-hand furniture, car parts, and other merchandise from the roadside.

Many Gypsy and Traveler populations—or significant segments of them—are still peripatetic, exploiting narrowly-defined markets within the host economy. Families are successful because their overhead is minimal, they are willing to accept a narrow profit margin from multiple sources, and generally lack interest in material accumulation and capital expansion. They also use wage-free household labor. Typically, household income is produced by all family members—men and women, young and old. When larger work units are needed, they are drawn from the kin network or else the lowest socioeconomic stratum of the host society (e.g., the homeless).

While nomadism remains an important feature of many groups—and is the image instantly evoked by the very words 'Gypsy' and 'Traveler'—substantial numbers today are sedentary for all or much of the year. Some Western European groups are also sedentary. Spanish Gitanos, for example, have been sedentary for centuries. Although many Gypsies and Travelers in Ireland and Great Britain remain nomadic, the pressure from government to settle is strong. In Eastern Europe, Gypsies were long ago forced into wage labor—generally low-status, unskilled jobs—and have been sedentary for generations. In North America today, only a few families in each Gypsy and Traveler group are predominantly nomadic. Most own or rent homes, and maintain a mixed pattern of settlement and travel.

3. Social and Political Organization

It is difficult to generalize about the social organization of Gypsy and Traveler groups. Many groups reckon descent bilaterally and have no formalized or corporate kin groups. Individuals have equal rights and obligations towards both maternal and paternal kin. At marriage, a couple can choose to affiliate with either spouse's family, and later, may periodically live on their own or affiliate with nonkin. Other groups—such as the Rom and Ludar in the United States—trace descent through the male line, have named patrilineages, and practice preferential patrilocal residence at marriage, at least until the birth of a young couple's first child. Descent in most South Asian groups is also patrilineal.

Residential groupings larger than the household, whether they are travel clusters or stationary enclaves

within cities, are fluid. Kinship is the fundamental basis for association, but group composition and size is continually being renegotiated in response to changing economic opportunities and a host of social and legal concerns. Groups split apart due to personal animosities, the desire for change, the need to scatter in order to find new clients, or as a result of punitive actions (e.g., evictions) by local authorities. Likewise, they coalesce for many reasons. Scattered kin come together to celebrate life crisis events such as marriages and funerals, to protect a valuable economic territory from the encroachment of other groups, to defend a kinsman from insult or attack, and, sometimes, to make evictions by local authorities more difficult.

Political organization is also diverse. The most formalized mechanisms of social control and political leadership are found among some Gypsy groups and South Asian Travelers. American Rom, for example, have a *Rom Baro* (big man) who speaks for his extended family and controls economic activities in the territory they claim. Important disputes are adjudicated by a *kris*, an *ad hoc* Gypsy court, composed of popularly-nominated, male family heads who act as 'judges' and representatives from each kin grouping within the vicinity who act as witnesses and jury. The *kris* seeks consensus; its proceedings are spontaneous and often volatile; and the fines or punishments it metes out are morally, not legally, binding. Other American Gypsy groups such as the Romnichel, however, lack both the *Rom Baro* and the *kris*. Various South Asian groups have loosely structured *panchayat* councils. These are informal meetings convened primarily to settle disputes, with respected elders acting as arbitrators. Both the *kris* and the *panchayat* are mechanisms for airing grievances, alleviating tension, asserting (and sometimes reassessing) group values, arriving at a compromise, and restoring order.

Researchers working with diverse groups of Gypsies and Travelers in Europe, North America, and South Asia have noted the importance members attach to assembly, both at annual events like seasonal fairs and at periodic events like religious pilgrimages, marriages, and funerals. During assemblies, group solidarity is reinforced through informal social interaction (including music, song, and drinking), marriage negotiations, religious ceremonies, and dispute settlements. Such gatherings demonstrate and reinforce a common identity that overrides, at least temporarily, localized kinship and political alliances. English Gypsies appear to recognize the important role fairs play in their collective life. When authorities tried to close Appleby Fair in 1965 and to prevent them from assembling at Epsom in 1967, they united in protest.

Unless prevented from doing so by the state, Gypsies and Travelers seem to respond eagerly to opportunities for assembly and social engagement. Their gatherings also have an emotional intensity—evident in the total absorption of buleria performances, flamenco, and 'deep song' as performed by

Spanish Gitanos and in the drinking and aggressive interpersonal interactional style of many groups—that is striking to the researchers who have observed them. It is as if what these Gypsy and Traveler groups lack in formal organization or structure they make up for by periodic assembly and intense emotional engagement.

4. Harassment and Assimilation

Gypsies and Travelers have sometimes enjoyed the liberties of other citizens. Under Ottoman rule, for example, Gypsies had the same citizenship rights as anyone else as long as they paid the taxes required of their religious group: Christian Roma paid higher taxes than Muslim Roma. Much more frequently, however, they have been persecuted. In Europe, Gypsies and Travelers have been subject to punitive legislation for many centuries. Individuals as well as entire groups have been denied entry, forcibly settled, had their trades outlawed, forced to adopt wage labor, had their children taken and adopted by non-Gypsy families, been sterilized, imprisoned, enslaved, or deported. In Moldavia and Wallachia—Romania's two historic provinces—Gypsies were sold into slavery as early as the fifteenth century; legal emancipation for Romany slaves or *robi* finally came in 1864. During the Holocaust a half to more than a million Gypsies were exterminated. Deep-seated anti-Gypsy prejudice continues today throughout Eastern Europe and parts of Western Europe, periodically erupting in physical assaults by local residents and the police.

In the second half of the twentieth century, many Western European governments and private agencies became involved in programs ostensibly aimed at providing Gypsies and Travelers with 'choice,' 'options,' or 'self-determination.' Many of these movements came about as modernization in the host society eliminated the need for the rural-based trades and services nomadic groups had provided, forcing them to seek new clients. In Ireland and Great Britain, for example, Travelers and Gypsies converged on cities looking for work, camping along motorways, next to housing estates, and on rapidly diminishing amounts of open land. This led to a public outcry and their definition as a 'social problem.' Public policy has fluctuated over the years. Liberal programs (i.e., providing campsites and mobile classrooms for nomadic families, creating culturally-sensitive curricula) have vied with more straightforward attempts to assimilate Gypsies and Travelers through housing, laws prohibiting camping, and conventional vocational training education. In recent years, however, Gypsies and Travelers have become more politically active. Many organizations have emerged to articulate their concerns and lobby government for the same rights as any other minority. Cooperation across national boundaries with other Gypsy and Traveler groups is also becoming more common.

In Eastern Europe, government policy had focused more on forced assimilation, including aggressively settling Gypsy families that were nomadic, dispersing those who had lived in settled enclaves, enrolling children in school, licensing or banning specific trades, forcing adults to accept wage labor, and officially denying their existence as ethnic minorities. Many Gypsies were able, nevertheless, to preserve their separate identity in spite of official communist policy. The collapse of state socialism in Eastern Europe in 1989 brought new hope to the approximately five million Gypsies in the region who responded by organizing a plethora of cultural groups and political parties to articulate and represent their diverse interests. Some common goals include achieving full recognition and civil rights as distinct ethnic minorities, having schools use Romani as a second language of instruction, and getting state-supported social and economic programs to create opportunities and address poor living conditions. In Macedonia, Gypsies called upon the United Nations to establish a Romany state to be called 'Romanestan.' Most groups efforts, however, have been hampered by internal leadership problems, the multiplicity of competing Gypsy organizations within each country, and, ultimately, their reliance on the State to accord their organizations and demands legitimacy. Anti-Gypsy sentiment in Europe remains strong. Attacks on Gypsies in the 1990s targeted both long-term residents of settled communities in Eastern Europe and recent immigrants fleeing to Western countries from Romania, Bulgaria, Hungary, and the former Yugoslavia.

Ghetto

It is a paradox that, while the social sciences have made extensive use of the 'ghetto' as a *descriptive term*, they have failed to forge a robust *analytical concept* of the same. In the historiography of the Jewish diaspora in early modern Europe and under Nazism, the sociology of the black American experience in the twentieth-century metropolis, and the anthropology of ethnic outcasts in Africa and East Asia, its three traditional domains of application, the term 'ghetto' variously denotes a bounded urban ward, a web of group-specific institutions, and a cultural and cognitive constellation (values, mindset, or mentality) entailing the sociomoral isolation of a stigmatized category as well as the systematic truncation of the life space and life chances of its members. But none of these strands of research has taken the trouble to specify what makes a ghetto *qua* social form, which of its features are constitutive and which derivative, as they have, at each epoch, taken for granted and adopted the *folk concept* extant in the society under examination—which explains that the notion, appearing self-evident, does not figure in most dictionaries of social science, including previous publications of this encyclopedia.

1. A Woolly and Shifting Notion

Thus the semantic range of the 'ghetto' in American society and social science, which has dominated inquiry into the topic both quantitatively and thematically, has successively expanded and contracted in keeping with how political and intellectual elites have viewed the vexed nexus of ethnicity and poverty in the city (Ward 1989). At first, in the latter half of the nineteenth century, the term designated residential concentrations of European Jews in the Atlantic seaports and was clearly distinguished from the 'slum' as an area of housing blight and social pathology. It dilated during the Progressive era to encompass all inner-city districts wherein exotic newcomers gathered, namely lower-class immigrants from the Southeastern regions of Europe and African Americans fleeing the Jim Crow regime of caste subjugation in the US South. Expressing ruling-class worries over whether these groups could or should assimilate into the predominant Anglo-Saxon pattern of the country, the term then referred to the intersection between the ethnic neighborhood and the slum, where segregation combined with physical disrepair and overcrowding to exacerbate urban ills such as criminality, family breakdown, and pauperism, and thwart participation in national life. This conception was given scientific authority by the ecological paradigm of the Chicago school of sociology. In his classic book *The Ghetto*, Louis Wirth (1928, p. 6) assimilates to the Jewish ghetto of

medieval Europe the 'Little Sicilies, Little Polands, Chinatowns, and Black Belts in our large cities,' along with the 'vice areas' hosting deviant types such as hobos, bohemians, and prostitutes—all of which are said to be 'natural areas' born of the universal desire of different groups to 'preserve their peculiar cultural forms' and each fulfilling a specialized 'function' in the broader urban organism.

The notion contracted after World War II under the press of the Civil Rights movement to signify mainly the compact and congested enclaves to which African Americans were forcibly relegated as they migrated into the industrial centers of the North. The growth of a 'Black Metropolis in the womb of the white,' wherein Negroes evolved distinct and parallel institutions to compensate for and shield themselves from unflinching exclusion by whites (Drake and Cayton 1945), contrasted sharply with the smooth residential dispersal of European Americans of foreign stock. Writing at the acme of the black uprisings of the 1960s, Kenneth Clark (1965, p. 11) made this relationship of ethnoracial subordination epicentral to his dissection of the *Dark Ghetto* and its woes: 'America has contributed to the concept of the ghetto the restriction of persons to a special area and the limiting of their freedom of choice on the basis of skin color. The dark ghetto's invisible walls have been erected by the white society, by those who have power.' This diagnosis was confirmed by the Kerner Commission (1968, p. 2), a bipartisan taskforce appointed by President Johnson whose official report on the 'civil disorders' that rocked the American metropolis famously warned that, due to white racial intransigence, America was 'moving toward two societies, one black, one white—separate and unequal.' But over the ensuing two decades, the dark ghetto collapsed and devolved into a barren territory of dread and dissolution due to deindustrialization and state policies of welfare reduction and urban retrenchment. And, as racial domination grew more diffuse and diffracted through a class prism, the category was displaced by the duet formed by the geographic euphemism of 'inner city' and the neologism of 'underclass,' defined as the substratum of ghetto residents plagued by antisocial behaviors, acute joblessness, and social isolation (Wilson 1987). By the 1990s, the neutralization of the 'ghetto' in policy-oriented research culminated in the expurgation of all mention of race and power to redefine it as any tract of extreme poverty, irrespective of population and institutional makeup, in effect dissolving the ghetto back into the slum.

The extension of the term to the study of the distinctive sociocultural patterns elaborated by homosexuals in the cities of advanced societies 'in response to both stigma and gay liberation' after the Stonewall riots (Levine 1979, p. 31) and its recent resurgence in Western Europe in heated scientific and political debates over the links between postcolonial

immigration, postindustrial economic restructuring, and urban dualization (Mingione 1996) would seem only to further muddle its meaning. Yet one can extract out of these varied literatures common threads and recurrent properties to *construct a relational concept* of the ghetto as an *instrument of closure and control* that clears up most of the confusion surrounding it and makes it a powerful tool for the social analysis of ethnoracial domination and urban inequality. For this it suffices to return to the historical inception of the word and of the phenomenon it depicted in Renaissance Venice.

2. *A Janus-faced Institution of Ethnic Closure and Control*

Coined by derivation from the Italian *giudecca*, *borghetto* or *gietto* (or from the German *gitter* or the Talmudic Hebrew *get*: the etymology is disputed), the word 'ghetto' initially refers to the forced consignment of Jews to special districts by the city's political and religious authorities. In medieval Europe, Jews were commonly allotted quarters wherein they resided, administered their own affairs, and followed their customs. Such quarters were granted or sold as a privilege to attract them into the towns and principalities for which they fulfilled key roles as money-lenders, tax collectors, and long-distance tradesmen. But, between the thirteenth and the sixteenth century, in the wake of the upheavals caused by the Crusades, favor gradually turned into compulsion (Stow 1992). In 1516, the Senate of Venice ordered all Jews rounded up into the *ghetto nuovo*, an abandoned foundry on an isolated island enclosed by two high walls whose outer windows and doors were sealed while watchmen stood guard on its two bridges and patrolled the adjacent canals by boat. Jews were henceforth allowed out to pursue their occupations by day, but they had to wear a distinctive garb and return inside the gates before sunset on pain of serious punishment. These measures were designed as an alternative to expulsion to enable the city-state to reap the economic benefits brought by the presence of Jews (including rents, special taxes, and forced levies) while protecting their Christian residents from contaminating contact with bodies perceived as unclean and dangerously sensual, carriers of syphilis and vectors of heresy, in addition to bearing the taint of money-making through usury, which the Catholic Church equated with prostitution (Sennett 1994, p. 224).

As this Venetian model spread in cities throughout Europe and around the Mediterranean rim (Johnson 1987, pp. 235–245), territorial fixation and seclusion led, on the one hand, to overcrowding, housing deterioration, and impoverishment as well as excess morbidity and mortality, and, on the other, to institutional flowering and cultural consolidation as

urban Jews responded to multiplying civic and occupational restrictions by knitting a dense web of group-specific organizations that served as so many instruments of collective succor and solidarity, from markets and business associations, to charity and mutual aid societies, to places of religious worship and scholarship. The *Judenstadt* of Prague, Europe's largest ghetto in the eighteenth century, even had its own city hall, the *Rathaus*, an emblem of the relative autonomy and communal strength of its residents, and its synagogues were entrusted not only with the spiritual stewardship but also with the administrative and judicial oversight of its population. Social life in the Jewish ghetto was turned inward and verged 'on overorganization' (Wirth 1928, p. 62), so that it reinforced both integration within and isolation from without.

One can detect in this inaugural moment the four constituent elements of the ghetto, viz., *stigma, constraint, spatial confinement, and institutional encasement*. The ghetto is a social-organizational device that employs space to reconcile two antinomic purposes: to maximize the material profits extracted out of a group deemed defiled and defiling and to minimize intimate contact with its members so as to avert the threat of symbolic corrosion and contagion they carry. This same dual rationale of *economic exploitation cum social ostracization* governed the genesis, structure, and functioning of the African-American ghetto in the Fordist metropolis during most of the twentieth century. Blacks were recruited into northern US cities after World War I because their unskilled labor was indispensable to the industries that formed the backbone of the expanding factory economy. But there was no question of them mixing and consorting with whites, who regarded them as inherently vile, congenitally inferior, and shorn of ethnic honor owing to the stain of slavery. As blacks moved in from the South in millions, white hostility increased and patterns of discrimination and segregation that had hitherto been informal and inconsistent hardened in housing, schooling, and public accommodations and were extended to the economy and polity (Spear 1968, Osofsky 1971). African Americans had no choice but to seek refuge inside the bounded perimeter of the Black Belt and to endeavor to develop in it a network of separate institutions to procure the basic needs of the castaway community. Thus arose a parallel city anchored by black churches and newspapers, black block clubs and lodges, black schools and businesses, and black political and civic associations, nested at the core of the white metropolis yet sealed from it by an impassable fence built of custom, legal suasion, economic discrimination (by realtors, banks, and the state), and by violence manifested in the beatings, fire-bombings, and riots that checked those who dared stray across the color line.

This forced institutional parallelism predicated on enveloping and inflexible spatial seclusion—not extreme poverty, housing blight, cultural difference, or mere residential separation—is what has distinguished African Americans from every other group in US history, as noted by leading students of the black urban experience from W.E.B. Du Bois and E. Franklin Frazier to Drake and Cayton to Kenneth Clark and Oliver Cox (Wacquant 1998). It also characterizes the trajectory of the Burakumin in the Japanese city after the close of the Tokugawa era (Hane 1982). As the descendants of the *eta*, the lowest of the four castes forming the estate order of feudal Japan, the Burakumin were untouchables in the eyes of the Buddhist and Shinto religions, and they were legally confined from sundown to sunup in out-of-the-way hamlets (*buraku*), obliged to wear a yellow collar and to walk barefoot, expected to drop on their hands and knees when addressing commoners, and restricted to marrying solely among themselves. Though they were officially emancipated in 1871, as they moved into cities they were funneled against their will into notorious neighborhoods near garbage dumps, crematoria, jails, and slaughterhouses, widely viewed as nests of criminality and immorality. There, they were barred from industrial employment and locked in low-paying and dirty jobs, sent to separate schools, and compelled to remain endogamous by the indelible taint of their blood as traced through ‘family registration records’ (DeVos and Wagatsuma 1966). In the late 1970s, according to the Burakumin Defense League, they were estimated to number 3 million, trapped in 6,000 ghettos in some thousand cities across the main island.

Spread over three continents and five centuries, the Jewish, African-American, and Burakumin cases demonstrate that the ghetto is not, *pace* Wirth (1928, pp. 284–285), a ‘natural area’ arising via environmental adaptation governed by a biotic logic ‘akin to the competitive cooperation that underlies the plant community.’ The error of the early Chicago school here consisted in falsely ‘converting history into natural history’ and passing ghettoization as ‘a manifestation of human nature’ virtually coterminous with ‘the history of migration’ (Wirth 1928, p. 285) when it is a highly peculiar form of urbanization warped by asymmetric relations of power between ethnoracial groupings: a special form of *collective violence concretized in urban space*. That ghettoization is *not* an ‘uncontrolled and undesigned’ process, as Robert E. Park asserted in his preface to *The Ghetto* (Wirth 1928, p. viii), was especially visible after World War II when the black American ghetto was reconstructed from the top down through state policies of public housing, urban renewal, and suburban economic development intended to bolster the rigid separation of blacks from whites (Hirsch 1983). It is even more glaring in the instance of the ‘caste cities’ built by colonial powers to inscribe in

space the hierarchical ethnic organization of their overseas possessions, such as Rabat under French rule over Morocco and Cape Town after the passage of the Group Areas Acts under the apartheid regime of South Africa (Abu-Lughod 1980, Western 1981).

Recognizing that it is a product and instrument of group power makes it possible to appreciate that, in its full-fledged form, the ghetto is a *Janus-faced institution* as it serves opposite functions for the two collectives that it binds in a relation of asymmetric dependency. For the dominant category, its rationale is to *confine and control*, which translates into what Max Weber calls the ‘exclusionary closure’ of the dominated category. For the latter, however, it is an *integrative and protective device* insofar as it relieves its members from constant contact with the dominant and fosters consociation and community building within the constricted sphere of intercourse that it creates. Enforced isolation from the outside leads to the intensification of social exchange and cultural sharing inside. Ghettos are the product of a mobile and tensionful dialectic of external hostility and internal affinity that expresses itself as ambivalence at the level of collective consciousness. Thus, although European Jews consistently protested relegation within their outcast districts, they were also deeply attached to them and appreciative of the relative security they afforded and the special forms of collective life they supported: Frankfurt’s ghetto in the eighteenth century was ‘not just the scene of confinement and persecution but a place where Jews were entirely, supremely, at home’ (Gay 1992, p. 67). Similarly, black Americans took pride in having ‘erected a community in their own image,’ even as they resented the fact that they had done so under duress, as a result of unyielding white exclusion aimed at warding off the specter of ‘social equality,’ that is, sexual mixing (Drake and Cayton 1945, p. 115).

3. *Disentangling Poverty, Segregation, and Ethnic Clustering*

Articulating the concept of ghetto makes it possible to disentangle the relationship between ghettoization, urban poverty, and segregation, and thence to clarify the structural and functional differences between ghettos and ethnic neighborhoods. It also enables us to spotlight on the role of the ghetto as a symbolic incubator and matrix for the production of a spoiled identity.

1. *Poverty is a frequent but derivative and variable characteristic of ghettos*: the fact that most ghettos have historically been places of endemic and often acute misery owing to the paucity of space, the density of settlement, and the economic exploitation and generalized maltreatment of their residents does not imply that a ghetto is necessarily a place of

destitution, nor that it is uniformly deprived. The *Judengasse* of Frankfurt, instituted in 1490 and abolished in 1811, went through periods of prosperity no less than penury and it contained patches of extraordinary opulence as court Jews helped the city become a vibrant center of trade and finance—part of its glamor to this day comes from it being the ancestral home of the Rothschild dynasty (Wirth 1928, Chap. 4). James Weldon Johnson (1930, p. 4) insisted that the Harlem of the 1930s was ‘not a slum or a fringe’ but the ‘cultural capital’ of black America, where ‘the Negro’s advantages and opportunities are greater than in any other place in the country.’ Likewise, Chicago’s ‘Bronzeville’ was far more prosperous at mid-century than southern black communities and harbored the largest and most affluent African-American bourgeoisie of its era (Drake and Cayton 1945). Whether a ghetto is poor or not depends on extraneous factors such as demography, ecology, state policies, and the shape of the surrounding economy.

Conversely, not all dispossessed and dilapidated urban districts are ghettos. Declining white neighborhoods in the deindustrializing cities of the US Midwest and British Midlands, depressed rural towns of the former East Germany and southern Italy, and the disreputable *villas miserias* of the greater Buenos Aires at the close of the twentieth century are territories of working-class demotion and decomposition, not ethnic containers dedicated to maintaining an outcast group in a relationship of seclusive subordination. They are not ghettos other than in a metaphorical sense, no matter how impoverished—if extreme rates of poverty sufficed to make a ghetto, then large chunks of the former Soviet Union and most third-world cities would be gargantuan ghettos. The *favelas* of the Brazilian metropolis often portrayed as segregated dens of dereliction and disorganization turn out to be working-class wards with finely stratified webs of ties to industry and to the wealthy districts for which they supply household service labor. As in the *ranchos* of Venezuela and the *poblaciones* of Chile, the families that dwell in these squatter settlements span the color continuum and have extensive genealogical bonds to higher-income households; they are ‘not socially and culturally marginal, but stigmatized and excluded from a closed class system’ (Perlman 1976, p. 195; also Quijano 1968). Given that not all ghettos are poor and not all poor areas are ghettos, one cannot collapse and confound the analysis of ghettoization with the study of slums and lower-class districts in the city.

2. Similarly, *all ghettos are segregated but not all segregated areas are ghettos*. The select boroughs of the West of Paris, the exclusive upper-class suburbs of Boston or Berlin, and the ‘gated communities’ that have mushroomed in global cities such as São Paulo, Toronto, and Miami are monotonous in terms of wealth, income, occupation, and often ethnicity, but

they are not for all that ghettos. Segregation in them is entirely voluntary and elective, and for that reason it is neither all-inclusive nor perpetual. Fortified enclaves of luxury package ‘security, seclusion, social homogeneity, amenities, and services’ to enable bourgeois families to escape what they perceive as ‘the chaos, dirt, and danger of the city’ (Caldeira 2000, pp. 264–265). These islands of privilege serve to enhance, not curtail, the life chances and protect the lifestyles of their residents, and they radiate a positive aura of distinction, not a sense of infamy and dread.

This suggests that residential segregation is a necessary but not a sufficient condition for ghettoization. For a ghetto to emerge spatial confinement must, first, be imposed and all-encompassing and, second, it must be overlayed with a distinct and duplicative set of institutions enabling the group thus cloistered to reproduce itself within its assigned perimeter. If blacks are the only ethnic group to be ‘hypersegregated’ in American society (Massey and Denton 1992), it is because they are the only community to have combined involuntary segregation with organizational parallelism entrapping them in a separate and inferior social cosmos of their own, which in turn bolstered their residential isolation. That even involuntary segregation at the bottom of the urban order does not *eo ipso* produce ghettos is demonstrated by the fate of the declining French *banlieues* after the 1980s. Although they have been widely disparaged as ‘ghettos’ in public discourse and their inhabitants share a vivid feeling of being cast out in a ‘penalized space’ suffused with boredom, anguish, and despair (Pétonnet 1982), relegation in these depressed concentrations of public housing at the urban periphery is based on class, not ethnicity; as a result they are culturally heterogeneous, typically harboring native French families along with immigrants from two dozen nationalities; and their inhabitants suffer not from institutional duplication but, on the contrary, from the lack of an ingrown organizational structure capable of sustaining them in the absence of gainful employment and adequate public services. Like the British or Dutch inner cities and the immigrant clusters of urban Germany or Italy, the French *banlieues* are, sociologically speaking, *anti-ghettos* (Wacquant to be published).

3. *Ghettos and ethnic neighborhoods have divergent structures and opposite functions*: moving beyond a gradational perspective to scrutinize the peculiar patterning of social relations within the ghetto as well as between it and the surrounding city throws into sharp relief the differences between the ghetto and the ethnic clusters or immigrant neighborhoods such as newcomers to the metropolis have formed in countless countries. The foreign ‘colonies’ of interwar Chicago that Robert Park, Ernest Burgess, and Louis Wirth—and after them the liberal tradition of assimilationist sociology and historiography—mistook for so many white ‘ghettos’ were scattered and

mobile constellations born of cultural affinity and occupational concentration. Segregation in them was partial and porous, a product of immigrant solidarity and ethnic attraction instead of being imposed by outgroup hostility. Consequently, residential separation was neither uniformly nor rigidly visited upon these groups: in 1930, when the all-black Bronzeville harbored 92% of the city's Afro-American population, Chicago's Little Ireland was 'an ethnic hodge-podge' of 25 nationalities composed of only one-third Irish persons and containing a paltry 3% of the city's denizens of Irish ancestry (Philpott 1978, pp. 141–145).

What is more, the distinctive institutions of European immigrant enclaves were turned outward: they operated to facilitate adjustment to the novel environment of the US metropolis. They neither replicated the organizations of the country of origin nor perpetuated social isolation and cultural distinctiveness, and so they typically waned within two generations as their users gained access to their American counterparts and climbed up the class order and the corresponding ladder of places (Nelli 1970; a similar process of spatial diffusion via class incorporation of Belgian, Italian, Polish, and Iberian immigrants in the French industrial city is reported by Noiriel 1988), all of which is in sharp contrast with the immutable racial exclusivity and enduring institutional alterity of the Black Belt. This Chicago illustration dramatizes the fact that immigrant neighborhood and ghetto serve diametrically opposed functions: one is a springboard for *assimilation* via cultural learning and social-cum-spatial mobility, and the other a material and symbolic isolation ward geared toward *dissimilation*. The former is best figured by a bridge, and the latter by a wall.

4. *A Tainted Identity Machine*

The ghetto is not only the concrete means and materialization of ethnoracial domination through the spatial segmentation of the city but also a potent *collective identity machine* in its own right, for it helps incrustate and elaborate the very division of which it is the expression in two complementary and mutually reinforcing ways. First, the ghetto sharpens the boundary between the outcast category and the surrounding population by deepening the socio-cultural chasm between them: it renders its residents objectively and subjectively more dissimilar from other urban dwellers by submitting them to unique conditionings, so that the patterns of cognition and conduct they fashion have every chance of being perceived by outsiders as singular, exotic, even aberrant (Sennett 1994, p. 244; Wilson 1987, pp. 7–8), which feeds prejudicial beliefs about them. Second, the ghetto is a cultural combustion engine that melts divisions among the confined group and

fuels its collective pride even as it entrenches the stigma that hovers over it. Spatial and institutional entrapment deflect class differences and corrode cultural distinctions within the relegated ethnoracial category. Thus Christian ostracism welded Ashkenazic and Sephardic Jews under an overarching Jewish identity such that they evolved a common 'social type' and 'state of mind' across the ghettos of Europe (Wirth 1928, pp. 71–88, 1964). America's dark ghetto similarly accelerated the sociosymbolic amalgamation of mulattos and Negroes into a single 'race' and turned racial consciousness into a mass phenomenon fueling community mobilization against continued caste exclusion (Drake and Cayton 1945, p. 390).

Yet this unified identity cannot but be stamped with ambivalence as it remains tainted by the very fact that ghettoization proclaims what Weber calls the 'negative evaluation of honor' assigned to the group confined. It is therefore wont to foster among its members sentiments of self-doubt and self-hatred, dissimulation of one's origin through 'passing,' the pernicious derogation of one's kind, and even fantastical identification with the dominant (Clark 1965, pp. 63–67). And, because ghettoization is typically bound up tightly with ethnicity, segregation, and poverty, it is difficult to discern empirically which of the properties exhibited by ghetto dwellers are 'ghetto-specific cultural traits' as opposed to properties expressive of class, community, or masculinity (Hannerz 1969, p. 79). Also, cultural forms forged in the ghetto seep across its boundaries and circulate through the surrounding society where they often become outward signs of cultural rebelliousness and social eccentricity—as indicated by the fascination of bourgeois teenagers around the world for black American 'gangster rap.' This makes it difficult to distinguish between cultural forms effectively in currency among ghetto residents and the public imagery of them diffused in the broader society (including via scholarly writings).

It is fruitful to think of ghetto and ethnic cluster as *two ideal typical configurations situated at opposite ends* of a continuum along which different groups can be located or travel over time depending on the intensity with which the forces of stigma, constraint, spatial confinement, and institutional duplication and completeness coalesce with each other and impinge upon them. Ghettoization can then be turned into a *multilevel variable* for comparative analysis and empirical specification. It can become attenuated to the point where, through gradual erosion of its spatial, social, and mental boundaries, the ghetto devolves into an elective ethnic concentration operating as a springboard for structural integration and/or cultural assimilation into the broader social formation. This describes well the trajectory of the Chinatowns of the United States from the early to the late twentieth century (Zhou 1992) and the status of the

Cuban immigrant enclave of Miami that fostered integration through biculturalism after the Mariel exodus of 1980 (Portes and Stepick 1993). It also characterizes the 'Kimchee Towns' in which Koreans have converged in the metropolitan areas of Japan, which sport a blend of features making them a hybrid between ghetto and ethnic cluster (DeVos and Chung 1981): they are places of infamy that first arose through enmity and constraint, but over the years their population has become ethnically mixed and they have enabled Koreans to socialize and intermarry with Japanese neighbors as well as obtain Japanese citizenship through naturalization. This schema also fits the so-called 'gay ghetto,' which is more aptly characterized as a 'quasi-ethnic community' since 'most gay persons can "pass" and need not be confined to interacting with their "own kind"' and none are forced to reside in the areas of visible concentration of gay institutions (Murray 1979, p. 169).

The double-sidedness of the ghetto as a weapon and shield implies that, to the degree that its institutional completeness and autonomy are abridged, its protective role for the subordinate group is diminished and risks being swamped by its exclusionary modality. In cases where its residents cease to be of economic value to the dominant group, ethnoracial encapsulation can escalate to the point where the ghetto serves as an apparatus merely to warehouse the spoiled group or to prepare it for the ultimate form of ostracization, i.e., physical annihilation. The first scenario fits the evolution of the black American 'hyperghetto' in the post-Civil Rights era: having lost its function of reservoir of unskilled labor power, it has become symbolically linked to the hypertrophied carceral system of the United States by a triple relationship of structural homology, functional surrogacy, and cultural fusion (Wacquant 2004). The second scenario is that implemented by Nazi Germany, which revived the *Judenghetto* between 1939 and 1944, first, to impoverish and concentrate Jews with a view toward relocation and later, when mass deportation turned out to be impractical, to funnel them toward extermination camps (Friedman 1980, Browning 1986).

The unchecked intensification of its exclusionary thrust suggests that the ghetto might be most profitably studied not by analogy with urban slums, lower-class neighborhoods, and immigrant enclaves but alongside the reservation, the refugee camp, and the prison, as belonging to a broader class of institutions for the forced confinement of dispossessed and dishonored groups. It is not by happenstance that the Bridewell of London (1555), the *Zuchthaus* of Amsterdam (1654), and the *Hospital général* of Paris (1656), designed to instill the discipline of wage work to able-bodied vagrants, beggars, and criminals via incarceration, were invented around the same time as the Jewish ghetto.

And that today's sprawling refugee camps in Rwanda, Sri Lanka, and in the occupied territories of Palestine look ever more like a cross between the ghettos of late medieval Europe and gigantic gulags.

Habit: History of the Concept

A family of expressions found in many ordinary languages, habit and its linguistic cognates compose a malleable vocabulary that, for over two millennia, has been incorporated into a wide range of intellectual projects in the domains of the social sciences and beyond. Commonly used for the purpose of describing various *recurrent and relatively automatic features* of human conduct, 'the discourse of habit is one of the great, albeit largely unacknowledged, cultural legacies of Western civilization' (J. M. Thomas 1993, p. 8). Until the early twentieth century, the history of this discourse was roughly coextensive with Western intellectual history itself and scarcely more amenable to brief summary, though broad phases may be distinguished.

1. The Concept of Habit

In the course of its long history, habit has been a polysemous term. Common to most of its meanings and usages, however, has been the conceptualization of habit as a more-or-less self-actuating disposition or tendency to engage in previously adopted or acquired forms of action. When these forms of action are differentiated in terms of their content, distinctions then arise between moral habits, cognitive habits, emotional habits, and motor habits.

Of greater historical importance, however, has been another basis of differentiation. The forms of actions whose repetition is designated as habit may range from simple and circumscribed to complex and generalized. Among the social thinkers who have invoked the concept, habit has most frequently been applied to recurrent patterns of activity of moderate complexity and generality, i.e., to habits of economic, political, religious, and domestic conduct, habits of obedience to rules and to rulers, habits of sacrifice, disinterestedness, and restraint, and so on. But, at various points in the history of the concept, habit has referred primarily to certain simpler, or at least more elemental, behavioral regularities, such as habits of talking, walking, eating, dressing, routine problem-solving, etc.

At the opposite extreme, habit has sometimes been applied to the highly generalized and durable disposition that suffuses an individual's mode of action and discernment in entire spheres of activity or even throughout an entire lifetime. in which case the

concept has been largely synonymous with 'character,' a term encapsulating the whole manner or mold of a human personality. When employed in this extended sense, habit has often been spoken of as *habitus*. That habit has historically taken on this full range of meanings serves as a precaution against projecting on to all instances of the concept connotations only applicable in restricted cases. The contemporary supposition that habit is a fixed, mechanical reaction to discrete stimuli and thus devoid of subjective meaning is, for example, a view that has historically been associated mainly with habit in the sense of simple behavioral regularities, not with more complex habitual forms of action.

At no point has the vocabulary of habit been a free-standing one; to a significant degree, its usage has varied because of the different ways in which habit has been opposed to or aligned with other concepts. At a decisive period in its history, habit was counterposed to instinct, such that all *non*-instinctual behavior was regarded as necessarily habitual. Prior to and subsequent to this period, however, habit was ordinarily set over against purposive, reflective types of action that involve the selection of means and ends according to various normative standards; in this case, habit contrasts with those types of action presupposed by most twentieth-century social-scientific *reflective models* of human conduct. At still other moments, however, habit has been taken not as the opposite of, but as the precondition for reflexive action. The same flexibility is evident with regard to moral conduct, which has sometimes been contrasted with habitual action, other times held to depend upon it. Further, conceptual variability has appeared at the aggregate level, as the similar habits of the several members of a social group have sometime been equated with custom, while other usages reserve custom for practices done in compliance with social sanctions and hence distinct from forms of action that have become somewhat more automatic owing to repetition or other habit-formation processes. (For a fuller treatment of the issues in this section, see Funke 1958, Camic 1986.)

2. Historical Course

2.1 Antiquity to the Early 1800s

The discourse of habit came naturally to Greek philosophers as they opened pathways for later social

thinkers. Aristotle's *Ethics* (Book 2, Chapter 1) (Aristotle [1973]) laid it down that 'none of the moral virtues arise in us by nature,' that 'we are adapted by nature to receive them and are made perfect by habit'; and the same discourse molded as well to the varied teachings of Plato, Plotinus, Quintilian, Aquinas, Luther, Montaigne, Pascal, and Wolf, among a great number of others (Funke 1958).

In the Age of the Enlightenment, amid determined efforts to launch a science of man, the concept of habit was subject to more systematic formulations which reaffirmed habit's vast empirical role but appraised this role differently. In France, Helvetius celebrated habit as the wellspring of public and private morality and accepted it as a 'principle by which [humans everywhere] are actuated' (Helvetius [1758] 1807, p. 57); in Scotland, Ferguson declared habit the force 'by which the good or bad actions of men remain with them and become part of their characters' (quoting Hill 1996, p. 210); while from Prussia Kant averred that 'all acquired habits are objectionable'—that 'virtue is moral strength in the pursuit of one's duty, which should never be a matter of habit' (Kant [1798], 1978, pp. 32–34). Hume, Berkeley, Reid, Condillac, Rousseau, Hegel, and the German idealists were among the many thinkers who took part in the discussion. (On the thinkers named here and others, see Funke 1958, Camic 1986.)

2.2 *A Century of Ferment*

From the middle of the nineteenth century until the early decades of the twentieth century, the language of habit was even more ubiquitous in European and American thought. It found expression in the work of a wide range of social thinkers that included James and John Stuart Mill, Spencer, Bagehot, Marshall, Bradley, and Bosanquet in England, Comte and LePlay in France, and Nietzsche, Simmel, Tönnies, and Husserl in Germany. In the United States, the discourse of habit was also drawn upon extensively by, among others, popular reformers, churchmen, and educators, pragmatist philosophers (Peirce, James, and Dewey), and leading thinkers involved in establishing the social sciences as independent academic disciplines (Sumner, Giddens, Veblen, Thomas).

Typical of the plaint ways in which the discourse was used were the views held by Emile Durkheim and Max Weber as they laid the foundations for modern sociology. Throughout his career, Durkheim took the position that 'habits... are the real forces which govern us' (Durkheim [1905–6] 1956, p. 152). For him, as for the American pragmatists, human reflection is a process that generally 'overloads or paralyzes action'; only 'when habit is disrupted,' and the individual or collective 'being is... at a cross-roads situation [facing] a whole range of possible solutions,' does reflection

arise in order to restore 'equilibrium' and allow 'habits of all kinds' to reassert themselves (Durkheim [1913–14] 1983, pp. 38, 79–80). Accordingly, Durkheim's plans for the moral regeneration of modern society relied heavily on habit: on developing in children 'the habit of self control and restraint' and 'habits of group life'; on cultivating in occupational specialists 'an absolute regularity in habits' and interactional 'habits [that], as they grow in strength, are transformed into rules of conduct'; and on instilling in society's leaders 'a habitus of moral being' (Durkheim 1902–3 [1961], pp. 149, 249, 1893 [1984], pp. 187, 302, 1904–5 [1977], p. 29).

Driven by a different intellectual agenda, Weber held similar views. Occupied with the various forms of reflective action, he nonetheless affirmed the importance of habit, holding that 'the further we go back in history, the more we find that conduct, and particularly social action, is determined in an ever more comprehensive sphere exclusively by the disposition toward the purely habitual': that 'individuals are still markedly influenced' by this force 'even today,' with 'the great bulk of all everyday action [approaching an] almost automatic reaction to habitual stimuli which guide behavior in a course which has been repeatedly followed' (Weber [1922] 1978, pp. 320, 337, 25 [modified translation]). The vocabulary of habit thus figured significantly into Weber's treatment of economic, political, and religious traditionalism, into his writings on economic, political, legal, and communal action in the modern world, and even into his analysis of the process by which Protestantism promoted the spirit of modern capitalism. Conceptualizing the spirit of capitalism as a 'particular habitus,' Weber credited the early Calvinists with creating, 'out of their religiously conditioned family traditions and from the religiously influenced life-style of the environment, [a distinctive] 'habitus' among individuals which prepared them in specific ways to live up to the specific demands of early modern capitalism' (Weber [1910a] 1968, [1910b] 1978, p. 1124).

Yet, as social thinkers mobilized the language of habit in these ways, contemporary natural scientists increasingly moved to appropriate it to refer to a far more elementary range of activities, both human and subhuman. This, for example, was the practice of Lamarck, and Darwin followed the model, regularly speaking of the flowering habits of plants, the feeding habits of insects, and the flying habits of pigeons (Darwin [1859] 1964, pp. 11, 183, [1872] 1975, pp. 29–31). This was also the practice of many European physiologists and psychologists as they turned attention to the study of the neural foundations of simple animal and human reflexes, widely using the term habit to describe well-established neural pathways (Fearing 1930). This usage gained great currency among late-nineteenth and early-twentieth century American psychologists, convinced with James that even 'the most complex habits [are] nothing but

concatenated discharges in the nerve-centres, due to the presence there of systems of reflex paths' (James [1890] 1950, p. 108). Extending the same view into their own domain, turn-of-the-century American social scientists ascribed vital significance to habits rooted in 'the physiology of the nervous system,' convinced 'that education and social control are largely dependent upon our ability to establish habits in ourselves and others' (quoting Park [1915] 1969, see also Camic 1986).

2.3 The Decline of Habit

The culmination of these developments came with the behaviorist revolution which John Watson launched in American psychology during World War One and which overran the field in the next two decades. Taking the position that *every* 'mode of acting... not belonging to man's hereditary equipment must be looked upon as a habit,' conceived physiologically in terms of 'muscular and glandular changes which follow upon a given stimulus,' Watson and his followers touted habit-psychology as the way 'to guide society... towards the control of group and individual behavior' (Watson 1919, pp. 270, 14, 2–3). From this point of view, the science required for the study of the social world was 'not [a social science like] sociology, but psychology,' which derives from 'biology, chemistry, and the other natural sciences' (Allport 1927, pp. 167–168).

The challenge to the legitimacy of their own fledgling academic disciplines now manifest, social scientists swiftly recoiled from the language of habit. Countering the behaviorist effort to eliminate the reflective forms of action that had long stood alongside habitual forms, sociologists of the inter-war period led an aggressive campaign to rescue purposive human conduct, deliberately forsaking their previous use of the concept of habit. This campaign was inaugurated by Thomas (a former proponent of the concept) and Znaniecki, whose work attacked the 'behavioristic school' for its 'indistinct [application] of the term 'habit' to [all] uniformities of behavior' and urged that 'habit'... be restricted to the biological field, [since] it involves no conscious, purposeful regulation of [conduct], but merely... is unreflective, [whereas] the uniformity [that constitutes social life] is not a uniformity of organic habits but of consciously followed rules' (W. I. Thomas and Znaniecki [1918] 1958, pp. 1849–1852). Within a generation, this view became dogma, displacing the discourse of habit with the language of 'attitude,' which Thomas and Znaniecki brought to the fore and which subsequently furnished American social scientists with a new vocabulary with which to encompass regular tendencies in human conduct while holding to reflective action models (Fleming 1967, Camic 1986). Parallel movements away from the concept of habit occurred in European thought (as

even Durkheim and Weber excised the concept from sociology) and in European and American literature (Fisher 1973, J. M. Thomas 1993). In the aftermath of this turnabout, at least outside the natural sciences, the language of habit became dormant for the half century from the late 1920s to the late 1970s, with very few exceptions. In the heyday of the behaviorist revolution, Dewey resuscitated a broader conception of habit, and Merleau-Ponty in France subsequently did likewise (Kestenbaum 1977, see also Berger and Luckmann 1966); but such efforts did not stem the behaviorist view of habit, nor the resulting widespread reaction against the concept. Only among psychologists working in the behaviorist tradition, and among a few economists focused on consumer behavior, did the language of habit remain a presence (Deaton and Muelbaur 1980, Smith 1986). Otherwise, social scientists essentially abandoned the discourse, conceiving of all human action as a reflective process of fitting means to ends according to various normative standards.

3. Recent Developments

The last quarter of the twentieth century brought little fundamental alteration in the stance that had been taken toward the language of habit during the previous half century. By and large, reflective conceptualizations of human action have continued to dominate the social sciences. This dominance has been less complete, however, as the concept of habit, understood in non-behaviorist terms that simultaneously accommodate reflective action, has periodically been revived: by social psychologists (Ouellette and Wood 1998), by a wider range of economists (Scitovsky 1976, Campbell and Cochrane 1995), and by sociological theorists, some developing earlier pragmatist and phenomenological approaches (Ostrow 1990, Joas [1992] 1996), others aligned also with the traditions of Durkheim and Weber, most notably Bourdieu ([1980] 1990), in whose writings 'habitus' receives extended attention (see also Giddens 1984). Still largely disconnected from one other, these lines of work open promising future possibilities for the eventual transformation of exclusively reflective models of human conduct in the social world.

C. Camic

Habituation

If a drop of water falls on the surface of the sea just over the flower-like disc of a sea anemone, the whole animal contracts vigorously. If, then, a second drop falls within a few minutes of the first, there is less contraction, and finally, on the third or fourth drop, the response disappears altogether. Here in this marine polyp with the primitive nerve net is clearly exhibited one of the most pervasive phenomena of the animal kingdom—decrement of response with repeated stimulation. Almost every species studied, from amoeba to man, exhibits some form of response decrement when the stimulus is frequently repeated or constantly applied. The ubiquity of the phenomenon plus its obvious survival value suggests that this kind of plasticity must be one of the most fundamental properties of animal behaviour. (Sharpless and Jasper 1956, p. 655)

With these words, Sharpless and Jasper introduced their now classic study of habituation of the electroencephalogram (EEG) arousal response. Their study had a profound impact on behavioral neuroscience and served to kindle the interest of neural scientists in brain mechanisms of habituation. *Habituation* is a decrease in response to repeated stimulation, and *sensitization* is an increase in response as a result of stimulation. Virtually all behavioral responses, as well as autonomic and EEG responses and signs of arousal, habituate rapidly and to a profound degree. The processes responsible for habituation of behavioral responses probably occur largely after the primary sensory pathways of the brain and before the motor neurons that move muscles—somewhere between initial processing of sensory information and the execution of decisions to respond. Sensitization, the increase in response that often occurs when strong stimuli are given, may be similarly localized, although some evidence indicates that sensitization may occur in motor systems and motor neurons.

In early work on brain processes of habituation, it was thought that virtually all measures of neural activity might habituate, ranging from first-order sensory nuclei to the cerebral cortex. An early experiment to report evoked response habituation was that of Hernández-Peón et al. (1957); they recorded responses to click stimulation at several levels of the

auditory system. Trains of clicks were delivered once every two seconds for long periods of time and evoked responses of the cochlear nucleus (the first relay of the auditory system) were reported to habituate.

Careful studies by Worden and associates (see Marsh et al. 1962) demonstrated that click-evoked responses at the cochlear nucleus do not show habituation. Instead, amplitudes of responses at this first relay nucleus in the auditory system are rigidly controlled by the physical properties of the sound stimulus. Because of acoustic factors, the intensity of a sound is often weaker at the floor of a test cage. If an animal gradually became bored and rested his head on the floor, the cochlear nucleus-evoked response to click would decrease because of reduced sound intensity.

In an extensive and careful study, Wickelgren (1968) found that habituation of evoked responses to auditory stimuli was not prominent below the level of the thalamus and cortex in the auditory system. This appears to be a general finding in all sensory systems—the lower ascending relay nuclei do not exhibit habituation. It would be most surprising if there were marked habituation in sensory systems. If our sensory systems habituated to sensory stimuli, we would rapidly cease to have sensation—a most unadaptive state of affairs. However, behavioral responses and phenomena that seem to be related to the probability of behavioral responding, such as EEG arousal and autonomic signs of orienting, show marked habituation. It is very adaptive to cease responding to arousing stimuli that have no particular significance.

Historically, such processes as habituation and sensitization were viewed simply as reflexes and not as phenomena of learning and memory. However, the broad definition of learning as a change in behavior as a result of experience certainly encompasses both phenomena. When this was recognized, analysis of neural mechanisms became 'legitimized' (Sharpless and Jasper 1956, Thompson and Spencer 1966). Habituation and sensitization are now seen as examples of nonassociative learning and memory. Greater progress has been made in analysis of the basic neuronal mechanisms underlying habituation than in more complex forms of behavioral plasticity such as classical and instrumental conditioning. Major reasons for this progress lie in the widespread occurrence of habituation, in its simplicity, and in the reliability with which the behavioral properties of habituation can be specified and determined. Habituation occurs both in spinal reflexes of the vertebrate (Sherrington 1906) and for responses of simple animals, as well as in complex human behavior. Consequently, neural mechanisms of habituation can be studied in simplified systems.

As noted earlier, behavioral habituation is simply response decrement as a result of repeated stimulation. For example, if a moderate electric shock is delivered to the foot of a normal but restrained animal for the

first time, the animal will show marked struggling and leg flexion movements. However, if the stimulus is repeated a few times, the responses decrease considerably and may even disappear. Habituation is commonly differentiated from response decrements due to trauma, growth, aging, etc. In the example above, if the shock to the foot is withheld for a period of time after habituation and then given again, the response will reappear with normal strength. This spontaneous recovery is a common control used to show that habituation is a *reversible* response decrement.

Response decrements due to altered sensitivity of receptors are often termed *receptor adaptation*, and response decrements due to decremental effects occurring at the neuromuscular junctions of muscles are often termed *muscular fatigue*. Neither of these processes is considered to be habituation; it is a central rather than a peripheral process. Almost all behavioral responses of the intact organism initially elicited by a given stimulus, ranging in complexity from leg flexion to exploratory and play behavior, show habituation with repeated stimulation.

Response sensitization may be defined simply as an increased response strength to a given stimulus as a result of some other, usually strong, stimulus. The galvanic skin reflex (GSR) is a good case in point. Suppose we were to measure the GSR activity of sweat glands in the palm of the hand in response to a sound of moderate intensity. The response would probably be of relatively low amplitude and somewhat irregular in occurrence. If a strong shock were delivered to the skin, the sound alone now would evoke a much larger GSR response; the response would have been sensitized. The response increase due to sensitization is distinguished from conditioning in that no pairing of shock and sound is necessary to produce the effect. Sensitization itself typically habituates; after a number of shock presentations the response to the sound decreases to the initial weak level. In fact, it seems to decay spontaneously following a sensitizing stimulus.

The study of habituation has a long history; some of its basic properties were described in classic works by Jennings (1906), Humphrey (1933), Prosser and Hunter (1936), and Harris (1943). Thompson and Spencer (1966) surveyed the by then very extensive behavioral literature on habituation and identified some nine basic parametric properties or characteristics exhibited by behavioral habituation.

1. Properties of Habituation

(a) Given that a particular stimulus elicits a response, repeated applications of the stimulus result in decreased response (habituation). The decrease is usually a negative exponential function of the number of stimulus presentations.

(b) If the stimulus is withheld, the response tends to recover over time (spontaneous recovery).

(c) If repeated series of habituation training and spontaneous recovery are given, habituation becomes successively more rapid (this might be called potentiation of habituation).

(d) Other things being equal, the more rapid the frequency of stimulation, the more rapid and/or more pronounced is habituation.

(e) The weaker the stimulus, the more rapid and/or more pronounced is habituation. Strong stimuli may yield no significant habituation.

(f) The effects of habituation training may proceed beyond zero or asymptotic response level.

(g) Habituation of response to a given stimulus exhibits stimulus generalization to other stimuli.

(h) Presentation of another (usually strong) sensitizing stimulus results in recovery of the habituated response (dishabituation or sensitization).

(i) Upon repeated application of the sensitizing stimulus, the amount of dishabituation produced habituates (this might be called habituation of sensitization).

It is important to emphasize that these characteristics of habituation are simply the empirically observed properties in a wide variety of behavioral studies on many species and as such do not imply particular theories or inferences. These properties have come to serve as the detailed definition of habituation. Thus, any particular stimulus-response system is said to exhibit habituation if the response decrement to repeated stimulation exhibits these properties.

The most potent variables determining the course of habituation are stimulus frequency and intensity. The frequency range must be behaviorally relevant. Very high frequencies can yield fatigue, potentiation, and other processes. The range of stimulus frequencies over which habituation occurs, i.e., behavioral response decrements exhibiting the properties noted above, is an empirical question dependent upon the organism, the stimulus, and the response system engaged. For the orienting or arousal response, the effective range may be from minutes to hours to days; for the spinal flexion reflex, the range is over seconds.

The fact that rate and degree of habituation are inversely related to stimulus intensity (property (e)) is true if the same intensity is used for test and habituating stimuli (the test stimulus is given sufficiently infrequently that it does not by itself cause habituation). However, if the test and habituating stimuli differ in intensity, more complex effects can occur (Davis and Wagner 1968).

2. Dishabituation vs. Sensitization

Thompson and Spencer (1966) employed habituation of the spinal flexion reflex, first used as a model system to study habituation by Prosser and Hunter (1936), to

characterize the detailed properties of habituation and analyze possible neuronal mechanisms. They discovered that the process of 'dishabituation' caused by presentation of a strong extra stimuli was not in fact dishabituation. That is, it did not disrupt the process of habituation at all. Instead, it added a superimposed, independent process of increased excitability, namely sensitization. The fact that dishabituation, *per se*, does not appear to exist as such, but rather reflects a separate process of sensitization, appears to hold for all vertebrate preparations studied, ranging from reflexes to the startle response to EEG arousal and the orienting response. One exception to this rule has been reported for a monosynaptic system in the invertebrate *Aplysia* (Marcus et al. 1988). However, the neuronal mechanisms underlying the processes of sensitization/dishabituation appear to differ in vertebrates vs. the *Aplysia* circuit. In the latter, 'dishabituation' appears to be a presynaptic process, occurring at the sensory neuron terminals on the motor neurons (see Sect. 3 and Kandel 1976); whereas, at least in spinal reflexes, sensitization can involve increased excitability in motor neurons (Thompson and Spencer 1966). Actually, recent evidence suggests that changes may occur in motor neurons in the *Aplysia* circuit as well (Murphy and Glanzman 1997).

The fact that dishabituation does not exist as such, but rather reflects a separate independent process of sensitization in vertebrate preparations led Groves and Thompson (1970) to develop the dual-process theory of habituation: the outcome of repeated stimulus presentations is due to the net interaction of the inferred processes of habituation and sensitization. This theory is able to account for an astonishingly wide range of behavioral phenomena (see, e.g., Peeke and Herz 1973).

A somewhat differently construed and widely influential theory of habituation is the stimulus-model comparator theory developed in Russia by Evgeny Sokolov (1963), based largely on data from the human orienting response. In this view, repetition of a given stimulus results in the development of a neuronal 'model' of the stimulus in forebrain structures. If a repetitive stimulus matches the model, then there is little output, only the habituated response, which could be no response, i.e., no EEG arousal. However, if there is a mismatch, then the difference is amplified via the reticular formation and a larger response results.

The dual-process theory is more successful in accounting for basic phenomena of habituation and sensitization in a wide range of species; the model-comparator theory can more easily account for more complex phenomena like the 'missing stimulus' effect (increased response to the absence of one presentation of the habituating stimulus, a phenomenon sometimes seen in EEG arousal but not in reflex systems). But note that a process of synaptic depression could underlie the formation of the neuronal model of the

stimulus in the model-comparator theory; the theories are at different levels and not incompatible. A view somewhat similar to that of Sokolov was developed by Wagner (1979) to account for long-term habituation. Thus, the central model of the habituating stimulus is considered as a relatively long-term memory trace, yielding the basic properties of a learned response. In their classic study of human EEG arousal habituation, Sharpless and Jasper (1956) stressed the distinction between short-term and long-term habituation.

As noted earlier, primary sensory afferent system neurons do not exhibit habituation. This makes perfect sense; in order to 'decide' how much to respond to a stimulus it is necessary to know what the stimulus is. Virtually all behavioral responses elicited by stimuli show habituation to repeated stimulation under at least some conditions. Central brain processes that are behavior-related like cortical EEG arousal show clear habituation, as do brain motor systems. Davis and associates completed a comprehensive analysis of the startle circuit and startle habituation in the rat (Davis 1984). The circuit includes auditory relay nuclei: the cochlear nuclei and the nuclei of the lateral lemniscus; a nucleus in the brainstem reticular system (nucleus reticularis pontis caudalis) and its projections to brainstem and spinal cord premotor and motor nuclei. Evidence suggests that habituation to the acoustic startle stimulus occurred before the motor systems, i.e., at the nucleus reticularis pontis caudalis (Davis et al. 1982). The reticular nucleus is a 'bridge' nucleus between sensory and motor systems.

3. Neural Mechanisms

Unlike associative learning, in habituation the stimulus-response neuronal circuit is hardwired. In systems where some degree of analysis of neuronal mechanisms is possible, the neural substrate of habituation occurs within the stimulus-response circuit itself and is not due to any extrinsic circuit action like external inhibition acting on the habituating circuit.

Greatest progress in analyzing neural mechanisms of habituation and sensitization has come from simplified neuronal systems. Two of these are the gill withdrawal reflex of the mollusk *Aplysia* and vertebrate spinal reflexes. Kandel (1976) and his many associates completed a detailed analysis of the processes of habituation and sensitization in the *Aplysia* monosynaptic circuit. They were able to show that habituation was a presynaptic process involving a decrease in the probability of neurotransmitter release as a result of repeated activation. Similarly, a process of synaptic depression is responsible for habituation of the tail-flip escape response in the crayfish, another very productive invertebrate model system (Krasne 1969). In the *Aplysia* model, synaptic decrement is due to a persisting decrease in calcium ion influx into the terminals. Sensitization, elicited for example by strong

shock to the tail of the animal, was due to activation of a polysynaptic circuit that acted presynaptically on the sensory neuron terminals, the same terminals that habituated. The effects on calcium channels are due in turn to complex and not fully understood biochemical cascades within the neurons. Kandel and associates have also described a long-term sensitization effect involving structural changes in the synapses that they have used as a model for long-term memory storage (Hawkins and Kandel 1984).

In the vertebrate spinal cord, the flexion reflex is polysynaptic. Thompson and Spencer (1966) were able to rule out any changes in excitability in the sensory neuron terminals and in the motor neurons themselves during habituation. However, sensitization did involve increases in motor neuron excitability, as noted above. They suggested, but could not prove, that a process of low-frequency depression in the interneurons was responsible for habituation, a process analogous to the presynaptic depression process demonstrated by Kandel and associates in *Aplysia*. Using a monosynaptic pathway in the isolated frog spinal cord, Farel and Thompson (1976) demonstrated a presynaptic process for habituation. The story concerning neuronal mechanisms of habituation is particularly satisfying because the same process of synaptic depression appears to underlie habituation in both invertebrate and vertebrate systems. This simple process of synaptic decrement can account for a wide range of behavioral phenomena of habituation.

The study of habituation continues to be a most active field of research, ranging from responses of nematode *C. elegans* (Wicks and Rankin 1996) to the startle response in mammals (Pilz and Schnitzler 1996) to behaviors in the human fetus and infant (Leader 1995, Kaplan et al. 1990).

R. Thompson

Halévy, Élie (1870–1937)

Élie Halévy was a French historian and philosopher who made three principal contributions to the social sciences: a study of the English Utilitarians; a historical account of English society in the eighteenth and nineteenth centuries which is noteworthy for the role it attributes to Methodism and Evangelicalism in maintaining political stability; and an analysis of the development of European socialism culminating in what he designated an ‘era of tyrannies.’

1. Biography

Élie Halévy was born at Étretat to wealthy, artistic parents on September 6, 1870, which marked a turbulent period in French history, with the origins of the Third Republic, France’s defeat by Prussia, and the collapse of the Paris Commune. His father, of Jewish descent, was a successful librettist for such composers as Bizet and Offenbach, while his mother was of Swiss Calvinist origins. Both Élie and his brother Daniel were brought up as Protestants under her strong moral influence: like Élie’s contemporary Max Weber (see *Weber, Max (1864–1920)*) there was a strong familial influence on the study of religious—and especially Christian Protestant—ideas. Halévy’s grandfather had been a disciple of Saint-Simon and succeeded Comte as his secretary for a time. Though the family had important connections in French political life, Élie remained distant from, but also keenly concerned with, political affairs.

While still a student at the *Lycée Condorcet* he planned, with his brother and other associates, the *Revue de Métaphysique et de Morale*, a journal with which he was associated for the whole of his life. At the *École Normale Supérieure* he studied philosophy, completing a thesis on Platonism. Already his political and moral principles had become established as liberal, individualist, rationalist, and secular—principles that were to characterize him for the rest of his career. In 1898 Halévy was invited to lecture at the *École Libre des Sciences Politiques*, which had been founded after France’s defeat in 1871 with the goal of diagnosing French political instability, and he remained there all his professional life. The *École Libre* was much admired in Britain by the group of Fabians and their associates who founded the London School of Economics and Political Science, and Halévy came to know them well as he moved in British intellectual circles.

The Dreyfus affair and the defense of the Third Republic were issues which united Halévy with Émile Durkheim (see *Durkheim, Emile (1858–1917)*), though on a philosophical level he rejected Durkheim’s positivism and collectivism. On the other hand he attributed his initial interest in socialism, to which he

devoted half of his scholarly life, to Durkheim's lectures on socialism at Bordeaux in 1895. The affinity that Halévy perceived between communist and fascist régimes—since he viewed 1914 as the start of an 'era of tyrannies'—was an unpopular stance in the intellectual climate of the interwar years, but he persisted in his opinion until his death at Sucy-en-Brie on August 21, 1937. The enthusiasm of the Webbs and Shaw for fascist or communist experiments in no way surprised him, and he ended his life firmly committed to the liberal, rational, democratic ideals of his youth.

2. Intellectual Contributions

In his thesis, published in 1896 as *La théorie platonicienne des sciences*, Halévy explicated a dialectical approach, which he labeled Platonic, by means of which the contradictions in a subject were stated as systematic dichotomies. By exposing the core assumptions and practical implications behind a doctrine or belief system, which usually involved logical conflicts, his own analysis of it could proceed. This fundamental principle of methodology was deployed in his subsequent studies of Bentham's thought, of Wesleyan doctrine, and finally of socialism. In his study of the English utilitarians he found just such a contradiction between Bentham's political and economic theories and argued that 'the contradiction was continually breaking out in the current formulae of Benthamism' (Halévy 1952, p. 489). In his political theory, Bentham postulated the necessity of a legislator who would reconcile conflicts of interest and thus secure the greatest good of the greatest number: this he called the artificial identity of interests. In his economic theory, however, Bentham assumed with Adam Smith (see *Schumpeter, Joseph A (1883–1950)*) and his successors that there was a spontaneous identity of interests and that individual interests were naturally harmonious. Halévy's book is a reminder that the Bentham who designed the *Panopticon*—'a new application of the principle of the artificial identification of interests, the idea of which he had found in Helvetius' (Halévy 1952, p. 82)—also propagated a belief in *laissez-faire* and the 'hidden hand.'

Soon after the completion of *The Growth of Philosophic Radicalism*, Halévy's interest turned to Methodism in eighteenth- and nineteenth-century England. Sometimes regarded as the complete antithesis of utilitarianism, he regarded Methodism as an ally of utilitarianism in shaping the social morality of modern England. In 1905 he traveled to England to work on material relating to the early history of Methodism and it was at this time that he expressed his intention of writing a history of England in the nineteenth century. The Methodism project had a more immediate outcome, however, in two articles on *La naissance du Méthodisme en Angleterre* in the *Revue de Paris* in 1906. With very few exceptions these articles

went unremarked by historians until their translation into English in 1971 (Halévy 1971).

The fundamentals of Halévy's interpretation of the role of Methodism in *La naissance* correspond with his later treatment in *A History of the English People* in 1815 (Halévy 1924)—the first volume of his five-volume *A History of the English People* which was published in French between 1912 and 1926 and in English between 1912 and 1932—but the focus and detail of the earlier work provide a particularly strong statement of the 'Halévy thesis.' He traces the earliest development of manufacturing industry in the first three decades of the eighteenth century and points to the growth of pauperism in the industrial centers. By the late 1730s this was compounded by a commercial crisis of overproduction accompanied by working class agitation, and it was this that stimulated the 'eruption,' in 1739, of Methodism. He argues that working class despair was transformed by Methodist doctrine and discipline into a religious and mystical movement of a conservative nature.

In this process Halévy gave a key role to the *bourgeoisie*, a class which he saw as an essential component of leadership in harnessing the enthusiasm of the proletariat. Had the *bourgeoisie* in 1739 been fired by revolutionary ideals there might well have been the conditions for social revolution, but the English *bourgeoisie* retained a strong element of Puritanism and a revulsion against the excesses of the seventeenth-century Civil War. In Halévy's words, 'There was the raw material for a general revolt. But popular discontent took the form the discontent of the *bourgeoisie* wanted to give it: a religious and conservative form' (Halévy 1971, p. 75).

On this foundation is constructed the broader thesis with which Halévy is more generally known. In *A History of the English People* in 1815 he stated the problem as that of explaining 'the extraordinary stability which English Society was destined to enjoy throughout a period of revolutions and crises; what we may truly term the miracle of modern England, anarchist but orderly, practical and businesslike, but religious, and even pietist' (Halévy 1924, p. 339). The explanation he gives is complex and is focused not exclusively on Methodism, nor solely on the working class, for Methodism's impact is traced first on Nonconformity, then on the Evangelical wing of the Church of England, and through them on the ruling class, and finally on secular thought. In contrast to the view of religion as an 'opiate' which Marxian critics of Halévy such as E. P. Thompson have employed, the thesis is better interpreted as a version of *embourgeoisement*. Halévy did not attribute the influence of Methodism to the depths of the working class but saw it as having an impact on upwardly mobile workers. Methodism, originating in the Church of England, occupied an interstitial position between that Church and Nonconformity, offering a means of passage between the two: 'Puritan nonconformity thus tended

to become a transitional creed, a stage in the history of an English family. The unskilled laborer becomes in turn a skilled workman, an artisan, the head of a small business, a businessman possessed of a modest capital, and as he rises out of the barbarism in which the working class was plunged, he becomes a Nonconformist. If he himself rises still higher on the social ladder, or if his children rise after his death, he, or they go over to the Church of England' (Halévy 1924, p. 371). Wesleyan Methodism, he claimed, rendered the transition imperceptible. Paradoxically, as the religious institutions facilitated such upward social mobility they also served to sharpen status distinctions, for while the middle-class Nonconformist might be despised by members of the Church of England, to which his family might one day belong, compensation could be found in contempt shown towards the working class from which the family had come. Hence, Halévy's opinion that 'the élite of the working class, the hard-working and capable bourgeois' had been instilled with values which did not threaten the existing order of society.

Wesleyan Methodism had originated in the Church of England among a group of conservative High Church clergy. In preaching an egalitarian doctrine of salvation for all it had successfully mobilized an important segment of the rising working class. Here is an excellent example of Halévy's utilization of systematic dichotomy at the core of a belief system. He goes on to demonstrate the influence which Methodism had on establishment opinion by proposing that Wesley had left a 'rear-guard' in the Church of England in the form of the Evangelical movement, which sought to realize his original goal of Church regeneration: 'If the Wesleyan sect, with its hierarchic constitution, and frank political conservatism, constituted the High Church of Nonconformity, the new Low Church or evangelical party was a species of Anglican Methodism' (Halévy 1924, p. 379). With powerful representatives at the University of Cambridge, and with wealthy and influential advocates in the 'Clapham sect' (which was comprised principally of Members of Parliament like William Wilberforce), the Evangelicals were in a position to influence not only ecclesiastical reform but also to campaign for a wider reform of morals—including those of the ruling class. In these several ways, argued Halévy, the influence of Wesleyan Methodism had permeated throughout English society and had helped establish the temper of Victorian England. By contrast, no comparable institution or creed had existed in eighteenth-century France.

Halévy's *Histoire du socialisme européen* (1948) and *L'ère des tyrannies* (1938) are the most cited of his works in France. They further extend the central theme of his work on English ideas, where the contrast between reform and revolution provided his comparative focus. Just as the contradiction between natural and artificial interests had been identified in

utilitarianism, and that between egalitarian salvation and hierarchical discipline in Wesleyanism, so the contradiction in socialism derived from the conjoint goals of human emancipation and the zeal to organize society. The decisive event in Halévy's view of socialism, which changed from a skeptical liberalism to a critical pessimism, was the First World War. The growth of the power of the state and the spread of bureaucracy were seen not only as threats to parliamentary democracy but also as evidence of the dominance of the organizational over the emancipatory principle in socialism.

Halévy's central thesis is clearly stated: 'Since its beginnings, in the early years of the nineteenth century, socialism has suffered from an internal contradiction. On the one hand, its partisans often present it as the outcome and fulfilment of the Revolution of 1789, a revolution of liberty, a liberation from the last remaining subjection after all the others have been destroyed: the subjection of labor by capital. But, on the other hand, it is also a reaction against individualism and liberalism; it proposes a new compulsory organization in place of the outworn institutions destroyed by the Revolution ...' (Halévy 1966, p. 265). It is known that the pessimistic conclusions he drew from this diagnosis surprised many in his intellectual circle at the *Société Française de Philosophie*, and arrangements were being made for a further debate on his propositions when he died in 1937.

3. Impact and Controversy

Halévy's work continues to be a focus of research and debate among social scientists. Two biographies have appeared, the first relating him to the French and European contexts of his time and the second emphasizing the major themes of his work: both characterize the 40-year span of his writing with the same term, 'unity' (Bramsen 1978, p. 348, Chase 1980, p. 3). In Chase's work there is a particularly clear exposition of the 'Halévy thesis' which gives effective treatment to aspects of his argument which have sometimes been obscured in subsequent debate, such as the broader significance of Nonconformity and his portrayal of the 'hard-working and capable bourgeois' as the 'élite of the working class.' The republication in 1995 of a French edition of his book on English utilitarianism has stimulated critique of a work that had been widely accepted as a definitive analysis of its subject. Thus, Halévy has been taken to task for allegedly interpreting the principle of utility, or seeking of pleasure, as both a positive and a normative statement—as both an 'is' and an 'ought' (Vergara 1998).

Even more extensive has been the attention paid to his claim that the Methodist and Evangelical movements were responsible for England's remarkable stability during a period of political ferment in Europe.

Shortly after the publication of the first volume of *A History of the English People in the Nineteenth Century*, the Hammonds offered their portrayal of Methodism as having a repressive and intolerant stance towards the working class. In 1957, in *History Today*, E. J. Hobsbawm questioned Halévy's claims of the extent to which Methodism penetrated the working class and offered an alternative explanation of England's political stability deriving from the ruling classes's ability to retain control. E. P. Thompson's *The Making of the English Working Class* in 1963, however, attributed even more influence to Methodism in subduing the working class than had Halévy. In a 'Postscript on the Halévy Thesis' in *Victorian Minds*, Himmelfarb (1968) commented on the curious status of the thesis in current historical literature, where it was often assumed that the thesis had been discredited or greatly modified while in reality there had been no substantial exploration of it. After reviewing the main features of the debate she concluded by paraphrasing Halévy: 'Will Halévy defeat Marx as the interpreter of this crucial period in English history?' (Himmelfarb 1968, p. 299).

Himmelfarb's postscript became the preface to two decades of research into 'the Halévy thesis.' Semmel's 1971 translation of Halévy's 1906 articles *The Birth of Methodism in England* (Halévy 1971) was published with an introduction which noted that 'the full dimensions of the thesis, as Halévy stated them, have been imperfectly understood'. This was because the 1906 articles had gone virtually unread. The thesis was further explored in *The Methodist Revolution* (Semmel 1973), which began by noting that in the major discussions of the 'Halévy thesis' the role of Methodist theology had been afforded little significance, in contrast to social scientific discussions of seventeenth-century Calvinism. Semmel devoted several chapters to the elements which contributed to the synthesis of Methodist beliefs, restating Halévy's observation of an underlying contradiction between the revolutionary and counter-revolutionary elements of Wesleyan doctrine.

The thesis continued to be the subject of discussion throughout the 1970s and attracted the attention of sociologists examining religion and social change: in this context the 'Halévy thesis' has been described as 'the political corollary, applied in a more restricted historical and geographical context, of the broader thesis put forward by Weber' (Hill 1973, p.183). As closer attention has been paid to Halévy's work, some of his specific historical observations—and their interpretation by more recent writers—have provided further stimulus for debate. One such area has been the role of foreign missions, and specifically of the Wesleyan Methodist Missionary Society. Did such activity provide a safety valve for social and religious tensions, rechanneling potentially disruptive enthusiasm by exporting it, or was there equal concern for home missions? These questions have been addressed

in a revisiting of Halévy's original account (Piggin 1980).

In a wide-ranging review of the debate, Itzkin, like Himmelfarb before her, has noted that many of the contentious issues remain unresolved. While Halévy's antagonists have succeeded in revising some of his claims, the central thesis has remained viable and continues to constitute a 'working historical hypothesis' (Itzkin 1975, p. 56). In the work of revision, attention has focused on the numerical strength of Methodism together with its geographical distribution; on the nature and political stances of the variety of bodies which came within the overall rubric of Methodism; and on the way in which moderate political deviance can make 'an important contribution to public order and political stability' (Gilbert 1979, p. 392).

With the culmination of two decades of lively debate over the 'Halévy thesis,' a collection of most of the important statements was published in Olsen (1990). Extracts from Halévy, from historians of Methodism and Evangelicalism such as Maldwyn Edwards, John Walsh, and Kiernan, and from critics like the Hammonds, Hobsbawm, and E. P. Thompson provide a striking testimony to the continuing vitality of a thesis first advanced in 1906. The parallel with the 'Weber thesis,' first published in 1904–5, is too close to ignore.

Halévy's lectures on the history of socialism, reconstructed from his students' notes and published posthumously as *Histoire du Socialisme Européen* in 1948, remains untranslated into English. *The Era of Tyrannies*, first published posthumously in French in 1938, has, however, been translated and published in English (Halévy 1966). In the latter work the author provides not only a summary account of socialism but also a treatment of the era of tyrannies—using the term in the classical Greek sense of a group of armed men who seize the state—under Stalin, Hitler, and Mussolini. At the end of World War One Halévy had written: '... I recognize that socialism holds the key to the secret of the future. But I cannot decipher this secret nor can I say whether socialism will lead us to a Swiss-type, universalized Republic or to European Caesarism' (Aron 1984, p. 407). In the last years of his life he took an increasingly pessimistic view of Europe's future in the event of another war, which he thought likely. For him, that would represent the final blow to liberal traditions; but for this judgment Aron has criticized him. While cautioning against over-confidence, Aron thought Halévy had 'sinned through over-pessimism' (Aron 1984, p. 422). With the benefit of hindsight Aron's criticism may be justified, but it should be recalled that in the era of the 1930s Halévy was not alone among social scientists who believed that the capitalist élite were becoming 'highly placed bureaucrats.'

M. Hill

Hall, Granville Stanley (1844–1924)

The age of the modern research university began with the founding of the Humboldt University in Berlin in 1810. One of the 9,000 Americans who studied at this and other German universities during the nineteenth century was Granville Stanley Hall. He, like they, sought to gain more advanced knowledge and research skills than was available elsewhere. This educational opportunity aided him in becoming the first professor of psychology and pedagogics at the new Johns Hopkins University, and later the first president of research-oriented at Clark University in the USA. During his academic career, Hall launched the American discipline of psychology (Ross 1972, 1979) and the science of education (White 1992), out of the then

broader study of philosophy. He achieved these intellectual accomplishments through his long faculty and presidential career, numerous books and more than 400 other publications, creation of research journals, and extensive professional conference presentations. In this way, Hall played the initial pivotal and defining role in founding psychology and education as social and behavioral sciences in American higher education (Mitchell and Haro 1999, p. 50, Lagemann 2000).

1. Hall's Early Life, Career, and Intellectual Pursuits Until 1880

Born in Ashfield, Massachusetts on February 1, 1844 to Granville Bascom Hall and Abigail Beals Hall, Stanley was the oldest of nine siblings. His upbringing on the family farm offered his inquisitive mind opportunities to observe nature intimately, which would so powerfully shape his future intellectual outlook. Eschewing agrarian life, Hall completed college preparatory studies at Williston Seminary in Easthampton, Massachusetts in 1862 and entered Williams College in the following year. There he studied under two famous American educators and philosophers, Mark Hopkins and John Bascom. Their influences shaped his interest in philosophy and theology, respectively. Finishing his bachelor's degree in 1867, Hall next decided to study for the ministry and entered Union Theological Seminary in New York. Yet, two years of study, some pastoral experience, and a frank discussion about his intellectual interests with the imposing American theologian Henry Ward Beecher resulted in Hall's first trip to Germany to study philosophy at the University of Berlin in 1869. In Friedrich Adolf Trendelenburg's seminary, he became an avowed Hegelian and contemplated becoming a philosopher. With the outbreak of the Frank-Prussian war, Hall returned to New York and finished his bachelor's degree in divinity in 1871. Yet, his intellectual and philosophy study there led him to embrace the evolutionary ideas of Charles Darwin and Herbert Spencer (Hall 1923).

Forsaking the ministry then, Hall sought the academic life. He became a professor at Antioch College in Ohio, where he taught English, French, and German from 1872 to 1876. Becoming increasingly disenchanted with Hegel intellectually during this time, Hall openly became an enthusiast for Darwin, Spencer, and Huxley and positivistic science (Hall 1923, p. 199, Ross 1972, pp. 58–9). The turning point in his intellectual life occurred with his reading of Wilhelm Wundt's (1873) first volume of *Physiological Psychology*, after which he decided to specialize in psychology. Leaving Antioch, Hall completed a Ph.D. at Harvard University in 1878 under William James; it was the first doctorate in psychology awarded in the USA. His dissertation explored the physiological

relationships between muscles, nerves, and consciousness from a genetic perspective (Ross 1972, pp. 70–5, Wilson 1914, p. 64). Hall's research showed his fascination with experimental psychology and its links to Darwinian and Spencerian evolutionary thought. To bolster his research in the study of psychology, and because he could not obtain a suitable professorial appointment at a major university, Hall again went to Germany to study under Hermann von Helmholtz and William Wundt at the universities of Berlin and Leipzig, respectively (Goodchild 1996, pp. 72–3).

2. Hall's Faculty Appointments at Johns Hopkins University from 1882 to 1887

After returning to the USA in 1880, Hall lectured at Harvard at the invitation of President Charles W. Eliot and then at Hopkins by courtesy of President Daniel Coit Gilman. Later the Hopkins president appointed him a lecturer in 1882 and then Professor of Psychology and Pedagogics in 1884. From these positions, Hall furthered the study of education and psychology through a series of major articles exploring their relationships to human development. First, he surveyed pedagogical study in the USA and then explored the moral and religious training of both children and adolescents in one of his first discussions of child development. In analyzing the needs of education later, the professor stated boldly that 'we must study and follow the child's nature as it actually is' (Hall 1883a, p. 286). Hall further proclaimed his new concept of 'natural' methods of education where education and psychology may both be utilized to understand the relationship between intelligence and human development in his important article, *New Departures in Education* (Hall 1885a, pp. 147–8). Finally, he and one of his doctoral students outlined the entire field of education in their 1886 book, *Bibliography of Education* (Hall and Mansfield 1886).

Second, in psychology, Hall quickly created one of the first experimental psychological laboratories in America at Hopkins and authored many of its early articles in experimental psychology (Boring 1950, Hawkins 1960, pp. 202–3). One of his important contributions was the publication of 'The new psychology' (1885b) which outlined this developing field. In 1887, he created a new research journal, the *American Journal of Psychology*, to publish psychological research. It was pivotal in establishing this new discipline. Third, his pedagogical and psychological ideas had already coalesced a few years earlier in his first major empirical studies using questionnaires on child development. 'The contents of children's minds' (1883b) and *The Study of Children* (1883c) described 'the real nature' of children, used the reports of actual teachers' observations from the questionnaires, and suggested appropriate pedagogical techniques. They

played a major role in launching Hall's national reputation and his central position as the founder of the child study movement in the USA (White 1990). Some of his doctoral students followed him as his career evolved; others, particularly John Dewey and James McKeen Cattell, were not favored and moved onto their own significant accomplishments (Ross 1972, pp. 144–7). Thus Hall's work at Hopkins set the stage for the remainder of his scholarly career and publications as he pursued research in education, psychology, and their mutual implications for understanding human development.

3. Hall's Presidency of Clark University from 1888 to 1920

In Worcester, Massachusetts, wealthy industrialist Jonas Clark founded an institution of higher learning with a \$1 million gift in 1887. He intended it to have a research mission for older male students and be a 'useful' college for local boys (Koelsch 1987, pp. 9–12). Hall was named its first president in April 1888. He was determined to create a new graduate research university comparable to Hopkins, following the German ideal. The first three years saw considerable fulfillment of his vision. However, conflict with the founder over the college and loss of many faculty members to the new University of Chicago severely constrained the president. The struggling and much smaller institution still embraced the primacy of research as the reform ideal for the mission of all American universities (Goodchild 1996, Goodchild and Miller 1997). Eventually, Hall allowed an undergraduate college to be created when funds from the founder's estate became available. The president remained highly productive in his research and continued to oversee the institution until his retirement in 1920.

4. Hall's Prolific Scholarly Achievements During his Presidency

The president's accomplishments in psychology, education, and their implications for a new genetic interpretation of human development established the American prominence of these new scientific fields of study. In psychology, Hall founded the American Psychological Association in 1892, became its first president, and anchored his *American Journal of Psychology* to the organization. It remained the pre-eminent national association for this growing academic discipline. In 1904, Hall's most famous psychological study, *Adolescence: Its Psychology and Its Relations to Physiology, Anthropology, Sociology, Sex, Crime, Religion and Education*, appeared. This definitive two-volume work on adolescence comprised many of his earlier ideas on the child's next stage of development, established this stage as a scientific

concept, related this developmental period to various human behaviors, and discussed its meaning for other emerging academic fields, especially education. Hall's interest in the sexual development of youth in this work was ground breaking. It led him to invite Sigmund Freud, Carl Jung, and many other leading psychologists to the famous 1909 twentieth Anniversary Conference of the founding of Clark University (Koelsch 1987, pp. 246–7). As if to secure his role in this developing discipline, Hall published the valuable book, *Founders of Modern Psychology*, in 1912. After World War I, the scholarly president turned to his lifelong interest in religion and its psychological meaning. He authored a major reinterpretation of Christianity's founder in his *Jesus the Christ, in the Light of Psychology* (1917) and its application in the advocacy of a new life ethic in his *Morale: The Supreme Standard of Life and Conduct* (1920a) in which Hall espoused a holistic understanding of health and well-being as the rule for human conduct. With retirement from Clark's presidency in 1920, Hall reflected on his accomplishments in his *Recreations of a Psychologist* (1920b), and *Life and Confessions of a Psychologist* (1923). Hall achieved another scholarly triumph by completing his work on the last stage of human development with the publication of *Senescence: The Last Half of Life* (1922). In all this pioneering work, he made some significant missteps, especially claiming child development recapitulates human evolution (White 1990, p. 31) and a too pervasive Darwinian and Spencerian 'evolutionism' (Ross 1972, p. 92). On the other hand, he awarded the first doctorate in psychology to an African-American and encouraged Asian students to study psychology at Clark (Goodchild 1996).

By his death on April 24, 1924, Hall had established psychology as an American discipline and study, almost entirely graduated the next generation of psychologists (Goodchild and Miller 1997), and secured the role of behavioral and genetic psychology as being an integral part. To insure the continuation of his work, Hall's estate established at Clark an endowment for a genetic psychology professorship and for his educational journal that was redirected and renamed *The Journal of Genetic Psychology*.

Similarly, his work in education commanded national attention. Hall believed that education was applied psychology. He followed identical approaches in establishing the importance of education as a field of study, as he had done in psychology. Hall offered a series of university lectures on kindergarten, elementary, secondary, and higher education (Goodchild 1991). He next founded a research journal, *The Pedagogical Seminary: An International Record of Educational Literature, Institutions, and Progress*, in 1891. It provided a new research outlet from studies intended to reform education from American and international perspectives. Further, he extracted his pedagogical ideas from his books on adolescence and

released them as *Youth: Its Education, Regimen, and Hygiene* (1906) to serve educators and teachers who were implementing his ideas in the classroom. Five years later, Hall presented his definitive study on education with another extensive two-volume work, *Educational Problems* (1911). He claimed to have fomented an American educational revolution where 'now the school, including its buildings, all its matter and method, revolve about the child' (p. 1: vi). This 'natural' education was to be individualized to the student's developmental stage, sex, and race. Thus pedagogy was to assist in the intellectual development of every person, although higher education was intended for the most able. At Clark, Hall had been instrumental in creating the study of education—particularly in conducting empirical research on children to develop better pedagogy, offering the first courses in higher education, and espousing genetic psychology as the basis for educational practice. His extensive publications in higher education focused on the mission of the new research university and its faculty (Goodchild 1996). Similarly, missteps occurred in education as Hall advocated separate education for women, decried 'identical' coeducation, and espoused elitism in higher education (Ross 1972, pp. 311–12). Nevertheless, the president greatly assisted in the arrival of education as an academic field of study (Cremin 1961).

Hall's most significant contribution may be the creation of developmental psychology and its relationship to education (White 1992). His research on child study, adolescence, and old age enabled him to argue for five stages of human development: (a) childhood; (b) adolescence; (c) middle life, from 25 to 45; (d) senescence, after 40; and (e) senectitude, approximately near the end of life (Hall 1922, p. vii). His psychological and educational ideas and practices were focused on what he believed, would further the human race. His Darwinian and Spencerian concepts of evolution pervaded his understanding of human genetic development. He consistently maintained these ideals, even in the face of demands for coeducation in schools, growing behaviorism in psychology, and expansive progressivism in education. Hall was a man of his times, his scientific worldview centered on the mid- to late nineteenth century ideas and their implications for professional practice.

Finally, Hall's most important achievement when assessing the rise of the social and behavioral sciences was to engender the development of psychology and education from their philosophical progenitor. His patterns consisted of a critical assessment of the condition of the field first, next an assertion of a new position for the field, then a new research journal to publish these findings, and finally definitive works exploring the field of study. Hall thus played an essential role in the establishment of psychology and education as new academic fields of study in the USA. In 1992, the centenary meeting of the American

Psychological Association pointed to his pivotal role in these founding moments (Goodchild 1992, White 1992).

L. F. Goodchild

Hallucinations, Neural Basis of

Hallucinations, by definition, are percepts experienced in the absence of sensory input. They can be expressed in any of the sensory modalities and arise from a wide range of pathological conditions. Hallucinations are also a normal component of conscious experience. For instance, they arise routinely as ordinary dreaming during sleep. Sometimes daydreams and relaxed waking consciousness produce imagery so vivid that it is momentarily experienced as real (Foulkes and Fleisher 1975). The main types of hallucinations and their distinctive phenomenological characteristics have been the subject of considerable prior study (Brown 1985, Benson and Gorman 1993). A brief summary of the major types follows:

Visual hallucinations: Peduncular hallucinations consist of animals, face, or human figures and are traditionally associated with vascular lesions in the upper brainstem (involving, especially, the cerebral peduncles). They can also occur in cases of encephalitis or during the transition from waking to sleep (Lhermitte 1922, from Brown 1985). *Charles Bonnet syn-*

drome is similar and occurs in the elderly, generally with significant visual impairment. However, human figures are characteristically small and doll-like, and can actually amuse the subject (Benson and Gorman 1993). *Palinopsia* is a pathological persistence of a visual percept originating from external stimulation that arises from lesions of the occipital cortex, seizures, or drug-induced states (Benson and Gorman 1993, Brown 1985). So-called *elementary* hallucinations consist of bands of light or phosphenes that can arise from pathology of the retina or optic nerve, and certain drug-induced states (Brown 1985). *Hypnagogic* hallucinations occur normally during the transition from sleep to wakefulness and are experienced as the continuation of a typical dreamstate. Hallucinations of faces or human figures are reported by approximately 20 percent of patients with schizophrenia. Visual hallucinations also often occur during seizures in patients with epilepsy. These hallucinations can have a geometric design or reflect a recollection of visual images based on past experience. Severe alcohol withdrawal often is accompanied by visual hallucinations of bugs or spiders. Lysergic acid (LSD) and related compounds often produce visual hallucinations consisting of light flashes, colors, geometric figures, and generally are accompanied by distortions of the geometric form of percepts (Crowley 1995). Higher doses produce fantastic forms, distorted facial images, etc. So-called *autoscopic* hallucinations reproduce an actual visual image of the self and are generally associated with epilepsy though these experiences also can occur in patients with schizophrenia or depression (Denning and Berrios 1994).

Auditory hallucinations: Most commonly, auditory hallucinations consist of spoken speech. These hallucinations are reported by 70–80 percent of patients with schizophrenia and less commonly by patients with other psychiatric disorders, such as depression or mania. These patients may also experience hallucinations of non-speech sounds, such as rattling, footsteps, etc. Other common causes of auditory hallucinations of speech include chronic alcoholism and phencyclidine use, or chronic amphetamine abuse. Hallucinations of speech consist of one or more ‘voices’ which comment on the patient’s speech, thought, or behavior, command them to perform certain actions, or converse with each other. A nonpathological variant of this experience is the momentary experience of hearing one’s name being spoken in the absence of an actual speaker. Both pathological and non-pathological variants of hallucinated speech are often triggered by indistinct sounds such as background conversation, street sounds, and running water. Often, if visual hallucinations are also experienced by patients with schizophrenia, they are phenomenologically linked with the auditory hallucination, e.g., a face will appear to speak the hallucinated words. Auditory hallucinations of music can occur in psychiatric patients with an affective disorder such as depression

(Wengel et al. 1989) as well as in patients with deafness and steroid-induced psychotic states. *Palinacousis* is the auditory analogue of *palinopsia* and consists of the persistence of previously heard sounds, music, or speech.

Tactile or haptic hallucinations: These experiences commonly occur during the *delirium tremens* stage of severe alcohol withdrawal and consist of *formication*, i.e., the sensation of insects crawling on the body. Amphetamine or cocaine-induced psychosis can also lead to formication experiences. *Phantom limb* hallucinations follow arm or leg amputation and consist of the persistent sensation of the lost limb that can include the experience of movement and/or pain. Sensation of altered or duplicated body shapes can

occur in epilepsy, toxic encephalopathy, or with hallucinogenic drugs. When such hallucinations are accompanied by delusions that are fantastic, they are likely to be related to a schizophrenic process (Benson and Gorman 1993).

Hallucinations of bodily sense and movement have also been reported following direct electrical stimulation of the temporal lobe in humans (Ishibashi et al. 1964).

Olfactory hallucinations: These hallucinations most typically occur during seizure auras, migraine attacks, or as a result of damage to the olfactory bulb at the base of frontal lobe (e.g., by tumors). Olfactory hallucinations generally have a noxious content, consisting of a burning smell or some other foul odor. They are also reported occasionally by patients with schizophrenia and depression.

Mechanisms of hallucinations: Benson and Gorman (1993) outline a simple, but intuitively appealing, approach dividing hallucinations into two categories: the first ‘release’ hallucinations and the second ‘ictal’ hallucinations. The former arise when ‘normal sensory processing channels are blocked, allowing stored images to be experienced’ (pp. 266–267). Typical examples would be musical hallucinations following deafness or the Charles Bonnet syndrome arising from visual impairment in the elderly. These hallucinations tend to be longer in duration, can often be well-formed and quite elaborate, and occur only in the defective receptive field. ‘Ictal’ hallucinations arise from ‘abnormal neuronal discharge’ and tend to be briefer, less well-formed, and associated with alterations in consciousness. Benson and Gorman also highlight the importance of alterations in attention/arousal in producing certain types of hallucinatory phenomena (1993, p. 278). Examples include dream-like hallucinations arising from the transition from sleep to arousal, the disturbed consciousness of drug-induced states, sleep deprivation, narcolepsy, or delirium. The postulated mechanism is an alteration in the gating of material into conscious awareness. In addition, limbic disorders and frontal dysfunction were postulated to cause hallucinations. We will discuss below some evidence suggesting a role of the former.

More recent work on the details of hallucinatory phenomena, considered in the remainder of the article, suggests some revision may be necessary in the useful framework introduced by Benson and Gorman.

First, consider again phantom limb phenomena, a classic example of 'release' hallucination. These experiences are almost universal, occurring in approximately 85 percent of amputees (Benson and Gorman 1993) and are experienced as if the cortical representation of the limb is retained somehow as a conscious experience. Phantom limb experiences, especially early on, often are finely articulated with detailed sensations of the digits of the hands or feet. After loss of a hand, the person may still, for instance, re-experience the sensation of a long-worn ring. One puzzling observation is that patients who also lose sensation and use of a limb due to spinal cord injuries do *not* generally have phantom limb hallucinations or, if they do, these are very indistinct and fleeting. Why does loss of limb produce these experiences, while paraplegia does not? In both cases, deafferentation has occurred and 'release' phenomena should, in theory, arise.

Recent work by Spitzer et al. (1995) has provided an updated model suggesting that phantom limb hallucinations arise from a progressive reorganization of the sensory area of the cerebral cortex responsible for limb representation. The critical observation underlying Spitzer's model is that sensory ganglia in the spinal cord are known to fire randomly following denervation. These random impulses are then projected in a sustained fashion to the somatosensory cortex. Random firing from these sensory ganglia is not generated, in contrast, in the case of spinal cord injury. Using computer simulations, Spitzer demonstrated that chronic random inputs cause a deafferentized cortical sensory system to reorganize so that activation patterns become self-sustaining. Moreover, a cortical region whose input is limited to noise was shown to assimilate receptive field properties of neighboring cortical areas gradually. Consequently, representations of the original limb representation are gradually usurped. Progressive reorganization of limb cortical maps in this fashion could produce the characteristic subjective 'shrinking' of these hallucinations over time—the phantom limb grows smaller over a period of weeks to months so that, in later stages, it is only experienced as, say, the size of a postage stamp superimposed on the stump.

The limits of the Benson/Gorman approach are also suggested by the hallucinations experienced during amphetamine psychosis. These hallucinations typically consist of spoken speech of whole phrases or sentences or the perception of faces or bodily forms and are often accompanied by paranoid fears. Their phenomenology often resembles that of schizophrenia. Consequently, amphetamine psychosis is studied as an experimental model of this disorder.

These hallucinations do not readily fit a reduced attention/arousal model of hallucinations since

amphetamine generally heightens attention and arousal. There are other data to suggest that perhaps amphetamine-induced hallucinations reflect an 'ictal' or 'neuronal activation' model of hallucinations. It is well-known, for instance, that a single dose of amphetamine produces widespread, heightened activation of the cerebral cortex (Porrino et al. 1984). However, amphetamine-induced hallucinations almost invariably do not emerge unless the person is a chronic abuser of the drug (Bell 1973).

Induction of apparent hallucinatory behavior in monkeys also requires repeated exposure to this drug (Castner and Goldman-Rakic 1999). Thus, it seems clear that the hallucinations induced by amphetamine do not arise simply from heightened brain activation—which is readily detected following a single exposure to the drug—but instead reflect complex changes in brain function generated over time by repeated drug exposure. The exact nature of these brain 'sensitization' changes has yet to be determined. However, recent studies suggest that alterations of neural circuitry in brain regions which receive projections from dopamine neurons and ordinarily respond to amphetamine are critical (Pierce and Kalivas 1997). These alterations probably involve a cascade of molecular events that enhance cellular aspects of learning/conditioning mediated by receptors for the excitatory amino acid neurotransmitter, glutamate, as well as elaboration of new neuroanatomic connections (Robinson and Kolb 1999, Wolf 1998). These changes produce widely distributed neurocircuits that consequently become 'primed' to respond to the activating effects of amphetamine.

Reports of direct electrical stimulation in the human brain also suggest that neural activation alone is not sufficient to cause hallucinations. These studies have been conducted in patients with intractable epilepsy who were evaluated for neurosurgical resection of seizure loci. Penfield, a pioneer in this area, reported that complex hallucinations whose content consisted of 'engrams' of previous memories could be elicited in unanesthetized human subjects by electrically stimulating temporal lobe neocortical gray matter (cf. Penfield and Perot 1963). Penfield proposed that such stimulation directly accessed neural networks that actually coded for memories. Later workers found it difficult to obtain similar results, however. Halgren et al. (1978), Gloor et al. (1982), and Horowitz and Adams (1970), for instance, were able to elicit experiential responses but by stimulating deeper limbic structures (i.e., hippocampus and amygdala) rather than neocortical areas.

These experiences tended not to be memories but did include a range of hallucination-like experiences including unformed sensory experiences (lights, streaks, flashes) and complex visual experiences of persons, scenes, or objects or autoscopic experiences of the self. The location of sites that elicited hallucinations is curious since it is generally assumed that only

neocortical structures (not limbic structures) code for actual sensory experiences. This raises the question of how hippocampal and amygdala stimulation, whose known functions pertain to registration of emotional salience, memory storage, and memory reactivation, could produce hallucinations.

One clue was that hallucinations were more likely to emerge when limbic stimulation produced not simply activation, but sustained afterdischarges, i.e., rhythmic activity detected via EEG recordings (Halgren et al. 1978, Horowitz and Adams 1970). After-discharges of this sort are more likely to lead to a temporary functional lesion of neural systems rather than activation of coded information (Gloor et al. 1982). Analogously, rhythmic electrical stimulation of neocortical tissue produces temporary aphasia or speech arrest if directed to language processing areas of the brain (Ojemann and Mateer 1979). Halgren et al. (1978) and Horowitz and Adams (1970) proposed that sustained disruption of limbic structures induced by after-discharges lead to the 'release' of sensory material from neocortical regions into consciousness. Consistent with this view are EEG studies in animals showing that the REM stage of sleep and LSD administration, which each produce vivid hallucinations in humans, cause dramatic *reductions* in hippocampal activation (Halgren et al. 1978). These observations suggest that the actual production of hallucinations by intracerebral stimulation arises from a dynamic interaction between neocortical and limbic systems, rather than simple activation of a group of neurons.

As with other forms of hallucinations, a new picture of auditory hallucinations in patients with schizophrenia is now emerging. Functional neuro-imaging studies indicate that these hallucinations are accompanied by activation from speech perception and auditory neurocircuitry (Silbersweig et al. 1995, Dierks et al. 1999); one of these studies also strongly implicated activation of hippocampal structures as well (Silbersweig et al. 1995). However, it is not clear if this distributed pattern of activation produces auditory hallucinations or arises as a consequence of some other pathophysiological process. For instance, shifts in attention due to the experience of hallucinations (from outward focus to internal imagery focus) may produce regional brain activation effects. If so, brain activation of this type will accompany hallucinations but will not in itself signal a causal mechanism.

Transcranial magnetic stimulation (TMS) is a method whereby an electromagnet placed on a scalp transmits magnetic pulses or waves to a small portion of the brain. Repetitive transcranial magnetic stimulation (rTMS) delivered at a low frequency (once per second) has been shown to reduce the reactivity or excitability of the part of the brain stimulated and other brain regions functionally connected to the region stimulated (Chen et al. 1997, Wassermann et al. 1998). A pilot study using a double-blind, crossover

design compared effects of active versus sham low frequency rTMS in schizophrenic patients with auditory hallucinations (Hoffman et al. 1999, 2000). Based on the aforementioned neuro-imaging studies, the left temporoparietal cortex, a brain region critical for speech perception, was stimulated. A total of forty minutes of rTMS was administered over a four-day period. Statistically robust improvements in auditory hallucinations following active rTMS relative to sham rTMS were observed. These rTMS data support the hypothesis that activation of speech processing neurocircuitry contributes to the production of these hallucinations rather than emerging as a 'downstream' consequence of some other pathophysiological process.

These findings still do not address why speech processing areas of the brain, such as temporoparietal cortex, are pathologically activated in patients with schizophrenia. To understand this process better, computer simulations of neural networks have been developed that reproduce some aspects of speech processing of continuous narrative speech (Hoffman and McGlashan 1997). These simulations suggest that the ultimate 'cause' of auditory hallucinations is a loss of neuronal connections within these networks. Reductions in cortico-cortical connectivity are a normal component of 'late' development in human association cortex that continues during human adolescence (Huttenlocher and Dabholkar 1997). There are empirical data suggesting that reductions in synaptic density accompany some forms of learning (Scheich et al. 1991). Along these lines, computer simulations demonstrate that selective pruning of connections within recurrent neural networks produces significant information processing advantages (Hoffman and McGlashan 1997). In this model, pruning connections caused the system to fill in some of the gaps due to ambiguous phonetic input. It is well known that ordinary continuous speech, when produced at normal rates, has significant phonetic ambiguity that we do not 'hear' because our brains are also very skillful in 'filling in the gaps.' When pruning was excessive in our simulated networks, however, the system began to produce outputs in the absence of any phonetic input at all, thereby simulating speech hallucinations. This model therefore suggests that the hallucinations of schizophrenic psychosis arise as a result of an otherwise normal neuro-developmental trend that is excessive or unregulated. An appeal of this model is that it provides an account for the characteristic age of onset of schizophrenia, namely late adolescence and young adulthood.

Overall, the 'release' and 'ictal' models of hallucination described by Benson and Gorman appear to be good starting points. A comprehensive understanding of their nature, however, needs to consider interactions between different brain regions as well as between different 'levels' of neural processes involving molecular and neuroplastic alterations on the one

hand, and large-scale neural networks dynamics on the other. In spite of our current limited understanding of hallucinations, this fascinating area is likely to provide important insights into the pathophysiology of brain disturbances, as well as the normal physiology of perception and consciousness.

R. E. Hoffman

Harlow, Harry Frederick (1905–81)

Open any Introductory Psychology textbook published since 1960, start thumbing through the pages, and most likely you will come across a photograph of a rhesus monkey infant clinging to a cloth-covered dummy adjacent to another dummy, this one with a wire surface and a protruding milk-filled bottle. Along with the photo will be a description of Harry Harlow's classic 'surrogate mother' experiments, in which he

dramatically demonstrated that tactile contact was more important than feeding in establishing a monkey infant's bond to its surrogate. Harlow's conclusions from these studies, that 'there is more to mother love than mere milk' (Harlow 1958), had important and lasting consequences. They effectively demolished the prevailing theoretical consensus that an infant's primary social relationship is formed as a direct consequence of the feeding process, be it through oral gratification, as advocated by orthodox psychoanalysts, or by its reinforcement history, the contemporary behaviorist view. More importantly, Harlow's findings also provided compelling empirical support for specific biological foundations underlying Bowlby's attachment theory, which went on to become the predominant view of social and emotional development over the latter third of the twentieth century. But Harlow's contributions to, and influences on, both psychology and a remarkably diverse range of other disciplines went far beyond his legacy as the father of the surrogate mother. His numerous ground breaking discoveries over a lifetime of research with monkeys have not only stood the test of time and scientific debate, but indeed provided the very basis for many new areas of scientific inquiry that still remain active in the year 2001.

Harry F. Harlow was born Harry F. Israel on October 31, 1905 in Fairfield, Iowa, where he spent his childhood years. He left this small Midwestern town to go to college, initially matriculating at Reed College for a year (as an English major) before transferring to Stanford University, where he changed his major and then earned both his BA (1927) and Ph.D. (1930) in psychology. His graduate advisors at Stanford, concerned that his family name might restrict his academic employment opportunities during a time of economic depression and latent anti-Semitism, suggested a name change. Harlow obliged, and later in life he often quipped that they had given him not only his degree but his very name as well. In the fall of 1930 he was hired as an Assistant Professor in the Department of Psychology at the University of Wisconsin in Madison, where he remained for the rest of his professional career. Following his retirement in 1974 Harlow moved to Tucson, Arizona, where he served as a Emeritus Professor of Psychology at the University of Arizona until his death on December 3, 1981.

Although Harlow's graduate training in comparative psychology had been largely limited to research with rodents, he began working with non-human primates shortly after his arrival at Wisconsin, carrying out his initial studies with a variety of monkeys and apes then residing in Madison's public zoo. He quickly discovered that the standard types of conditioning and memory tests then being used in studies with rats or pigeons were simply not adequate to tap the considerable cognitive capabilities of his non-human primate subjects. He and his students therefore began creating new tasks and test batteries

that were substantially more challenging. Shortly after moving into his own laboratory building on the University campus, Harlow designed and built the first prototype of a apparatus that would profoundly alter the course of research in primate cognition and that continues to be used in primate laboratories around the world in the year 2001. This testing device was named the Wisconsin General Test Apparatus (WGTA); it enabled an experimenter to present a large number of discrete learning and memory tasks in a rapid and highly standardized fashion to subject after subject (Harlow and Bromer 1938). At the same time, he began directing most of his efforts away from broad cross-species comparisons to more focused studies using a single species—the rhesus monkey (*Macaca mulatta*), an unusually hardy and adaptive species that thrived in captivity.

Armed with a laboratory specifically designed to house and test primates, in which individual monkeys could be maintained in good physical health for year after year, and a testing apparatus that enabled the same monkey to be tested repeatedly under standardized conditions, Harlow began changing the field of animal learning. In the 1940s he and his students created a battery of learning and memory tasks that provided a standardized 'intelligence test' for his monkeys. He then proceeded to study cortical localization of learning capabilities by lesioning different brain areas and recording subsequent differential patterns of deficits across the various components of the test battery. This research established his credentials as a physiological psychologist and it opened up areas of inquiry and an experimental methodology that continue to be pursued in neuroscience research.

In 1949 Harlow made a major conceptual and methodological breakthrough with his discovery of 'learning sets' in rhesus monkeys. He found that monkeys presented with a long series of six-trial two-choice discrimination problems soon learned to achieve near-perfect performance on the second and all subsequent trials of each problem. This demonstrated unequivocally that the monkeys had acquired a general strategy for problem solution, i.e., an abstract concept (in his words, 'learning to learn'), rather than a product of simple associative learning (Harlow 1949). This finding rendered untenable the neo-Decartes characterization of animals as 'reflex machines,' and it ultimately has led to increasingly more sophisticated studies of primate cognitive capabilities that foster direct comparisons with those of young human subjects. Largely because of this discovery, Harlow was elected to the National Academy of Sciences in 1951.

Harlow became interested in the ontogeny of rhesus monkey cognitive capabilities in the early 1950s when he developed a program of research designed to precisely establish when specific cognitive capabilities first emerged during development and when they subsequently achieved adult levels. He demonstrated

that infant monkeys could be both classically and operantly conditioned and performed associative learning tests at adult levels as early in life as such tests could be administered. In contrast, monkeys did not achieve adult levels of performance on more abstract problems such as learning set and oddity until their juvenile and adolescent years, respectively (Harlow 1959). In the process of carrying out these studies he also observed that young monkeys would solve problems and otherwise engage their physical environment in the absence of appetite rewards. This led him to conclude that in many circumstances curiosity was a more powerful motivator than a reduction of any primary drive (Harlow 1953). These observations provided the conceptual foundation for the 'surrogate mother' studies cited above.

In the 1960s Harlow shifted the major focus of his research from primate cognition to the development of social behavior, both normal and abnormal. He developed the concept of 'affectional systems,' in which he characterized emerging relationships formed by monkey infants with their mothers, peers, and others in the social group as differing in qualitative fashion and serving complementary roles in the socialization process (Harlow and Harlow 1965). He and his students also studied the consequences of blocking the formation of different affectional systems via various degrees and duration of social deprivation initiated at birth (Harlow and Harlow 1962, 1969). These studies established convincingly the importance of early social experiences for the development of species-normative adult social activities, including reproduction and maternal behavior, and they provided the conceptual and methodological basis for current studies of early experience effects on brain as well as behavior. In recognition for this research Harlow was awarded the National Medal of Science, America's highest official scientific award, in 1967.

Harlow continued his investigations of abnormal behavior during his final years at Wisconsin, generating two more areas of research in the process. First, he and his students demonstrated that the devastating behavioral consequences of total social isolation for the first 6 months or year of life, previously thought to be permanent, could be largely reversed by exposing the monkeys upon emergence from isolation to conspecific 'therapists' deliberately chosen to not only be socially normal but chronologically younger than the isolates themselves (Suomi and Harlow 1972, Novak and Harlow 1975). These findings directly refuted a strict 'critical period' interpretation of social deprivation effects, providing compelling evidence of developmental plasticity and once again opening up a new area of study that remains at the forefront of developmental neuroscience research today. At the same time, Harlow set out to create a rhesus monkey model of human affective disorders, relying on earlier observations by Rene Spitz and Bowlby that certain forms of social

deprivation were associated with infant and childhood depression. He and his students used a variety of social separation procedures to precipitate analogous behavioral states in young monkeys and then employed both social and pharmacological interventions to reverse to behavioral disorders (Harlow and Suomi 1974, Suomi and Harlow 1977). In recognition of these efforts, Harlow received the Kittay Scientific Award in 1975, the most prestigious award in the field of psychiatry at that time.

Harlow's influence on the field of psychology extended far beyond his empirical contributions, which resulted in over 323 original scientific publications over his 40-year career (a complete bibliography of Harlow's works may be found in Suomi and LeRoy 1982). He served as Editor for the *Journal of Comparative and Physiological Psychology* for over a quarter century. He also took an active role in many scientific societies, including the National Academy of Sciences, the Society for Experimental Psychology, and the American Psychological Association, for which he was elected President in 1958. Harlow served as the Chief Psychologist for the US Army during the Korean War, and he subsequently was appointed to numerous US government planning and review committees. He played a major role in the establishment of the US Regional Primate Research Center System in the early 1960s and was instrumental in establishing the University of Wisconsin as the site for one of the 7 original Centers, which he directed from 1964 from 1971.

Despite all of his research activities and administrative responsibilities, Harlow maintained an active teaching role throughout his career. Not only did he train numerous graduate students and postdoctoral fellows (a total of 35 students completed their Ph.D. dissertations under his tutelage), but he was also legendary as an undergraduate instructor, especially for Introductory Psychology, which he taught nearly every year during his tenure at Wisconsin. In addition, Harlow worked hand-in-hand with veterinary and technical personnel to establish numerous basic advances in primate husbandry, including the development of the first self-sufficient primate colony, the first large-scale primate neonatal nursery, and various quarantine and screening procedures that are still used.

Harlow was a colorful character who enjoyed dealing with controversy. He delighted in generating empirical findings that directly challenged existing theoretical dogma. In addition to his considerable skills as a writer and editor, he was a gifted public speaker, who for years was one of the most sought-after scientific lecturers in the country. As a result, he was able to present his findings not only to psychologists around the world but also to representatives of numerous other scientific disciplines, as well as to lay audiences. Indeed, 20 years after his death Harlow's scientific contributions were still cited not only by

comparative, physiological, developmental, cognitive, and clinical psychologists but also by others in fields ranging from anthropology to zoology. Clearly, he was much more than the ‘father of the cloth mother.’

S. J. Suomi

practice at the Chancery Bar throughout the 1930s. In 1940, he became a civil servant working in military intelligence; in 1941 he married Jenifer Fischer Williams, a civil servant in the Home Office, who was later herself to become an academic.

During the war, Hart’s keen interest in philosophy was stimulated by regular conversations with Stuart Hampshire and Gilbert Ryle, who were working in a related Department, and who introduced him to the new movements in linguistic philosophy. In 1945, after some hesitation, but encouraged by his close friend Isaiah Berlin, Hart accepted a fellowship in philosophy at New College. Despite his 16 years outside the academy, he established himself quickly as a leading member of the influential group of analytic philosophers, including Ryle, J. L. Austin, G. A. Paul, and Friedrich Waissman, working in Oxford at the time. Such was his reputation that, notwithstanding having published only one article and a book review, he was in 1952 elected Professor of Jurisprudence at University College, Oxford. During his tenure of the Chair, he revived what had become an intellectually sterile subject, bringing to jurisprudence the rigor of a philosophical method of which it had been deprived since the days of Bentham and John Austin, and introducing the fresh insights of Wittgenstein’s and, primarily, J. L. Austin’s philosophy of language.

Outside the UK, his reputation was especially strong in the US, where he spent several periods, notably at Harvard in 1956–7, and in Israel, which he first visited in 1964. He was elected President of the Aristotelian Society in 1959 and Fellow of the British Academy in 1962. In 1968 he resigned from the Chair, taking up a Senior Research Fellowship at University College, Oxford, in order to devote himself to the editing and analysis of the works of Bentham. From 1967–73 he served as a member of the Monopolies Commission; he also chaired a committee that made important recommendations for the reform of Oxford’s governance in the light of student unrest in the late 1960s. From 1973–8 he was Principal of Brasenose College; following his retirement he returned to University College as an honorary fellow. He died in Oxford on December 19, 1992.

Hart, Herbert Lionel Adolphus (1907–92)

Herbert Lionel Adolphus Hart was born on July 18, 1907 in the spa town of Harrogate where his family, which was Jewish, ran a furrier’s business. Hart’s was the first generation of the family to receive a university education: he studied at New College, Oxford, where he took an outstanding First Class degree in Greats (ancient history and philosophy) in 1929. He then qualified as a barrister, and enjoyed a successful

1. Hart’s Contribution to Legal, Moral, and Political Philosophy

Hart’s intellectual contribution lies in two distinct but related fields. First, he revived the tradition of analytical jurisprudence, exploring both the concept of law in general and a number of specific concepts—causation, rights, obligation, responsibility, rules—which structure legal reasoning and doctrines. In this work, Hart emphasized J. L. Austin’s assertion that one may use a ‘sharpened awareness of words to sharpen our perception of phenomena.’ He insisted,

however, that the task was not one of simple definition: rather, the aim was to build a theory or elucidation of the relevant concepts by examining their operation within the practical contexts in which they are used, and paying heed to the ‘open texture’ of language, with its core meaning surrounded by an unsettled penumbra. Perhaps the most outstanding example of these methodological commitments lies in Hart’s and Honoré’s monumental *Causation in the Law*, first published in 1959, which sets its conceptual analysis of causation within the context of hundreds of legal cases, and which draws criteria for the identification of causes out of the common sense understandings which underlie everyday usage in the relevant contexts.

Hart’s second contribution was in the fields of normative legal, moral, and political philosophy. Building out from his analytic conceptions, he made highly influential interventions in normative and policy debates about matters such as capital punishment, abortion and the regulation of homosexuality. His treatment of these issues was located within a tradition stretching back to Hobbes, Hume, Locke, and, most obviously, J. S. Mill, to which Hart contributed, among other things, an elaboration of principles limiting the proper scope of state action, a novel account of the justification of punishment, and an analysis of the relationship between utility and rights.

To understand why Hart’s work in analytical jurisprudence had such an extraordinary impact, one has to understand something about the development of jurisprudence in the century preceding his election to the Oxford Chair. From the late eighteenth to the mid-nineteenth century, the utilitarian thinkers Jeremy Bentham and his disciple John Austin had developed an influential theory of law known as ‘legal positivism.’ Rejecting the idea that law derives its authority from God, or from some metaphysical conception of nature or reason—so-called ‘natural law’—Bentham and Austin argued that law is essentially man-made: it is a command, backed by sanctions, issued by a political superior or sovereign, to whom the populace is in a habit of obedience. This positivist theory had, however, been little developed since Austin’s death. The one exception was the brilliant Austrian jurist Hans Kelsen, whose theory of law as a system of norms was, however, mainly influential on the continent of Europe. In Britain, the slow development of legal education in universities contributed to the impoverishment of the jurisprudential tradition, which in the first half of the twentieth century concerned itself primarily with the decontextualized analysis of legal terms such as ownership, possession, or the corporation. This analysis was not enriched by any systematic exchange with philosophy, nor was there any attempt to link it to any broader idea of the nature of law, or to consider how technical legal concepts assisted law to serve its various social functions. In the USA, by contrast, jurisprudence had moved in a sociological direction which arguably

emphasized the empirical at the expense of a sustained examination of the conceptual dimensions necessary to an analysis of law’s distinctive normativity. Prescriptive questions about what purposes law ought to pursue were left to the attention of moral and political philosophy—the latter itself a field that was relatively stagnant at this time.

Hart’s first single-authored book, *The Concept of Law* (1961), which stands as his most important work, claimed to provide a general, descriptive theory of law which was at once a contribution to ‘analytical jurisprudence’ and to ‘descriptive sociology.’ In other words, he sought to elucidate a concept of law that would be relevant to an understanding of all forms of law, wherever or whenever they arose. In pursuing this project, Hart returned to the insights of Austin and Bentham, but—in a crucial innovation—combined their methods with those of the new linguistic philosophy represented by J. L. Austin and Ludwig Wittgenstein.

The nub of Hart’s theory is the startlingly simple idea that law is a system of social rules structurally similar to the rules of games such as chess or cricket. The rules are of different kinds, with complementary functions. Some—‘primary rules’ such as criminal laws—directly govern behavior; others—‘secondary rules’—provide for the identification, interpretation, and alteration of the former. Distinctive among these ‘secondary’ rules is the ‘rule of recognition.’ This rule provides criteria by which officials identify valid rules belonging to the legal system. It, therefore, also serves to identify the content of one particular legal system. Yet it is not, Hart argued, itself a valid rule of the system. Rather, it exists in the constellation of official attitudes and practices. The existence of a legal system is hence, fundamentally, a complex matter of social fact.

Like his nineteenth-century counterparts, Hart therefore insisted that law is a social, human invention: though legal rules generate genuine obligations, they are not moral rules. Their authority derives not from their content but from their source, which lies in a distinctively institutionalized system of social recognition. For example, the rule that we should drive on the left is authoritative not because there is any intrinsic value to driving on the left. Rather, it is because the rule can be identified in accordance with an agreed set of criteria for recognition, such as parliamentary enactment or judicial precedent. Precisely the same is true, moreover, of legal rules that overlap with moral standards: the legal prohibition on murder is not the same as, and derives its validity in a different way from, the moral injunction against killing. Hart also teased out, however, what he saw as important grains of truth in the natural law tradition. While he insisted that the connection between law and morality was a contingent one, he also pointed out that a rule-based legal order brings with it a distinctive conception of formal justice. He also argued that,

given certain features of human being—our physical vulnerability and limited altruism, and the limited resources of the natural world, for example—legal systems, given their purpose of facilitating human survival, would have to include a core set of rules governing—justly or unjustly—matters such as physical integrity and property. This he termed, perhaps misleadingly, ‘the minimum content of natural law.’

Hart’s account of how legal rules are recognized as valid served, on the other hand, to distinguish law from a mere system of force, or ‘orders backed by threats.’ For—crucially—according to Hart, legal rules have not only an external but also an internal aspect: we know that a rule is in existence not only because it is regularly observed, but also because those subject to it use it as a reason or standard for behavior, criticizing themselves or others for breaches of the rules. Here the linguistic philosopher’s focus on the understandings embedded in ordinary usage becomes important. For example, Hart explores the distinction between habitual behavior (going to a café on Sunday morning) and rule-governed behavior (going to Church on Sunday morning); between being obliged to do something (handing over money because someone threatens to kill you if you refuse) and having an obligation to do it (paying your taxes). Of crucial importance to his status as a positivist is his insistence that the decision to adopt an ‘internal attitude’ to legal rules may be based on a variety of reasons, ranging from moral commitment to mere pragmatism: indeed, for a legal order to exist, it is theoretically only necessary for the officials of the system to adopt an internal attitude to its rules. In his elucidation of the internal attitude, Hart claimed to have detached the concept of law from that of sanction: the normativity of law derives from the internal aspect of rules and not from the threat of punishment for their breach.

By moving from the early positivist notion of law as a sovereign command to the notion of law as a system of rules, Hart produced a theory that resonated with the impersonal idea of authority embedded in modern democracies, providing a remarkably widely applicable rationalization of the nature of law in a secular and pluralistic world. He also offered an account of legal validity that purported to explain the (limited) sense in which citizens have an obligation to obey the law. Unlike the ‘command’ theory, it accounts not only for laws which impose duties but also the wide variety of laws which confer powers upon or create normative facilities for citizens: the law of property, contract, marriage, or succession, for example.

Hart also succeeded in reviving the idea that the project of jurisprudence should be not only to provide a clear, descriptive concept of law; but also—though as a separate project—to elaborate a framework for systematic criticism of law and for law reform. Hart’s work became increasingly concerned with these prescriptive questions: from the late 1950s on he published highly influential papers dealing with issues such as the

punishment of those who had committed what would now be regarded as serious crimes in Nazi Germany; capital punishment, the decriminalization of homosexuality, and the legalization of abortion. In these works, and in his widely publicized debate with the conservative judge Patrick Devlin, he regenerated a liberalism that finds its roots in J. S. Mills’s *On Liberty* (1859). In *Law, Liberty and Morality*, Hart (1963) argued, as against Devlin, that democratic states are not entitled to enforce moral standards for their own sake. With the exception of special cases where paternalistic legislation can be justified, or where grave public offence is at issue, the state should respect individual freedom, intervening only to punish the commission of tangible harms. This book stands, over 30 years after its publication, as the resounding late twentieth-century statement of the most influential genre of liberal social policy. The philosophical ideas on which it rests are articulated closely with those expressed in Hart’s conception of rights as founded in respect for individual human liberty and choice (‘Are there any natural rights?’), and in his argument that consequentialist aims of punishment should be tempered by considerations of individual fairness in the distribution and quantum of punishment (Hart 1968).

2. Hart’s Importance for the Social Sciences

Since the mid-1960s, Hart’s work has been subject to intense scrutiny and criticism. The most significant criticism has come from two different directions. First, from the direction of ‘natural law’ theory, it has been argued that, ultimately, the reason why those subject to legal rules adopt an ‘internal attitude’ to them has to do with moral factors, and that consequently Hart’s restricted sense of ‘legal obligation,’ and with it his distinction between law and morality, collapse. Second, from the direction of the social sciences, it has been argued that although the techniques of analytic philosophy may establish that law is simply one form of social rule, the further question of just what is distinctive about legal as opposed to other social rules can only be understood in terms of historical and social facts in which Hart shows surprisingly little interest. Notwithstanding these criticisms, there is strong reason to think that Hart’s work has real significance for the social sciences.

First, in reviving the tradition of descriptive legal theory—the attempt to provide a systematic elucidation of law—Hart illuminated an institution whose distinctive importance in the organization of modern societies has become a fundamental preoccupation of the social sciences. In spite of his universalistic philosophical ambitions, and of the undoubted tension in his work between his ‘analytic’ and his ‘descriptively sociological’ methods, his theory can be argued to provide a persuasive account of the distinctive nature of legal authority—law’s normativity—while main-

taining that law's existence is, ultimately, a matter of social fact and hence susceptible of empirical inquiry.

Second, therefore, in elucidating the nature of law as a social institution, Hart arguably provides precisely the sort of legal theory which social scientists need in incorporating law into broader social analyses. In his insistence on the structural continuity between legal and other social rules yet on law's distinctive mode of institutionalization, Hart provides a vision that is at once analytically well delineated yet relatively modest in terms of its substantive assumptions. Hence, the feature of his theory which might at first sight seem least sympathetic from a social science point of view—its pretension to provide a universal theory of law—may in fact be argued to be one of its strengths. For it provides a clear model for the purposes of testing hypotheses about, for example, the relationship between legal and other forms of social authority. This idea of his concept of law as, at root, a social science model is backed up by his own insistence, in terms reminiscent of Weber (though, in a significant ambiguity, also of Aristotle), that he is delineating a 'central case' with reference to which other, 'penumbral' cases can be identified and analyzed rather than 'banished to another discipline.'

Third, in his insistence on the internal aspect of rules, and hence on the idea that the social phenomenon of law can only be understood by reference to the attitudes and understandings of the agents who are its subjects, Hart's thinking meshed with a cluster of theoretical developments in disciplines such as sociology and anthropology. In this respect, his theory is a vast step forward from the cruder empiricism of the nineteenth-century positivists. Although it is not something with which Hart himself was centrally concerned, this feature of his method undoubtedly opens up the possibility of an analysis of the symbolic aspects of legal power and authority such as would be central to any adequate social science account of legal practices. In his emphasis on the importance of linguistic usage, moreover, his ideas relate, albeit obliquely, to the so-called 'linguistic turn' in much social theory of the late twentieth century.

Finally, in his revival of the utilitarian tradition of systematic critique of law and argument for its reform, Hart provided an example of the way in which conceptual analysis can be marshaled in aid of social policy. Clear thinking and reason—Hart's deepest intellectual commitments—are used, in an apparently modest and sometimes painstaking way, to clear the confusion in social and political debate, opening up in often unexpected ways paths forward in the development of policy and the construction of social consensus. Though Hart's own work is surprisingly little concerned with empirical—social, psychological, economic—evidence, his arguments often serve to clarify the relevance of just this sort of social science data. Though the fulcrum of his work lay firmly at the analytical-philosophic rather than the descriptive-

sociological end of the spectrum, he can, therefore, justly claim a place among those whose thinking has made a significant contribution to the social and behavioral sciences.

Hate Crimes

1. What is a Hate Crime?

There is no universally accepted definition of what precisely constitutes a hate crime, nor agreement as to the precise conceptual boundaries that delimit hate crimes from mundane crimes. The sole factor stressed uniformly is the motivation of the perpetrator. In hate crimes the principal motivation is one of negative affect (*animus*) toward the victim because of his or her skin color, ethnicity, religion, sex, national origin, or sexual orientation, for example. It is this *animus* that drives the criminal behavior rather than more common motives of pecuniary gain, retribution, jealousy, or status seeking. Thus, any crime may become a hate crime if the perpetrator's motivation is *animus* toward the victim based on some socially constructed category.

Some care must be taken to differentiate two seemingly related circumstances: (a) situations where the fundamental cause of the behavior is hatred; and (b) situations where hatred is coincident, with the primary motivation being something other than hatred. Presumably, it is only a true hate crime if the former condition exists. In other words, having extreme negative affect founded on skin color, ethnicity, religion, sex, national origin, or sexual orientation is both a necessary and sufficient condition for a hate crime.

In terms of behavior, hate crimes range from spray-paint vandalism and verbal harassment to physical assault and murder. The perpetrators may be single individuals, organized or unorganized groups, or entire nation-states. Similarly, the victims may be solitary individuals, small groups, or large aggregates of human population. In fact, a hate-crime universe can be conceptualized in terms of a three dimensional space: along one dimension is the degree of aggregation or organization of the perpetrator (ranging from single persons to nation-states), along another dimension is the degree of aggregation of victims (from single persons to nation-states), and the third dimension is the degree of severity (extending from vandalism to lethal sanctioning). Within this heuristic model, behavior can be located as diverse as a sole actor desecrating a synagogue with swastikas, to nation-states with genocidal policies aimed at despised populations. Yet underlying each is the assumption that the primary motive is negative affect based on a socially constructed status such as race or religion.

While the term hate crime, and the public notoriety it has received, has been particularly discernible during the 1980s and 1990s, the phenomenon is far from recent and has long been a frequent factor in human societies across the globe. This century alone has witnessed the genocide of Christian Armenians at the hands of Muslim Turks (1915–18), the Nazi attempt to exterminate European Jewry and the Roma, the mass murder of Vietnamese and Cham Muslims by the Khmer Rouge in Cambodia in the 1970s, the 1994 Hutus inspired genocide of Tutsis in Rwanda, and the Serbian ‘ethnic cleansing’ of Muslims from Bosnia. These are but a few examples of mass-hate crimes involving large numbers of perpetrators and with their victims experiencing the most severe levels of sanctioning. Often, however, public attention has been drawn to smaller-scale events involving fewer victims: for example, in 1991 skinheads in Hoyerswerda, Germany attacked several Asians and fire-bombed a hostel used by asylum-seekers (similar attacks were made on immigrants and refugees in many, if not most, Western European countries during the 1980s and 1990s)—the burning of some African-American churches in the American South during the early 1990s—or the 1998 lynching of James Byrd Jr, a 49-year old African-American in Texas by three white supremacists.

In sum, hate crimes can range from killing of genocidal proportions perpetrated by a nation state to verbal harassment by a single actor. They are frequent in human societies globally.

2. Why Hate Crime?

Most theories of hate crime involve, implicitly or explicitly, the notion of ‘threat’: that hate crime perpetrators perceive members of the target group as representing danger or peril to their life chances, lifestyles, social status, or belief systems. This threat does not have to be ‘real’ in any demonstratively physical sense—it only needs to be thought to be real to motivate some persons to commit crimes of hate.

Macropolitico-economic theories emphasize the importance of large-scale changes in the economic, political, or demographic arenas in generating apparent threats to the status quo. Typically these theories postulate that social change brings uncertainty, disruption, and competition between dominant and emergent groups for economic standing or political power. That contested terrain breeds fear and motivates some to strike out against members of the perceived threatening group. The effect of intergroup competition (threat) seems to be especially pronounced when the target group is culturally dissimilar from the dominant one. This is a point emphasized by cultural explanations of hate crime. Cultural theories stress threats to traditional or dominant belief-systems. Differences between the dominant culture and the target group subculture are seen as incompatible, if not totally hostile—the culture and belief systems of the victim group may be viewed as contaminating the dominant culture and in that sense, representing a threat to the cultural status quo. It is quite likely, for example, that the hate crime directed at guest workers, asylum seekers, and refugees in many counties was rooted in both the fear that new immigrants would take jobs away or lower wages of the native labor force and in the fear that a ‘foreign’ culture would fundamentally challenge traditional values and beliefs.

3. Hate Crime and Hate Speech Laws

Hate crime laws often take the form of sentence enhancements to penalties for crimes motivated by animus. For illustration, in the United Kingdom the 1998 Crime and Disorder Act provides that the maximum sentence for common assault increase from 6 months to two years if the assault was racially motivated. In the USA, the vast majority of states have enacted legislation providing for sentence enhancements for some hate crimes (but not others). At the federal level, the Hate Crimes Sentencing Enhancement Act of 1994 increased sentencing by about one-third when a crime is proven to have been hate motivated and occurred on federal property.

In many countries, hate speech, as well as hate crime, is criminalized. In the UK, speech or writings that may provoke racial animosity are prohibited by the Public Order Act. Similarly, Section 319 of the Criminal Code of Canada prohibits deliberately inciting or promoting 'hatred against any identifiable group.' There are comparable provisions in the criminal codes of Austria, Poland, Sweden, France, and Ireland. The Indian penal code not only criminalizes racial and religious-hate speech but caste-hate speech as well. In Germany it is illegal to incite violence or racial hatred against groups or minorities, and it is a crime to deny the Holocaust. Likewise, 1995 laws in both Switzerland and Belgium prohibit denying or defending genocide. There are no comparable laws against hate speech in the USA, however.

4. Trends in Hate Crimes

There is considerable rhetoric by advocacy groups that many countries are undergoing an unprecedented wave of hate crime, yet there is little undisputed empirical evidence supporting that claim. All authorities acknowledge that existing data on hate crime are fraught with errors, so any apparent rise in frequency of hate crimes may be due to: (a) a more sensitized public willing to report incidents of hate that had gone previously unreported; (b) the media and advocacy groups more frequently publicizing hate crimes; (c) an actual increase in the incidence of hate crimes; or (d) some combination of these. Where 'official' statistics are offered, it is suspected that they too may be seriously compromised because of under reporting of hate incidents by victims, the reliance upon local authorities to recognize and define an incident as a hate crime, and changes and ambiguities in the definition of what constitutes a hate crime. Given the shortcomings of official hate crime data and the unknown reliability and validity of anecdotal data from advocacy groups, it would seem impossible to state definitively whether hate crimes are actually increasing in frequency, decreasing, or remaining the same.

Given that caveat, what meager empirical data exists suggests that in the USA the frequency of hate crime incidents increased from the early 1990s until 1996, and has been declining since. In most of Western Europe, the trend appears that hate crimes may have become somewhat less frequent toward the end of the 1990s than they were earlier in the decade, with the possible exception of the UK.

5. Victims of Hate Crimes

While time trend data on hate crimes are especially problematic, a cross-sectional inspection of official reports of hate crime can illuminate who were the

victims. In many European countries during the time 1970–2000, reported hate crime has targeted immigrants, refugees, asylum-seekers, and guest workers. Additionally, there have been many attacks on Jewish cemeteries and synagogues. In the USA, the situation is somewhat different.

Based on hate crimes reported in 1998 by 10,730 local law-enforcement agencies covering a population of 216,235 million, the US federal government cites 7,755 incidents of hate crime involving 9,722 victims. Of these incidents, 56 percent involved race hatred, and of those over two-thirds were anti-black. While race-hatred incidents were the most common, incidents of religious hatred were frequent, and 78 percent of these incidents involved anti-Jewish activity. Reports of sexual orientation bias were also common, with 67 percent of these incidents targeted at male homosexuals. Of all the hate crimes reported in 1998, 62 percent (4,832 incidents) were incidents that were anti-black, anti-Jewish, or anti-gay male. Of those offenses where the suspected offender's race was known, whites committed 76 percent of the hate crime offenses.

6. Consequences of Hate Crimes

Being a victim of virtually any crime extracts a definite psychological toll, but there is some evidence that the emotional mark of hate crimes may be more severe and longer lasting than the impact of normal (nonhate motivated) crime. Furthermore, some argue that when one member of the targeted group is victimized by hate crime, then all members of the group are adversely affected—that is, the negative effect of hate crime permeates the victim community more thoroughly than other forms of victimization. Because of the very nature of hate-motivated crime, a poignant and unmistakable message is delivered to both the victim and his or her community.

E. M. Beck

Hayek, Friedrich A von (1899–1992)

Friedrich von Hayek is regarded generally as the most influential intellectual figure in the twentieth-century revival of classical liberalism (Kukathas 1990) and as the most articulate critic of socialist doctrines (Caldwell 1997). He also deserves recognition as one of the preeminent social philosophers of that century. In an age of increasing specialization within the social sciences and the humanities, he developed an approach to social analysis and social reform that integrates insights from economics, law, politics, philosophy, psychology, and evolutionary theory into an impressively coherent outlook at the foundations and the evolution of social order. Hayek's scholarly writings span more than six decades and include numerous books and articles, republished in a 19-volume edition of his collected works (Hayek 1988).

1. Biography

Hayek was born in Vienna on 8 May, 1899. He earned doctorates in law (1921) and in political economy (1923) at the University of Vienna, where he became *Privatdozent* for Political Economy in 1929. Interrupted by a year of study in New York (1923–4) he worked from 1921–6 as a legal consultant in a government office in Vienna, directed by his mentor Ludwig von Mises, in whose famous *Privatseminar* he participated and with whom he founded, in 1927, the Austrian Institute for Business Cycle Research, of which he was director until 1931. A series of invited lectures that Hayek gave at the London School of

Economics (LSE) in 1931 led to his appointment to the Tooke Chair of Economic Science and Statistics at the LSE, a position Hayek held from 1932 to 1950, the year he was appointed Professor of Social and Moral Sciences at the University of Chicago's Committee on Social Thought. After retiring from Chicago in 1962 he taught as Professor of Economic Policy at the University of Freiburg, Germany, until 1967. An honorary professorship at the University of Salzburg from 1969 to 1974 brought Hayek back to his native Austria. In 1977 he returned as professor emeritus to Freiburg where he died on 23 March, 1992. In 1974 Hayek was awarded the Nobel Prize in Economics.

2. Hayek's Social Philosophy

About his personal development Hayek (1967, p. 91) has said that he was led 'from technical economics into all kinds of questions usually regarded as philosophical.' It was his early work on monetary theory, capital theory, and business cycle theory that earned him his appointment at the LSE, and it was about these themes that he engaged in controversies with John Maynard Keynes, Piero Sraffa and Frank H. Knight in the early 1930s. An important turning point in his scholarly interests is marked by his work, in the mid-1930s, on an English edition of selected contributions to the 'socialist calculation debate,' including Mises' early (1920) article on the subject (Hayek 1935). As Hayek has noted in retrospect, in preparing this edition he began to develop his growing interest in questions of the nature and unavoidable limitations of our knowledge, and in the issue of what these limitations imply for our theoretical efforts at understanding the social world as well as for our practical efforts at organizing our social life. The concern with these questions, often referred to as the 'knowledge problem,' was to become the core theme of Hayek's life work.

In Hayek's own assessment, the critical step in his move towards social philosophy was his 1937 article on 'Economics and Knowledge' (1948, Chap. 2), an article in which Hayek addressed what he describes as the 'central question of all social sciences,' the question of how the fragments of imperfect knowledge that exist dispersed in individual minds are coordinated in the social process to allow for productive cooperation among multitudes of persons. With his 1945 article on 'The Use of Knowledge in Society' (1948, Chap. 4), his most often cited publication, Hayek restated and extended his earlier argument, stressing that the 'problem of what is the best way of utilizing knowledge initially dispersed among all the people is at least one of the main problems of economic policy—or of designing an efficient economic system' (1948, p. 78). In these two articles, which he considered his most

original contributions to economics, Hayek developed a fundamental critique of two bodies of thought prevalent at the time, of formal equilibrium economics on the one hand and of socialist concepts of central planning on the other, censuring both of them for failing to account for the theoretical and practical difficulties that are posed by the imperfect, fragmentary, and dispersed nature of human knowledge.

In Hayek's view, the models of mathematical equilibrium economics provide only a pseudo-answer to the question that they are meant to illuminate, namely, how markets work. As he put it, with its 'assumption of a perfect market where every event becomes known instantaneously to every member' (1948, p. 45), formal equilibrium analysis begs the very question that an empirically contentful theory of market processes would have to answer, namely how 'a solution is produced by the interaction of people each of whom possesses only partial knowledge' (1948, p. 91). Ironically, the failure committed in concepts of central planning is of a very similar kind. By assuming perfect knowledge on part of the planners, advocates of central planning provide only a pseudo-answer to the practical problem of how effective coordination of economic activities can be achieved in the absence of markets. Assuming that all relevant knowledge is available to, and can be administered by, a planning agency, raises the question of how such an agency is supposed to come to terms with the fact that much of the relevant knowledge 'never exists in concentrated or integrated form, but solely as the dispersed bits of incomplete... knowledge which all the separate individuals possess' (1948, p. 77), as knowledge that can be activated only by these very individuals.

What is needed, Hayek argued, is a theory that accounts for 'the unavoidable imperfections of man's knowledge and the consequent need for a process by which knowledge is constantly communicated and acquired' (1948, p. 91). He called on his colleagues in the economics profession to turn their attention from the formal statements of equilibrium analysis to empirically contentful 'propositions about what happens in the real world' (1948, p. 46), propositions about how knowledge is actually acquired and communicated. While his call did not find much response in the profession, in his own work Hayek very much pursued the research agenda that he suggested.

Hayek has especially addressed the issue of how we acquire knowledge in his *The Sensory Order* (1952a), a most unlikely book for an economist and one of his least known, but nevertheless one that is of greatest systematic significance for his entire work. In this book (based on an early manuscript from Hayek's student days), subtitled 'An Inquiry into the Foundations of Theoretical Psychology,' Hayek develops a theory of the human mind, the essence of which is in amazing accord with modern cognitive science. Seeking to explain how the human mind establishes its connections 'between the input of (external and

internal) stimuli and the output of action' (1988, p. 288), Hayek interprets the working of the mind as an adaptive process of constant classification and re-classification on many levels (sensory perceptions, emotions, concepts), as a process in which conjectural internal models of the outside world are adaptively formed and guide actions.

The issue of how knowledge is communicated and advanced in society is the theme of Hayek's theory of the market as a communication system (1976, Chap. 10) and of competition as a discovery procedure (1978, Chap. 12), a theory that forms the centerpiece of his work. The prices formed in the competitive market process, Hayek argues, signal to all market participants the relevant general information about changes in relative scarcities that they need to know in order to adjust their behavior adequately, utilizing their unique local knowledge of the particular circumstances of time and place, knowledge that could never be communicated to, and utilized by, a central planning agency. Beyond serving in such fashion as a device for utilizing dispersed knowledge, the market serves also as an arena for the continuous competitive exploration of new and potentially better solutions to economic problems, thus inducing the discovery and creation of new knowledge.

The relevance of Hayek's work, not only for economics but for the social and behavioral sciences more generally, is most clearly visible in his theories of spontaneous social order and of cultural evolution that he has developed as generalizations and extensions of his arguments on market processes and competition. The thrust of these theories is that human societies are highly complex phenomena, and that the processes of social coordination and societal evolution are inappropriately simplified and misconceived if they are approached in the spirit of the mechanistic models of physics (1952b). He argues that acknowledging the complexity of social phenomena means to acknowledge that all we can reasonably hope to achieve in the social realm, as in all areas of complex phenomena, are explanations of the principle and pattern predictions, by contrast to the explanation and prediction of specific events (1967, Chap. 2).

Hayek places his own social theoretical outlook in the tradition of the Scottish moral philosophers (David Hume, Adam Smith, Adam Ferguson and others), whom he credits with the discovery of 'the twin concepts of the formation of spontaneous orders and of selective evolution' (1988, p. 146). Central to this paradigmatic tradition is a methodological individualism and subjectivism, that is, on the one hand, the notion that social aggregate phenomena are, ultimately, to be explained in terms of the actions and interactions of individual human beings and, on the other hand, the insight that 'the analysis of what people do can start only from what is known to them' (1948, p. 44), that is, from their subjective view of the world. Equally central to it is the notion that the

productive coordination and division of labor that we observe in society is to a large measure not due to deliberate planning and conscious design, but to forces of spontaneous mutual adjustment and evolution, as are the rules and institutions on which societal cooperation is based. From these premises important conclusions are drawn with regard to the limits of our ability to improve our social condition by deliberate construction.

According to Hayek, there are essentially two basic ways in which the actions of individuals can be socially coordinated, namely either through spontaneous mutual adjustment within a framework of general rules of conduct, or through the commands of a central coordinator (1973, Chap. 2). As he argues, the respective merits and limits of the two kinds of order—spontaneous order and organization—have to do with the nature of their principal means of coordination, namely general rules versus commands. Command-based organization is an effective method of social coordination where specific, limited purposes are to be achieved. Because of its reliance on central decisions it is, however, severely limited in its capacity to utilize the knowledge dispersed among its individual participants. The advantage of rule-based spontaneous social orders is that, by allowing individuals to pursue their own ends within the general confines defined by the rules, they can utilize and activate to a much higher degree localized, dispersed knowledge. The price that has to be paid for their greater capacity for utilizing knowledge is that the particular outcomes that they generate must inevitably remain largely unpredictable. In Hayek's view, considering the respective merits and limits of the two kinds of order should lead us to conclude that, while organization can be a useful method for solving a multitude of specific, limited tasks, it cannot possibly be appropriate for the extended order of an economy or a society at large. There is ample room for organizations within the spontaneous order of society, but efforts to turn society itself into an organization can only end in disaster.

An important element in Hayek's theory of spontaneous social order is the insight that, while the particular outcomes of a rule-based spontaneous order remain necessarily largely unpredictable, the general patterns of its outcomes are determined systematically by the nature of its rules. There exists, Hayek emphasizes, a systematic interplay between the 'order of rules' and the 'order of actions' (1967, Chap. 4), that is, between the nature of the 'rules of the game' on which the interactions of the participating individuals are based, and the nature of the action-patterns that emerge from the individuals' behavioral choices within the rules, just as the rules of a sport allow us to predict—if not particular outcomes—the general patterns that we observe on the playing field. In fact, Hayek argues, our knowledge of the systematic relation between the order of rules and the order of

actions is the principal instrument that we can employ to improve our condition, by choosing rules of the game that can be predicted to generate more desirable overall patterns of outcomes.

Hayek's emphasis on the basic facts of 'the dispersion and imperfection of all knowledge' leads him to be highly critical of a mind set that he labels 'rational constructivism' or 'constructivist rationalism' (1978, Chap. 1). Under this rubric he subsumes approaches to issues of social policy and social reform whose recommendations are based on a 'pretence of knowledge' (1978, Chap. 2), that is, on unjustified presumptions concerning the extent of our knowledge and our intellectual powers. The primary targets of Hayek's critique are approaches that, like socialist concepts of central planning, amount to the 'claim that man can achieve a desirable order of society by concretely arranging all parts in full knowledge of all the relevant facts' (1967, p. 88). Against such claims Hayek points out that, because it is simply impossible for us to take 'conscious account of all the particular facts which enter into the order of society' (1973, p. 13), we need to rely on general rules 'as the means to create order in social affairs' (1948, p. 19), and that our efforts at building a better society must largely rely on the indirect method of improving the rules and institutions under which we live, instead of on attempts to directly produce desired outcomes through specific interventions.

To be sure, in our efforts to improve the framework of rules and institutions under which we live, we need, Hayek stresses, to be no less careful to avoid the pitfalls of a pretense of knowledge. Since the desirability of the outcome patterns that particular rules or institutions tend to generate can only be judged appropriately in terms of their working properties over extended periods of time, it would be presumptuous to claim that we can easily design, at the drawing board, rules and institutions that serve us better than those that have evolved over generations. Just as, in the ordinary market, the discovery process of competition helps us to find out how our 'economic' problems can be solved better than before, competition in the realm of rules and institutions can serve the function of allowing us to find out what kinds of rule arrangements are better suited to allow for mutually beneficial cooperation among multitudes of persons. A process of competitive selection can here, just as in ordinary markets, help gradually to evolve solutions that are much more effective than what any rational design could have ever invented at the outset. In fact, so Hayek argues, the institutions on which our civilization rests, including the rules of the market, must be viewed as the outcome of a process of cultural evolution that extends over thousands of generations and that reflects the experience of many more trials and errors than the most wise and intelligent rule designer could ever consider. Our efforts at institutional reform and rule design should, therefore, always

be informed by due respect for the potential wisdom implicit in inherited institutions, and we should expect further improvement ‘more from slow experimental piecemeal evolution than from redesign of the whole’ (1964, p. 8).

The theory of cultural evolution is the theme to which Hayek devoted much of his later work (1979, Epilogue, 1988), and it is this part of his theory that has become a primary focus of discussions on his ideas. A central issue in these discussions is how the notion of competition among institutions—a notion that is at the heart of Hayek’s ideas on cultural evolution—is to be specified, and under what conditions such institutional competition can be expected to generate ‘good’ rules, that is, rules with working properties that are desirable to those who are affected by them.

3. Impact and Significance of Hayek’s Work

With his arrival at the LSE in the early 1930s Hayek became almost instantaneously a well-recognized figure in the economics profession, engaged in prominent controversies on economic theory with such opponents as John Maynard Keynes, and on the issue of rational economic calculation under socialism with Oskar Lange and others. As his involvement in the latter debate induced the shift in his interest towards general issues of social and political philosophy, he increasingly removed himself from the standard professional discourse. He turned his attention to a fundamental critique of the philosophical foundations and the political implications of socialist doctrines, reflected most prominently in the publication of his most famous book *The Road to Serfdom* in 1944, a book that quickly made him a widely known public figure, in particular in the USA, where a condensed version appeared in the *Reader’s Digest* in 1945. While the book earned him public fame, it was met with considerable hostility among his colleagues in the economics profession, many of whom were, at the time, much more inclined to interventionist views than to Hayek’s warnings against socialist concepts of social and economic planning. With the rise of Keynesianism in the 1950s and 1960s, Hayek’s work fell almost into oblivion, in academia as well as in public debate, and when in 1960 his major restatement of the principles of classical liberalism, *The Constitution of Liberty*, appeared, it was widely regarded, even by sympathetic observers, as an outdated treatise, out of step with modern economic and political thought. It came as a surprise to many, including Hayek himself, when in 1974 he was awarded the Nobel Prize in Economics. Even if the fact that he had to share the prize with Gunnar Myrdal, an economist of a quite different orientation, reflected significant ambivalence on part of the Nobel committee, the

award was an early indicator of a reawakening interest in classical liberal thought in general, and Hayek’s work in particular, an interest that grew significantly in the later half of the 1970s, as a response to an increasing disillusionment with Keynesian economic policies and to accumulating evidence of the failure of ‘real socialism.’ In fact, Hayek became very much the symbol of what has been described as the ‘modern rebirth of classical liberalism.’ His work regained increasing attention in the academic community, his ideas influenced politicians like Margaret Thatcher and Ronald Reagan, and his publications found growing interest among dissidents and reformers in the disintegrating communist world. Hayek lived long enough to witness the final collapse of the communist regimes in Europe as a confirmation of his lifelong critique of socialist constructivism.

In modern theoretical economics Hayekian ideas play an important role in a number of approaches that seek to advance an alternative theoretical outlook to the orthodox equilibrium paradigm. His ideas on the nature of human knowledge and learning are finding increasing attention among scholars who seek a corrective for deficiencies of the traditional rational choice model. Recent developments in evolutionary economics, in the new institutional economics, and in the economics of complex adaptive systems, either explicitly draw on, or give support to core ideas of his work, to his theory of the market as a spontaneous order, his outlook on competition as discovery process, and his evolutionary approach to institutions.

The reception of Hayek’s work in social sciences other than economics is still in its infancy, yet his approach to social theory may well come to play a significant role as a paradigmatic contribution towards a theoretically integrated social science. It was one of Hayek’s major concerns that the disciplinary fragmentation of modern social science left what should be its central issue, namely ‘the problem of an appropriate social order,’ without adequate attention. As he put it, even though this issue ‘is studied today from the different angles of economics, jurisprudence, political science, sociology, and ethics, the problem is one which can be approached successfully only as a whole’ (1973, p. 4). More than any of his contemporaries in the social sciences Hayek has made an effort in his own work to address the fundamental issue of an ‘appropriate social order’ from a general social theoretical perspective that cuts across traditional disciplinary boundaries. With his ideas on the two kinds of social order, on the function of rules and institutions, and on cultural evolution he has made important steps towards a theoretically integrated social science.

Healing

In the context in which healing is studied here, it applies to any human or socially organized intervention having as its purpose the improvement of a physical or mental condition. In sociological analysis healing is judged by its intention, not by its effect. However, the differential success rates of opponent forms of healing are the basis of conflict between their practitioners and of the legitimization of the organizations within which they are practiced. The evidence is that while religious organizations are in other spheres of human life losing ground to secular agencies, there has been a recent increase of the resort to forms of healing that are alternative to secular medicine.

1. Types of Religious Healing

The widely used concept of shaman is a precise one, having been crystallized in a classic work by Mircea Eliade in the 1960s. A shaman is a person who enters a state of abnormal consciousness, being induced either by rhythmic music or by psychedelic drugs in the form of snuff or mushrooms. As a functionary in the

business of healing, the shaman may be distinguished from looser and more popular concepts such as witch doctor and medicine man that suggest skills in the use of locally available medications without the element of trance or ecstasy. Again, the role of the shaman in healing is not that of magician: whereas the magician uses ritual or other mysterious means to control the course of natural events, the shaman is merely a channel or borrower of the powers of the universe through whom some benign outcome is effected. The word shaman is taken from a tribe in north Siberia but shamanism within this narrow conception may be found also in, for example, the upper Amazon, the Orinoco basin, Australia, and in south-east Asia.

Mental healing, which is based on the diagnosis of illness as a condition of the mind, may be traced within modern Christian practice to the theology of Emanuel Swedenborg (1688–1772), a Swedish scientist and initiator of the religious sect which bears his name. He perceived healing as a harmony of physical and spiritual realities, achievable by the adjustment of the body to the mind, the mind to the soul, and the soul to the angelic order. In mid-nineteenth century America the Swedenborgian idea of mental adjustment was current in the fashionable mesmerism of Charles Poyen, in the teachings of Phineas Quinby, and subsequently in the writings of his most famous patient, Mary Baker Eddy, the founder of Christian Science. In her seminal *Science and Health with Key to the Scriptures* (1875) she turned to Matthew 9, 2–8 to demonstrate the central tenet that sickness and pain were delusions curable by the correction of mental error.

The notion of faith healing implies a degree of prior belief, even confident expectation, either in the seeker or in the healer. Healing which is reckoned to depend on the commitment of the patient lends itself to explanations in terms of the will power of the individual and other psychological factors. But the term faith healing is sometimes applied also to practices in which the healer claims authority over evil spirits or practices the laying on of hands in confidence of a miraculous outcome.

Divine healing, by contrast, is believed to be an intervention that does not rely on the faith of those involved. These conceptions of healing are prevalent in various of the Christian sects though not exclusive to them. Most notable among these are the ‘Four-square’ pentecostal churches of north America, one of the four squares being ‘Christ the Healer.’

In recent years there has been a burgeoning interest in healing in the mainstream churches in which the term healing is used in a more general way to include acts of reconciliation of individuals or groups, either as a result of conflicts between themselves or in changing circumstances such as tragedy and bereavement. The ministry of healing which is particularly associated with the Church of England does not connote the sense of the miraculous which distinguishes

divine healing and faith healing. It recognizes the skills of the minister who will accordingly remain conscious during the consultation.

The conciliation of mind and spirit that takes a variety of forms and is pursued by a still greater variety of methods is the essence of spiritual healing. It is not to be confused with spiritualist healing in which the practitioner is said to be in contact with spirits in another domain, such as that of the dead.

2. *The Social Context of Faith and Healing*

The pentecostal churches have flourished lately among the dispossessed of central and south America (Martin 1990, Chesnut 1997). The routine Marxist explanation is that the hope of a life hereafter enables the faithful to endure the discomforts of the present world. In Brazil, however, Chesnut found relatively less conviction in remote consolation than hope of immediate relief from the illnesses that attend poverty. The gravitation to the Pentecostal churches may to that extent be compared with the pilgrimages to Lourdes, to the sacred waters of the Ganges, and to the healing shrines and centers that abound in India and in the Catholic world.

What is more distinctive of recent years is the interest in ritual healing among the American middle class. Maguire (1988) recognizes in 'the metaphysical movement' the confluence of a number of nominally Christian traditions from New Thought, mesmerism, the mind-cure groups of the 1880s, Spiritualism and Christian Science, and an experimental interest in currents of spirituality that are or were native American, Latin American, Caribbean, and Polynesian. The turning to metaphysical healing in the suburbs has an intellectual basis involving an alternative pathology, a redefinition of illness and disharmony, and an open-minded disposition to eastern thought emanating from student subcultural movements in the late 1960s.

The host of life and death concerns which are addressed by hands-on therapy rituals in the religious life of middle America provide the agenda too for the ministry of healing in the Church of England. This neither trades on the expectation of the spectacular nor publishes its results against those of the medical services. The ministry operates, for example, in the rehabilitation of counseling and psychotherapy within the sacred domain, in the hospice movement pioneered in Britain by Dr Cicely Saunders, and in the provision of healing services within the regular ministrations of the mainstream churches.

Church-type healing is distinguishable from that of the sects in a number of ways: (a) the sectarian cult of the personality tends to elude church-type practitioners; (b) the expectation is not of the miraculous, nor are successes celebrated; (c) ministry to the dying will have the purpose of enabling them to die well, not

to recover to full health; (d) needs and benefits are largely reserved within the private domain; (e) the ministry is integrated with the Church's sacraments; (f) practitioners tend not to claim divine gifts so much as seek to enhance their effectiveness through conventional training of knowledge and skills; (g) the Church's ministry of healing is reckoned to complement conventional medicine and not to supplant it. While the miraculous healing tradition is rooted in the Pauline formulation of spiritual gifts—notably in Corinthians 1, 12—and denotes the healer as a direct agent of divine power, the Churches' ministry of healing looks to the Gospel for a motivation but to contemporary science for a method.

This movement by the mainstream churches may be seen as an attempt to evolve a new role and purpose in a secularizing world. In Mexican folk religion, too, *curanderismo* has adapted to address current issues and aspirations such as love, marriage, and happiness.

Some religious communities in which the practice of healing is central may stand or fall by their results. Others, however, lay hands on the sick because they are directed to do so (Mark 16, 18) and not with the primary purpose of a validating outcome. In an age of accountability, of the perception of an audience as a market, and of the importance of reputation and the fear of litigation, there has been a systematic movement to professionalize the alternative practice of healing. Practitioners have formed themselves into associations, established courses of study and qualifications, written ethical codes, and introduced a corporate discipline. These developments have been much more evident within complementary medicine outside the churches than within them.

3. *The Charisma of the Healer*

There is a tendency for the personalities of those involved in healing in sects and new religious movements to be rather higher in public profile than those who practice therapy in the suburbs and within the ministrations of the churches. Their names and faces are better known and are used in drawing crowds to religious meetings. The consequences of divine workings through them are more spectacular. Their disposition to secular medicine is more rejectionist and there is a triumphalism about their healing stories. When Melvin Banks testifies to the miracles God has worked through him, he shows the picture of a woman holding aloft her walking stick in defiance of the doctors who said she would always need it. Similarly, Her Holiness Mataji Nirmala Devi Srivastava, the 'Divine Mother' and teacher of Sahaja Yoga passes on to her disciples healing skills, including the use of vibration therapy in the cure of cancer. In the rhetoric, if not always in the understanding of the faithful, it is made explicit that the power is divine and the healer a mere agent. The claim to be a channel of divine power

is of course a greater enhancement of charisma than the claim to possess skills. The shaman possesses knowledge about healing which is not available to the community and which signifies an exclusive relationship with the spiritual domain. However, no man or woman would describe himself of herself as a shaman: the sense is that the power is invested in the shaman and an ethic of humility restrains self-promotion (Doore 1988). Of course, humility can itself be an element of charisma. Many *curanderos*, the folk-healers of Mexico, believe their healing powers to be a gift from God, invested in them and giving them certain responsibilities to alleviate misery. They claim no credit for themselves and, far from rejoicing in their powers, they may even regret the burden of their responsibilities: albeit they are full-time and charge fees.

But charisma invites suspicion from the secular world and from mainstream churches. It is in view of the capacity to exploit the charisma in the role of healer, both Church and the medical establishment distance themselves from alternative healing practices of new religious movements.

4. *Conflicts of Faith and Secular Practice*

It is reported (2 Chronicles 16, 12) that King Asa 'in the thirty and ninth year of his reign was diseased in his feet, until his disease was exceeding great: yet sought he not unto the Lord but the physicians: ... and in the one and fortieth year of his reign Asa slept with his fathers.' The Chronicler implies an error of judgement on Asa's part with a fatal consequence. Asa lacked faith. In modern times the resort to secular medicine frequently is perceived to compromise religious conviction.

The *curanderos* are condemned with suspicion by the fundamentalist churches which attribute to the devil the mysterious source of their power. For its part the medical establishment has invoked both research and the law to counter the rising tide of religious healing. The British Medical Association (1986) issued a report warning against the use of healing in new religious movements to confirm allegiance; it contended that they had caused harm to recruits and their families. The report was not well received, either by politicians or by the BMA's own members, but it survives as a significant expression at the high point of a conflict between the medical profession and alternative practitioners.

In the tradition of King Asa, Christian Scientists and the Peculiar People in England and others have at various times appeared in courts of law for refusing medical attention to the children. One of the more publicized conflicts between secular medicine and religious principle relates to the belief of Jehovah's Witnesses that blood transfusions are unscriptural and dangerous; in the United States, Canada, and

Australia medical decisions to transfuse children without parental consent—for example, by making children wards of court—have been more frequent than in the United Kingdom.

The rejection of secular medicine is, for some groups, axiomatic in the rejection of the world and its wisdom. For others, medicine does not need to be rejected with the world: the boundaries that exclude electricity and the motor car from Amish territory do not resist conventional medicine.

The conflict of religious and secular may be overcome by a strategy of incorporation: the religious organization may reckon to control not only its own ministrations but also those which are conducted outside it. So Christians in the church tradition may pray for those in hospital 'that by thy blessing upon them and upon those who minister to them they may be restored ...' while those in the Pentecostal church may ask, 'We pray thee, use that surgeon Lord to thy great glory.' And again, 'We prayed about the medicine and it began to work.'

5. *Conclusion*

The process by which religious organizations lose control of aspects of human life is familiar to students of religion as secularization. In recent years conventional medicine has suffered a similar attrition and the revival of religious healing has traded upon it.

There have emerged in the western world two movements that function as alternatives to conventional medicine and compare themselves with it. The religious tradition typified by but not exclusive to the practice of the Pentecostal churches has compelling parallels with shamanism from which it does not directly draw. The second tradition is that of complementary or alternative medicine which has burgeoned since the 1960s. The alternative is distinguished by the claim of its therapists to understand and control the process of cure while the religious involves the engagement of rituals in the expectation of a miraculous effect. There are several features common to both movements, including a suspicion if not rejection of conventional medicine and the role of physical contact between the healer and the healed, be it in the form of massage or manipulation or of the ritual laying on of hands. However, there are significant differences between the two movements. Complementary medicine has highly organized professional structures and the authority to practice comes from formal study and qualification. Clients of alternative medicine seek practitioners because of their methods, not for their charisma or personal reputation.

Such a typification highlights the peculiar case of the Church's Ministry of Healing which conforms much more to the secular alternative model than to the religious: its practitioners cultivate skills that have been developed in secular practice: it draws on the

Gospel for the spirit of its ministry but not for the letter of its technique.

Health and Illness: Mental Representations in Different Cultures

Mental representations of health and illness are the cognitive structures that guide people's response to symptoms and illness as well as to various kinds of health threats. These mental representations have variously been described as 'cognitive schemata,' 'mental prototypes,' 'structured vocabularies,' and 'social representations.' However one describes them, they provide the foundation for responding to states of health and illness. These mental representations also vary from culture to culture and provide a basis for the wide variety of ways in which people in different cultures respond to health and illness related events. This article explores the nature of these mental representations, the ways in which they vary from culture to culture, and some of the implications of this variation.

1. Understanding Mental Representations of Health and Illness

Although the biological nature of disease remains constant from one culture to another, the evidence is

very clear that how diseases, and health and illness in general, are understood varies dramatically. This variation occurs from culture to culture as well as between individuals and subgroups within the same culture. As such, illness, which refers to the experiential component of disease and ill health, is best understood as a social and cultural construction. Whereas disease refers to objective pathology, illness, as experience, is constructed on the basis of shared understandings in addition to individual experience (Angel and Thoits 1987, Landrine and Klonoff 1992).

This construction of health and illness has been described in various ways. At one level it can be described in terms of structured vocabularies used by people to define and express feelings of distress. The basic idea is that culture and experience provide people with categories for defining experience as well as a language for expressing feelings of distress. For example, the common concept of influenza provides many people with a category for understanding the experience of fever, chills, headache, nasal congestion, sore throat, and general achiness, whereas the concept of *susto pasado* is a Mexican-American category used for understanding the experience of stomach trouble, diarrhea, lack of appetite, lethargy, irritability, and loss of weight after experiencing a strong fright.

A useful approach to understanding the shared nature of health and illness concepts is via the theory of social representations. The key idea in this approach is that in the process of attempting to understand their bodily experience, people create socially shared representations of health and illness that then become part of the heritage of the society as a whole or of a subgroup within the society. These representations influence the way that individuals think about health and illness but are a property of the larger social collective. This approach emphasizes the essential social nature of concepts of health and illness and the way in which they are shared between individuals, a key prerequisite for communicating private bodily experience to others. A good example of this approach is Herzlich's (1973) examination of illness beliefs in France.

A contrasting but complementary perspective is the information processing approach that examines the cognitions which individuals have about health and illness. This approach has its roots in cognitive psychology and, in particular, work on cognitive schemata and prototypes. Research using this approach has shown that people have implicit theories of disease that exert a strong influence on how they cope with health problems as well as how they deal with treatment. For example, Leventhal and Diefenbach (1991) have shown that the mental representations held by hypertension and cancer patients strongly influence their behavioral response to treatment. Research using this approach has also pointed out that such mental representations operate at different levels (sensory, affective, and conceptual) and have a number

of components. These components include the identity of the condition (the label it is given as well as the symptoms involved), its cause, time line (expected length and course), consequences, cure, and perceptions of the type of person who gets the condition. Taken together these components make up the prototype that a person has of a particular disease. For example, a common prototype of 'heart disease' among British young people includes symptoms of lack of stamina, breathlessness, and chest pains as well as the beliefs that it is caused by lifestyle and high blood pressure, is serious but can be cured by surgery, and mainly affects older people (Lalljee et al. 1993). These prototypes, in turn, affect the recognition of disease conditions (see *Symptom Awareness and Interpretation*) as well as the person's illness behavior (see *Illness Behavior and Care Seeking*). Research from the information processing perspective has also explored the cognitive organization of disease concepts, noting that these concepts are organized cognitively in characteristic ways that have implications for how people interpret illness threats and how they respond to people with particular diseases (Bishop 1991).

2. Cultural Differences in Mental Representations

One of the more striking features of health and illness concepts is the way in which they vary from culture to culture. This variation is obvious even to the casual observer, as concepts common in one culture or society may not even exist in another. Although there are any number of ways in which health and illness concepts may vary, three major ways stand out. First, cultures show substantial variation in conceptions of the basic nature of health and illness. For example, in Western societies placing a strong emphasis on the scientific understanding of health and illness, these concepts are understood in natural terms with disease considered as pathology deriving from natural causes, such as germs, injury, or genetic aberrations. By contrast, in other societies, as well as among some ethnic-cultural minorities within Western societies, illness is understood more in interpersonal as well as supernatural terms. For example, illness may be seen as resulting from violations of standards of interpersonal behavior or other social norms, particular emotions (such as jealousy or envy), transgressions of moral and/or religious taboos, or such quasinatural agents as hot-cold foods, drinks, weather, 'balance,' or particular characteristics of one's blood (e.g., thin, weak, or bad) (Landrine and Klonoff 1992). These differences in the general nature of health and illness are then reflected in the beliefs people hold about specific conditions.

Second, cultures often differ in their disease vocabularies. In some cases the differences may result from using different terminology for what appears to be the

same condition. For example, Kleinman (1980) notes that symptoms that are often diagnosed as depression in the West are interpreted as neurasthenia in China. In other cases, however, a condition defined in one culture may have no referent in another. For example, conditions such as *susto*, *empacho*, *caída de mollero*, and *mal de ojo*, experienced by some Mexican-Americans, have no direct referent among conditions known to Anglo-Americans or to medical professionals.

Third, the underlying structure of illness representations often differs between cultures. Work using techniques such as multidimensional scaling and factor analysis has shown that the mental representations people have of different diseases show characteristic organization in memory and that this organization differs between different cultures. For example, research with Anglo-Americans has found that disease representations appear to be organized along with dimensions of contagiousness and severity, whereas those of Mexican-Americans were organized according to concepts of 'hot' vs. 'cold' and whether a disease was associated with children or old people (D'andrade et al. 1972). As one might expect, the organization of disease concepts is closely related to the general models of health and illness that people are exposed to. Thus among Anglo-Americans whose folk model of health derives primarily from the biomedical model, contagiousness, and severity, central concepts in the biomedical model, have been found to be prime organizing dimensions. However, among Chinese in Singapore where Chinese traditional medicine exists side-by-side with Western scientific medicine, disease concepts are organized according to dimensions deriving from both Chinese and Western medicine (Bishop 1998).

3. Implications

The mental representations that people have of health and illness, and cultural differences in these representations, have a number of implications for health and illness related behavior. First, the disease concepts that people have can be expected to have a strong influence on their interpretation of symptoms and bodily experience in general. In brief, having specific disease concepts makes it possible, and perhaps likely, that a person will interpret bodily experience in line with that concept. Thus, having available the concept of *susto* makes it possible for Mexican-Americans to experience this condition, an experience that is not available to others not possessing this concept. Along these same lines, the relative currency of the concept of neurasthenia in China and of the concept of depression in North America increases the likelihood that the similar symptoms associated with these two conditions

will be interpreted, and perhaps experienced, differently in these two cultures.

Second, and following from this, health and illness representations have implications for what people do when they experience distress. For one thing, these representations provide a definition for when bodily distress represents illness and requires assistance from a medical professional or other healer. For example, research with heart attack patients points out that one reason for delay in seeking treatment is that the person misinterpreted the symptoms and failed to recognize the seriousness of the situation. In addition, disease representations serve to direct the person's help-seeking behavior. For example, research in Singapore has noted that degree of adherence to beliefs associated with Chinese traditional medicine is a key determinant of whether the person seeks help from a practitioner of Western or Chinese traditional medicine (Bishop 1998).

Third, once help is sought, disease representations play an important role in determining whether the person stays in treatment and follows the treatment advice. A good example of this is research with hypertension patients showing that the cognitive 'model' they had of hypertension and its relationship to specific symptoms was a major determinant of whether they stayed in treatment (Leventhal and Diefenbach 1991).

Finally, illness representations play a key role in how people respond to potential health threats. Specifically, the beliefs that people have about particular diseases, how they are contracted, and their consequences have a strong influence on how they respond to people having the condition as well as what precautions, if any, they take to prevent the disease. For instance, beliefs among some Africans that anyone who has ever had sex with a person who has died of AIDS will automatically die as well appear to lead to refusal on the part of those holding such beliefs to seek medical advice, be tested for HIV, or change their sexual behavior so as to reduce their risk of infection (Ankrah 1991).

4. Remaining Questions

In many respects work to date has only scratched the surface of this fascinating topic. As noted, progress has been made in the theoretical understanding of mental representations of health and illness but much more can be done to flesh out this understanding and, in particular, explicitly account for cultural differences. Also much remains to be done in further exploring the content of health and illness concepts in different cultures and relating these to other aspects of the cultures in question as well as to dimensions, such as individualism-collectivism and power distance, used to describe cultures.

Health and Mortality, Body Stature as a Measure of

In recent years a rapidly expanding research on the determinants and consequences of human stature has become central to the study of health and mortality processes. Human stature—as measured by height, weight, body mass (which combines height and weight), and a host of other anthropometric measures—has been shown to reflect health status and mortality risk across the life course. Stature is an indicator of health *in utero*, in infancy, and in childhood, and is an important predictor of chronic disease and mortality among adult populations. Moreover, anthropometric measures can be used to com-

pare health and nutritional status across populations, social classes, and historical time periods.

1. Stature as an Indicator of Nutrition, Health, and Mortality

1.1 The Importance of Height

Although auxology (the study of human growth) began as early as the seventeenth century, it was not until the nineteenth century that scholars began realizing that environment can systematically affect human growth. For instance, Villerme argued, based on a study of French soldiers, that poverty was much more important than climate in influencing growth. A few decades later, Charles Roberts estimated fitness for factory employment using frequency distributions of key anthropometric measures such as weight-for-height and chest circumference. In the early 1890s, Franz Boas conducted a national growth study, which was used to develop national standards in the USA. In later years, Boas was a pioneer in the use of statistical methods to analyze growth and furthered the work of linking environment and heredity to growth (Steckel 1995).

In the twentieth century, it became clear that a child's growth rate is likely the best single indicator of his or her health and nutritional status. Furthermore, mean values of childhood heights and weights provide powerful summary statistics of the public health of the population, and childhood anthropometric measures can be used to make meaningful comparisons of health and nutritional status across populations (Eveleth and Tanner 1990).

Adult height can also be used as a measure of public health, since adult height is a proxy for the childhood nutritional status of a population. However, adult height reflects a complex interaction of genetics, environment and the timing of nutritional shortfalls. If nutritional deprivation occurs during the 'sensitive periods' of development, differences in adult height may be quite striking. The sensitivity of growth to nutritional deprivation depends upon the age at which it occurs. Catching up is possible, but prolonged and severe deprivation results in stunting or a reduction in adult size.

Height is a significant predictor of older age mortality. Overall, mortality risk declines as height increases. One of the most comprehensive modern studies was completed by Waaler (1984) on the entire Norwegian population. He found that men measuring 165cm in height face a mortality risk that is 71 percent greater than those measuring 182.5cm. Obviously height is also strongly influenced by genetic factors, but genetics cannot explain the significant differentials in height that exist today according to socioeconomic status, nor the narrowing of differentials in industrialized nations (Floud et al. 1990).

1.2 Weight and BMI

In both children and adults, weight is an important anthropometrical measure. Whereas height is typically used as a proxy for past nutritional development, weight is seen as a measure of current health and nutritional status. In the developing world, low weight remains a significant indicator of nutrition and health. In the developed nations, high weights are the principal concern. Obesity rates, especially in the USA, have risen over recent decades and obesity is frequently found to be a risk factor for serious chronic illnesses, including cardiovascular disease, a leading cause of adult mortality in developed nations. Obesity has also shown to be correlated with race and social class.

Obviously weight can be more effectively exploited in epidemiological analysis if it is standardized for height. A common standardization is to use body mass index (BMI), which is defined as height (in meters) divided by the square of weight (in kilograms). The mortality risk is relatively constant in the range of 21–28. However, as BMI falls below 21, adult mortality rises sharply. Mortality also rises for BMI higher than 28. BMI is associated with higher mortality from all causes, though the relative importance of BMI may be confounded by a history of smoking and by previous diseases, and the impact of BMI declines with age. Some studies suggest that much of the increased mortality risk from low BMIs in the USA can be attributed to smoking. Interestingly, excess mortality among African-American women in the USA is not attributed to BMI, even though they have high rates of obesity.

2. Determinants of Stature

Over the last century, scholars have made considerable strides in characterizing and understanding human growth and how various genetic, nutritional, and environmental factors interact with the growth process. Clearly the most important time is infancy, in which the growth rate is greater than at any point thereafter. Not coincidentally, infancy is also the time when humans face the greatest risk of mortality. After infancy, the growth rate declines irregularly until adolescence, during which it rises, at its peak, to about one-half the rate during infancy. The most important study on human growth is by Eveleth and Tanner (1990), and the following sections draw heavily from this work.

2.1 Genetics

Within a community facing similar environmental influences, the distribution of heights is dominated by genetic influences. Systematic studies of heights within families confirm this everyday observation. Studies of twins and other sibling relationships provide the most

convincing evidence. Wilson (1976) reports that monozygotic (MZ) twins, who share the same genes and, in most cases, a common family environment, have, on average, only 1.1 cm difference in height at age four, while dizygotic (DZ) or fraternal twins have a 3.2 cm difference at the same age. Furthermore, differences in height in MZ twins decline as the twins get older, but the difference increases for DZ pairs.

Numerous studies of twins and other siblings provide strong evidence that the closer the genetic relationship, the closer the growth patterns. MZ twins are more closely intercorrelated than DZ twins, but siblings in general are much more similar to each other than they are to nonrelated individuals. Furthermore, the heights of parents and children are highly correlated, though no evidence exists that one parent is more important than the other.

2.2 Nutrition

Even though genetic influences are an important determinant of *individual* variation in height, differences in average height across *populations* are almost entirely the product of environmental influences, not genetics. Although many environmental factors affect body stature, chief among them is nutrition. Of particular importance is nutrition in early life. Numerous scientific studies have shown that severely malnourished children have a greatly increased mortality risk relative to normal children (Behrman and Deolalikar 1988).

Infancy is the period of life in which both the human growth rate and the risk of mortality is at its highest. It is not surprising, therefore, that it is also the time during which nutritional intake is the most critical. Indeed, the concern for nutrition may begin *in utero*, and several studies have shown that supplementing the diet of pregnant women in developing nations significantly increases birth weights—the most important predictor of infant mortality. Even in developing nations, infant mortality is higher than any other period of life. By the age of two, much of the deficit characteristic of adults has already accumulated. Nutrition during the adolescent growth spurt may be important, though the evidence is mixed. In any case, the impact on morbidity and mortality of adolescent malnutrition is nowhere near as dramatic as it is in early childhood.

Many sub-populations in developing nations have mean birth weights that are similar to those in developed nations. In these developing nations, however, weight gain begins to diminish at about six months, the time when mothers' lactating ability declines and children are often weaned. Although food supplements can help, the prevention and treatment of infectious diseases is also critical in this period in developing nations.

2.3 Infectious Disease

Infectious disease interacts closely with nutrition in the growth process. Even in nutrition-rich environments, the undeveloped immune systems of children make them more susceptible to disease. When diet is poor, most of the body's resources are devoted to basic maintenance; malnourished children, therefore, are even more susceptible to disease. Furthermore, infection reduces the body's ability to absorb nutrients, which can make children even more malnourished. Infectious disease in childhood, therefore, can have long-term consequences on growth. Some controversy does exist on this topic, however. An alternative 'small but healthy' hypothesis has been promoted by a few researchers, though it has not received widespread support.

2.4 Socioeconomic Correlates

Economic growth (which results in better nutrition, public sanitation, improved hygiene, improved medical treatment, etc.) has been the driving force behind the secular increases in height around the globe. Variation in national income can also explain much of the variation in mean heights across nations. Steckel (1995) calculates correlation coefficients between mean height and the log of per capita income that are between 0.8 and 0.9. National income remains a powerful correlate of height, even after controlling for other demographic characteristics of the nations such as urbanization and age. And in nearly all nations, both developed and developing, children with moderate to high socioeconomic status are larger than their counterparts with low socioeconomic status, where socioeconomic status is determined by education, occupation, and income.

Of course the effect of socioeconomic status is interwoven with nutritional intake and infectious disease environments. Consequently, socioeconomic differentials are much more pronounced in developing nations. Socioeconomic differentials in height are most pronounced in childhood, but exist for adults as well. Several studies show that the social class effects are greater for boys than for girls.

3. Stature and the Study of Health and Mortality

3.1 Historical Populations

In the last decades of the twentieth century scholars began using body stature, and height in particular, to determine the living standards and health status of populations for several historical time periods and in various locations around the globe. Health and mortality details, particularly at the individual level, are generally unavailable in historical data, but height data are available (typically from military service records) in several American and European popu-

lations since the seventeenth century. Height, therefore, is the most important indicator of health status we have when investigating the historical record.

These studies have confirmed traditional notions of public health, such as the abysmal living conditions in eighteenth- and nineteenth-century urban areas. There have also been some unexpected findings. For example, the USA, in contrast to European nations, achieved near-modern average height as early as the mid-eighteenth century, though heights declined somewhat over the nineteenth century (from 173 cm in 1800 to 171 in 1900 for adult men), mostly during the middle part of the century. Mortality evidence from genealogies and from plantation records indicates that life expectancy deteriorated while heights declined during the ante-bellum period. The cause of the nineteenth-century decline in height is still a puzzle. Hypotheses include increased urbanization, nutritional decline, an increase in infectious diseases created by trade, migration, and public schooling, and the disruption of the US Civil War.

Before the twentieth century, European men were smaller than Americans, probably due to far poorer diets, but there was significant diversity in height across European nations. In the early nineteenth century, residents of Ireland and Scotland were the tallest (168 cm) followed by Norway, Sweden, England, France and Austria-Hungary (163 cm). In the twentieth century, geographic distributions of height shifted. Based on data collated by Eveleth and Tanner (1990), the Dutch and Norwegians were now the tallest, followed by Americans, British, French and Austrians. Socioeconomic differentials were pronounced in Europe. Floud et al. (1990) report, for instance, that in nineteenth-century England, 14-year-old Sandhurst boys (mostly the children of aristocrats, high-ranking officers, and professionals) exceeded the stature of boys from the Marine Society (mostly from the slums of London) by 10 to 15 cm.

3.2 The Modern World

The period from the late-nineteenth to the mid-twentieth century was characterized by dramatic increases in stature and equally dramatic reductions in mortality. Life expectancy was about 40 years in 1860 but had risen to 68 years by 1950 (see *Mortality: The Great Historical Decline*). There is no single cause for this dramatic increase, but several contributing factors have been identified. Widespread public health programs were implemented, such as vaccinations, purifications of water supplies, sewage disposal, and milk pasteurization. Medical advances, such as an understanding of the germ theory of disease and the development of antibiotics, as well as increasing access to medical care, also contributed. Increases in income also facilitated better diets and housing.

Stature remains an important variable in modern studies of health and mortality, though its use varies

by the economic development of the population under study. In developing nations, stunting and wasting are still critical indicators of nutritional status and the overall health of the population. In developed nations, most of the focus is on increased mortality of the obese, as indicated by high levels of BMI. Significant differentials in all health indicators, including anthropometric measures, still exist across cultures and social classes.

Central to the improvements in the twentieth century was the fight against infectious diseases. In a wide-ranging study of numerous populations from 1900 to the early 1960s, Preston (1976) attributed 25 percent of the mortality decline to influenza, pneumonia, and bronchitis; 15 percent to 'other infectious and parasitic diseases'; 10 percent to respiratory tuberculosis; and 10 percent to diarrheal diseases (the remaining portion of the decline is most likely attributable to cardiovascular disease). As noted earlier, the impact of infectious disease, particularly among children, is impacted significantly by nutrition.

Many factors, such as the development of antibiotics, contributed in the twentieth century to the decline in infectious disease prevalence and in the associated reduction in mortality. During the period between 1950 and 1970, life expectancy in developed nations increased only slightly (see *Life Expectancy and Adult Mortality in Industrialized Countries*), which many attributed to the successful fight against infectious diseases. Some argued that because so much early mortality was due to infectious disease, modern populations were facing an era of increased life but worsening health. People with frailer constitutions were living to older ages and, it was thought, would face higher rates of chronic illness than previous cohorts of elderly (Verbrugge 1984). However, most recent evidence suggests that age-specific morbidity and disability rates have been declining in the elderly population. Also surprising to most demographers has been the sharp increase in life expectancy after the period of stagnation between 1950 and 1970. The sources behind this increase remain largely a puzzle, and little consensus exists on future projections of life expectancy.

Towards the end of the twentieth century, birth weight, as well as other infant anthropometric measures, was linked not only to infant and child mortality, but also to disease and mortality in later life. The work of Barker (1994) suggests that development *in utero* may be critical to long-term health. This and other research suggests that anthropometric measures will remain an important component in an understanding of the complex and changing relationship between nutrition, health and mortality.

Health: Anthropological Aspects

Health and health practices are part of the inmost complexities of social existence, permeating the domains of politics, economics, and religion and almost always connected with dimensions that go beyond the body, such as interpersonal, family, and community relationships. Health is at once an end and a means. Explanations of the causes and patterns of health and disease often convey value judgments, senses of right and wrong, and of accountability and blame, as well as revealing what is morally at stake in definitions of health and its failures. Medical anthropological studies have built upon historical and cultural analyses over a long period of time that indicate an array of difference with respect to the metaphors and meanings that signify health. These studies have emphasized cultural fabrics that give coherence and depth to these meanings such that cosmology and ethical traditions come to define the body in states of sickness and well-being.

Anthropological studies of health focus on local contexts where health and illness are recognized and responded to. Such studies also trace the effects of global flows of commodities, information, finance,

images, people, and pathogens on such worlds. Anthropologists have been as interested in the social roots and consequences of health (and illness) as in their cultural representations. But what most particularly characterizes the anthropological perspective is the use of ethnography to understand health, illness, and health care. Anthropological perspectives on health bring together individual and collective realities in the way they are organized, narrated, contested, and in every sense lived as social trajectories (Kleinman 1995).

What anthropologists have learned through research in different societies is a story of diversity in experiences of health and health care giving, as well as of the ways social relationships and emotional processes interfuse in the mediation of health-relevant experiences. The meanings of health range from holistic and organic interpretations to hyperindividualistic ones. While biomedicine has treated health as a separate domain, popular meanings and interpretations of healthy states are often inseparable from other moral, political, and economic domains. Anthropologists have been particularly concerned with the transformations in health as those transformations express differences in power, social position, and social inequality, particularly as experienced by marginal groups and individuals. But in recent years, equal interest has been devoted to studies of health professionals, bureaucrats, and scientists who contribute to the public definition of health and health problems. Culture affects health as much through the culture of biomedicine and bureaucratic institutions as through the popular culture; indeed in the age of the Internet the two are closely related.

Applied medical anthropology addresses issues such as the ones raised and addresses them at the policy level. In heterogeneous societies such as North America and Western Europe, cultural differences continue to matter in the health field in large part because of differences in health conceptions which affect the panoply of health-relevant practices, from popular assessments of risks and responses to them to the uses and misuses of health care resources. Those differences contribute to different health outcomes for people, but they also contribute to different health systems, which are themselves undergoing transformation owing to both local and global economic and social changes.

1. Images of Health and Diverse Experiences of Health

The contemporary world contains impressive variations of images of health, modes of health maintenance, efforts at prevention, and illness experiences. Much of this variation is subsumed under what demographers and epidemiologists have termed the

'health transition.' This phrase refers to an increase in life expectancy, decline in mortality, and overall decrease in infectious diseases in the twentieth century by means of interventions such as vaccinations and dietary improvements. Health status measures have been introduced and are continually revised to develop policy, planning, and evaluation; these measures shape ideas of health and health improvement according to specific indices that promote interventions and socio-behavioral change. The health transition has also been accompanied by major changes in patterns of morbidity, increases in chronic degenerative diseases, old and new epidemics and behavioral and mental pathologies and is thus more complex than its original conceptualization (Chen et al. 1994). The very economic, technical, and industrial development that has benefited so many coexists with ongoing massive societal disruptions. Developing countries, for example, are experiencing the social and health costs of rapid urbanization and economic restructuring, costs that are confirmed in statistical increases of preventable disease and illness, and borne in terms of health problems such as infant mortality, life-threatening dehydration, urban violence, and hunger (Scheper-Hughes 1992).

Such acts as war, political persecution, and homicide contribute to a deliberate production of suffering and death. The era of infectious diseases is by no means past as the spread of HIV/AIDS, multidrug resistant tuberculosis, and other infectious diseases clarify. With the collapse of authoritarian rule came the collapse of public health measures and treatment regimes, demographic changes, travel, and other human actions that intensify the flows and resistance of pathogens. It is through such mechanisms that Paul Farmer has shown the ways social forces alter disease distribution and contribute to the persistence of new microbial conditions; indeed, the way 'social forces and processes come to be embodied as biological events' (1999, p. 5). The appearance of these disorders, closely correlated with poverty and social inequality, challenges the notion of a single biological etiology for disease and illustrates that these infectious diseases are mediated by multiple interacting causes that require anthropological inquiry and policy intervention.

The burden of chronic diseases—heart disease, cancer, stroke, diabetes, asthma—continue to be distributed unevenly across minority groups. Yet statistics also disclose impressive variations. In the United States, for example, there is the so-called Latino Epidemiological Paradox: Latinos, who generally experience a low socioeconomic status, nonetheless, have health outcomes that are either equal or better than non-Hispanic Whites. African Americans, by comparison, experience significantly higher rates of infant mortality, death, diabetes, HIV/AIDS, heart attacks, strokes, and homicides. Differences in levels of institutionalized racism, dietary patterns, and the influence of the Spanish language as a protective

cultural barrier have been pointed to as possible explanations for this paradox. Notably, health indices of Latino immigrants worsen from generation to generation in the United States, owing perhaps to a loss of balanced diet or tobacco or substance abuse as well as limited accessibility of health care services (Hernandez and Charney 1998).

The latest cluster of disorders to receive attention in the health transition is the rising rates of substance abuse, violence, psychological trauma, depression, suicide, and related mental health problems (Desjarlais et al. 1995). This group of health problems has increased to epidemic proportions both in developed and developing societies. Anthropological studies indicate that these problems often cluster together in settings of deep poverty, and societal breakdown. They are compounded by the fact that services tend to be limited, and health care financing and resources are inadequate. Many psychiatric hospitals in China, Russia, and Latin America continue to rely on a model of care involving prolonged stays in locked wards with antipsychotic medication and physical treatment (Phillips 1998).

Anthropological interventions have gone beyond explication of the 'soft' variables underpinning mental health problems, and focus on the ways social, economic, and political contexts shape the formation, distribution, and manifestation of disorders. Thus in the anthropological perspective, health problems and social problems are inseparable; health policies and social policies are viewed as necessary complements in defining criteria and techniques of successful rehabilitation.

2. Local Variations in Illness and Health

In response to emerging sets of health issues, anthropologists have identified the need for cross-cultural studies of health, healing, and patterns of morbidity in local contexts. One thread linking these studies is the importance of understanding patterns of everyday life experience, local knowledge, and social networks that influence personal agency and access to health care, as well as modes of transmission of diseases. From this perspective, health is seen as not simply originating in individuals themselves or deriving strictly from social forces, but as being engendered in complex interactions between individuals and their social contexts. Such lived responses may occur in the contexts of medical pluralism where several therapeutic systems coexist in one cultural setting, or in circumstances in which symptoms are subject to several distinct classifications, diagnoses, and hence, therapeutic courses of action or, once again, where different moral and religious values shape health promoting and disease preventing activities related to diet and lifestyle practices and support (Leslie and Young 1992). By stressing contingencies and detailing local histories of

particular places and peoples undergoing many kinds of social change, these ethnographies highlight the way particular worlds define health and conceive of health equity, while also illuminating the ways in which risks to disease and illness inter-relate.

It is not surprising that ethnographers have focused on illness whose event structure is relatively defined. Emphasized is the experience of illness as an interpersonal phenomenon as it is narrated through stories of illness. Ethnographies disclose how suffering is transformed through language and cultural meanings into distinctive illness narratives whose shared metaphors, voices, and genres represent distinctive experiences and political processes. This transformation, in turn, shapes the lived experience of illness through embodiment of cultural meanings and social relations into body-self processes. Ethnographers have focused on different mediating processes—ritual, devotional practices, music, poetics—that structure a sociosomatic continuum between moral and emotional processes. This approach relates to the concept of ‘local biologies’ by which is meant the different means of relating social worlds and biological processes such that those processes become particularized. Examples include Margaret Lock’s demonstration of fundamental differences in the experiences of menopausal symptoms and the aging process among women in Japan and North America (1993); Lawrence Cohen’s contrast of distinctive interpersonal experiences of dementia in India and the West (1998); and Rayna Rapp’s description of how experiences of class in the United States and technologies of the female reproductive life cycle come to alter experiences of pregnancy, infertility, abortion, and delivery (1999).

Ethnographers have also analyzed the trajectory and outcome of illness experiences on the social course of illness. Thus, Benedicte Ingstad and Susan Reynolds Whyte (1995) have shown how disability is as much a product of social definitions and restrictions and opportunities of access as it is a physical or functional limitation or disease, thus turning disability into an experience of potential wholeness and health. Other anthropologists have investigated societal responses to highly stigmatized disorders that respond to feelings of threat with practices aimed at marginalizing sufferers. Still others have studied experiences of chronic conditions like chronic fatigue syndrome, chronic pain syndrome, and fibromyalgia—disorders that are in a limbo of partial or minimal authorization where patients feel discredited or discreditable because of the lack of social legitimacy. Research here shows how patients often resist biomedical responses that are perceived as undermining and delegitimizing.

More recently, this area of research has expanded well beyond biomedically defined conditions to include a variety of forms of violence—structural, political, domestic—that represent significant threats to health. Here researchers of violence such as Veena Das (1995) have shown how different societal idioms

of those institutions authorized to deal with social problems—legal, welfare, religious, and of course medical—construct distinctive objects of programs and policies that not only differ greatly but that coerce different courses of health and disease and outcomes of these conditions.

Perhaps the largest field of anthropological inquiry has examined the varieties of community healing systems that parallel state institutions. Studies of herbalists, shamans, and other folk practitioners (and practices) illustrate how experience is manipulated, how meaning is negotiated, and how illness comes to serve some societal ends such as social control, cultural remembering, and political resistance. The point being that the collective significance of illnesses goes beyond individual and even familial concerns and plays a role in how societies remember, how social reality is legitimated, and how social worlds change.

The anthropology of health and medicine largely began as an applied field. There continues to be important segments of the field that seek application in public health and biomedical settings and in the policy arena. Such applied work classically demonstrated that health beliefs could either facilitate or become a substantial barrier to implementing policies and progress (Paul 1955). More recently, anthropologists have engaged the nongovernmental, administrative, and political dimensions of international health agencies and the policy development process, indicating how community organization can positively inform health and social programs in arenas such as HIV/AIDS prevention, cancer or infectious disease control, and family planning (Hahn 1999). Hence, anthropology has moved from a stance of critique of application to a stance of generating novel applications combining anthropological knowledge and public health technologies to enhance health.

3. Culture of Biomedicine

Distinctions between health and disease or illness are patterned according to norms. Norms of health and disease often emerge through a combination of statistics patterns, public consensus around desirable health outcomes, and social definitions and responses to deviance (Mechanic 1997). The extent to which biomedical norms have achieved a position of preeminence in health care systems and definitions of disease is undeniable. Biomedicine’s success in eradicating certain diseases and prolonging life shows that norms, however value-laden and socially constructed they may be, can indeed be health-enhancing (DeVecchio Good 1995). Yet anthropological studies have questioned biomedicine’s reductionism, primary value of efficiency, and authority in mediating interpretations of health, illness, and suffering (Good 1994, Kleinman 1995); they point to the fact that physiological measures alone fail to capture the

subjective dimensions of health. The growth of biomedicine, its characteristic quality of redefining social problems as health problems needing biomedical intervention, and its global cultural reach have also been analyzed. That biomedicine has been closely allied with the growth of industrial capitalism has led many ethnographers to examine biomedicine as a conduit of social regulations and discipline influencing all sectors of life, from definitions of disability to norms of occupational health, to definitions of mental illness and fitness (Turner 1995). This process has led to strong critiques regarding the necessity and indeed at times harmfulness of biomedical interventions, particularly with respect to the unpredictable side effects of technical procedures and drugs used to diagnose and treat patients. Concerns for iatrogenesis are reflected in current US debates regarding the consumption of psychiatric drugs by preschool children for example.

Attention to the international political economic context in which biomedicine operates is central to understanding how ideas of health modify, as well as to understanding the modes through which they are integrated as a set of values and practices in local contexts. Cross-cultural studies reveal the extent to which this integration with local experience is contested or resisted by highlighting: (a) the many discrepancies between biomedical knowledge and subjective accounts of illness and health, particularly in non-Western countries; (b) the moral and religious tensions underlying choices of medical systems; and (c) the degree to which distinctions between health and disease are rooted (or uprooted) by global ideologies and beliefs.

4. Biotechnology and Health

In response to the large influence that public health has achieved in our times due to the advances of biomedicine and advances in technology, the power of state action in the public domain, and market forces, health has increasingly become a specialized domain. The history of public health has been marked by major advances in population-level health in the nineteenth and early twentieth centuries through sanitary and workplace improvements, housing, and nutrition. Public health has shifted priority from social medicine to individually targeted health promotion. The launching and completion of the largest biology project ever conceived—the mapping and sequencing of the human genome—has already accelerated this process of individualizing health vis-à-vis the genetic profiling of diseases and increased prognostic information. For example, silicon chips embedded with hybrid bits of DNA that can test for various genetic conditions in individuals are currently in development. Such diagnostic tools are refocusing medical practice away from intervention to risk factor analyses and disease prevention.

The diseases individuals might be predisposed to, how they might react to particular medicines, and what health-promoting behaviors they might take to prevent future illness are all encompassed in this revolution (Rabinow 1996, Eisenburg 1999). Genomic information and the multitude of genomic sequences represent novel targets for therapeutic intervention. In short, the ‘life sciences industry’—knowledge of the genetic code and how to manipulate it and therapeutic advances—is transforming public health and biological knowledge. The prospect of widespread genetic testing has prompted concerns about how such information is being used to discriminate against those labeled as having genetic risks in terms of restricting or denying insurance coverage, as is already the case with women who are BRCA1 or BRCA2 positive.

These developments also highlight the depth of demand for ‘health.’ They attest to the power of biomedicine as a rationality in everyday life (in the organization of health care and delivery, legal procedures, policy analysis) that comes up against other forms of knowledge such as religion, and that coexists with older power structures related to family, gender, ethnicity, and class. Health as commodity, to be bought and sold in the marketplace, has led to new freedoms to pursue health but also raise dilemmas and create new risks: who is caretaker of genomic information? Who will have access to genetic therapies? These questions highlight some of the dangers regarding the social uses of genetic knowledge in the genomic and postgenomic era; they make it difficult to say what counts as success in this drive toward health and profits, a drive which has both sacred and secular sources and consequences.

The tradeoff between benefits to individuals and risks to populations of any given new technology must also be carefully assessed. Xenotransplantation, which promises to end the so-called shortage in donor organs by engineering transplantable animal organs, offers one prominent example. While such breakthrough technologies may save the life of a few, they pose dangers to populations in terms of the resistant viral strains and antibodies that might develop as a result of such transplant procedures. Another example of the way scientific advancement produces new social risks is found in the case of the traffic in human organs. Such traffic has been afforded by the availability of cyclosporine, among other things. This availability, combined with demand for human organs, has turned vulnerable populations in Brazil, South Africa, and India, into potential organ suppliers. Inconsistencies across the globe regarding the rights of donors as well as the lack of follow-up care for many of them have led to prolonged suffering or premature deaths, or both. Processes related to the globalization of the life sciences industry demand ethnographic attention to technical advances in terms of their development and diffusion; patterns of accessibility and differences in improved health outcomes between the poor and the

nonpoor; and the new forms of health and vulnerability these advances engender.

Images of health, illness, and healing have become key media, a 'fragile salvation,' through which societies and groups struggle with central values and beliefs, and negotiate social and political progress. The invention and implementation of techniques of health improvement have taken on many forms, including epidemic control, disease eradication, and combinations of environmental and individual behavioral change and medical advance. Yet definitions of health depend on normative and oftentimes conflictual values. Health as an individual goal coexists with new threats to health worldwide. The spread of advertising for cigarettes or the dumping of expired pharmaceuticals in low-income countries are all part of the globalization of disease. Under such conditions, what was once health now becomes disease. Health maintenance and promotion, once so influential a concept, can be undermined owing to new political and economic realities.

Contexts of health are themselves undergoing changes and are influenced by transformations in economy and polity, in science and technology, and in culture. These contexts shape the conditions of health and are in turn affected by it. These processes demonstrate that health as an experience is irreducible to a set of norms of physiological and mental activity, or strictly to a set of cultural differences. Only through concrete understandings of particular worlds of suffering and the way they are shaped by local histories and political economies can we possibly come to terms with the complex human dimensions that protect or undermine health. Health, seen in this way, is a construction as well as a contested way of being in the world.

Health Behavior: Psychosocial Theories

The term 'health behavior' is used very broadly in this article to refer to any behavior that influences, or is believed to influence, physical health outcomes, either by increasing or decreasing their risk or severity. A number of psychosocial theories (or models—the two terms are used interchangeably in this article; see also *Health Behaviors*) has been developed to predict, explain, and change such health behaviors. These theories can be divided into two main groups which

are commonly referred to as social cognition models and stage models, respectively. These are discussed in turn.

1. Social Cognition Models

The term 'social cognition models' is used to refer to a group of similar theories, each of which specifies a small number of cognitive and affective factors ('beliefs and attitudes') as the proximal determinants of behavior. These models do not deny that behavior is influenced by many other factors (e.g., social structural, cultural, and personality factors), but they assume that the effects of such distal factors are largely or completely mediated by the proximal factors specified by the model. Unlike the distal factors, the proximal factors are assumed to be amenable to change, for example by provision of relevant information. Thus social cognition models can be used as the basis for health behavior interventions.

The five models that have been used most widely by health behavior researchers in recent years are shown in Fig. 1 in the form of causal diagrams. The diagrams depict the core constructs in each model; numerous variations appear in the literature.

1.1 The Health Belief Model

The health belief model (HBM; Becker 1974) was developed in the 1950s by a group of social psychologists working in the field of public health who were seeking to explain why some people do not use health services such as immunization and screening. The model is still in common use. There are four core constructs: the first two refer to a particular disease whereas the second two refer to a possible course of action that may reduce the risk or severity of that disease. Perceived susceptibility (or perceived vulnerability) is the individual's perceived risk of contracting the disease if he or she were to continue with the current course of action. Perceived severity refers to the seriousness of the disease and its consequences as perceived by the individual. Perceived benefits refer to the perceived advantages of the alternative course of action including the extent to which it reduces the risk of the disease or the severity of its consequences. Perceived barriers (or perceived costs) refers to the perceived disadvantages of adopting the recommended action as well as perceived obstacles that may prevent or hinder its successful performance. These factors are commonly assumed to combine additively to influence the likelihood of performing the behavior. Thus, high susceptibility, high severity, high benefits and low barriers are assumed to lead to a high probability of adopting the recommended action. Another factor that is frequently mentioned in connection with the HBM is cues to action (events that

trigger behavior), but little empirical work has been conducted on this construct.

There have been two meta-analyses (quantitative reviews) of research using the HBM. Janz and Becker (1984) calculated significance ratios showing how often each HBM construct was statistically significant in the predicted direction across 46 studies. These ratios were 81 percent for susceptibility, 65 percent for severity, 78 percent for benefits, and 89 percent for barriers; the pattern of findings was similar when only the prospective studies were examined. Thus, barriers is the most consistent predictor of behavior and severity is the least consistent. Harrison et al. (1992) used extremely strict inclusion criteria; they included only 16 of the 234 studies they originally identified. Across these 16 studies, the mean correlations between HBM components and behavior were 0.15, 0.08, 0.13, and -0.21 for susceptibility, severity, benefits, and barriers, respectively. While statistically significant, these correlations are small in substantive terms. Harrison et al. found that benefits and barriers had significantly larger effect sizes in prospective compared with retrospective studies, whereas severity had a significantly larger effect size in retrospective studies.

1.2 Protection Motivation Theory

Protection motivation theory (PMT; Rogers 1983) was originally developed to explain how people respond to fear-arousing health threat communications or 'fear appeals.' It can be regarded as an adaptation of the HBM. Protection motivation refers to the motivation to protect oneself against a health threat; it is usually defined operationally as the intention to adopt the recommended action. Of the determinants of intention specified by the model, the four that have received the most empirical attention are vulnerability and severity (equivalent to perceived susceptibility and severity in the HBM), response efficacy (the belief that the recommended action is effective in reducing the threat), and perceived self-efficacy (the belief that one can successfully perform the recommended action; Bandura 1997). Thus, a person will be more motivated to protect himself or herself (i.e., have a stronger intention to adopt the recommended action) to the extent that he or she believes that the threat is likely if the current course of action is continued, that the consequences will be serious if the threat occurs, that the recommended action is effective in reducing the likelihood or the severity of the threat, and that he or she is able to carry out the recommended action.

In many studies using this model (e.g., Wurtele and Maddux 1987), specific PMT variables are experimentally manipulated in a factorial design and their effects on intention (and sometimes behavior) are measured. In fact, PMT is unique among social cognition models with respect to the relatively large

Health Belief Model (HBM)

number of experimental tests that have been conducted.

To date, two meta-analyses of PMT studies have been conducted (Floyd et al. 2000, Milne et al. 2000). The analyses used different study inclusion criteria and different effect size measures. Floyd et al. analyzed 65 studies with about 30,000 research participants whereas Milne and colleagues included 27 studies with about 8,000 participants. There were only 12 studies in common. Both analyses found support for each of the main PMT variables as predictors of intentions and/or behavior. Self-efficacy had the strongest, most consistent, and most robust effect.

1.3 Self-efficacy Theory

Self-efficacy theory (SET) is a subset of Bandura's (1986) social cognitive theory. According to this approach, the two key determinants of behavior are perceived self-efficacy and outcome expectancies. The latter construct refers to the perceived positive and negative consequences of performing the behavior. See Schwarzer and Fuchs (1996) for a version of this model that incorporates risk perceptions and behavioral intention, as well as components of the action phase of behavior change. No meta-analysis of SET has been published, though there is substantial evidence for the predictive validity of self-efficacy (Schwarzer and Fuchs 1996).

1.4 The Theory of Reasoned Action and the Theory of Planned Behavior

The theory of reasoned action (TRA; Ajzen and Fishbein 1980) developed out of social-psychological research on attitudes and the attitude-behavior relationship. The model assumes that most behaviors of social relevance (including health behaviors) are under volitional control, and that a person's intention to perform a behavior is both the immediate determinant and the single best predictor of that behavior. Intention in turn is held to be a function of two basic determinants: attitude towards the behavior (the person's overall evaluation of performing the behavior) and subjective norm (the perceived expectations of important others with regard to the individual performing the behavior in question). Generally speaking, people will have strong intentions to perform a given action if they evaluate it positively and if they believe that important others think they should perform it. The relative importance of the two factors may vary across behaviors and populations.

Although not shown in Fig. 1, the TRA also specifies the determinants of attitude and subjective norm. Attitude is held to reflect the person's salient behavioral beliefs concerning the possible personal con-

sequences of the action. For example, a person who believes that performing a given behavior will lead to mostly positive personal consequences will hold a favorable attitude towards the behavior. Specifically, attitude is held to be a function of the sum of the person's salient behavioral beliefs concerning the outcome of the action each weighted by their evaluation of that outcome. An indirect, belief-based, measure of attitude can be created by multiplying each behavioral belief by its corresponding outcome evaluation and then summing over outcomes. In a similar way, subjective norm is a function of the person's beliefs that specific individuals or groups think he or she should, or should not, perform the behavior. A person who believes that most significant referents think he or she should perform the behavior will perceive social pressure to do so. Specifically, subjective norm is held to be a function of the person's salient normative beliefs with respect to each referent, each weighted by their motivation to comply with that referent. An indirect measure of subjective norm can be created by multiplying each normative belief by its corresponding motivation to comply and then summing over referents.

Many behaviors cannot simply be performed at will; they require skills, opportunities, resources, or cooperation for their successful execution. The theory of planned behavior (TPB; Ajzen 1991) was an attempt to extend the TRA to include behaviors that are not entirely under volitional control, for example giving up smoking or using a condom. To accommodate such behaviors, Ajzen added a variable called perceived behavioral control to the TRA. This refers to the perceived ease or difficulty of performing the behavior, and is assumed to reflect past experience as well as anticipated obstacles. According to Ajzen, perceived behavioral control is a function of control beliefs in just the same way as subjective norm is a function of normative beliefs. It is assumed to have a direct influence on intention. For desirable behaviors, greater perceived behavioral control should lead to stronger intentions. Perceived behavioral control may also have a direct predictive effect on behavior, through two different mechanisms. First, holding intention constant, an individual with higher perceived behavioral control is likely to try harder and to persevere for longer than an individual who has lower perceived control. Second, people may have accurate perceptions of the amount of actual control they have over the behavior.

A number of meta-analyses of the TRA/TPB have been conducted. The findings show that when intention is predicted from attitude and subjective norm, or from attitude, subjective norm and perceived behavioral control, between 40 and 50 percent of the variance is explained, on average. When behavior is predicted from intention alone or from intention and perceived behavioral control, between 19 and 38 percent of the variance is explained (Sutton 1998).

1.5 Comparison of Social Cognition Models

The five social cognition models outlined above show a number of important similarities and differences. Some constructs are common to more than one model. For example, perceived susceptibility or perceived vulnerability occurs in both the HBM and PMT. Other constructs appear to be very similar, for example, perceived behavioral control and self-efficacy. Resolution of current controversies concerning the extent of overlap between such constructs requires the development of clear definitions, so that similar constructs can be distinguished on conceptual grounds, and more frequent tests of discriminant validity to investigate whether sets of apparently similar measures are tapping the same or different constructs.

All the models assume that individuals are future oriented and that they weigh up the costs and benefits of possible future courses of action. They all incorporate to a greater or lesser extent the expectancy-value principle which derives from the classical expected utility model, a normative model of decision making. In its weak form, this principle states that expectancies (subjective probabilities) and values are important determinants of behavior. In its strong form, the principle states that expectancies and values are combined multiplicatively, or at least that people behave as if they combine their cognitions in this way. Both the TRA and the TPB employ the strong form of the expectancy-value principle. The most systematic application of the principle is found in the subjective expected utility model (SEUM; Edwards 1954) which is based directly on expected utility theory. Versions of the SEUM have been applied to a number of health behaviors (e.g., Sutton et al. 1987). Researchers who use models such as the TPB and the SEUM need to be aware of the problems that arise from the use of multiplicative composites (Evans 1991).

This raises the thorny issue of rationality. Social cognition models are often criticized for offering an unrealistically rational account of how people form intentions and make decisions. However, the models do not imply that individuals always deliberate carefully and always make optimal decisions. People may not be aware of all the options available to them and of all the consequences that may follow from their actions. They may hold incorrect beliefs about the outcomes. They may make rapid decisions based on a few salient considerations. Having made a considered decision (e.g., to go jogging every Sunday morning), they do not necessarily have to weigh up the pros and cons again unless circumstances change; they may simply retrieve their previously formed intention from long-term memory and act on it. Thus, social cognition models imply a more limited rationality than is sometimes suggested by their critics.

Social cognition models are also sometimes criticized for being static. This criticism is unfounded:

social cognition models summarize dynamic causal processes. In the TRA, for example, changes in behavioral beliefs and/or outcome evaluations are assumed to produce changes in attitude which in turn lead to changes in intention which ultimately produce changes in behavior. Models of health behavior should specify the time lags involved in these causal processes but most of them do not. However, it is often assumed implicitly that effects on intention are almost instantaneous whereas effects on behavior may be delayed.

Social cognition models differ in the degree to which they specify the content of the cognitions they identify. With the TRA, for example, once the behavior of interest has been defined, it is possible to generate questionnaire items for intention and for the direct measures of attitude and subjective norm. However, in order to generate items for behavioral beliefs, outcome evaluations, normative beliefs and motivations to comply, it is recommended that researchers gather information on salient beliefs from members of the target population. These constructs remain 'content-free' until such information is obtained.

Compared with the other models, research on the TRA and the TPB shows a relatively high degree of standardization of measures based on published recommendations (Ajzen and Fishbein 1980). In addition, these authors emphasize the principle of correspondence (or compatibility) which, put simply, states that for maximum prediction the measures of all the constructs in the model should use similar wording. This principle is not widely applied in research using the other social cognition models.

The models also differ with regard to their scope of application. Key constructs in the HBM and PMT include perceived susceptibility and perceived severity with respect to a given health threat. Although these components can be extended to nonhealth-related events, for example the risk of financial loss, the scope of both models is necessarily limited by the nature of these two constructs. By contrast, the other three models are general theories that can be applied to any domain or behavior, for example voting, career, and purchasing decisions. Stated differently, SET, and the TRA and the TPB, regard health behaviors as having the same proximal determinants as other kinds of behavior. Thus, they offer the potential benefit of parsimony.

2. Stage Models

Stage models use similar concepts to social cognition models but organize them in a different way. They are fundamentally different in structure from social cognition models (Weinstein et al. 1998). According to this approach, behavior change involves movement through a sequence of discrete, qualitatively distinct, stages. Different factors are assumed to be important at different stages. Hence, people in different stages are

Table 1

Stage definitions (from DiClemente et al. 1991)

Precontemplation

Currently smoking and 'not seriously considering quitting within the next 6 months'

Contemplation

Currently smoking and 'seriously considering quitting within the next 6 months'; 'were not considering quitting within the next 30 days, had not made a quit attempt of 24h in the past year, or both'

Preparation

Currently smoking, 'were seriously considering quitting in the next 6 months and were planning to quit within the next 30 days,' and 'had made a 24h quit attempt in the past year'

Action

Currently not smoking; quit in last 6 months

Maintenance

Currently not smoking; quit > 6 months ago

assumed to require different interventions to encourage or help them to move to the next stage in the sequence.

Current models of health behavior that incorporate stage assumptions include: the transtheoretical model (TTM; Prochaska et al. 1992) and variants of it (e.g., De Vries and Mudde 1998), the precaution adoption process model (Weinstein and Sandman 1992), the health action process approach (Schwarzer and Fuchs 1996), and the health behavior goal model (Gebhardt 1997). This section focuses on the TTM because it is the dominant model in the field.

The TTM developed from studies of the processes of change in psychotherapy and smoking cessation. Smoking still accounts for the majority of applications of the model but it has been applied to a wide range of other health behaviors, including condom use, exercise, sunscreen use, and healthy eating (Prochaska and Velicer 1997). Although it is often referred to simply as the stages of change model, the TTM includes 15 different theoretical constructs drawn from different theories of behavior change. These include the stages of change (which provide the basic organizing principle), the 10 processes of change, the perceived pros and cons of changing, and self-efficacy and temptation. The TTM was an attempt to integrate these different constructs in a single comprehensive framework—hence the name transtheoretical.

The version of the TTM used most widely in recent years specifies five stages: precontemplation, contemplation, preparation, action, and maintenance (DiClemente et al. 1991). Table 1 gives the operational definitions of the stages as applied to smoking cessation. Using a 'staging algorithm,' participants are classified into stages on the basis of their responses to a small number of questionnaire items. The first three categories contain the current smokers, the remaining two the ex-smokers; people who have never smoked are not represented in this scheme. Precontemplation, contemplation, and preparation are defined in terms

of current intentions and past behavior (whether or not the person has made a 24h quit attempt in the past year), whereas action and maintenance are defined purely in terms of behavior; ex-smokers' intentions are not taken into account.

Prochaska et al. (1992) represented the stages of change as a spiral. People start at the bottom in precontemplation. They then move through the stages in order (contemplation, preparation, action, maintenance) but may relapse to an earlier stage. They may cycle and recycle through the stages several times before achieving successful long-term behavior change.

Of the other constructs in the TTM, the 10 processes of change refer to the things that people think and do to help them move through the stages, the pros and cons are the perceived advantages and disadvantages of changing, self-efficacy is borrowed from Bandura's social cognitive theory, and temptation is a related concept that refers to the degree to which a person expects to feel tempted to lapse in different situations.

The TTM is popular among clinicians and practitioners and there is a large body of evidence which is interpreted by its proponents as supporting the model. However, a closer examination of this literature reveals a number of serious problems with the TTM itself and with much of the research based on it (Sutton 2000). These problems include: lack of standardization of measures, particularly of the central construct of stages of change; logical flaws in current staging algorithms; inadequate specification of the causal relationships among the different constructs; misinterpretation of cross-sectional data on stages of change; and confusion concerning the nature of stage models and how they should be tested.

It is unfortunate that the model that has dominated the field to date is surrounded by a 'thicket of problems,' to use Bandura's (1997) phrase. The notion that behavior change involves movement through a sequence of qualitative stages is an important idea that

deserves further consideration. Health behavior researchers should turn their attention to the other stage models that have been proposed.

3. Conclusion

One focus of current interest is the 'intention-behavior gap.' Researchers in the health behavior field are using Gollwitzer's (1993) concept of implementation intentions (the intention to do X in situation Y) and related ideas to explain why some people who have strong intentions to achieve a goal succeed whereas others fail, and to try to close this gap using simple interventions (e.g., Orbell et al. 1997). Related to this is the increasing interest in models of self-regulation (Abraham and Johnston 1998). Another trend, which has been apparent in social psychology in recent years and is now being imported into research on health behaviors, is to regard attitudes as being activated automatically (e.g., Fazio 1990). Although this seems to pose a challenge to social cognition models, the two approaches are not necessarily incompatible, especially if the idea is extended to automatic activation of previously formed intentions.

There is a plethora of models of health behavior and new models are continually being developed. Although this can be interpreted as a sign of a field rich in conceptual and theoretical development, it makes it increasingly difficult to accumulate research findings into a coherent body of knowledge. The field would benefit from clearer definition of concepts, greater standardization of measures, more tests of convergent and discriminant validity, greater concentration on a small number of models, and more empirical comparisons of models. The vast majority of studies use nonexperimental between-subjects designs. Obtaining repeated measures on the same individuals would allow models to be tested at the individual level (Hedeker et al. 1996). Experimental manipulation of constructs, as has been done in many studies of PMT, would provide much stronger evidence of causal effects.

Health Behaviors

1. Introduction

Interest in behaviors that have important impacts on our health and well being is based upon two assumptions; (a) that a significant proportion of the mortality from the leading causes of death is caused by the behavior of individuals, and (b) that such behavior is modifiable (Conner and Norman 1996). Behavior is held to exert its influence on health in three basic ways: by producing direct biological changes, by conveying health risks or protecting against them, or by leading to the early detection or treatment of disease (Baum and Posluszny 1999).

This chapter begins by offering a definition of health behavior and the different types of health behavior. The prevalence of key health behaviors and their relationship to morbidity and mortality is then examined. The chapter then considers who performs these different behaviors, why they might do so, and how health enhancing behaviors might be encouraged and health impairing behaviors discouraged.

2. The Definition of Health Behaviors

Health behaviors have been defined in various ways. For example, Conner and Norman (1996) define them as any activity undertaken for the purpose of preventing or detecting disease or for improving health and well being. Gochman (1997) in the *Handbook of Health Behavior Research* defines them as 'behavior patterns, actions and habits that relate to health maintenance, to health restoration and to health improvement' (Vol. 1, p. 3). Behaviors within this definition include medical service usage (e.g., physician visits, vacci-

nation, screening), compliance with medical regimens (e.g., dietary, diabetic, antihypertensive regimens), and self-directed health behaviors (e.g., diet, exercise, smoking, alcohol consumption). All have received considerable attention from social and behavioral researchers and we now have a good understanding of the factors influencing how and why individuals engage in such behaviors.

In describing health behaviors it is common to distinguish health enhancing from health impairing behaviors. Health impairing behaviors have harmful effects on health or otherwise predispose individuals to disease. Such behaviors include smoking, excessive alcohol consumption, and high dietary fat consumption. In contrast, engagement in health enhancing behaviors convey health benefits or otherwise protect individuals from disease. Such behaviors include exercise, fruit and vegetable consumption, and condom use in response to the threat of sexually transmitted diseases.

3. Key Health Behaviors

Numerous studies have examined the relationship between health behaviors and health outcomes (e.g., Blaxter 1990) and have demonstrated their role in both morbidity and mortality. One of the first such studies identified seven features of lifestyle which were associated with lower morbidity and higher subsequent long-term survival: not smoking, moderate alcohol intake, sleeping 7-8h per night, exercising regularly, maintaining a desirable body weight, avoiding snacks, and eating breakfast regularly (Belloc and Breslow 1972). Health behaviors also impact upon individuals' quality of life, by delaying the onset of chronic disease and extending active lifespan. Smoking, alcohol consumption, diet, gaps in primary care services and low screening uptake are all significant determinants of poor health, and changing such behaviors should lead to improved health. For example, in the USA, Healthy People 2000 (US Department of Health and Human Services [USDHHS] 1990) lists increased physical activity, changes in nutrition and reductions in tobacco, alcohol and drug use as important for health promotion and disease prevention.

3.1 Smoking

Smoking is the health behavior most closely linked with long-term negative health outcomes (see *Smoking and Health*). Morbidity and mortality from coronary heart disease (CHD) are increased among smokers (Doll et al. 1994). Moreover, there is a strong positive relationship between the number of cigarettes smoked per day and the incidence of CHD (Friedman et al. 1979). Smoking has also been linked to a number of cancers, including cancer of the lung, throat, stomach and bowel as well as a number of more immediate

negative health effects such as reduced lung capacity and bronchitis (Royal College of Physicians 1983). Despite the array of negative health outcomes, smokers often report positive mood effects from smoking and the use of smoking as a strategy for coping with stress.

The number of people smoking in the USA and UK has shown a steady decline over the past twenty years. Data from the General Household Survey showed that 28 percent of people over the age of 16 smoke in the UK. Smoking is more common among men and among unskilled manual workers (General Household Survey 1994). A similar pattern is evident in the USA and other First World countries, with smoking more common among less educated, lower income and minority groups (Rigotti 1989). Those who quit smoking reduce the risk to their health, particularly if they quit before 35 years of age (Doll et al. 1994) (see *Smoking Prevention and Smoking Cessation*).

3.2 Diet

The impact of diet upon morbidity and mortality are well established (USDHHS 1988). In the Third World, the problems related to diet and health are ones of under-nutrition; in the First World, the problems are predominantly linked to overconsumption of food. In Western industrialized countries excessive fat consumption and insufficient fiber, fruit and vegetable consumption are related to health problems. In addition, excess consumption of calories combined with insufficient exercise has made obesity a major health problem. Diet has been implicated in cardiovascular diseases (CVDs), strokes and high blood pressure, cancer, diabetes, obesity, osteoporosis, and dental disease.

It is generally agreed that elevated blood cholesterol level is a major risk factor for the development of CVD (Consensus Development Conference on Lowering Blood Cholesterol to Prevent Heart Disease 1985). Nutbeam and Catford (1990) estimate that 26 percent of men and 25 percent of women in the UK have cholesterol levels greater than 6.5 mmol l^{-1} (a level considered to be excessive). While in the USA, it is estimated that 50 percent of the adult population is at risk of CHD by virtue of elevated blood cholesterol levels (Sampos et al. 1989). The reduction of blood cholesterol via dietary change is now widely accepted as an important way of tackling CHD. Dietary recommendations include reducing fat in the diet and increasing soluble fiber intake. However, their impact upon cholesterol levels may be limited.

3.3 Exercise

The potential health benefits of engaging in regular exercise include reduced cardiovascular morbidity and

mortality, lowered blood pressure, and the increased metabolism of carbohydrates and fats, as well as a range of psychological benefits such as improved self-esteem, positive mood states, reduced life stress and anxiety (see *Physical Activity and Health*). Nevertheless, a significant proportion of the population lead a sedentary lifestyle. The General Household Survey (1989) indicated that only one in three men and one in five women in the UK participate in any sport or recreational physical activity. Moreover, the Allied Dunbar Fitness Survey (1992) of 6,000 English adults reported that one in six adults had done no exercise (i.e., for 20 minutes or more at a moderate or vigorous level) in the previous four weeks. Participation in regular exercise is strongly related to a number of sociodemographic variables. In particular, young people and males are more likely to engage in regular exercise. For example, the 1988 Welsh Heart Health Survey (HPAW 1990) reported that among 18–34 year olds, 61 percent of men engaged in moderately vigorous exercise at least two times a week compared with only 35 percent of women. For 35–64 year olds, the percentages drops to 37 percent for men and 17 percent for women. Overall, across First World countries the typical exerciser is likely to be young, well educated, affluent and male.

3.4 Health Screening

Individuals may seek to protect their health by participating in various screening programs which attempt to detect disease at an early, or asymptomatic, stage. In the UK, screening programs have been set up for various diseases, including anemia, diabetes, bronchitis, cervical cancer, and breast cancer. Considering breast cancer, it has been estimated that breast screening programs which include mammograms can reduce breast cancer mortality by up to 40 percent among women aged 50 and over (Strax 1984). However, participation rates in breast screening programs show great variability across different countries, ranging from 25 percent to 89 percent (Vernon et al. 1990). Participation tends to be negatively related to age, and positively related to education level and socioeconomic status.

3.5 Sexual Behaviors

Sexual behaviors are considered health behaviors because of their impact upon the spread of sexually transmitted diseases (STDs) such as gonorrhea and syphilis (see *Sexually Transmitted Diseases: Psychosocial Aspects*). More recently, the role of sexual behaviors in the spread of human immunodeficiency virus (HIV) has been a focus of attention. While early health education campaigns emphasized the need to reduce the number of sexual partners or avoid par-

ticular sexual practices (e.g., anal sex, penetrative sex), more recently the focus has been upon the use of condoms during penetrative sex to reduce the risk of HIV transmission. Condom use is particularly recommended for those with multiple partners or those who do not know their partners' sexual history. For these reasons, much of the health advice concerning condom use has been focused on young people (see *Sexual Risk Behaviors*).

There seems to be considerable variation in the use of condoms in response to the threat of HIV/AIDS. For example, studies in the UK and USA report rates of between 24 and 58 percent (Fife-Schaw and Breakwell 1992, Gerrard et al. 1996). The General Household Survey (1993) in the UK reported changes by age group in the use of condoms for the period 1983 to 1991. Among 16–24 year olds, condom use increased from around 6 percent to around 12 percent during this period, while among 40–49 year olds it dropped from around 18 percent to around 12 percent over the same period.

3.6 Alcohol Use

Moderate alcohol consumption has been linked to positive health outcomes. However, high alcohol consumption has been linked to a range of negative health outcomes including high blood pressure, heart disease and cirrhosis of the liver. High levels of alcohol consumption have also been associated with accidents, injuries, suicides, crime, domestic violence, rape, murder and unsafe sex (British Medical Journal 1982). While many of the adverse effects of high alcohol consumption are due to continued heavy drinking (e.g., cirrhosis of the liver, heart disease), others are more specifically related to excessive alcohol consumption in a single drinking session (e.g., accidents, violence).

The General Household Survey (1992) reported that the average weekly consumption of alcohol in the UK was 15.9 units (1 unit = 1 glass of wine, 1 measure of spirits, or 0.5 pints of beer) for men and 5.4 for women. In addition, 27 percent of men and 11 percent of women were drinking more than the recommended weekly sensible limits (21 units for men, 14 units for women). Heavy drinking is also more likely among younger age groups. In a survey of 12,000 Welsh adults, Moore et al. (1994) reported that 31.1 percent of drinkers aged 18–24 engaged in binge drinking (i.e., drinking half the recommended weekly consumption of alcohol in a single session) at least once a week.

4. Relationship of Health Behaviors to Sociodemographic Factors

A clearer understanding of why individuals perform health behaviors might assist in the development of

interventions to help individuals gain health benefits. A variety of factors have been found to account for individual differences in the performance of health behaviors. Demographic variables show reliable associations with the performance of health behaviors. For example, there is a curvilinear relationship between many health behaviors and age, with high incidences of many health risking behaviors such as smoking in young adults and much lower incidences in children and older adults (Blaxter 1990). Such behaviors also vary by gender, with females being generally less likely to smoke, consume large amounts of alcohol, engage in regular exercise, but more likely to monitor their diet, take vitamins and engage in dental care (Waldron 1988). Differences by socioeconomic status and ethnic group are also apparent for behaviors such as diet, exercise, alcohol consumption and smoking (e.g., Blaxter 1990) (see *Socioeconomic Status and Health*).

Generally speaking, younger, wealthier, better educated individuals, under low levels of stress, with high levels of social support are more likely to practice health protective behaviors. Higher levels of stress and/or fewer resources are associated with health risking behaviors such as smoking and alcohol abuse (Adler and Matthews 1994). Social factors seem to be important in instilling health behaviors in childhood. Parent, sibling and peer influences are important, for example in the initiation of smoking. Cultural values also have a major impact, for instance in determining the number of women exercising in a particular culture. For example, Steptoe and Wardle (1992) report that between 34 and 95 percent of women in their European student sample had exercised in the past 14 days.

5. Understanding the Distribution/Prevalence of Health Behaviors

Perceived symptoms control health behaviors when, for example, a smoker regulates his/her smoking on the basis of sensations in the throat. Access to medical care has been found to influence the use of such health services (e.g., Black Report 1988). Personality factors have also been associated with health behaviors (Adler and Matthews 1994). Cognitive factors also determine whether or not an individual practices health behaviors and may explain how other factors influence behavior. Knowledge about behavior–health links is an important factor in an informed choice concerning health behaviors. Various cognitive variables have been studied including perceptions of health risk, efficacy of behaviors in influencing this risk, social pressures to perform the behavior, and control over performance of the behavior. The relative importance of various cognitive factors in determining who performs various health behaviors constitutes the basis of different models. Such models have been labeled social cognition models (SCMs) because of their focus

on cognitive variables as the primary determinant of individual social behaviors. These SCMs provide a basis for understanding the determinants of behavior and behavior change (see *Health Behavior: Psychosocial Theories*). Each of these models emphasize the rationality of human behavior and assume that behavior is based upon elaborate, but subjective, cost-benefit analysis of the likely outcomes of differing courses of action. It is assumed that individuals generally aim to maximize benefits and minimize costs in selecting a behavior.

5.1 Health Belief Model

The Health Belief Model (HBM) attempts to conceptualize two types of health beliefs that make a behavior in response to illness more or less attractive (Sheeran and Abraham 1996): perceptions of the threat of illness and evaluation of the effectiveness of behaviors to counteract this threat. Threat perceptions depend upon the perceived susceptibility to the illness and the perceived severity of the consequences of the illness. Together these variables determine the likelihood of the individual following a health-related action, although their effect is modified by demographic variables, social pressure and personality. The particular action undertaken is determined by the evaluation of the possible alternatives. This behavioral evaluation depends upon beliefs concerning the benefits or efficacy of the health behavior and the perceived costs or barriers to performing the behavior. Hence, individuals are likely to follow a particular health behavior if they believe themselves to be susceptible to a particular condition or illness which they consider to be serious, and believe the benefits of the behavior undertaken to counteract the condition or illness outweigh the costs. It is assumed that this whole process is set in motion by cues to action. Cues to action include a diverse range of triggers to the individual taking action and are commonly divided into factors that are internal (e.g., physical symptoms) or external (e.g., mass media campaigns, advice from others) to the individual. Other influences upon the performance of health behaviors, such as demographic factors or psychological characteristics (e.g. personality, peer pressure, perceived control over behavior) are assumed to exert their effect via changes in the components of the HBM.

5.2 Theory of Planned Behavior

The Theory of Planned Behavior (TPB) was developed by social psychologists and has been widely employed as a tool to aid our understanding of a variety of behaviors including health behaviors (Ajzen 1991, Godin and Kok 1996). The TPB details how the influences upon an individual determine that indi-

vidual's decision to follow a particular behavior. Within the TPB, the determinants of behavior are intentions to engage in that behavior and perceived behavioral control (PBC) over that behavior. Intentions represent a person's motivation. The construct is conceptualized as an individual's conscious plan or decision to exert effort in order to engage in a particular behavior. Perceived behavioral control is a person's expectancy that performance of the behavior is within his/her control. Intentions are determined by three variables. The first is attitudes, which are an individual's overall evaluation of the behavior. The second is subjective norms, which consist of a person's beliefs about whether significant others think he/she should engage in the behavior. The third measures the extent to which the individual perceives that the behavior is under their personal control and is labeled PBC.

The attitude, subjective norm and PBC components are determined by underlying beliefs. Attitude is a function of a person's salient behavioral beliefs; which represent perceived likely consequences of the behavior (e.g., taking exercise will reduce my risk of heart disease). Subjective norm is a function of normative beliefs, which represent perceptions of specific salient others' preferences about whether one should or should not engage in a behavior (e.g., my family think I should take exercise). PBC is based on beliefs concerning access to the necessary resources and opportunities to perform the behavior successfully (e.g., I have easy access to a place where I can exercise).

So, according to the TPB, individuals are likely to engage in a health behavior if they believe that the behavior will lead to particular outcomes which they value, if they believe that people whose views they value think they should carry out the behavior, and if they feel that they have the necessary resources and opportunities to perform the behavior.

5.3 Perceived Self-efficacy

Self-efficacy is one of the most powerful predictors of health behavior (Bandura 1997, Schwarzer and Fuchs 1996). It has its origins in Bandura's social cognitive theory, which states that behavior is a function of both incentives (i.e., reinforcements) and expectancies. Three kinds of expectancies can be identified, these being: situation-outcome expectancies, which refer to beliefs about how events are connected; outcome expectancies, which refer to beliefs about the consequences of performing a behavior; and self-efficacy expectancies, which refer to beliefs about one's ability to perform the behavior. Thus, in order to perform a health behavior, individuals must value their health (i.e., have an incentive), believe that their current lifestyle poses a threat to their health (i.e., situation-outcome expectancy), believe that adopting the new behavior will reduce the threat to their health (i.e., outcome expectancy), and believe that they are capable

of performing the behavior (i.e., self-efficacy expectancy). While all these beliefs are seen to be important in the initiation and maintenance of health behavior, perceived self-efficacy is seen to be the most important. Individuals with a strong sense of self-efficacy are believed to develop stronger intentions to act, to expend more effort to achieve their goals and to persist longer in the face of barriers and impediments. Perceived self-efficacy is therefore believed to play a crucial role in the determination of health behavior (see *Health: Self-regulation*). According to Bandura (1997), self-efficacy can be conceptualized and measured in terms of three parameters; magnitude, strength and generality, with strength being the key parameter. This is reflected in its measurement (e.g., 'I am confident that I can refrain from smoking, even if someone offers me a cigarette').

5.4 Stage Models of Health Behavior

A number of researchers have suggested that there may be qualitatively different stages in the initiation and maintenance of health behavior, and that to obtain a full understanding of the determinants of health behavior it is necessary to conduct a detailed analysis of the nature of these stages. One of the first stage models was put forward by Prochaska and DiClemente in their transtheoretical model of change (TTM). Their model has been widely applied to analyze the process of change in alcoholism treatment, smoking cessation, and psychotherapy. In its most widely applied form, Prochaska et al. (1992) identify five stages of change: precontemplation, contemplation, preparation, action, and maintenance. Individuals are seen to progress through each stage to achieve successful maintenance of a new behavior. Taking the example of smoking cessation, it is argued that in the precontemplation stage the smoker is unaware that his/her behavior constitutes a problem and has no intention to quit. In the contemplation stage, the smoker starts to think about changing his/her behavior, but is not committed to try to quit. In the preparation stage, the smoker has an intention to quit and starts to make plans about how to quit. The action stage is characterized by active attempts to quit, and after six months of successful abstinence the individual moves into the maintenance stage characterized by attempts to prevent relapse and to consolidate the newly acquired nonsmoking status.

6. Changing Health Behaviors

The above models detail the key cognitive determinants of health behavior. To the extent that these models outline the key social cognitive determinants of health behavior, interventions which target these variables should lead to associated changes in beha-

vior. For example, the HBM would suggest that encouraging health behaviors is best achieved by increasing individuals' perceived susceptibility to negative health outcomes and making individuals aware of the severity of such outcomes. Such approaches have been commonly employed in health promotion messages. In addition, the HBM might suggest the need to focus on the benefits of health behaviors and the fact that barriers to action are easily overcome. However, there has been little systematic evaluation of their effectiveness, perhaps due to the common sense appeal of these approaches.

Relatively few studies have used the TPB as a framework for developing interventions, despite the fact that the theory would suggest a number of interventions focusing on different components of the model. Brubaker and Fowler (1990) did examine the effect of persuasive messages tackling behavioral beliefs upon men's intentions to perform testicular self-examination in response to the threat of cancer. A persuasive message was found to increase intentions to perform testicular self-examination compared to a no message control. The TPB would also suggest the need to tackle normative beliefs and control beliefs in any attempt to change behavior. A number of studies have attempted to use persuasive messages aimed at tackling normative pressures. For example, in relation to preventing adolescent smoking, prevention programs commonly attempt to tackle the perceived pressure from teenage peers who smoke. Tackling control beliefs has been seen to bear many similarities to changing perceptions of self-efficacy (see below).

Another interesting approach has focused directly on the immediate determinant of behavior in the TPB: intentions. Where individuals do have an intention to engage in a health behavior (goal intentions), but are having trouble implementing their intention, forming a specific plan about where and when to act has been found to help (Gollwitzer 1993). For example, Orbell et al. (1997) gave out a questionnaire about breast self-examination in response to the threat of cancer. Half the women were asked to indicate when and where in the next month they intended to perform breast self-examination (a specific plan or implementation intention). A one month follow-up found that 64 percent of these women had performed breast self-examination that month compared with only 16 percent of women who hadn't made an implementation intention, despite having similar goal intentions.

Several studies have focused on enhancing feelings of self-efficacy as a means for encouraging health behavior change. As Bandura (1997) outlines, there are four main sources of self-efficacy, each of which could be addressed in interventions. First, individuals can develop feelings of self-efficacy from personal mastery experience (e.g., it may be possible to split a behavior into various subgoals, such that the easiest subgoals are achieved before more difficult tasks are attempted). Second, individuals may develop feelings

of self-efficacy through observing other people succeed on a task (i.e., vicarious experience). Third, it is possible to use standard persuasive techniques to try to instill feelings of self-efficacy. Finally, one's physiological state may be used as a source of information, such that high levels of arousal or anxiety may indicate to the individual that he or she is not capable of performing a given action (e.g., relaxation techniques may be employed to help maintain feelings of self-efficacy).

Stage models have also been used as the basis for designing interventions. The main distinction from the approaches already presented is that this approach suggests that interventions need to be matched to the needs of each individual. So, for example, an individual at the pre-contemplation stage in relation to exercise needs to be made aware of the health problems associated with a lack of exercise. A different individual in the contemplation stage needs information about the pros of changing their exercise behavior and the cons of not changing. While an individual in the preparation or action stage needs helps with acting on their plans to engage in exercise. Whilst these ideas appear entirely plausible, to date relatively few studies have managed to demonstrate that such stage-matched interventions are more effective than presenting the same intervention to all individuals.

7. Conclusions

Health behaviors have important consequences for both the quality and length of life by influencing disease outcomes. Nevertheless, there is still considerable variation in those individuals who perform these behaviors. Social cognition models provide one approach to understanding the variation in who performs health behaviors. These models are also useful because they suggest ways in order to change health behaviors in order to improve health. Perhaps the greatest challenge for social and behavioral research on health behaviors is the demonstration that such theory-based interventions can produce effective and long-lasting behavior change that will lead to real health benefits for all individuals.

Health Behaviors, Assessment of

1. Introduction: Health Behaviors as a Multidimensional Construct

In the field of health psychology, health behaviors are most often defined as behaviors that people engage in to maintain or improve their current health. These definitions focus on subjective health beliefs since they include any behaviors performed by a person in order to protect, promote, or maintain his or her health, whether or not such behaviors are objectively effective towards that end. In contrast, most empirical studies in public health and epidemiological research focus on behaviors which are defined by experts as having a substantial relationship to health. Therefore, the term health behavior has two different connotations. First, a subjective one which focuses on which behaviors lay people believe may affect their health, and second, an objective one which focuses on what experts evaluate and define as health-affecting behaviors. However, lay and expert views on which behaviors are related to health may not be consistent. In addition, several studies have found little consistency in people's health habits. Therefore, a person who exercises will not necessarily go for a regular check-up at the dentist. One reason people's current health habits are not more interdependent is the fact that health behaviors differ on a number of dimensions and may be

influenced by different factors. The modest link between health behaviors and the high variability in their diffusion raises the question of whether it makes sense to talk about health behavior as a unitary construct.

Furthermore, health behaviors could be examined as antecedents or causes of health status. Such an approach is taken by social epidemiologists. In contrast, health educators are interested in health behaviors as objective dimensions for systematic interventions directed at producing behavioral changes. Finally, as subjects of scientific study, health behaviors are analyzed as consequences or outcomes, as well as correlates of personal factors. For an accurate and reliable measurement of health behaviors it is essential to distinguish between their different dimensions and to define clearly the topic to be investigated.

2. Measurement of Health Behaviors

There are various methods to assess health behaviors. On rare occasions, physiological methods can be used. This is the most accurate way to measure alcohol consumption (via blood or urine sampling), drug consumption (via immunoassay, hair or sweat bioassay procedures), habitual dietary intakes (via biochemical markers), or physical activity (via doubly labeled water). However, such bioassay methods are only required when a high level of accuracy about recent health behavior is needed (e.g., for workplace drug testing) or used in addition to self-reported data to provide a means of confirming or falsifying self-reported information (e.g., about recent drug use). However, in some circumstances it may be appropriate only to make respondents believe that there is a way of finding out about their behaviors via physiological measures to reduce misreporting.

Other direct methods are behavioral observation techniques, which are used to assess physical activity among children or a driver's choice of speeds, to name two examples.

Another alternative for observing 'true' health behaviors is unobtrusive, seminaturalistic measures, such as video-based simulation which involves participants viewing a video film of various situations relating to the task at hand and measuring responses to that task (e.g., a video-simulation measure of drivers' speed choice). This method could provide ecologically valid measures which simultaneously satisfy the demands of internal and external validity. Another possibility for seminaturalistically measuring health behaviors has been proposed by Rothman et al. (1993), who offered participants the opportunity to order a free sample of suntan lotion and to indicate their preferred protection factor rather than asking for behavioral intention. However, these techniques can only be approximations of 'reality' because they are often confounded with other variables. In the study of

Rothman et al. (1993), one could argue that the participants ordered the suntan lotion because it was for free. In addition, behavioral observation techniques are often impractical for broader samples as well as for complex and habitual health behaviors. Therefore, self-reports are a crucial—and often the only—source of information about health behaviors. There are different kinds of self-reports, which can be distinguished roughly into qualitative and quantitative methods.

3. Qualitative Methods

Unstructured or semistructured interviews are useful qualitative techniques for researchers interested in understanding individuals' cognitive and conceptual models of health behavior and the frames of reference that individuals use to organize health behaviors. Therefore, qualitative methods are mainly concerned with exploration and analysis of health behavior because they allow the interviewee room to address the issues which he or she feels relevant to the topics being raised by the investigator. For instance, detailed interviews and ethnography could give insight into subjective and experiential dimensions of those behaviors related to substance misuse. One major disadvantage of qualitative methods is the fact that generality is, by definition, not quantifiable. Furthermore, since anonymity is not given, self-reports elicited by interviews may be affected by social desirability biases which lead to over-reporting of socially desirable behavior as well as under-reporting of socially undesirable behavior. The results from the National Household Survey of Drug Abuse (NHSDA) showed that the proportion of the respondents reporting marijuana use was higher when questions were self-administered than when they were administered by an interviewer.

Alternatively, one could introduce a 'reality check' on the respondent's account by using the *method of focus groups* (Morgan 1997). A focus group is a collective, discussion-based interview orchestrated by a moderator who uses the small group setting to achieve a group dynamic to construct a supportive social context that allows respondents to reveal thoughts and behaviors they would normally be reluctant to disclose. Hence, this method could be useful for generating information about behaviors that are rarely talked about (e.g., sexual behaviors and drug use).

4. Quantitative Methods

Stone and Shiffman (1994) have labeled strategies for collecting self-reports of respondents' momentary or current state as *Ecological Momentary Assessment*

(EMA). EMA studies usually consist of repeated assessment of participants' momentary state as they go about the tasks of daily life in their natural environment. There are several ways to approach this sampling task. *Interval-contingent* assessments require assessment at regular intervals. One example is the method of *interactive voice response* (IVR), where alcoholics are asked to call in on a regular basis to report their drinking to interviewers. Another way is asking subjects to record every episode of smoking, eating, or some other behavior of interest. This *event-contingent* approach may not lead to a representative sample of the participant's general state and requires a clear definition of the triggering event. In contrast, *signal-contingent* sampling supplies participants with an external signal cue, which is usually timed to be emitted at random, to prompt subjects to complete a written assessment or an electronic diary. As signal devices, beepers, electronic watches, and palmtop computers have been used. Investigations of temporal and contextual patterns of smoking have shown that global self-reports are largely inaccurate in comparison with a computerized EMA. Hence, EMA is a method which precisely assesses recent health behaviors. The major advantage of this method is that it minimizes reliance on recall from memory by relying on respondents' reports of their experience at the moment of the inquiry.

Diary log techniques are data collection strategies which gather information in relation to the passage of time. Therefore, the distinctive feature of this method is that it yields information which is temporally ordered. It tells the sequence of events and the profile of actions across time. Diary techniques can be particularly useful when data from the same person are required over a considerable period of time and/or very frequently, such as for assessing smoking behavior, alcohol consumption, or dietary habits to provide a general estimate of an individual's consumption. For example, alcohol consumption diaries often include questions about the frequency of consumption, the type of drink taken, and the quantity consumed on each occasion. In comparison to questionnaires, the diary log format minimizes recall biases associated with retrospective reporting, but daily reporting may be more reactive. In addition, diaries could be valuable for getting access to so-called 'intimate' information (e.g., sexual behavior).

Timeline Followback Method Reports (TLFB) have been developed by Sobell and Sobell (1995). They provide a detailed insight into health behaviors such as smoking, drug abuse, or drinking over a designated time period. Participants are required to provide retrospective estimates of their daily behavior by using a calendar over a certain time period, which can range up to 12 months prior to the interview. With this method, the pattern, variability, and level of drinking or smoking can be profiled, which is especially useful when relatively precise estimates are needed or when

researchers wish to evaluate specific changes in health behaviors before, during, and after interventions.

A *questionnaire*, which assesses past behavior frequency, is the most commonly used method to measure health behaviors. There are numerous questionnaires which ask for the average or typical quantity and frequency of alcohol use (see Sobell and Sobell 1995), dietary habits, or physical activity (see Pereira et al. 1997). However, the information provided by quantity and frequency measures (QF estimates) is limited by the fact that respondents must abstract an estimate from highly variable experiences. QF estimates often reflect less drinking and tend to misclassify drinkers compared with daily diary or timeline reports. They also provide lower absolute food intake estimates than a longer, interviewer-administered diet history.

5. Distortions in Self-reports of Health Behaviors

There are a series of methodological problems shared by all surveys relying on self-reports which could seriously decrease the internal and external validity of a survey, such as the ambiguity surrounding health behavior terminology. The term 'sexual partner,' for instance, may be interpreted in many different ways by the respondents, ranging from describing someone with whom one has experienced orgasm to someone with whom one has shared a bed while naked. In addition, the target population should be carefully selected because health behaviors have different meanings for adolescents and adults.

Furthermore, short-term fluctuations, for example in substance use, produced by environmental (e.g., social settings) and psychological (e.g., mood or stress) variables, may affect the psychometric properties of use measures. Hence, seasonal effects and short-term fluctuations may lead to superficial behavioral changes which could be misinterpreted by researchers as genuine changes.

Survey questions must be fair and unbiased to obtain valid answers. Asking leading questions, which suggest an expected answer, or loaded questions, which have emotionally laden connotations, can quickly invalidate a survey. In addition, by their very nature, questions about past behaviors assume accurate memory for events as well as willingness to report these to a researcher. However, respondents may not recall the actual events, employing instead various cognitive heuristics (rules of thumb) to estimate frequencies. This could result in certain biases. People use different strategies to answer frequency questions over different time spans. Episodic enumeration (recalling and counting individual incidents) is more likely to be used when shorter time spans are involved in frequency reports, whereas rate-based estimation (projecting the typical rate over the length of the recall period) is more likely to be used when longer time spans are involved. Reported behavioral

frequencies for a year are generally less than 12 times the equivalent frequencies for a month. This phenomenon has been coined as the *time span effect*. Use of different time spans over or within studies may lead to inconsistent or even misleading results.

Beside memory-based information, respondents may use context-based information to make frequency judgments. One context-based heuristic involves the use of information provided by response alternatives. For example, respondents may use the range of the response alternatives provided to them as frame of reference in estimating their own behavioral frequency.

Accurate and reliable measurements of health behaviors, especially drug usage and sexual activity patterns, have proven difficult to obtain because of social desirability influences. People's tendency to under-report smoking and to underestimate their alcohol consumption are two well-established facts. In addition, studies that focus on behavioral frequencies consistently yielded *illusory superiority*: people report lower frequencies of unhealthy behaviors and higher frequencies of healthy behaviors for themselves than for an average peer.

6. Conclusion

If high accuracy is needed, health behavior should be assessed by physiological measures or (if these are not available) by behavioral observation, EMA, or diary techniques. However, these assessment strategies are resource consuming and often not practicable for researchers in the field studying large samples or complex, habitual health behaviors. Although self-reports may have a decreased validity and reliability in comparison with these methods, due to memory or motivational biases, they can nevertheless provide very useful information for scientific studies of the consequences of health behaviors. To ascertain the accuracy of self-reports, researchers should consider different possible connotations of questions in different samples, and construct questions carefully in order to reduce autobiographical memory biases and social desirability influences.

Health Care Delivery Services

Delivery systems for health care services are nested within health care systems, which are in turn nested within health systems. In fact, the topic of this article is best defined with reference to those more macrolevel systems, which are themselves addressed by other articles in the Health section. *Health care delivery services* consist of that segment of any society's *health system* which is specifically focused on the delivery of health care services. A *health system* encompasses a complex set of structural relationships among populations and institutions that have an impact on health, broadly defined. Further, as described by Ruggie (see *Health Care Systems: Comparative*), each country's *health care system* is defined as those specific macrostructures focused on financing, delivering, and evaluating health care, all of which are contained within a singular context of culture, history, politics, and economics.

This article will focus on defining and elaborating the dimensions of *health care delivery services* in a manner that is generally consistent with the literature on health services research, and comparable to discussions of 'health care delivery systems' in the United States and most developed nations. Commonly accepted definitions of health care delivery system emphasize the formal arrangements constructed to deliver health care services to specific populations, identified either by market, geographic location, type of service, or subpopulation characteristics (such as age or gender). Thus, this is a level of structure that is slightly more narrow than Ruggie's treatment of 'health care systems,' and represents a specific substructure within Frenk and Murray's definition of a 'health system.' Further, there are multiple types of health care delivery systems within any health system, depending on the type of health care service being delivered, whether preventative, diagnostic, or thera-

peutic, and the type of population or subpopulation being served.

This article will explore, in order: (a) the principle actors or components within health care delivery systems; (b) the variety of system types often present in highly developed health systems; (c) major characteristics of contemporary health care delivery systems; and (d) strategies for assessing health care delivery system performance. A number of recent trends in the health sector and among health care organizations will be examined, particularly since they highlight the difficulties in assessing delivery system performance in the twenty-first century, using standard measures of performance, most of which were developed during simpler times.

Given the brevity of this article, bibliographic emphasis will focus largely (although not exclusively) on US health care systems. Although the concepts to be explored in this article are applicable across most developed countries, the enormity of changes unfolding in many countries would require several chapters of dedicated comparative analysis. For example, economic and political turmoil in Eastern Europe is currently wreaking havoc with fragile public health and health care delivery systems. A prime example is Russia, where economic resources and basic medical supplies are scarce, government promises to cover basic health care go unfulfilled, and physicians must barter and beg to acquire needed medical equipment and drugs (Shishkin 1999). An 'underground' medical system has developed providing care for those few who can pay privately. Massive change also characterizes Latin American health care systems. In Chile free market reforms adopted during the Pinochet regime privatized much of what had been an extensive and effective government supported health care system. What remains now is a nonsystem with considerable problems of access (Reichard 1996). For more extensive comparative discussions of contemporary changes in health care systems, the reader is encouraged to consult recent work by Field (1989), Light (1999), or Day et al. (1998).

1. Components of Health Care Delivery Systems

The primary actors involved in delivering health care services are the members of the *health care workforce* (physicians and non-MD professionals, technicians, paraprofessionals; see *Health Professionals, Allied*), various *health care organizations* where care is either delivered or coordinated, and the agencies or firms which *finance* the delivery of services. Throughout the last half of the twentieth century, the medical and health division of labor has expanded dramatically, an expansion that has been fueled by the development of sophisticated medical technologies and specializations. Similarly, a variety of health care organizations deliver or coordinate care services along every step of the care continuum, and the number and type of

provider organizations mushroomed during the 1980s and 1990s. Diversification of health care organizational forms has both produced new organizational types (ambulatory surgery centers, women's health centers) and led to the adoption of new product lines by traditional organizational forms. For example, hospitals have diversified by adding a component of geriatric care, or vertically integrated into a comprehensive health care system, complete with ambulatory clinics and long-term care units (Fennell and Alexander 1993).

The *agencies and firms which finance health care service delivery* are also part of this system. In the US, a mix of actors, from both public and private sectors, play this role. Insurance carriers and the federal government have historically been important financiers of health care; more recently private sector corporations have been exerting considerable control over service delivery as major purchasers of health care for their employees. Toward the end of the 1990s the US health system came to embrace the concept of 'managed care,' an arrangement in which the financial partner (the health plan) becomes directly linked to both the providers of care and the client, through risk contracts. These arrangements have obfuscated the roles of the providers of care and the third-party payers of care, health insurance carriers or plans (Scott et al. 2000). Managed care arrangements contractually link providers to health plans, ensuring that an enrolled group of patients will seek care only from contracted (and somewhat controlled) providers. The providers are often paid a preset per capita rate for treating enrolled patients, and agree to 'gate-keep' or control the patient's use of services through utilization management strategies (see *Managed Care*). Large employers seek contracts with health plans that can promise low premiums and a variety of covered services; health plans compete for large employee groups to enroll as they are the most preferred, low-cost, healthy patient panels. Variations on this general strategy have resulted in a range of complex managed care organizational structures, in which the health plan is mediator between patients and providers, and between providers and payment. Managed care organizations combine provider and plan functions into one structure (Flood et al. 1998).

Although health care workers, organizations, and financing agencies constitute the major actors of health care delivery systems, there are a number of external factors which exert very important influences on these actors. Some influences are so important that it is sometimes difficult to separate the system actors from the external influences. Medical technology, for example, is both part of the environment of health care delivery and part of the health care organizations delivering the care. Continued expansion of medical diagnostic and treatment equipment, medications, biological agents, and devices has driven medical costs upward. The new technologies have created new types

of technical and patient care jobs and professions within the health delivery system, which in turn lead to more demand for those technologies (Osterweis 1996). Both medical professionals and patients still expect new technologies to be available, despite their certain impact on costs, and their sometimes uncertain effect on outcomes. The availability of new technologies is used as a primary marketing device by health care organizations to attract patients, professionals, and healthplan contracts.

Several other environmental forces influence the major delivery system actors, including changes in the age structure of the population, shifts from acute to chronic illnesses as the leading causes of morbidity and mortality, the explosion of information and telecommunications technologies, and the role of the state as both purchaser and regulator of health services delivery. Each of these factors has shaped delivery system structures and performances, and interact with system structures and processes so as to change expected outcomes and performances (Fennell and Flood 1998). Although a full discussion of their impact is beyond the scope of this article, the reader is encouraged to consult recent work by Scott and co-authors for a comprehensive case study of change in one local health care system. Using an institutional theory perspective, these authors examine both the material resources (technologies, population characteristics, economic shifts, market characteristics) and the institutional structures and expectations surrounding health care (regulatory changes, norms about care delivery, cultural beliefs) in the San Francisco Bay Area from 1945 through 1995. They conclude that material resources and institutional environments have interacted to change the local health system over time, with different factors more or less dominant during the historical eras of professional dominance, federal involvement in health systems, and the current era of market-oriented delivery. Scott et al. (2000) remind us that it is difficult to draw boundaries around systems in the process of change, as one set of changes begets other changes, which then churn into new combinations of forces, counterforces, and evolving structures (see also Light's discussion of countervailing powers, 1993). Further, change at the local level is influenced by changes in national policy as well as changes in social and cultural norms.

2. *Varieties of Health Care Delivery Systems*

Within any given health system there can be a variety of delivery systems, identified by the type of health service being delivered. For example, care systems can be defined by where in the continuum of care the service is located, such as primary care, secondary, tertiary, rehabilitative, and/or custodial care. Two frequently made dichotomous distinctions, based on the general type of care, are acute vs. chronic

care and mental vs. physical health systems. Additionally, care systems have been described on the basis of *where* that care is provided, and by which actors. Categorization by location used to be a fairly reliable and straightforward method. For example, complex surgical care was once always provided in the hospital. Ambulatory care meant that care happened in clinics and doctors' offices. Long-term care always occurred in nursing homes. Hospice care at the end of life was most often provided in freestanding hospice centers or by a home care team working with the family (Watt 1996).

More recently, however, those clear boundaries of care location have faded out of focus, and the sectors of care often blend into each other. What used to be considered inpatient care is now routinely delivered on an outpatient basis (many surgical procedures, for instance, and their adjuvant treatments), and significant rehabilitative care following an acute hospital episode is delegated to either the skilled nursing facility, the rehabilitation facility, or home with nursing visits. Early innovations in hospice care as an alternative setting for end of life care, which moved the dying patient away from the technically-oriented hospital setting, first developed in the United Kingdom in the late 1960s, and then spread to the US in the 1970s (Boling and Lynn 1998, Keay and Schonwetter 1998). More recently in the US, hospice services are increasingly provided by special units embedded within hospitals or nursing homes. Efforts to evaluate the quality of hospice care within such a broad range of care settings are, of course, made more complex given the inevitable clash between the goals of acute care settings and end-of-life care (Mor 1987).

Similarly, the traditional definitions of acute, sub-acute, or postacute care services can no longer be made on the basis of care setting. Hospitals are increasingly providing more long-term care related services, and nursing homes have been providing care for more acute and subacute patients. It has even become more difficult to clearly differentiate the type of care services provided in particular care settings on even the most basic of distinctions: medical vs. mental health care. The prevalence of depression, for example, among older patients, whether located in primary care settings, inpatient settings, or long-term care settings has come under closer scrutiny. Some estimates suggest that up to 65 percent of elderly patients in nursing homes suffer from depression. Whether those institutionalized elderly actually receive appropriate mental health diagnoses or mental health care, however, is not at all certain.

Diversified health systems market their superiority over other health care providers, of course, on the basis of the 'seamless delivery system,' where all needed services are available in one location or from one large, multiunit provider (Shortell et al. 1996). Theoretically, the diversified system should be able to ensure better coordination of care and a much

smoother transfer of information from one division to another. But whether or not this type of delivery system structure actually results in net gains for care quality or continuity has yet to be demonstrated in any conclusive fashion. In fact, whether diversified delivery systems actually result in shared or compatible patient record systems, thus, assuring coordination of information about the patient within the system, still needs to be examined. Recent work on the difficulties of guaranteeing security and privacy of electronic patient records revealed that the systems presumed to coordinate electronic information across health care organizations are much further behind in development than expected. When health care organizations merge or are acquired by corporate systems, the details of developing shared information systems through which patient care can be coordinated across care settings are only attended to as an afterthought or far later in the merger process (National Research Council 1997).

3. *Characteristics of Contemporary Health Care Delivery Systems*

Traditional studies of the structure and process of health care organizations have provided a model for the study of health care delivery systems. The basic *structural characteristics* of size, ownership, profit orientation, range of service provision, and primary governance structure provide a template for plotting variation in delivery systems. Similarly, *process characteristics* describe systems in terms of what is done to and for the patient over the course of treatment. Key variables of process include system coordination mechanisms, information flows, decision-making processes, quality control, and communication flows between practitioners and patients. In the past two decades, health care delivery systems have been characterized by three major trends, the first of which was mentioned earlier: (a) an increase in the diversification of structural types and products; (b) change in traditional ownership and management configurations; and (c) the development of new inter-organizational patterns of care delivery and complex multitiered governance structures.

Changes in ownership and management patterns of delivery systems and their component organizations over the past two decades have drastically changed how we think about the delivery of health care services. There have been basically four major facets of ownership/management reconfiguration, affecting different health care organizations and systems in various ways: (a) an increased concentration of the acute care delivery system, through hospital closures and mergers; (b) a rise in the prevalence of corporate restructuring across both acute and long-term care sectors, and the spread of managed care philosophy and organizational structures; (c) a blurring of the once basic distinction between profit and not-for-

profit ownership (see *Health Care Organizations: For-profit and Nonprofit*); and (d) a drastic and pervasive change in the management 'climate' of most health care organizations, from an emphasis on nonprofit service and community responsibility to an emphasis on competitive business strategies. These trends have been discussed at length elsewhere (see Bibliography).

The development of new interorganizational patterns of care delivery and more complicated governance structures is best exemplified by the growth in multihospital systems, loosely structured provider networks or coalitions, and formally structured ownership arrangements linking hospitals, physician groups, health plans, and other care settings (best exemplified by the proliferation of managed care organizations, as discussed above). Both horizontally and vertically integrated forms have made substantial inroads in most health care markets, and they vary by size, composition, and level of integration. The governance structures that have developed along with these complicated multiunit structures are generally described as business-oriented, no matter what their profit status. Governing boards within integrated delivery systems often take a two-level form: the separate units (such as a hospital) may retain an internal board, with at least some members drawn from the community. But these local boards tend to focus only on community fund raising and local public relations. Significant strategic planning and investment decisions are usually under the control of the 'corporate' board of the system.

4. Assessing Health Care Delivery System Performance

Two criteria for evaluating the performance of health care delivery systems and the organizations within them have dominated the health services literature: the quality of care received by patients (including their satisfaction with services) and the cost efficiency with which health care services are delivered. Quality of care can be evaluated by examining actual care outcomes (changes in health or functioning) or by benchmarking, that is, comparing actual performance or structures to state-of-the-art standards. Evaluations of care delivery focused on processes or structures assume, of course, that an excellent structure in place enhances the likelihood of high-quality processes being performed and, consequently, the likelihood of better outcomes occurring. These assumptions therefore rest on correctly identifying state-of-the-art standards or validating that their use does in fact lead to improved outcomes.

Fueled by physician profiles and public report cards, the 1990s have brought about an increased sophistication in measuring outcomes. Most health services researchers are also careful to control for the myriad of patient-level differences that can affect appropriate

accountability for care delivered within a single organization within the delivery system, such as adjusting for patient health factors while assessing outcomes following surgical care. Very sophisticated measures attempt to include posthospital outcomes to assess hospital care. Nonetheless, most of these outcome measures have been designed to focus on health statuses typical of young and middle-aged patients, and rarely do they focus on the most commonly seen age group of health service users—the elderly. Outcome measures are also most likely to be built around acute medical problems, and rarely are they modeled on the health problems of the elderly or of the chronically ill, who typically have several concurrent, complex, interrelated chronic diseases with the potential for acute episodes. Nor are they able to measure accurately the outcomes for people with interrelated mental and physical health problems, people who are facing end-of-life scenarios, or people for whom the goals of care delivery need to emphasize pain relief, palliation, or functional maintenance (Lamers 1990).

4.1 Problems with Outcome Measure Validity

Indeed, the convergence of several recent trends in health care delivery structures and environments (discussed briefly above) are of particular concern when assessments of service delivery system performance are considered: the graying population of most developed countries, shifts in the prevalence of acute and chronic diseases, the proliferation of new inter-organizational patterns of care delivery, and the spread of managed care. A variety of methodological and design issues need to be addressed in order to properly model and evaluate health care delivery system performance under this confluence of conditions. As an example, consider the situation of terminally ill patients: what outcomes should be used to evaluate hospices, which are designed to provide psychological, social, and spiritual care for dying persons and their families? Evaluations in the past have typically focused on the costs of care and the range of services provided (Mor 1987). Quality of hospice care is usually defined in terms of its effect on the quality of life for the patient receiving hospice services and is often 'customized' to reflect differences in each state's goals for the hospice program. But what truly constitutes a 'positive outcome' for dying patients? Whose care needs to be assessed—should we also consider the care of the dying patient's family? How should 'quality of life' be modeled? What is the set of 'costs' that needs to be included in evaluating the cost-effectiveness of hospices themselves or hospices compared to other sites where people die?

In addition to these issues regarding the proper 'outcomes' to measure, terminally ill patients receive their care from a wide range of providers and in a variety of settings. Despite the typical complexity of

care for any given patient, evaluations of the performance of health care delivery systems almost always have focused on a particular portion of that care attributable to a single provider or organization. Common examples include the Resident Assessment Instrument (RAI) for nursing homes (Morris et al. 1990), accreditation standards for hospitals, and NCQA standards for managed care organizations (Zinn and Mor 1998). How well, in fact, have these measures identified the portion of care that can be attributed to a single provider, when the true process of health care delivery involves multiple actors?

What is needed most is a reliable and valid measure of continuity of care, which should take into account the extent to which care is coordinated across care settings, care providers, and transitions between providers and settings. Even outcome measures based upon an illness episode (rather than a specific and standard unit of time, or service consumption event) do not necessarily capture care outside of a particular setting, such as when a hospitalization is the unit of analysis for an episode.

4.2 Problems in Defining the Unit/Level of Analysis for System Performance

Although there are obviously many possibilities for defining levels of systems of care delivery, it is conventional to identify at least three: (a) a single health care organization; (b) a larger, socially defined unit that contains the health care organization, such as a community or a system of health care organizations; and (c) the subunits contained within the organization, such as individual departments or practitioners. Researchers examining organizational issues typically inspect only one facet of care delivery at a time, or one level of analysis. All complex systems, however, tend to be nested units, that is, systems within systems within systems. While most analyses of delivery system performance attempt to bypass these issues by focusing on one or more of the standard three levels, they can instead fail to identify fully the processes and outcomes they are intended to study. The critical point is not that all nested levels must always be studied, but that one should be as clear as possible in identifying the level of analysis selected and about ensuring that the choice of level is aligned with the characteristics of the type of care delivered, the subpopulation of patients, and the goals of the delivery system under examination.

It is also important to recognize that system performance at any given level may not be analyzable as a simple aggregation of performance at lower levels. This is one of the principal features of any system: its performance is determined as much (if not more) by the arrangement of its parts, the types of coordination and integration achieved across units, as by the performance of the individual components. Specifying

the appropriate levels within the model, however, is not a simple matter, since multiple contexts can influence patient outcomes simultaneously and those effects may be difficult to distinguish due to nesting or overlapping. For example, a physician's clinical practice behavior can be nested within his/her clinic's setting, which itself may be nested within a particular diversified health care system, and a particular region or market with characteristic practice patterns.

5. Conclusion

Continuity of care, or clinical integration, has been recommended by Shortell and other researchers as the model on which managed care should be based, so that providers are explicitly recognized as able to bridge care settings along with the patient, so that information is coordinated and shared explicitly across care setting transitions, and so that the care manager may change with these transitions, even if the same actors are involved. Managed care at its best would embrace such a model, and by creating effective mechanisms such as case managers, real integration and coordination would result, presumably leading to better delivery outcomes. Similarly, the multi-institutional, multiprovider, diversified health care delivery system should, on the face of it, make the sharing of information a matter of routine, through uniform patient records and centralized record systems across care settings and providers, thus improving care continuity and a variety of outcomes.

This is the basis of the 'seamless delivery system.' But whether or not such changes in care structures actually result in net gains for care quality or continuity has itself yet to be demonstrated in any conclusive fashion. Understanding the complexity of service delivery systems, and the other systems within which they are embedded, will not simplify this task. But it will lead to better measurement and modeling, and thus, perhaps, to a more realistic assessment of what is needed to achieve 'seamless' system functioning.

M. L. Fennell

Health Care: Legal Issues

After years of relative stability, the relationship between law and health care in the USA is changing rapidly. These changes are both a response to, and a reflection of the transition to, a market-based health care system. How the courts and legislatures respond to these changes will, in part, determine the success of managed care's cost containment initiatives. This article broadly examines the relationship between law and health care, with a particular focus on how the courts have responded to challenges to managed care's cost containment innovations.

1. Law and Health Care: Framing the Issues

It should not be surprising that two of the USA's most important institutions, the legal and health care systems, are intertwined and intersect at various points. Since the early 1800s, medical jurisprudence, where physicians are called as expert witnesses and where the courts act to regulate the quality of medical care, has been an integral part of the growth of the health care enterprise. As Mohr noted, '... medical jurisprudence ... figured prominently in early American medical history ...; neither subject can be fully understood in its modern context without taking the history of legal medicine into account' (Mohr 1993, p. 251). As this quote indicates, the involvement of the courts in health care delivery is not new. Yet the relationship between law and health care has never been more visible or manifest than it is today.

Despite the inevitable ebbs and flows of the relationship between law and medicine, it is arguable that the relationship was essentially stable from the mid-nineteenth century until the mid-1960s (Stryker 1932). As recently as the late 1960s and early 1970s, health care attorneys and health care executives had a relatively easy set of legal rules to live with. Both sides could predict the nature and scope of the litigation since the essential rules establishing the standard of care and the types of litigation initiated varied little during this period. A typical court case involved one patient suing one physician, guided by liability rules that reflected judicial deference to physicians in setting the standard of care. That relative stability was largely shattered by the advent of managed care. At both the state and Federal levels, all three branches of the legal

system, the legislatures, regulatory agencies, and courts, have persistently been involved in setting health care policy and monitoring health care delivery since the mid-1960s. The framing of the legal issues in the managed care era thus reflects the dramatic changes engulfing the health care system since the mid-1980s and the resulting policy conflicts that have emerged.

1.1 The Litigation Context

For many years, courts have actively monitored quality of care through determining the standard of care for medical liability (Jacobson 1989, Furrow 1997) and interpreting contractual definitions of medical necessity (Eddy 1996, Hall and Anderson 1992). Courts have also been called upon to interpret the vast array of state and federal legislation regulating health care delivery.

In responding to litigation challenging managed care cost containment practices, judges face a threshold question of what role courts should play in monitoring the managed care environment relative to legislatures. Courts face the tension of applying common law liability principles to new situations (perhaps by depicting public policy considerations) or deferring to elected representatives to set public policy. In the new health care environment, courts will be asked to distinguish the economic aspects of managed care that order relationships between health plans, physicians, and patients, from the incentives that contribute to below-standard care. The former are more traditionally legislative prerogatives while the latter are traditionally within the judicial purview. For those cases resolved in the courts, judges will need to decide whether they should be resolved by contract or tort (civil wrongs such as negligence) law. The difference is that recovery under contract is more difficult and damage awards are lower. What complicates matters is that in managed care, the insurance (i.e., contract) and medical care (i.e., potential negligence) are combined in one entity.

1.2 Liability

Common law liability doctrine has traditionally emerged incrementally to adapt to changing circumstances. Thus, it will take some time before the actual contours of liability can be assessed. Nevertheless, certain themes have emerged in the litigation so far.

Despite variation in the state cases decided to date, the direction appears to be that courts are applying traditional liability doctrine to the new organizational forms, including health maintenance organizations (HMOs), independent practice associations (IPAs), and preferred provider organizations (PPOs) (Furrow 1997). For staff or group model HMOs, the law had

already developed holding them liable for torts (civil wrongs) committed by their employees. The primary issue is whether courts will apply indirect liability doctrine (i.e., vicarious liability and agency principles) to the other MCO organizational forms for malpractice committed by an independent physician.

In determining vicarious liability, the courts look to the MCO's control over the physician or how the plan markets its physicians. The greater the indications of control and the more the plan markets the quality of its physician panel, the greater the likelihood that the MCO will be held vicariously liable. In the leading case of *Boyd v. Albert Einstein Medical Center*, 547 A.2d 1229 (Pa. Super. 1988), for example, the court held that an IPA could be found liable for an individual physician's medical malpractice because the patient reasonably believed that the IPA controlled the physician. The court rejected the plan's argument that it was not liable because the physician was an independent contractor, holding that the physician could still be the plan's agent with respect to the patient. A key element is whether the MCO has sufficient control, such as through utilization management arrangements, to override a physician's clinical decision.

1.3 Challenges to Cost Containment Practices

The changes in the health care environment have inevitably resulted in a new set of issues to be litigated, particularly the conflict between population-based cost containment and access for individual subscribers (sometimes to experimental procedures), the multiplicity of actors in a given case, and the evolving nature of the organizational structures. Just as the courts had to adapt medical liability principles to the emergence of hospitals as central to health care delivery in the 1960s, the same process is now underway with regard to the emerging organizational forms comprising managed care. There is inevitably a learning curve as courts become educated about the underlying changes and begin to adopt principles derived for a different model to the new arrangements (Jacobson and Pomfret 1999). For example, instead of the simple model of litigation involving one physician and one patient, managed care litigation may include the patient, the physician, the health plan, the utilization review firm, and the administrator of an ERISA-covered plan. Sorting out which party is legally responsible for delayed or denied care and the acceptable level of care resulting from cost containment strategies remains a work in progress.

Nonetheless, the cases decided so far suggest that courts are not systematically impeding the implementation of cost containment initiatives (Jacobson 1999). While it may be that many of the most challenging cost containment innovations have yet to be litigated, courts seem willing to uphold cost containment programs, except, perhaps, if such programs are seen as

limiting access to life-sustaining treatment. For example, courts have generally rejected challenges to financial incentives (though some courts have allowed such challenges to proceed to trial), utilization management programs, and many contractual challenges to benefit denials.

Few courts seem willing to usurp legislative choices in formulating health policy or to obstruct the market in organizing and delivering health care services, with several courts specifically deflecting allegations that managed care incentives violate public policy to the legislatures. One reason for this is that courts have interpreted the Employee Retirement Income Security Act (ERISA) narrowly to block state court challenges to cost containment programs that deny benefit coverage. Another reason why cost containment initiatives have not been overturned is that courts are looking to contract law to determine the extent of the parties' obligations and responsibilities, especially in physicians' litigation against MCOs. Though the trend toward contract is neither unlimited nor uniform, it represents a potentially profound shift from the early 1970s, where courts were perceived as protectors of individuals, to courts as deferring to market-based changes.

1.4 Physician Autonomy

The initial litigation trends suggest that courts will not subordinate cost containment programs to physician autonomy. Courts are ruling that people who are dissatisfied with managed care, including physicians, should take their case to the legislatures. This represents a dramatic departure from the era when courts deferred to physician dominance.

It would be understandable if physicians expected that courts would protect the physician-patient relationship from interference by managed care plans. After all, the essence of the health care system lies with the physician-patient relationship, and courts have protected physician dominance in the past (Kapp 1985, Hall 1988). But courts have not done so in the managed care era. To the extent that physicians have been able to secure some gains through the courts, it has largely been through fair process protections and retaining the often-maligned legal standard of care.

The question is why courts are not deferring to physicians; what has changed over the past decade or so to cause the courts' shift from protecting physician dominance to reinforcing managed care's dominance? At this point, the answer is somewhat speculative because of the limited number of cases. One potential answer is that courts respond to changes in the underlying environment. As the nature of health care delivery has changed, it stands to reason that courts would begin to look at and incorporate those changes. Slowly but surely, courts are internalizing cost con-

tainment goals in developing legal doctrine, rather than ensuring the primacy of the physician-patient relationship. Since the dominant force in health care is institutional, it is not surprising that the legal dominance physicians maintained is now waning.

2. Future Directions and Challenges

During the next few years, the legal system faces four key challenges regarding health care: (a) how to allocate liability given the multiplicity of decision makers involved in managed care; (b) how to balance between the health care needs of individual patients and the cost containment goals of the health care system; (c) how to deal with the consequences of ERISA pre-emption, which now prevents state courts from resolving challenges to how cost containment goals are implemented; and (d) how can conflicting social policy goals (i.e., the cost/quality/access trade-offs) be reconciled.

2.1 Allocation of Liability and ERISA Pre-emption

The allocation of liability and ERISA pre-emption issues are both about imposing accountability on a system that has managed to shift legal accountability to physicians while maintaining the fiction of non-control. Either voluntarily or through legislation, MCOs should be held accountable for their actions.

2.2 Balancing

There is no easy solution to balancing the individual patient's access to health care with conserving the plan's assets for the entire patient population. One approach might be to articulate a set of fiduciary obligations that a plan must adhere to in balancing the two. The burden would be on the plan to justify denial of care to the individual patient by a preponderance of the scientific evidence and to demonstrate that the individual's medical care is not being subordinated to the patient population (Jacobson and Cahill 2000).

2.3 Social Policy Conflicts

The plethora of legislation has placed health care executives in somewhat of a bind. Some regulations, such as fraud and abuse, are specifically designed to reduce health care costs. Others, such as EMTALA, are designed to improve access regardless of cost. Taken alone, each individual law is defensible. Taken together, however, the social policy goals of cost containment, improving access to health care, and improving quality of care conflict across statutes and

regulations. Complying with all of the laws may be impossible, and may reflect incoherent social policy.

3. Implications for Other Countries

While other countries may not, for domestic social policy reasons, want to follow the managed care model, it seems likely that most countries will face the need to impose cost constraints on their national health care systems. These choices are already evident in the British and Canadian systems. What this brief survey of US health law trends suggests is that reconciling cost containment with various institutional objectives and interests will take careful planning to ensure that the changes are implemented fairly and equitably.

Health Care Markets: Theory and Practice

This article describes the origins, development, and proliferation of health care markets. It then reviews their performance, summarizes recent theory and research on their limitations, and concludes by suggesting new ways to conceptualize and research economic behavior in health care.

1. Origins

'Health care markets' is a relatively new term, framed by economical, structural, and social forces. It hardly existed 25 years ago but rose to prominence in response to the years of recession and high inflation ('stagflation') in the 1970s. The costs of social and welfare programs, such as health care, kept rising as revenues stagnated, prompting a 'crisis in the welfare state' (Esping-Andersen 1994). In addition, there were increasing complaints about government-run programs and about hospital-based specialists running up large bills without regard to the needs of payers or the population (Bengoa and Hunter 1991). In response, health economists recommended that payers (governments, employers, and insurers) apply the well-established principles and techniques of price competition theory to health care in order to constrain costs, increase efficiency, and make providers more responsive to the priorities of payers. This constituted a historical shift from professional dominance to buyer dominance among the countervailing powers of providers, purchasers, patients, and the state, over the control of power, costs, information, and the distribution of risks (Light 1995a).

1.1 Problems of Market Failure

Applying price competition theory to health care was unprecedented, for medicine had long been regarded by leading economists as lacking the basic qualities for markets (Arrow 1963, Fox 1979). The idea of health care as a commodity to be traded in a market was anathema to them. Clinical medicine is rife with uncertainties and too often contingent on diagnosis and response. Thus 'products' often cannot be defined, and property rights may be unclear. Physicians vary substantially in how they treat the same problem. Good market information is poor and highly asymmetrical. The absence of these requirements for beneficial competition can mean that competition is harmful to patients and society.

1.2 Managed Competition as a Possible Solution

These serious misfits between the attributes of clinical medicine and the requirements for competition led

Enthoven 1988) to develop the theory of managed competition. To overcome these forms of market failure, Enthoven emphasized competition between comprehensive health care plans and stipulated several requirements for a fair and beneficial market, such as universal health insurance or access, coverage of a common set of benefits, risk-adjusted contracts and good comparative information on quality, efficiency, and costs. He also held that health care markets had to be actively managed, because providers had proved so clever in manipulating or circumventing rules. This he called 'managed care' rather than 'regulated competition.'

Managed competition won critical acclaim and spawned international efforts to proselytize it as the 'only practical solution' to soaring costs, though the model had serious flaws. It assumed that some people (managers) can be trusted and others (physicians) cannot; it did not solve the problems of uncertainty or contingency but rather tucked them inside the health plans; and it led to oligopolies, which minimize price competition (Light 1995b). New businesses and a new industry developed to create health care markets and varieties of managed competition by monitoring services and bills, changing clinical behavior, and organizing providers into 'preferred provider organizations' and 'network HMOs.'

1.3 Proliferation and Variations

A signal event occurred when Prime Minister Margaret Thatcher decided in 1989 to transform the world's largest health care organization, the National Health Service, from an administered service to a market model of competitive contracts between purchasers and providers. Other governments, notably New Zealand and the Netherlands, followed suit. By the mid-1990s, however, most had pulled back from implementing markets in health care, as they came to realize that price competition could cause service dislocations, cost shifting, increased inequality, reduced choice, reduced care, and increased costs over government-run programs (Light 1997, *Social Science & Medicine*, special issue 2001). Some countries such as the United States did little to prevent adverse selection, service dilution, and cost shifting. In the meantime, important European variations on American models developed such as 'planned markets' and 'quasi-markets' (LeGrand and Bartlett 1993, Saltman and von Otter 1992). Behind them was the realization that markets themselves are never 'free' but rather structured and regulated to reflect a society's values and judgments about the limits of competition.

2. Performance Assessment

It has proven difficult to assess the performance of health care markets and different competitive schemes

because changes are introduced wholesale with no controls, or markets are introduced simultaneously with changes in coverage. American employers, for example, have simultaneously shifted costs to employees, increased forms of risk-rating and exclusions in policies, used policy churning and within-group underwriting, reduced the amount of service or reimbursement in areas like mental health, and limited access to specialty services and then credited the savings to 'competition.' Most stakeholders do not seem interested in well-functioning markets like the one developed by Enthoven. They want to save or make money, as the case may be. Reflecting a policy bandwagon more driven by conviction than scientific evaluation, the most systematic external analysis of research on US health care markets found that among hundreds of research articles, only a small percent systematically compared HMO performance to some alternate delivery model (Robinson and Steiner 1998). Evaluation of the market reforms in New Zealand also found the measures seriously flawed, efficiency no greater, health gain no greater, and fewer services leading to greater unmet need (Ashton 1999).

Operationally, the best tracking system in the United States reported that 'few private employers offer employees a choice of plans, give employees financial incentives to choose economical plans, or provide information so that employees can evaluate the quality of the care they receive—three hallmarks of managed competition' (Long and Marquis 1998, p. 1). The well-designed studies showed that managed care organizations reduced the high utilization rates and prices found in the United States, but there were no controls for better health status of enrollees which could explain lower utilization. Reinhardt (1996) summarized the American scene as employers hiring corporate health plans as 'bounty hunters' to reduce costs—no questions asked. Buyers have paid little attention to effects on quality. Zelman and Berenson (1998), two of the architects of managed care markets, concluded that the corporations took early large profits by selecting healthier and wealthier markets and patients, while compromising on quality. Now that most of the excess has been squeezed out of prices and utilization, it is unclear how corporate health plans will reward investors. Stung by widespread criticism and political backlash, competing plans have eased up on managing utilization to such a degree that they resemble the open choice of fee-for-service that originally prompted the development of health care markets and managed care organizations (Freudenheim 2000).

In other countries, Hsiao (1994) evaluated the impact of introducing health care markets in several Latin American and Asian systems and reported higher costs, reduced access, increased inequality, and profiteering. Evans' (1997, p. 427) international assessment concluded that '...greater reliance on the market is associated with inferior system perform-

ance—inequality, inefficiency, high cost, and public dissatisfaction...’ Stocker et al. (1999) reported that market-based reforms in Latin America are driven largely by American health insurance or other corporations who have taken the early profits out of American markets and now seek high profits in new countries by buying government support. Meantime, backlash to health care markets in the UK and New Zealand led to ousting the ruling party that installed health care markets, and substantially dismantling the health care markets in order to foster cross-sector partnerships and develop community-based programs that integrate public health with clinical services. Competitive markets are regarded as inherently anathema to community and public health.

A central challenge posed by health care markets is that they are costly to start up and operate. Good market information, contracting, monitoring, and managing together cost about 10 percent of revenues, so that comparable savings on clinical services must be achieved just to stay even. Another problem, related to what Hsiao found in several other systems, is that proper markets are often not set up with the necessary information and safeguards against inefficient but profitable strategies.

2.1 Contributions

In response to criticisms, market-oriented research has made a number of contributions. Health care markets evolved earliest and most extensively in the United States, as employers self-insured and began to ask new questions such as, ‘Which services are most cost-effective? Which providers have the lowest costs and prices?’ To answer such questions, new statistical techniques, methods, and theory were developed to measure effectiveness and efficiency, identify low-cost providers, estimate risk adjustments, and compensate for imperfect information (Folland et al. 1997). Accountability, performance, consumer satisfaction, and quality have become much more visible and have led to serious efforts to measure them. Health care market thinking has spawned a new and wide range of strategies for delivering more cost-effective care, even if those strategies do not themselves entail much market-like behavior. The major reports from WHO-Europe and the London School of Economics, for example, describe new developments in priority setting, contracting, capital formation, performance-related pay, decentralized management structures, and consumer involvement that would not have occurred without the radical challenge posed by market-like thinking (Saltman et al. 1998, Mossialos and LeGrand 1999).

2.2 Limitations of Health Care Markets

Restructuring clinical services into markets of corporations bent on growth and profit is likely to drive up

costs in the long run, abetted by the important natural advantages of sellers (providers). They diagnose, prescribe, and treat. They control the clinical record that determines charges. They also have the patient’s loyalty, if not dependency. A second structural problem in many health care markets is that each insurer or plan contracts with most of the providers in a given market in order to offer subscribers the widest choice possible. But that means no real competition is possible, because each provider in effect ‘competes’ against himself. This practice can lead to the third limitation, that there are so many plans and policies that no one can identify or evaluate real differences. In a sample of 2,277 patients, Grembowski et al. (2000) found there were 189 different provider organizations and 755 different policies. Behind so many policies and plans are high costs for designing, marketing, and managing them, and such numbers far exceed what one finds in real competitive markets.

At a micro-, empirical level, Rice (1998) has summarized studies documenting several practical problems. First, the preferences of patients and employers are not fixed but are affected by prior experience, current interactions, and advertising. This poses ‘a very big problem’ for researcher and competitors as well as for economic theory, as do problems posed by uncertainty and contingency. Second, consumers’ choices do not necessarily reveal their preferences and may be poor judges of them. Third, Rice observes, consumers have poor market information, and fourth, when they are given it, studies find they sometimes ignore the most relevant data. Finally, a majority of users are also unable to understand basic labels, instructions, and policies (Parker et al. 1999). What, then, actually takes places in health care markets, especially when ‘consumers’ do not consume or buy, even though standard texts characterize them that way (Follard et al. 1997, p. 21)?

3. Casting a Wider Research Net

Studies reviewed by Rice indicate there are variables not now being captured in economic models and research. These have been the focus of the burgeoning field of economic sociology, which attends to the influence of affiliations, networks, institutions, and culture, as well as to the role of power, hierarchy, and the past in shaping ‘path-dependent’ behavior (Smelser and Swedberg 1994). In a classic article, Granovetter (1985, p. 481) showed how economic behavior and institutions ‘are so constrained by ongoing social relations that to construe them as independent is a grievous misunderstanding.’ What passes for ‘rational decision-making’ differs substantially from one nation to another (Dobbin 1994) and even from one corporation to another.

Economic behavior begins with cognitive and cultural categories that get combined into scripts which actors routinely use in deciding what they value, buy, or sell (DiMaggio 1997). These scripts allow actors whose capacity for rationality is bounded by their ability to filter, sort, and apply what they know through 'selective attention' (Lindenberg 1998). The sociology of microeconomics, or actual market behavior closely observed, looks more like a negotiated construction of a reality that the parties can live with, even if front-stage behavior conforms to the scripts and symbols of market competition (Hughes et al. 1997). Institutionalized routines, once established, define paths which others follow, making future actions 'path dependent.' Most industries (and certainly health care) are 'oligopolies guarding carefully differentiated niches through strategies that aim to preserve rents by avoiding ruinous competition' (DiMaggio 1998, p. 700).

Key dimensions for analyzing economic interactions in health care are: (a) the relative frequency of transactions; (b) their relative complexity; (c) their relative specificity; (d) their relative size and risk; (e) their relative quality of information; and (f) the degree of social relationship over time. Each of these continua must be assessed in terms of each major party affected. Sociological dimensions of the relationships between parties in an economic transaction include: (g) the degree of autonomy vs. mutual obligations between the; (h) the degree of tightness or looseness in the network or organization; (i) the size of the organizations or networks; and (j) the structure of power relationships. This approach is likely to deepen our understanding of health care markets in the future.

At a second level, the concept of 'health care markets' and its recent rise to dominance in certain countries, but not others, needs explaining. In a historical study of the 'conceptions of control' that prevail in a given industry from one period to another, Fligstein (1990) has described how a crisis in an industry prompts its leaders to construct or select a model of their business and its realities that will provide them with a coherent account of what went wrong and how to succeed in the future. The theories of price competition and managed competition in the late 1970s and 1980s seemed to have been embraced by payers for these reasons. Fligstein notes that the prevailing conception is interpreted as suits individual leaders, an observation that conforms to the selective and partial ways in which corporations and governments implement theories for how to have cost-effective models of health care markets. As a result, health care markets has become an international business and policy movement, spurred by international consulting firms, even as some countries have spurned them. The World Bank, the International Monetary Fund, and other major lenders began to require, or strongly urge, scores of developing countries to restructure their services into health care

markets as a condition for receiving financial help with their economies (World Bank 1993, Stocker et al. 1999).

Selective and partial implementation probably explains why managed care and managed competition have not resulted in greater efficiency or better services in some countries and why they have held cost increases at bay in the United States for only a few years. As the crisis of sharply increasing costs during the 1980s resumed in 2000, employers were concluding that health care markets as a 'conception of control' could not hold down costs and were losing faith in it (Freudenheim 2000). Like leaders in some other countries, they may start to search for a new conception of control, one that will explain why the health care markets of the previous 20 years were only partially successful and how to manage costs more effectively.

D. W. Light

Health Care Organizations: For-profit and Nonprofit

This article must begin with an explanation of the meaning and boundaries of its subject. First, its focus is on organizations, not on the motivation of individuals. Second, it pertains to two ownership categories that by convention, partly rooted in the US experience, stand in distinction to public or governmental ownership. That is, this article pertains to non-governmental organizations, which may be established as for-profits or as nonprofits.

Third, it pertains to a legal characteristic of organizations that is defined under the law of the jurisdiction in which they exist. In the USA, health care organizations are typically incorporated under state laws. Variations among these state laws are not important for our purposes, but the fact that fundamental aspects of the ownership and control of health care organizations (as well as the roles they play in the health care system) are defined by the laws and traditions that are specific to particular countries is. A recent effort to measure and compare the size of the nonprofit sectors in different countries had to define 'nonprofits' in terms of certain organizational characteristics (not profit-distributing, self-governing, voluntary) rather than legal form, because nations do not make the same legal distinctions between private and governmental or between for-profit and nonprofit (Salamon et al. 1999). To cite an example from health care, ownership by identifiable individuals is incompatible with the nonprofit form under US law, while Japan, where most hospitals are owned by physicians, is often said to prohibit for-profit ownership of hospitals because of a prohibition of ownership by corporations that pay dividends (Rodwin and Okamoto 2000).

Fourth, this article pertains primarily to types of health care organizations in which a mix of for-profit and nonprofit ownership is found. Thus, attention will not be directed to organizations that manufacture pharmaceuticals or hospital supplies (which are typically all for-profit corporations), to physicians' practices (which are seldom incorporated as nonprofit organizations), or to charitable fundraising organizations (such as the American Cancer Society or the Royal Commonwealth Society for the Blind), which are all nonprofit. Our focus is on the types of organizations among which both for-profits and nonprofits can be found, as is the case with hospitals, nursing homes, health maintenance organizations, and home care agencies in the USA.

Most literature on for-profit and nonprofit health care comes from the USA, which has an unusually pluralistic health care system on both the provider and purchaser sides (Starr 1982). Although the health care systems of other countries are much more typified by governmental or quasigovernmental ownership, the private ownership of important components, such as

hospitals, is not peculiar to the USA. In some countries there are doctor-owned clinics, small hospitals, or nursing facilities that are outgrowths or extensions of private physicians' offices. Some countries that have universal health insurance systems nonetheless have private hospitals. These countries may either prohibit for-profit ownership, as does Canada, or they may exclude private hospitals (including for-profits) from participation in the national health insurance system, while permitting for-profit hospitals to serve people who have the desire and wealth to opt out of that system. Several investor-owned hospital companies from the USA also own hospitals in other countries, serving such niches. And at least one German hospital company owns some US hospitals. In recent years, American companies have begun to export versions of managed care to other countries, notably in Latin America (Stocker et al. 1999).

In the main, however, in Western countries other than the USA for-profit organizations that provide health services are extensions of doctors' practices or constitute a sector that serves a small market outside of the governmental health system (and is often not included in statistical information about that system). This, plus the nation-specific nature of the laws that define the legal form of health care organizations, probably explains the paucity of research comparing for-profit/nonprofit organizations in countries other than the USA or making cross-national comparisons of ownership forms. Policy debates about privatization have stimulated research on public versus private provision of services in a number of countries, but these are outside the scope of this article.

1. The Nonprofit/For-profit Distinction

In this article, the terms 'for-profit' and 'nonprofit' (or its less economical synonym, 'not-for-profit') are used as they are commonly defined under state statutes and federal tax law in the USA. The term 'nonprofit' invites confusion, since nonprofit organizations are not forbidden from generating surpluses of revenues over expenses. Indeed, such surpluses, which are called profits in the for-profit world, are essential to economic health and survival of nonprofit organizations. It is important, therefore, to be clear about the shared characteristics of for-profit and nonprofit organizations and the ways that they differ.

Table 1 shows that there are important similarities and differences between for-profit and nonprofit health care organizations in the USA (Gray 1992). Two key families of legally defined characteristics are particularly important in distinguishing these organizations. The first pertains to ownership, governance, and purpose. For-profit organizations have owners (proprietors, partners, or the shareholders of corporations), who share in the profits and increases (or decreases) in the value of the enterprise and who, in the corporate form, elect the board of directors. Those who operate the for-profit organization are thus either owners or are managers who are directly accountable to owners. Thus, those who control the organization have a direct stake in the financial performance of the organization.

By contrast, nonprofit organizations do not have owners (except insofar as they are subsidiaries of other nonprofit organizations) and are legally prohibited

Table 1

Basic legal and economic differences between for-profit and nonprofit hospitals

For-profit	Nonprofit
Corporations owned by investors	Corporations without owners or owned by 'members'
<i>Purpose:</i> Management has legal obligation to promote wealth of shareholders within the boundaries of law; does so by providing services	<i>Purpose:</i> Has legal obligation to fulfill a stated mission (provide services, education, research, etc.); must maintain economic viability to do so
Can distribute some proportion of profits (net revenues less expenses) to owners as dividends; owners also share in increases in the value of the enterprise	Cannot distribute surplus (net revenues less expenses) to those who control the organization; there are no owners entitled to proceeds if organization is sold
Management ultimately accountable to owners (stockholders) through boards of directors elected by stockholders	Management accountable to voluntary, often self-perpetuating boards of trustees
Sources of capital include:	Sources of capital include:
Equity capital from investors	Charitable contributions
Debt	Debt (generally tax-exempt)
Retained earnings (plus depreciation and deferred taxes)	Retained earnings (plus depreciation)
Revenues derived from sale of services	Government grants
	Revenues derived from sale of services and from charitable contributions
Pay property, sales, and income taxes	Generally exempt from most taxes

from distributing surplus revenues to those who control the organization—a characteristic that Hansmann (1980) called the nondistribution constraint. Nonprofit organizations are governed by boards of trustees whose members are typically chosen by the existing board and who are responsible for assuring that the organization operates soundly and adheres to the mission (charitable, educational, religious, etc.) for which it was chartered. Importantly, the boards to which management is accountable have no direct stake in the profitability of the institution.

The second family of differences pertains to the tax treatment of for-profit and nonprofit organizations (Simon 1987). Nonprofit organizations that meet qualifying standards have a variety of tax-related benefits under federal, state, and local laws. The tax treatment of nonprofits varies according to the kind of organization it is (for example, there are differences in how churches, grantmaking foundations, charitable organizations, and professional associations are treated) and according to governmental jurisdiction (criteria for exemption from local property taxes may differ from criteria for exemption from federal corporate income tax). However, most nonprofit health care organizations are exempt as charities from federal corporate income tax under Section 501(c)(3) of the Internal Revenue Service Code. Charity in this case is defined in terms of benefiting the community at large, not in terms of providing free care (Fox and Schaffer 1991). (Some health maintenance organizations and insurers are exempt under Section 501(c)(4) as social welfare organizations and receive less-favorable tax treatment than do the charitable organizations.) Other tax benefits also apply to organizations that are exempt in the eyes of the Internal Revenue Service. Charitable nonprofits are generally able to receive contributions that are tax deductible to the donor, to borrow at favorable rates under bond issues whose interest is not taxable to the lender, and to be exempt from local and state property taxes and certain excise taxes.

However, in health care there are important financial similarities between for-profits and nonprofits. First, the revenues of both for-profit and nonprofit health care organizations come overwhelmingly from the sale of services. For most nonprofit health care organizations, charitable contributions represent no more than one percent of revenues. To survive, these nonprofit organizations must compete successfully for business in a very crowded and heavily regulated marketplace. Though not businesses, they must operate in a very businesslike fashion.

Second, although nonprofit hospitals and HMOs have benefited in earlier periods from governmental grant and lending programs, today's nonprofits and for-profits depend upon similar sources of capital—primarily retained earnings and debt (Institute of Medicine 1986). Thus, just as with for-profit organizations, the primary capital sources on which nonprofit health care organizations depend are a function of the

organization's economic performance. The fact that the typical nonprofit health care organization is tax exempt as a charitable organization under the Internal Revenue Service code suggests that they are subject to complex and somewhat conflicting social expectations.

Notwithstanding the importance of their common reliance on retained earnings and debt, for-profit and nonprofit organizations each have access to unique sources of capital. Unlike nonprofits, for-profits have the paid-in equity capital of individual and organizational investors or stockholders. Access to equity capital provides a substantial advantage during periods of growth, particularly for publicly traded firms whose stock price in relationship to earnings may be very high. The unique form of capital to which nonprofits have access is charitable contributions, as well as debt financing from instruments whose interest payments are not taxable for the lender.

These differences in sources of capital are enormously important regarding the expectations placed on these organizations—with stockholders seeking value, economic returns, and capital growth, and contributors seeking charitable behavior. The two families of differences have driven theoretical and empirical work in the social sciences (Powell 1987, Powell and Clemens 1998) and stimulated an array of public policy debates.

2. The Role and Performance of Nonprofit Organizations

The question of why some segments of our capitalist economy are predominantly for-profit while others are predominantly nonprofit has intrigued social theorists and economists, who generally start with the premise that the incentives internal to the for-profit structure create a drive toward efficiency. So, what is the role of nonprofits? Several answers have been offered. Weisbrod (1990) suggests that nonprofits occupy a niche created by, on the one hand, the failure of for-profit organizations to provide services that benefit the community at large, not just the purchasers, and, on the other hand, the failure of governmental programs to meet the demand for other than average services. Hansmann (1980) posits that the nonprofit form provides a comparatively efficient alternative in situations of contract failure in which purchasers are not well situated to monitor the performance of sellers of services. The nondistribution constraint makes nonprofits less likely than for-profits to exploit the purchaser's vulnerability. For services to be financed by donations, the nonprofit form gives potential donors some confidence that their funds will be used for the promised purpose (e.g., for charitable services). For services that are difficult for purchasers to monitor (and medical care is an example), the nonprofit form may provide some assurance that vulnerabilities of patients and payers will not be exploited.

Such theories suggest three directions in assessing the performance of nonprofit organizations—their costliness (in the absence of accountability to owners, are they less efficient?), their charitability (very important for tax-exempt organizations in a health care system with more than 40 million uninsured patients), and their effectiveness or trustworthiness as providers of services/care. The empirical literature that has attempted to assess these topics in different types of health care organization is large, growing, and impossible to summarize adequately in a brief article. Citations to most studies can be found, however, in the Institute of Medicine (1986) report on for-profit and a 1999 literature review that is available on-line (Gray et al. 1999) and that summarizes some 75 studies.

First, in health care, for-profit organizations are not necessarily less costly to purchasers than are nonprofits. Most studies of hospitals have found that costs to purchasers are higher in for-profits (Gray et al. 1999). This appears to be a response to 'reimbursement maximization' strategies based on exploiting the weaknesses of third-party payment systems, not to some inherent inefficiency disadvantage of for-profits vis-à-vis nonprofits. For example, several studies have shown that expenses incurred in the production of hospital services are similar in for-profit and nonprofit hospitals, but that markups of price over expenses are higher in for-profits.

Second, taken as a group, nonprofits are more likely to engage in charitable activities and public goods than are for-profits (Gray 1992, Claxton et al. 1997, Gray et al. 1999). For example, nonprofits care for more uninsured patients (Frank et al. 1990), provide more uncompensated care (Lewin et al. 1988), provide more services focused on vulnerable populations (LeBlanc and Hurley 1995, Shortell et al. 1987), and engage in education and research (Institute of Medicine 1986), and they are less likely to discourage admission of uninsured patients (Schlesinger et al. 1987) and less likely to avoid location in areas with large numbers of the uninsured (Norton and Staiger 1994). However, the charitable performance of nonprofits is quite variable, with charitable activities and public goods heavily concentrated in urban teaching hospitals. The performance of nonprofit hospitals as charitable organizations has come under criticism in recent decades, and in the 1990s eight US states established requirements for nonprofit hospitals to report on their community benefit activities. There is evidence that the charitable performance of nonprofits is enhanced by articulated community expectations and active public oversight (Schlesinger 1998).

Third, although the Institute of Medicine (1986) study found no clear pattern of ownership-related quality differences among hospitals, several more recent studies have found a quality advantage for nonprofits regarding hospital mortality (Hartz 1989, Kuhn et al. 1994, Sloan et al. 2000) and post-hospital recovery (Sloan et al. 2000). Quality advantages have

been reported among nonprofit nursing homes (Hawes and Phillips 1986) and HMOs (Himmelstein et al. 1999), two fields characterized by serious contract-failure problems. In nursing homes, many residents are unable to look after their own best interests and have no one else to do so and so must rely on their notoriously difficult-to-monitor relationship with the facility to protect their interests. In HMOs, the complexity of the incentive relationship between health plans and physicians may make it difficult for patients to be certain that contracted-for services are actually being provided.

At a more general level, the research findings to date suggest that for-profits are indeed more responsive to economic incentives than are nonprofits, which can be a problem in a field with significant information asymmetries between sellers and purchasers of service (Arrow 1963). In view of the similarities of for-profits and nonprofits in revenue capital and revenue sources and the regulatory regimes under which they must operate, the overall pattern of performance differences that are often small but generally in the predicted direction is notable. It is clear that the comparative performance of nonprofits and for-profits is not a simple function of ownership form, but of an interaction of ownership form with market forces, payment systems, and regulatory environments.

3. Ownership Trends in Health Care

The concentration of different forms of ownership varies in the USA across fields (nursing homes are predominantly for-profit; hospitals are mostly nonprofit) and over time (Marmor et al. 1987, Gray 1999). Among acute care community hospitals, surveys conducted early in the twentieth century reported that about half of all hospitals were for-profit (Stevens 1989, Starr 1982). The for-profit share of hospitals declined through the century, falling to 15 percent in 1965, with nonprofits comprising 60 percent and the remainder governmental—a level that has remained roughly the same, with a slight increase in for-profit and a slight decrease in governmental. However, the character of the for-profits has changed since the mid-1960s, with ownership by large, powerful, publicly traded investor-owned firms replacing ownership by local entrepreneurs (often doctors) as the predominant for-profit form, and with the average for-profit facility being larger as measured by the number of beds.

There are, however, a number of signs that the US health care system is moving toward an increased for-profit character. Even among hospitals, where the nonprofit share has been stable at 60 percent for 30 years, a shift toward for-profit has occurred beneath the surface. First, if beds rather than hospitals is used as the measure, the for-profit share of acute-care hospitals doubled between the mid-1960s and the mid-1990s (from 6 percent to 12 percent, largely at the

expense of public hospitals). Second, even with hospitals as the unit of analysis, if one includes nonprofit and public hospitals that are managed by for-profit firms, as well as non-acute care hospitals (e.g., psychiatric and rehabilitation facilities), the for-profit sector among hospitals grew to about 25 percent of the total by the late 1990s.

Great increases in for-profit ownership have occurred elsewhere in the US health care system since the 1980s, as is shown in Table 2. Health maintenance organizations (HMOs), which were almost exclusively nonprofit in 1980, are now predominantly for-profit (Gray 1999). Strong trends in the for-profit direction also occurred among home health agencies and dialysis treatment centers. Within the trend toward for-profit ownership has been a second trend—ownership not by individual proprietors but by investor-owned corporations that own multiple units (Institute of Medicine 1986, Corrigan et al. 1997). Similar trends toward multi-institutional arrangements have also occurred among nonprofits. This, along with increased entrepreneurial activity by nonprofits (Sloan 1998) has led to concerns among many observers that the

character of many nonprofit health care organizations has changed in ways that mirror the for-profits.

Comparing the cases of community hospitals and HMOs, some of the factors that are involved in the persistence and change in ownership patterns among health care organizations can be seen (Gray 1999). On the side of persistence, many nonprofit hospitals, with their multiple important community roles (care giver, employer) and their governing boards often made up of prominent citizens, have received both charitable and governmental support in bad economic times. The difficulty of closing a nonprofit hospital has been frequently noted in health policy circles as hospital occupancy has declined since the 1980s. Nonprofits have also engaged in a variety of strategies to compete and grow—entering into multihospital systems, merging, joint-venturing, and establishing for-profit subsidiaries. Use of these strategies has carried a price, however. The increased commercialism of the nonprofits has attracted criticism and fanned doubts about their deservedness of tax exemption.

The most important factor affecting the ownership composition of the health care field is public policy. It

could hardly be otherwise since the basic corporate structures of for-profit and nonprofit organizations are themselves products of public policy. But the role that public policy plays in influencing the composition and performance of health care organizations has become increasingly apparent since the 1950s. The creation and growth of the investor-owned hospital industry was a direct result of capital reimbursement policies built into the Medicare legislation in 1965 (Gray 1992). The interest costs incurred in borrowing money to purchase hospitals was a reimbursable expense under Medicare, and gave purchasers annual payments for the noncash expense called depreciation. Since Medicare payments to hospitals were based on reimbursing them for costs incurred, the legislation also provided for giving for-profit hospitals generous 'return-on-equity' payments so that investors would receive a return on their investments. All of these provisions stimulated the growth of the investor-owned companies into the early 1980s, when, in separate actions, Congress reduced return-on-equity payments and changed the depreciation rules so that Medicare would pay for the depreciation of any particular asset only once. After these changes were made, the leading investor-owned companies all stopped growing at a time in which it was being predicted that they were going to take over the system.

Similarly, the growth of the nonprofit HMO industry in the 1970s and the for-profit transformation of the field in the 1980s were direct results of public policy. First, provisions of the HMO Act of 1973 made capital available to nonprofit HMOs. But the field was transformed in the for-profit direction in the 1980s as a result of the Reagan administration's decision to phase out the HMO Act's support of nonprofit HMOs and to undertake a program to stimulate investment in for-profit HMO companies, which had not previously existed; a surge in demand for managed care from the corporate sector which was experiencing large increases in health care costs; and inattentive state regulators who allowed many nonprofit HMOs to be acquired for a pittance by their leadership and converted into for-profit organizations (Gray 1999).

Permissive state regulation also created the environment for a surge in the acquisition of nonprofit hospitals by large investor-owned firms (Columbia/HCA, Tenet) in the early and mid-1990s (Gray 1997). This, along with conversions involving HMOs and state Blue Cross insurance companies, led more than 25 states to pass legislation in the late 1990s to regulate nonprofit conversions. Some 120 new foundations were created in the 1980s and 1990s from the proceeds of the sale of nonprofit health care organizations (Isaacs et al. 1997). Studies of the consequences of hospital conversions have generally shown them to have occurred among financially troubled institutions and that few negative consequences could be documented, either because the institutions had previously engaged in only low levels of charitable activity or

because strong contractual protections had been built into the sales agreement (Mark 1999, Young and Desai 1999). Interestingly, there have also been examples of for-profit hospitals that reverted to the control of nonprofit organizations, though the trend remains in the direction of greater for profits.

4. Conclusion

The American health care experience has shown that for-profits and nonprofits can coexist in the same field. It has also shown that the comparative performance of the two forms of organizations are influenced by contextual factors such as the incentive structures built into the systems by which they are paid, regulatory regimes, professional values, and public expectations. Although for-profits generally appear to be more responsive to economic incentives than are nonprofits, nonprofits cannot be indifferent to economic realities. It is increasingly apparent that policy-makers need to pay attention to the characteristics of the organizations that provide health services as they design programs, payment systems, and regulatory structures to achieve desired health policy goals.

The US experience also shows that the for-profit/nonprofit composition of fields can change, sometimes quite rapidly, as can the ownership form of particular organizations. In a policy-sensitive field such as health care, the future of for-profit and nonprofit health care organizations is likely to be affected quite substantially by public policies. These policies may be focused specifically on some aspect of the ownership issue, but the most important ones may have an ownership-neutral motivation, such as the desire to control costs in large governmental programs. For segments of the health care industry in which government is the dominant payer, it may be difficult for investor-owned companies to generate revenues in the long run that will be satisfactory to investors. High profitability is likely to lead to cuts in the programs that fund that profitability. For-profits also face suspicion that has been driven by highly publicized fraud-related scandals involving some leading health care companies, plus widespread distrust of the predominantly for-profit HMO industry.

For their part, nonprofits face a twin challenge. In a highly competitive health care system dominated by large purchasers and without direct governmental subsidies, they must perform well enough economically to be able to continue paying their bills and to maintain their access to capital, which depends upon lenders' confidence in their ability to repay their debts. As they do this, they must also contend with a growing skepticism, fed in part by their own economically driven policies and practices, regarding whether they engage in sufficient charitable activity to deserve the tax-related benefits they receive.

With health care accounting for almost 15 percent of the US economy, investor money is likely to be available to fund new ideas for making money from the provision of health services, and there is interest among American companies in making investments in other countries as well. The clear advantages that the for-profit form might offer are the ability to raise capital, a willingness to take risks and innovate, and, perhaps, a reservoir of experience that might be transferable into new contexts. But will countries that have had little experience with this organizational form in their health care system find such factors outweigh possible costs in terms of a changed ethos of the health care system, major shifts in power and control, and potential serious problems of exploitation of the informational asymmetries that typify health care?

B. H. Gray

Health Care, Rationing of

The term 'rationing' is used with different meanings in health care discussions (Mechanic 1979). Most generally, it refers to processes of allocation when demand for care exceeds the available supply or the willingness of payers to increase it. In its more narrow application, it refers to how a scarce medical resource, such as hearts, kidneys, or livers, is allocated among competing recipients, only some of whom can receive it. Medical care has always been rationed in both senses, but the concept itself is associated with much affect and denials that rationing occurs.

To the extent that medical care is treated substantially as a commodity, as in the USA, then the market distributes services. Individuals with more comprehensive insurance or the ability to pay out-of-pocket command a greater quantity of and more sophisticated services. But even in market systems, some life and death services in scarce supply transcend the market and are governed by different rationing schemes. In publicly funded medical systems, where most of the population has health care entitlement, whether through national health insurance or a national health service, the availability of services depends on decisions about what services will be financed and their comprehensiveness and intensity (Klein et al. 1996). Some such systems, for example the British National Health Service, allow competing private systems of care. In contrast, Canada prohibits private provision of services covered by its health insurance program.

Rationing processes and decisions are implemented at different levels of government, by sick funds, large insurance plans, provider organizations such as hospitals, clinics, and health maintenance organizations, and at the point of service delivery between clinician and patient. Disagreements are common on where in the hierarchy of health care organization varying types

of rationing decisions should be made (macro, meso, or micro) and on appropriate processes for making such decisions (Mechanic 1997). At each level, rationing may be more or less explicit.

1. Explicit vs. Implicit Rationing

Explicit rationing refers to the detailed specification of how resources will be allocated by a rationing authority. Explicit rationing includes specifying eligibility rules, the specific services to be covered, the amount of coverage for recipients, intervals for receiving services, copayment requirements, the proportion of the budget to be allocated to varying services, the geographic allocation of services, the specific form and location of many services, and appliances and drugs that may or may not be allowed.

Implicit rationing, in contrast, involves setting budgetary limits but allowing the processes of allocation to be worked out at lower organizational levels (Mechanic 1979). Implicit rationing includes prospective reimbursements or capitation payments. In each case the authority sets the financial limits but then allows the budgeted or capitated entity to establish the processes for decision-making. Total responsibility is sometimes delegated to the lower unit but more typically there are some explicit guidelines and constraints over discretion. All medical systems combine explicit and implicit processes but the balance may differ considerably from one nation to another and within varying national contexts.

Klein et al. (1996) describe a range of strategies for implicitly limiting resources allocated to individuals. These include denial as beneficiaries or for the services claimed; selection of beneficiaries or services on the basis of need or likely success, or demographic characteristics such as age; deflection of care to other sectors or providers; deterrence through bureaucratic barriers such as waiting lists and other delays; diluting services by reducing intensity or restricting specialty care; and premature closure or early discharge.

2. Concerns About Rationing

Despite general acceptance of the inevitability of rationing, major issues of controversy include who should determine rationing strategies, the openness of decision processes, and whether decisions should be made by managers or clinicians (New 1997). Common criticisms are that the implicit rationing processes used are not open, often favor the privileged, and result in unequal care for persons of lesser status, education, and sophistication, and with less skill in managing bureaucratic systems (Churchill 1987). Critics also argue that implicit rationing gives doctors free reign to act on their prejudices. The lack of openness makes it difficult to assess the fairness of decision-making or to

allow aggrieved individuals to successfully appeal exclusions or dilution of care. Implicit rationing is also seen as undermining democratic processes through which communities can bring their preferences to bear in the allocation of important public resources.

A significant difficulty with explicit rationing, in contrast, is that it mobilizes interest groups who seek to affect decisions about coverage. Bringing medical decisions into the public arena energizes a political process and instability in the medical care system (Mechanic 1995). While a particular treatment may be of little value in general, there may be instances, difficult to specify beforehand, where it is appropriate. Explicit rationing can not, in most instances, accommodate the complex contingencies associated with the use of a particular treatment for an individual patient.

Questions about transparency apply at all levels of decision-making. The criteria used when a national government divides a health budget among regions can have significant consequences. Funds can be allocated politically, on the basis of historical funding, and on the basis of algorithms that take account of population characteristics and dispersion, and varying concepts of health status and need. The availability of facilities and specialists differs widely among population areas and accounts for large variations in expenditures among varying population groups. Nations can seek to bring greater equity among regions, types of services, and even individuals by how they decide to distribute resources.

Within organizations, decisions are made to allocate funding among primary and specialty services, among specialty units, and between medical and related health services. These decisions can have large consequences for the likelihood that a person with a particular need can receive responsive care. At the clinical level, decisions about waiting time, access to specialized services, availability of specialized treatments, or home or hospital treatment can profoundly affect patterns of care. Debate persists as to the extent such decisions should be governed by public discussion and decision-making or left to the discretion of clinicians based on their own professional judgment and experience (Symposium *The Law and Policy of Health Care Rationing* 1992).

Concerns about fairness and facilitating public discussion of priorities would support making practices explicit but there are significant competing concerns. Despite increasing interest in knowledge-based medical practice, much remains uncertain. There is no consensus, in most areas, on standards that apply to a diverse patient population with varying needs and inclinations and unique medical histories. Medical knowledge and practices are rapidly changing and it is uncertain whether explicit standards, once established, can be modified to keep pace with new knowledge. Moreover, medical care is an iterative process with assessment and disease management

developing over time. As a complex process of discovery and negotiation, clinical practice is not easily subjected to definitive technical rules.

The notion of explicit decision-making at the level of direct patient care implies that individuals with comparable conditions have similar needs and preferences. But treatment must be flexible and take account of varying social contexts, cultural inclinations, and personal preferences. Treatments of comparable medical effectiveness may have vastly different implications for work and family life, or for comfort under varying circumstances. To treat medical care simply as a technical process, devoid of meanings, preferences, and differential consequences, contributes to dehumanizing medicine, and is unacceptable to many professionals and patients.

3. Rationing of Specific Resources

Rationing becomes especially salient when problems result, not simply because of the unwillingness to provide more resources or allocate them fairly over some population (which may result in increased illness and death in a statistical sense), but when there is an inability to provide a life-saving resource to all identified individuals who seek it. Such situations involving the allocation of hearts, kidneys, livers, and lungs have been called 'tragic choices' because there are no fair or generally accepted rules for making the decisions as to who receives the resource and who dies (Calabresi and Bobbitt 1978). A variety of criteria have been applied from one occasion to another, such as allocation by age, by community contribution, by the largest opportunity to benefit, by family circumstances, by ability to cooperate in the treatment process, and many more, but all raise serious ethical conflicts (Elster 1992). Age is commonly suggested as a suitable criterion (Callahan 1990) and has been used in making tragic choices (Aaron and Schwartz 1984) but has been strongly contested. The most satisfactory criteria are medical ones based on likely technical success. But even these criteria do not adequately discriminate among potential beneficiaries, and social judgments and biases inevitably intrude (Halper 1989). For example, judgments about who can best cooperate in treatment typically give preference to patients with more education, higher intelligence, attractive personality characteristics, and strong social attachments.

Several analysts have concluded that because the equity issues cannot be resolved intellectually, the fairest mode of allocation is a lottery where persons with comparable medical qualifications have equal chances to be selected. There is little professional or public support for such selections because most people believe that consensual judgments can be made that would improve on any random process. Many rationally constructed strategies of allocation fail also

because of public perceptions. The public places greater value on rescuing identified lives than on saving statistical lives (Hadorn 1991).

4. Specific Rationing Policies/Practices

As evidence of inequalities in care increases, motivation to distribute limited health resources more equitably has led several countries to address rationing and seek explicit allocation principles and rules. The Oregon rationing program under Medicaid (the USA's federal-state partnership to provide health care to poor and disabled subgroups) was followed with great interest in Europe and represents perhaps the most extreme example of explicit rationing (Leichter 1999). This effort sought to increase enrollees under its Medicaid program by selecting to rank treatments consistent with judgments of efficacy and other community values. Through an elaborate process of evaluating condition-treatment pairs, a list was developed that prioritized these pairs. The basic idea was to establish a funding line, given available funds, that excluded from coverage the lowest ranking condition-treatment pairs. The formal evaluation and ranking process and the use of community meetings to involve consumers and professionals in defining the values for performing the rankings excited the imagination of many outside observers. The process was seen as a rational and fair way to make difficult public decisions about what would and would not be paid for. The Oregon program, however, was not quite what it appeared to be. It was a very public and explicit format for designing the benefit structure. The Oregon Medicaid program is predominantly a managed care program in which health maintenance organizations (HMOs) are capitated to provide all funded services. Once capitated, HMOs are free to provide whatever services they deem necessary and need not conform to the list. Thus, the list was more an instrument for bargaining over rates than an explicit set of rules for rationing health care. Early implementation was aided by increased state funding and a favorable economy, which allowed the establishment of acceptable capitation rates. The political sustainability of such an approach under more difficult times is yet to be tested.

The British National Health Service (NHS) exemplifies implicit rationing. There are no explicit guaranteed benefits in the NHS but the system seeks to provide all necessary care within the resources available. Care is rationed by the availability of professionals and treatment facilities, by professional decisions about intensity of care and referrals, and by waiting lists for various types of services (Klein et al. 1996, Aaron and Schwartz 1984). The extraordinary professional discretion within the NHS has led to efforts for greater equity and accountability in resource use. Under recent reforms, health authorities were given pur-

chasing responsibilities and could limit the treatments covered. The political difficulty of doing so explicitly in any but marginal aspects of medical care became evident. One exception was the effort to ration Viagra explicitly, a popular but expensive drug for treatment of impotence.

5. Ethical and Political Issues with Rationing Policies/Practices

A major ethical issue concerns the appropriateness of having physicians, acting as agents of their patients, also responsible for allocation decisions. Traditionally, doctors have been seen as sole agents of their patients, trying to get them what they need. Some believe it is unethical to dilute such agency with allocation responsibilities at the bedside. Others believe that physicians must have a dual responsibility for both their patients and the 'commons.' With the development of HMOs and managed care strategies in the USA, financial incentives are increasingly used to encourage doctors to allocate resources efficiently. There are worries that such incentives create ethical conflicts between the doctor's financial interests and patient care. Such conflicts are also common in unmanaged care when physicians have financial interest in diagnostic and treatment facilities to which they make referrals or in other practices for which they receive financial incentives. Studies have consistently found that such arrangements increase the use of ancillary services (Rodwin 1993).

There is widespread agreement that it is appropriate and necessary for some governing authority to establish financial constraints on health care expenditures. All national systems have such constraints in place for at least public expenditures. Few believe that it is any longer possible, even in the richest of nations, to provide open-ended financing, allowing physicians to provide all they deem useful. A more-contested issue is the extent to which such an authority, once having established such limits, should specify how the budget should be divided among different types of facilities, modes of care, professional groups, types of patient needs, and treatments and procedures, and by what criteria. The extent of authority given to the nation, as compared with regions, health districts, states, or even smaller population entities, elicits tensions in many contexts. Issues also arise as to whether organizational rationing decisions are best made by management, speciality services, or professionals exercising their best individual judgment.

A possible model that blends explicit and implicit rationing is one emphasizing clinical advocacy within a structure of procedural justice. Such a model would explicitly constrain some clinician and patient decisions through clear rules that are reasonably justified, while also allowing doctors and patients to challenge decisions and argue for revision through dispute

resolution mechanisms. Such compromise models offer opportunity for achieving more consensus.

Public views of rationing processes are important because any rationing process that lacks political legitimacy becomes unstable. One of the attractions of the Oregon program was its openness and the participation of large numbers of people. In contrast, in many areas of the USA, the implementation of utilization review (a form of explicit rationing) by managed care organizations overruling physician and patient definition of need has resulted in a significant political backlash. Managed care organizations are finding that transferring risk to professional groups (implicit rationing) kindles less friction than imposing explicit decisions on professionals and patients.

It will take decades for rationing issues to be sorted out. Health care systems and facilities are experimenting with a range of strategies that may improve decisions and help achieve legitimacy for rationing. These include community representation and involvement in decision-making, surveys to elicit community preferences, focus on evidence-based services, use of treatment guidelines and pathways, involvement of patients in treatment decisions, and implementation of disease management approaches. Rationing and the ability to sustain whatever system is preferred depends on achieving a sufficient level of value consensus so that the difficult choices are widely perceived as fair and responsive to individual need.

Health Care Systems: Comparative

1. Introduction

Each country's health care system is contained within a singular configuration of culture, history, politics, and economic capacity, and from these derive a specific mode of financing, delivering, and even evaluating health care. Yet, despite the uniqueness of each health care system, all are experiencing similar exogenous pressures, albeit to different degrees, arising from unprecedented developments in science and technology, demographic distributions, and patterns of disease, to name a few. And, despite their differences, many countries are responding to these pressures in remarkably similar ways. As Brown (1998, p. 36) puts it, 'Everywhere one hears the weary refrain: "We can no longer afford the [health care] system we have."'

To some scholars these similarities in pressures and responses suggest an impending convergence in health care systems, defined as 'a certain macro process in which a narrowing of system options takes place' (Mechanic and Rochefort 1996, p. 242). Mechanic and Rochefort emphasize, however, that convergence does not imply a blurring of social, cultural, and ideological distinctions among nations. Indeed, each nation's response necessarily builds on 'preexisting social institutions and professional organizations' (1996, p. 243). A number of scholars (cited throughout this article) have identified a specific kind of convergence in health care: many nations are turning to some type of market reform in order to control expenditures. This trend entails an unusual paradox: many of the ideas on market reform emanate from the United States, and yet the United States remains, not just an 'exception' among advanced industrial societies in its commitment to a welfare state in general and to health care in particular (Ruggie 1996), it is also a pariah from the perspective of universal coverage. At present, over 44 million Americans—approximately 18 percent of the population—are without health insurance, and millions more are underinsured. Adding to the paradox of the convergence, it is not altogether clear that the new methods offer a long-term solution to the problem of rising health care costs (Light 1997). For instance, an increase in administrative expenses is frequently as-

sociated with the need to assess competitive bids and manage the varieties of insurers and providers in a competitive market. In addition, concern about the consequences of market-based reforms on equity and access may already be diffusing, if not halting, recent innovations.

These inconsistencies in processes and outcomes suggest that the march toward marketization and the convergence it implies may be more apparent than real (OECD 1994, Gray 1998). Jacobs (1998, p. 5), among others, observes that while marketization connotes a direction of change and implies a choice of policy instruments, empirically it can become a 'highly eclectic venture.' His study shows that reforms—which introduced provider competition, greater cost-consciousness, and more patient choice—in the United Kingdom, Sweden, and the Netherlands actually resulted in divergence. Contrasting goals among political actors embedded in different institutional systems led to outcomes that were more significant for their dissimilarities than their resemblances.

Focusing on data from the 29 OECD countries and experiences from selected cases, this article explores the convergence/divergence debate by examining some of the main changes occurring in health care systems at present and some of the key issues driving change. It argues that convergence may be occurring at the level of interest among governments in experimenting with market-based forms of organizing health care, but whether this development constitutes what Max Weber would call a 'master trend' (a dominant movement in social change), sufficient to coalesce other distinctions, is far from clear. For an equally important concurrence is the resort on the part of governments to various types of regulation to mitigate the impact of market mechanisms. Hence, what we are witnessing is an oxymoron of modern society first identified by Karl Polanyi decades ago: planned markets. In general, this thesis also captures the experience of developing countries beyond the OECD, many of which are trying to introduce market reforms, and not only in health care. However, since planned markets require a relatively strong state, developing countries may be hindered in their capacity to harness viable market-based innovations.

2. Financing and Spending: An Overview

Health care systems are most commonly categorized according to three main methods of financing: general taxation, compulsory contributions to social insurance, and voluntary private insurance or direct payment (see Table 1). Health care systems funded through taxation tend to achieve the highest degree of universal coverage and, in principle, equity in access and provision. Within each category, however, significant differences occur in the delivery of health care services and these may affect patterns of coverage.

For example, Britain, Canada, Denmark, and Sweden all raise funds for health care through general taxation. But Britain considers its system to be a national health service, a concept more commonly associated with socialist countries. The other countries have national health insurance systems. The main difference is that under a national health service, ownership and/or control of the factors of production is public. Ownership of the factors of production in national insurance systems varies, but in general most hospitals are in the public domain whereas physicians consider themselves to be independently employed. Another difference pertains to the degree of centralization. In Canada, the national insurance system is funded by a combination of federal and provincial taxes. Also, the Canadian system is administered by the provinces, the Danish and Swedish systems by counties. While administration of the British national health service is decentralized, overall priorities emanate from the central government insofar as local governments have no independent source of revenue.

National or social health insurance systems are much more frequent than national health service systems. In most national health insurance systems, unlike in Canada and Scandinavia, financing is based on employer and employee contributions to an insurance fund (Belgium, France, Germany, the Netherlands, Norway); these contributions are compulsory for all employers and many workers. The funds may be administered privately (this is most likely if the funds are closely tied to employer or employee organizations) or publicly. Governments sometimes contribute to the funds as well and invariably set up some contributory mechanism to provide for special groups (such as low income or unemployed individuals). Social insurance systems generally achieve their universality by being tied to social security systems. Ownership of the factors of production varies considerably, but in general there is more private control than in systems funded through taxation.

Voluntary private health insurance is purchased by either employers or individuals or, in some cases, by a combination of the two. While this system predominates in the United States, it occurs in many other countries as a supplement to the national system. Depending on the country, private insurance may cover either private services only or some portion of public services as well.

Most countries house some mix of these models. For instance, in New Zealand hospital and specialist services are funded through general taxation, whereas financial support for ambulatory services and pharmaceuticals derives from an earmarked social security fund. In the United States, the Veterans Administration resembles a national health service and is funded through general taxation; Medicare is a national insurance system for those aged 65 and over as well as for the disabled, and is based on compulsory employer and employee contributions; and Medicaid is an

Table 1
Financing methods

General taxation	Compulsory social insurance	Voluntary private insurance
Britain (national)	Belgium France	USA Elsewhere to supplement national system
Canada (federal and provincial)		
Denmark (primarily county)	Germany	
New Zealand (hospital and specialist, national)	Netherlands	
	New Zealand (ambulatory and pharmaceutical)	
Sweden (county)	Norway	
USA (VA—federal; Medicaid—state and federal)	USA (Medicare)	

insurance program for the poor funded through general taxation.

Some recent efforts to control rising costs have tinkered at the margins of basic financial arrangements, but none has significantly changed a country's distinctive modality. Many cost-control efforts have sought to increase the contribution of private payments to overall expenditures. Even though all advanced industrial societies except the United States have 'national' systems, there is a considerable range in the public/private mix (Ruggie 1996). The term privatization suggests a direction of change away from the state, but actual cases of privatization demonstrate that the process is complex and does not necessarily shed government responsibilities.

Most countries have encouraged an increase in the role of private insurance by, for instance, granting a tax deduction to employers or individuals (Australia, Britain) or reducing the amount of public provision of certain services, leaving the private sector to fill the gap (Canada). Most countries have also increased charges to patients each time they use certain services (including hospital care in Sweden and general practitioners in New Zealand), but these additions tend to be nominal and aimed at enhancing cost consciousness and deterring frivolous or unnecessary use. Efforts to shift financial responsibility invariably introduce not only consumerism and commercialism but also stratification and selectivity. For instance, private insurance companies may discriminate by health status and social characteristics (such as age and class), charging certain individuals more while offering a greater range of services to those who can pay higher premiums. As a result, new government regulations have been deployed to correct these inequities.

For their part, private insurance companies are also engaging in cost-shifting by raising the price of premiums, deductibles, copayments, and so on. Similar increases in recipient contributions to social insurance funds have occurred as well. Some social insurance systems have attempted to increase cost consciousness by offering consumers greater choice

among plans (Germany, the Netherlands, and Sweden). While this fundamental market principle—choice—has increased competition within health care systems, its impact on costs is dubious because, unlike the predictions of market models of rationality, patients are not inclined to choose less care.

It is difficult to assess the effect of these privatization measures on the overall burden of health care expenditures, because they rarely appear alone. Also, while privatization by definition connotes some form of marketization, what exactly occurs is too variable and vague to be analytically useful. To confuse the issue even more, marketization can occur without privatization (as in Britain). However, just as privatization may in the end not entail a decline in the role of government, so too marketization is sometimes coupled with greater government regulations. Far from being contradictory, this combination may well provide the key to achieving the new triad of goals in health care: efficiency, effectiveness, and equity.

3. *Factors of Production: State vs. Market*

There is general agreement among scholars in the field of health policy that market mechanisms alone are not appropriate in matters of health care. Not only are consumers driven by need and not want, but when in need consumers do not exercise rational choice and prefer to spend to their limits (Evans 1999). However, few consumers are free actors in health care: governments and other third-party insurers buffer individual decisions and indeed shape them. What exists in all health care systems, then, are degrees of marketization and regulation, with pendulum-like swings between them reflecting the inevitable difficulty of staying too long on one side. That we are currently witnessing a (re)turn to market-based mechanisms indicates certain shortcomings in government controls, to be sure. But we ought not expect the market to replace the state, simply to stimulate correctives. Markets in health care, and especially those introduced by governments,

Table 2
Physician reimbursement

Fee-for-service	Salary	Capitation
Belgium	Britain (hospital specialists)	Britain (GPs)
Canada	Norway (some municipalities and counties)	Denmark ($\frac{1}{2}$ GP income)
Denmark (specialists and $\frac{1}{2}$ GP income)	USA (some HMOs)	Netherlands (GPs and for lower-income patients)
France (ambulatory)	Elsewhere in public hospitals and health centers	
Germany		
Netherlands (for higher income patients)		
New Zealand (ambulatory)		
Norway (ambulatory)		
Sweden		
USA (some Medicaid and Medicare, and much private insurance)		

are bound to be 'quasi' at best and reflective of the dominant social values and norms implicit in their construction.

Market forces have been introduced in various areas of the delivery and provision of health care. However, either the introduction of market reforms has been conducted within the framework of government regulations, especially as these pertain to issues of equity and access, or government regulations have been reintroduced when the negative consequences of market mechanisms on equity and access have exceeded acceptable norms.

3.1 Physicians

Of the three main methods of reimbursing physicians—fee-for-service, salary, and capitation—fee-for-service is the most open-ended and has been the most difficult to control. Governments (as payers) have attempted either to limit overall increases in fee schedules (as in Canada) or to specify prospective rates for procedures (as in the American Medicare Fee Schedule) (Table 2). In countries with social insurance systems, efforts to exercise these controls are frequently encumbered by corporatist negotiations involving representatives of employers, workers, and physicians. Private insurance companies have found it very difficult to impose reimbursement controls or develop other disincentives to increased utilization of physician services under fee-for-service plans, perhaps because the main competitive edge of private insurance is the greater choice it offers consumers who are willing to pay for higher-priced physician services. Because fee-for-service reimbursement controls encourage physicians to increase the number of patient visits in order to maintain their level of income, governments in Canada and Germany have begun to monitor the volume of physician services.

Physicians tend to be salaried when they work in public hospitals, health centers, or certain types of health maintenance organization (HMO). While salaries are inherently easier to control, they may elicit reduced service provision, especially when specialists also have private fee-for-service practices outside the health care facility. Capitation payments (a specified annual or monthly amount for each patient) commonly accrue to primary care physicians or general practitioners. Although there are outer limits on the number of patients on a physician's list, in order to control costs there must be strong disincentives to refer patients to specialist physicians or services.

Greater control over physician reimbursement has been facilitated by the introduction of managed care. Managed care is also responsible for ushering in a shift away from fee-for-service reimbursement toward either modified fees (with prospective fee schedules of some sort) or increased capitation if not salaried reimbursement within a physician's portfolio. Managed care plans rely on primary care physicians to serve as gatekeepers to the system of care, referring patients only when they deem it necessary. Various incentives exist to reward physicians for their efforts, ranging from bonuses in American HMOs to managerial independence among fundholding GPs in Britain. Fundholding GPs are allotted a lump sum payment for their practices and allowed to make all expenditure decisions themselves. Developments such as GP fundholding also represent an attempt to increase provider cost consciousness by making providers purchasers of health care with significant budgetary discretion.

Managed care has also introduced increased forms of competition among providers. Some managed care organizations negotiate contracts with selected providers for their services, encouraging providers to devise attractive offers that promote the goal of 'value

for money.’ Some managed care organizations simply enlist providers who are willing to offer their services for a discount; physicians are motivated to participate in these plans because of the promise of increased volume. In many countries competition is occurring among providers within the public sector, but, while reimbursements levels are affected, the practice is oriented more toward enhancing cost consciousness than achieving any significant reduction in overall expenditure on physician services.

Physicians and patients in the United States have undergone a dramatic and relatively abrupt transition to managed care, but at the same time, this revolution has been stymied by a shortage of primary care physicians. Unlike other countries the government in the United States exercises only weak control over physician supply and distribution, based entirely on monetary incentives. It is expected that the still growing market for managed care will continue to influence physicians to choose primary care as a field of specialization. Meantime, however, experiments are underway (for example, in New York City) in the use of highly trained advanced nurse practitioners as primary care providers. These nurses perform all of the functions of primary care physicians with regard to prescription, referral, and hospital admitting authority, and they are paid at the same rate. They and their employers insist that they are not threatening the livelihood of physicians, simply filling a gap. But their appearance is part of a wider movement to demote the level of skill in certain jobs. In all countries, most types of health care worker are undergoing a deskilling as hospitals cut middle-range positions while hiring lower-skilled replacements, some of whom work only part-time.

Other controls on physicians aim to standardize what in some cases has been wildly divergent practice patterns (Wennberg 1999). Clinical or practice guidelines, also known as medical audits, contain specifications for how physicians should go about treating certain ailments. In most countries these guidelines are developed by the medical profession and monitoring is based on peer reviews, but in other countries (such as the United States) government officials or other interested parties have a hand in the process as well. As protocols for treatment options, clinical guidelines have a dual purpose, for they are also central to efforts to improve quality assurance. Accordingly, in some places they have been extended to include primary care. Finally, in a number of countries, physicians’ expenditures on pharmaceuticals are coming under greater control. Britain and Germany are holding physicians directly responsible for spending over a specified limit.

These and related developments have led to the suggestion that the dominance and authority of the medical profession is declining (Mechanic and Rochefort 1996, Raffel 1997). Certainly, managed care has removed much clinical decision making from

the sole domain of the physician and muddled it with administrative rules and budgetary constraints. Further proof derives from the British experience. Having once enjoyed considerable clinical autonomy (especially compared to the United States), physicians in Britain are complaining about the introduction of a planned market with its greater managerial control over medical decision making (Harrison 1995). Alternatively, managed care has enhanced the role of primary care physicians in relation to the secondary sector. Even in countries that already had well-developed primary care services, the incorporation of managed care has strengthened the vertical integration of sectors and placed primary care physicians at the intersection.

There can be little doubt that the heyday of physician dominance over health care is past. But we must look beyond the medical bureaucracy to understand the forces behind this development. For example, better patient knowledge, triggered not only by successful health promotion programs but also by the media and increased access to the Internet, has greatly altered patient–physician relations. Medical authority is also being tested by negative reactions against increasingly more invasive technologies and procedures as patients are turning away from overly medicalized treatments and institutional settings. While we can note change, we ought not jump to conclusions about the endpoint. There is no reason why demedicalization cannot exist alongside a continuation of medical authority. Furthermore, demedicalization has generated greater accountability criteria on the practice of medicine. Accountability requirements have perhaps gone furthest in the United States, where some state and local governments are publishing physician (and hospital) ‘report cards,’ ostensibly to provide consumers with the information they need to make their health care choices. The status of physicians is undoubtedly coming under greater scrutiny, due as much to marketization and its competitively-based principles as to broader social changes in the culture of health care.

3.2 Hospitals

In most countries hospitals consume the greatest portion of health care budgets. By now, various forms of prospective payment systems to hospitals exist in most countries. Prospective payment systems frequently include additional incentives to contain costs, such as allowing hospitals that underspend to keep the difference and average out their costs. Some countries, such as Germany, have prospective *per diem* rates. Unless they are combined with disincentives to extensive lengths of stay, *per diem* rates do little to hold down hospital expenditures. Many more countries have already adopted or are shifting to prospective per case rates based on the American Diagnostic-Related Group (DRG) system. In this system each of several

hundred categories of diseases and disorders is assigned a numerical value based on service utilization that is then translated into a reimbursement level. Most hospitals responded to the incentives within the DRG system to contain costs by reducing lengths of stay (for example, in Sweden the decline was from an average of 21.3 days in 1985 to 7.8 days in 1995, OECD 1998). The number of hospital beds per population also decreased as a result. However, both of these indicators of reduced hospitalization have occurred in all OECD countries except Korea and Mexico, whether or not countries adopted the DRG system or similar cost containment methods, indicating that a more generalized decline may be occurring in the role of the hospital.

Another prospective payment system, used for years in Britain and Canada, and now being widely adopted elsewhere (France, the Netherlands, Sweden, Finland) is global budgeting on an annual basis. Spending decisions are usually decentralized to the local and even hospital level. In some countries there are strict controls on public sector capital investment in hospitals, sometimes with separate budgeting mechanisms.

A novel form of independent decision making by hospitals has occurred in Britain where hospitals are now self-governing trusts. The move was prompted by the expectation that hospital managers would become more cost conscious if they were responsible for all decisions—purchasing, servicing, delivering, administering, and even paying specialist physicians. Hospitals advertise their services and compete for contracts with, among others, fundholding GPs and local authorities. Similar developments have occurred in Italy and Denmark.

The introduction of cost control measures in hospitals has raised concern about declines in intensity of service and concomitant quality of care. Because of the great diversity among countries in the size of the hospital sector, goals regarding efficiency differ. Countries that are attempting to reduce total hospital output are faced with the challenge of closing hospitals or at least beds that are not being used efficiently (US, Britain). These countries nevertheless join others in striving to encourage hospitals to produce more so as to achieve certain goals, such as reducing waiting times for nonemergency treatments. The ability to regulate hospital costs goes beyond administration, however, for what happens in hospitals is highly dependent on technological advances. Yet, everywhere technology is undergoing contradictory developments.

3.3 Technology: From High to Low

While cause-effect relationships are always difficult to impute, it is safe to say that hospital cost containment has been made possible because of new technologies

that have both reduced the risks of certain surgeries and enabled an increase in outpatient surgeries. Paradoxically, rather than expanding megacenters of health care, as in the past, technological innovations may be contributing to the opposite effect. For instance, with the ability to perform more office-based procedures, physicians may be spending less time in traditional hospital settings.

At the same time, reactions against certain technological developments have engendered a number of nonmarket forms of cost containment and a search for less invasive and more personal forms of care, all of which signal new conceptions of what constitutes quality in health care. For example, there has been an exponential increase in the home health industry, which in many countries is contained within the private sector.

In some countries there is also renewed interest in supplementing both primary and secondary care with community care facilities. These provide a range of caregiving services either at home or in clinics, or day centers not only for those recovering from hospital treatment but also for the chronically ill, the mentally ill, and the elderly. Palliative care facilities and hospices are also proliferating to meet the demand for more personal and less technologized care for the dying.

Community care goes hand in hand with a renewed emphasis on preventive medicine, which was first heralded as a cost containment mechanism by the early health maintenance organizations. Insofar as community care, preventive medicine, and related alternative forms of health and healing entail a greater role for patients, both in self care as well as in determining the course of treatment, they also represent a demedicalization of sorts. Nevertheless, as with other evolving relations in health care, we may be witnessing less a replacement of allopathic medicine than a complement to standard modalities.

4. Managing Markets in Health Care

An American economist, Alain Enthoven, first introduced the idea of 'managed competition' in health care in 1978. For the American context emphasis was put on the term 'managed,' which carried a dual meaning. First, Enthoven was as much an advocate for the development of managed care as for the competition that he felt should occur among managed care organizations based on issues of quality and cost. As his formulations have been imported into other countries, this emphasis has shifted somewhat, but not entirely. Countries with strong primary health care sectors—whether these have been based on general practitioners or community care clinics, or both—have always had the foundations for managed care. For these countries competition among primary, secondary, and tertiary

care providers has been more important for enhancing cost consciousness than reducing health care expenditures.

Enthoven also suggested that competition itself should be managed, that is to say regulated, by public agencies who would act as sponsors for consumers. Each sponsor was to be: 'an active, intelligent collective purchasing agent on the demand side ... that creates, develops, administers and enforces the rules of competition in a never-ending effort to root out market failures and to perfect the market' (1994, p. 1416). Countries with systems of financing based on social insurance funds already had the foundations of such sponsorship. The incorporation of managed competition in these countries (Germany, the Netherlands, New Zealand) has primarily enhanced patient choice of fund, although some selective contracting by the funds has also occurred. The consequent increased competition among insurers has raised some predictable problems. In Germany the federal government has introduced risk adjustment schemes to compensate funds that have been negatively affected by the infusion of new patients. Some observers suggest that the equalization and standardization that is resulting may lead Germany toward a single national sickness fund—an odd consequence of managed competition (Freeman 1998). In other words, as new methods of competition are introduced into health care systems, their potentially unsettling consequences are eventually, if not immediately, controlled by new regulatory mechanisms. Even in the United States, proposals for a national Patients' Bill of Rights promise to reestablish fundamental criteria of justice over the exigencies of competition. Everywhere the result has been to tame market externalities without completely debilitating market mechanisms.

5. Policies, Politics, and People

Given the pressure to expand medical services and the reality of other demands on strained government budgets, countries have been struggling with the dilemma of trying to maintain full and equitable access to high quality health care while at the same time controlling cost increases if not actually cutting expenditure. During the 1980s and 1990s, most countries experimented with some form of market mechanism in order to balance the equation. Interestingly, the effort to contain costs has occurred regardless of level of expenditure. Among those OECD countries actively engaged in health care reform, expenditures on health as a percentage of GDP range from 6.4 in Denmark and 6.9 in Britain to 10.4 in Germany and 14.2 in the United States (OECD 1998). The rate of growth in expenditures has slowed in a number of countries. Many scholars attribute this consequence to the diffusion of a single idea—that the market is best suited to achieve efficiency. Because

marketization has occurred regardless of the degree of state vs. market penetration across diverse national settings, some scholars have suggested that a convergence in health care systems is occurring. To some extent countries have accepted new policy instruments cautiously and rationally, learning from each others' successes and mistakes. But to a larger extent as countries have borrowed ideas and instruments, and adapted these to their own situations, the inevitable tensions between market and state, state and society, professions and politics, values and rationalities have given full play to the rich diversities among health care systems. The current swing toward market solutions to economic problems in health care is limited in its penetration of health care systems, for few countries tolerate for long the negative consequences of market forces on equality and access. Indeed, 'planned markets appear as an attempt to find more effective administrative instruments, rather than as a conscious or intended surrender of political control over the main objectives of health policy to market forces' (Saltman and Otter 1995, p. 10).

In the end we must ask, however, whether we are witnessing actual reform of health care systems or something less tangible. If markets are constantly subject to government control, perhaps the underlying goal of reform is cost consciousness and the efficiency it purportedly entails. But beyond the buzzwords, a more profound eventuality is in the offing. If actors are expected to become more aware of the economic consequences of their decisions to utilize health care services, they must also become more attuned to their willingness to forego medical options, for themselves and for others. That health care must be rationed is probably the most difficult realization encountered by governments and citizens. It rests on the premise that health care is a scarce or at least finite resource, a premise that is hotly debated among medical professionals and ethicists. But as the discussion above has indicated, implicit forms of rationing abound—inability to pay; primary care practitioner 'gatekeeping'—limited number of professionals; limited number of technologies; queues for treatment—to name but a few. It is unclear how fully these practices are understood to be forms of rationing. Few governments have confronted the issue head on and developed explicit protocols.

The state of Oregon in the United States has one of the only plans specifically denying coverage for certain treatments. But the plan applies only to a population unable to purchase private insurance—Medicaid (poor) recipients. No matter what type of rationing exists, someone has to make the decision about denying access. How a country goes about this task reveals as much about prevailing values and norms as do decisions about financing. The Oregon plan, which on the surface appears to be a Leviathan in a land of individual freedom, was actually the product of considerable grass roots participation. In Britain,

government control over the macrolevel of expenditure and priority setting is coupled with confidential case-by-case rationing decisions made by physicians, a process that relies on an unusual level of trust. The persistence of these cultural features of health care systems explains the incomplete successes of market reforms.

Ultimately, however, the story of market-based reform, and the answer to the questions raised about convergence or divergence, rest on an understanding of the role of political institutions in health care systems. For reform to be effective, governments must have the political will to control the demands and behaviors of all relevant actors. But at the same time, for health care to be adequately and justly distributed, governments must marshal citizen involvement in decision making processes in order to construct and legitimate collective goals in health care. This is a universal point, applicable to newly industrializing countries or countries with struggling economies no less than to those discussed in this article.

Health Care Technology

1. Definition

According to the US Office of Technology Assessment, healthcare technology consists of ‘the drugs, devices, and medical and surgical procedures used in medical care, and the organizational and supportive systems within which such care is provided,’ (US Congress 1982) including diagnostic, preventive, therapeutic, rehabilitative, organizational, information, educational, and supportive technologies.

Social scientists routinely distinguish ‘advanced’ medical technologies from the more mundane healthcare technologies. The distinction between advanced and normal technology often implies that technology has become increasingly central in modern medicine. But in a broader historical perspective, technology has always been central to healthcare, indeed social life. Features of life once popularly regarded as advanced technology, such as patient records or needles, have now been absorbed into routine.

2. The Importance of Healthcare Technology for Social Scientists

The broad definition of healthcare technology encompasses any tool from a mundane shake-down thermometer to the latest version of the computerized patient record, presenting the healthcare field as layered with technologies. Social scientists have been mainly interested in the upper layers of the medical geology: they have written extensively about advanced

life-supporting technologies, organ transplantation innovations, reproductive advances, information technologies, and genetic breakthroughs that pose profound ethical and sociological questions about equity. The introduction of new biomedical technologies not only maps medical advances but also reflects changes in cultural understandings of health, illness, life, death, the body, and even the family (e.g., when reproductive technologies offer an alternative to sexual procreation), religion, politics, crime, nature, race, and gender.

A good example of how medical technologies influence cultural notions is the institution of brain death criteria by the Harvard Ad Hoc Committee on Death in 1968. In an archival study of the committee's correspondence, Mita Giacomini confirms the general suspicion that a significant factor tailoring the redefinition of death were the interests of the transplant community (Giacomini 1997). In 1967, after the first heart transplant in South Africa, the general public had become sensitized to the potential conflict of interest of transplant surgeons to declare patients dead before their heart had stopped beating. Up until that time, physicians and lay people had been unable to come up with criteria for death beyond the century old criterium of the heartbeat cessation. The tacit consensus seemed to be to view death as a bedside physician prerogative. The transplantation community needed more flexibility to receive timely access to comatose bodies and was actively involved in the creation of the new criteria. For example, clinical criteria were adapted to facilitate organ procurement. Even the term 'brain dead' rather than 'irreversible coma' fit with the transplant community's needs because only 'dead' people could serve as cadaver organ donors. In addition to the interests of the transplant community, the redefinition of death was influenced by the emergence of the electroencephalograph and the application of resuscitative and life support technologies.

While most sociological writings have had analytical purposes, some scholars have entered the field of health care technologies with interventionist intentions. The purpose of such socially engaged studies by feminists and other patient advocates is to influence health care policy. In their pioneering study of dying in hospitals, Barney Glaser and Anselm Strauss discussed how technological advances at the end of life created complicated lingering dying trajectories, posing special problems of information management for nurses and physicians (Glaser and Strauss 1965). Glaser and Strauss painted a poignant picture of dying patients and their relatives engaged in a painful game of extracting information from healthcare providers reluctant to reveal the terminal condition. As part of a general death awareness social movement which swept the United States in the 1960s, this study contributed to a revision of the medical school curriculum to include doctor-patient communication courses. Simi-

lar studies discussed how the rapid introduction of pharmaceutical, surgical, and technological innovations during the post-Second World War decades featured in the socialization process of individual physicians.

3. Different Conceptualizations of Healthcare Technology

Social scientists have viewed healthcare technology in at least three different ways, each of which comes with a number of assumptions about the role of technology, human actors, and the social world. At stake in the different conceptualizations is the autonomy of the technology and its power to shape social relationships. These different approaches greatly impact the critical potential of the analysis.

3.1 Social Science with Technology Perspective

In the first conceptualization, technology is not the central focus of the analysis but more a catalyzing variable in a network of social relationships. Healthcare technology remains unproblematic, assumed in the same way that most sociologists take the physical layout of hospitals for granted. What matters is how humans (as professionals, relatives, patients) cope with the new possibilities generated by an influx of instruments in technology-intensive medical settings. The primary goal of social scientists working in this approach is to analyze well-established topics of interests to observers of health and illness, that is, professionalization, social equality, social control, or medicalization, often relying upon the canon of a broad social constructivist perspective.

A good example of this approach is Renée Anspach's study of decision-making about life and death in a neonatal intensive care unit (Anspach 1993). She situates her ethnography in a technology-intensive environment and states that most of the dilemmas about keeping premature and sick infants alive result from the availability of the technology and expectations of staff and relatives. Yet, she does not name or describe what technology she is talking about, discuss its origins, or elaborate on the staff's work to keep the technology functioning and interpretive. Instead, Anspach writes about the neonatal intensive care unit as a complex social organization where different groups of people rely on diverse sources of information and weigh varying priorities to reach a decision about the continuation of aggressive treatment. Physicians, for example, rely more on technology-derived data than nurses who depend on closer, interactive contact with infants, leading to conflicts in life-and-death decisions. The healthcare technology confirms the power differences between an emerging and established profession.

Even scholars who make technology more central often rely on this socially determined conceptualization of medical technology. Susan Bell's interactive diffusion model of the artificial hormone DES (diethylstilbestrol) applies a social constructivist social network approach to healthcare technology (Bell 1989). Bell shows how the artificial hormone originated from within scientific and health communities with distinctive ways of defining problems and offering solutions. A broader political-economic context (US research funding post-Second World War) structured the relationships of these communities and reflected the way the technology diffused among physicians and their women patients. In this conceptualization, the focus of the social scientist's analysis remains with the social networks advancing the new technology. Bell explores how social communities gain or lose power because of their support for DES. Yet, how the meaning of the hormone itself changes as a result of those interactions remains unexplored.

The main assumption underlying this approach to healthcare technology is that the tools and instruments of medicine are shaped by social forces. Technology is a given (Anspach 1993), or a contingently diffused product following a trajectory set by social circumstances (Bell 1989). Dominant social groups invest values, power, and preferences in the healthcare technology, and it is these norms and paradigms that dominate the analysis. This approach offers interesting insights into the *social* aspects of healthcare technology but often glosses over the *technological* characteristics of medical technology. In other words, what makes health-care technology such a unique case, is often left unexamined.

3.2 Humanistic Social Science Argues Against Technology

The second conceptualization of healthcare technology originates from a humanist concern about the dangers of technology and is primarily intended as a critique of the healthcare field. In contrast with the first approach, the spotlight of the analysis is firmly centered on healthcare technology. Healthcare technology is singled out, its effects are scrutinized, compared to a technology-free past, and usually found wanting. Healthcare technology symbolizes here the power and arrogance of the medical professions, the hegemony of the medico-industrial complex, and the excesses of Western modernity. Technology becomes a modernist instrument by which some in society enforce power over others.

Authors working in this tradition emphasize how the presence of medical technology turns caregivers into technicians and leads to depersonalized and dehumanized care. Technology results in distancing and alienation in patient-care-provider interactions, a loss of dignity and integrity, and a colonization of the

body. This kind of analysis receives its persuasive power from a historical or cross-cultural comparison. The technology-saturated present is compared with idealized tropes of the 'natural' (the natural body, birth, or death) of past epochs and of others, unpolluted by modern healthcare technology.

This antitechnology analysis has been fueled by the Luddite legacy and the threat of a nuclear apocalypse, and is popular with both conservative scholars lamenting the moral, spiritual, and existential crisis in the secular West (Aries 1977) and Marxist scholars who analyze healthcare technology as an integral part of the capitalist profit structure (Waitzkin 1979). These politically diverse analyses of healthcare technology have in common that they believe that technology is a powerful force shaping social relationships. This belief has been referred to as *technological determinism*. Technological determinism comes in different strengths (Winner 1980): strong technological determinists believe that technology develops as the sole result of an internal dynamic and molds society to fit its patterns. In his book *Medical Nemesis*, for example, libertarian social critic Ivan Illich views the exportation of Western medical technologies as part of an international conspiracy to spread illness across the world and establish Western medical hegemony. According to Illich, international collaboration to eradicate virus-carrying mosquitoes resulted in short-term pyrrhic victories, in the long-term technological inference led to more virulent strains of tropical diseases and an aggravation of malnutrition (Illich 1976, Chap. 7). In a weaker version, medical technology is viewed as a political phenomenon in itself. Technology as politics occurs when a particular technological device or system becomes a way of settling an issue in a particular community or when technologies require particular kinds of political relationships. For example, physician-generated demand for expensive diagnostic technologies such as MRI scanners led to the consolidation and integration of large medical centers at the expense of many local community hospitals that did not have the patient load to justify the large capital investment. In both versions, the focus of the analysis is on what has been lost after the introduction of medical technologies. The purpose of these critiques is to warn of over-technologization and to recapture a mystified technology impoverished past.

This conceptualization of healthcare technology often works from an analysis of extremes and is therefore limited in the analytical insights it brings in the everyday workings of healthcare technology. Yet, because of its strong rhetorical packaging, this approach to technology has often lead to more social mobilization and actual social change than the other two conceptualizations. One can detect technological determinist tenets in the hospice movement, rallying for palliative care for terminally ill people and in the 'natural' birth movement, pointing out the physical

dangers of an overmedicalized birth. In both social movements, antitechnology sentiments united activists and led to concrete social change.

3.3 Technological Practice

A third conceptualization of healthcare technology finds a middle ground between the view that an interplay of social structure and culture shapes the use of technology and the belief that technology determines society. Drawing from the interdisciplinary field of science and technology studies, researchers have turned to what specifically is gained and lost in medical encounters when new instruments and drugs are introduced. This approach led to a number of detailed studies of the practice of healthcare technology in which the technology takes center stage. Healthcare technology is here not an *a priori* established entity but both the technological elements and the social characteristics emerge during the design process and while the technology is used. Social and technological characteristics are continuously reconfigured in interaction, to the point that it is difficult to tell where technology ends and the social begins.

As a prime example of this approach, sociologist Marc Berg addressed whether medicine has become more rational and scientific since the Second World War because of its reliance on formal tools such as standardized protocols, expert systems, clinical decision analysis, and automated decision systems (Berg 1997). Berg neither supported the Luddite camp which argues that such technologies primarily lead to deskilling nor bolstered the protechnology argument that the formal tools necessarily reduce the staff's workload, but instead showed how technologies have shifted medicine's understanding of rationality. Rationality was not a pregiven quality but achieved in tandem with the production and implementation of formal tools. Berg analyzed how the designers of the automated clinical decision analysis systems and protocols went beyond solving technical conundrums. The designers of formal tools studied the work activities and places in which their tools needed to function and made assumptions about users, environment, input, and expected output. For example, the designers of an automated cardiac decision-making system aimed for a computer that calculated a diagnosis and suggested treatment options after a healthcare provider entered diagnostic data about chest pain. The designers prescribed medical practice with guidelines (the algorithms of the diagnostic system), prerequisites (which data is mandatory or optional), and a reshuffling of existing professional relationships to make their devices work (not only physicians but nurses could enter data). In the end, the automated decision-making system provided a diagnosis and the tool worked, but not in the way the designers intended it because the tool's requirements became just one

element in the management of patients' medical conditions. For example, nurses quickly learned to enter the 'right' data based on the availability of beds in the intensive care unit. Medical practice and tools emerged simultaneously to constitute new forms of knowledges, new challenges, and problems to keep both the tools and the users on track, and ultimately new opportunities for diagnosing and curing.

The most radical conceptual innovation of the science and technology scholars was to extend agency from humans to things. According to the French sociologist Bruno Latour, this ontological extension of human agency occurs through the *delegation* of agency from humans to nonhumans (Latour 1987). Machines and instruments, such as thermostats and tape recorders, perform as agents because they substitute for the actions of people. As Stefan Hirschauer has shown, during surgery, pumps and monitors become a patient's 'externalized organs,' taking over vital functions (Hirschauer 1991). Because a malfunctioning ventilator might mean the end of life, there is no easy distinction between the human and the technical realm. Technology acts similarly to people. This does not mean that humans and nonhumans are equal. Andrew Pickering, for example, draws the line at intentionality; intentions cannot be attributed to nonhumans (Pickering 1995). Some critics have charged that analyzing technology as actors is disempowering, because ultimately humans need to be held accountable. But other researchers have linked the premise of technological practice to a more critical and interventionist agenda (Timmermans 1999).

The key characteristic of this approach is that changes in the social and the technical realm are investigated symmetrically as they enfold over time. Instead of assuming the predominance of social or technological forces in advance, the social scientist studies how technological innovations advance new medical practices and understandings about health and illness.

4. A Selection of Research Topics in Healthcare Technology

4.1 Organ Transplantation Technology

Like ethicists and physicians, social scientists have been particularly puzzled by the Janus face of biomedical technology: the instruments of medicine have the potential to postpone mortality and enhance the quality of life, yet, also possess the possibility of destroying the world as we know it. Nowhere is the Janus face of biotechnology better researched than in the area of the biomedical organ transplant technologies. The transplant of kidneys, hearts, lungs, heart and lungs, liver, and pancreas benefitted from the development of immunosuppressive drugs that counteracted the body's tendency to attack the foreign

organ and, in the case of US kidney transplants, from Medicare funding in 1972. Since the technology moved down a continuum from experimental to therapeutic, its utilization has prolonged and saved lives that would otherwise almost definitely be lost, but it also spawned many unintended, complex ethical, financial, legal, and social problems.

Renée Fox and Judith Swazey point out in a classic study that more than just organs are exchanged during organ transplantation (Fox and Swazey 1978). The technological procedure poses important questions about the corporeality of personal identity, the relationship of a body to its parts, and the boundaries that define social ties. Organ procurers present the donation of cadaver organs or, in the case of kidneys, live organs as the ultimate 'gift of life,' invoking Judeo-Christian values of altruism, generosity, humanitarianism, and freedom of choice. For the recipient, the donated organ might not only be under continuous threat of immunological rejection but might also carry a heavy symbolic load. Because a donated organ can not be reciprocated with another gift, the organ exchange locks two people and their relatives in an unequal relationship, creating what Fox and Swazey term 'the tyranny of the gift' (Fox and Swazey 1978, pp. 20–32). Relatives of donors might insist on developing kin relationships with recipients because a piece of their loved one 'lives on' in another person. For recipients, the reconstruction of the body requires an active reshaping of the self (Sharp 1995).

These social complications of organ donation are exacerbated by the 'scarcity of organs.' In the US, organ donation seems to have leveled off at 5,000 while the demand for organs has topped more than 33,000 and keeps rising (Sharp 1995). With a much higher demand than supply, who is more likely to receive organs? According to the American Medical Association, medical need should prevail. But does medical need mean that the person who is the sickest should get priority or the person who has the best chance of long-term survival? According to social scientists, the chance to receive an organ is positively correlated with socioeconomic status and patient's race (Kutner 1987). African Americans are less likely to be donors, organ procurers, or recipients of organs. In addition, people with history of mental, emotional, or family problems are less likely to receive organs, raising ethical questions about disability when patients with Down's Syndrome were initially refused a position on the organ donation waiting list. Economists have tried to move away from the gift giving ideology towards a market ideology that considers organs as any other commodity to be bought and sold. Several proposals circulating in medical circles propose to pay a financial benefit to the estate of the donor to motivate donation. In other countries and some US states, the governments have tried to enhance organ donation with a system of presumed consent: everyone is presumed to be an organ donor unless documented otherwise.

Anthropologist Margaret Lock's study of organ transplants and brain-death in Japan and the US (Lock 1989) offers an important counterargument against the idea of the 'technological imperative.' The technological imperative implies an inherent force in healthcare technology; once a medical technique is available there is virtually no objection possible for not using it. The concept, introduced by economist Victor Fuchs, has caught on in other studies to explain the quest for more and better technologies and the quick adoption of questionable technologies (Rothman 1997). Lock explained that any technological imperative is not inherent to technology but to the broader culture. Although Japanese physicians and scientists possess all the technical know-how and skills to implement organ transplants, Japanese people have until recently chosen not to take the cadaver organ transplant route but instead focus on the development of artificial organs. The reason for Japan's reluctance to jump the organ transplant bandwagon is that brain death is not accepted as a sufficient criterion of death for religious reasons and because Japanese families nurse their terminally ill and would be reluctant to accept that a breathing body with a heartbeat is 'dead.' In addition, Japanese have a different concept of the self and feel reluctant to just emulate every technological innovation from the West.

4.2 Reproductive Technologies

Another area flush with research attention is the field of reproductive technologies. Different infertility treatments, biotechnologies, and fetal surgeries have opened the categories of parent, child, fetus, human, family, and even population to some renegotiation. Key questions include control over the human body, the manipulation of eggs, sperm, and embryos, and the threat these technologies pose for the identity and legal status of the 'products' created. Reproductive technologies have been largely analyzed from feminist inspired perspectives but the emphasis of the analysis has shifted over time. Initially, feminist scholars looked at reproductive technology as a tool to liberate women because it could sever the link between sexuality and reproduction. A technological fix would erase some of the differences between men and women and create equal sexuality (Firestone 1970).

While reproductive possibilities seem to be more about fulfilling than rejecting the traditional female role, some feminist scholars gaze at new technologies as the next installment of patriarchal exploitation of women's bodies and reproductive processes. Reproductive technologies are viewed as attacking women, a modern incarnation of eugenics. The technologies become 'technical delegates,' tools used to compensate for the perceived deficiencies of its users. Women's bodies are opened up, manipulated, and controlled to be ultimately bypassed. The consequence is an alien-

ation, commodification, and depersonalization of women's bodies (Corea et al. 1985).

More recently, feminists have looked at the same reproductive technologies from a postmodern perspective (Casper and Clarke 1998), giving more agency to women themselves. The postmodern strategies concentrate upon the design and transformation of reproductive bodies. Poststructuralist feminists have rejected the notion that the 'real female body' is passively 'acted upon,' instead preferring to view it as being both inscribed and constituted through reproductive discursive practices and processes. Reproductive technologies generate different kinds of subjectivity. For example, Charis Cussins analyzed how undergoing infertility treatments figures in women's self making and at the same time transforming their body conceptions (Cussins 1998). She located the fertility treatment in women's biography. Before entering the infertility clinic, many women have already a history of trying not to get pregnant using anticonceptiva, followed by a period of increased awareness of what could have gone wrong while trying to conceive. Cussins showed that the objectification, naturalization, and bureaucratization of the women's bodies during pelvic exams, ultrasound, explanatory surgery, and embryology laboratory is associated with particular forms of agency. If the activities in the infertility clinic lead to pregnancy, the patient exercises agency in her active participation of the different forms of objectification. If the treatment cycle has been unsuccessful, women reported their lack of agency or insufficient attention to the specificity of the patient. The consequence of the process in which women render themselves compatible with instruments, drugs, and material surroundings is what Cussins called an 'ontological choreography' with the potential of transforming the women's long-term self-perceptions as potential mothers.

Most feminist writing, both past and recent work, is ultimately aimed at creating awareness of the reproductive technologies cost and benefits for women, a women centered reappropriation of the technologies, or to offer alternatives for social change (see the book *The New Our Bodies, Ourselves* (Boston Women's Health Book Collective 1992).

4.3 Technology and Healthcare Costs

With the explosion of healthcare costs worldwide, social scientists have also investigated the financial role of medical technologies in the healthcare system. Although there seems to be a general consensus that technology has contributed to rising healthcare raised costs, exact figures of how much cost has increased or mechanisms of cost raising are not well documented. Researchers at the US Office of Technology Assessment, for example, estimated that new technologies accounts for anywhere between one-third to three-quarters of the cost of hospital care—a range of

several billions of dollars (Banta et al. 1981). Others have estimated that healthcare technology takes up 10 to 40 percent of the increase in healthcare expenditures over time, again a very wide range (Neumann and Weinstein 1991).

Problems with calculating the cost of technology include the broad definition of healthcare technology and the scope of health expenditures. Should medical technology be limited to 'big ticket' items or include the entire technical geology? When calculating health expenditures, some researchers take only the capital cost, while other scholars combine the capital cost with more expensive operating costs and increased use of auxiliary services. Other problems include measuring cost saving and balancing health outcomes of life-saving technologies against long-term institutional expenditures. In some studies, all increases not explained by other factors are attributed to technology, while others focus on the cost of treating certain illnesses or the cost of particular technologies (Neumann and Weinstein 1991).

Relying on total healthcare costs, Frans Rutten and Gouke Bonsel note that labor intensive, low-technological interventions such as mental healthcare are two to four times as expensive as the cost of high cost technology, such as kidney dialysis and transplantation, megavolt therapy, CT tomography, cardiac surgery, *in vitro* fertilization, and picture archiving. They also found that even when one isolates technology, it is often the specialized and highly salaried personnel that take up the major part of the total cost. They conclude that 'high cost technology is expensive per item, but that its contribution to total healthcare expenditure is limited' (Rutten and Bonsel 1992). Economist Victor Fuchs calculated that technology contributed 0.6 percentage points of the 8 percent annual rate of increase in health expenditures from 1937 to 1967 (Fuchs 1972).

Pulitzer-prize winner sociologist Paul Starr has also offered a caveat to the reasoning that technology is to blame for financial healthcare woes. Big-ticket technologies such as new imaging machines, organ transplantation, intensive care units, and renal dialysis have undoubtedly brought higher costs 'But, only about a third of the higher levels of spending (in the United States), compared with Canada, reflects the expense of hospital care—and of that, only a portion is due to greater use of technology' (Starr 1994, p. 22). Starr instead suggested that we adopt a systemic view to explain the rising healthcare costs in the US. He located expanding costs in the historical development of a number of incentives for private decision makers to expand and intensify medical services.

The factors singled out to explain the importance of technology in the healthcare field relate to technological characteristics and the wider healthcare field. In the innovation literature, healthcare technologies are considered 'dynamic,' that is, they develop as they are diffused. This means that technological

innovations are regularly introduced before information about effectiveness and cost is established. Social observers also point to the billion-dollar medical industry, the public's seemingly unsatiable appetite for more technology, and varying incentive structures. Countries with stronger centralized government regulation have been able to curtail costs via planning and technology allocation. Countries following more of a market model create a situation where hospitals invest in technologies to remain competitive. The consequence of these incentives is, paradoxically, an under-use of services.

Consider the case of early detection of breast cancer through the use of mammography [in the US]. With fully utilized mammography machines, a screening mammography examination should cost no more than \$55 ... But because machines are typically used far beneath capacity, prices run double that amount. With prices so high, many women cannot afford a mammogram ... In other words, *because we have too many mammography machines, we have too little breast cancer screening* (Starr 1994, p. 25, emphasis in original)

5. Future Trends

The electronic patient record, telemedicine, artificial organs, and genetics will continue to raise the specter of healthcare technologies in the coming decades. The challenge for social scientists remains to keep up with the multitude of micro and macro changes healthcare technology poses for societies without falling into simplistic forms of technological determinism or social essentialism.

S. Timmermans

Health Economics

An individual writing an entry summarizing the field of health economics in 1960 would have had difficulty finding much to say. By contrast, an individual writing at the turn of the twenty-first century faces an embarrassment of riches: the field has exploded since the 1960s. There are now several textbooks, as well as a two-volume *Handbook of Health Economics* (Culyer and Newhouse 2000) and two international journals: the *Journal of Health Economics* and *Health Economics*. This article will thus necessarily be selective.

At least four reasons can be identified for the growth in health economics. The first is the enormous expansion of the health-care sector in almost every developed country during the second half of the twentieth century. Between 1960 and 1997 real health-care spending per person in the G-7 countries grew at annual rates between 3.7 percent (the United Kingdom) and 7.4 percent (Japan) (Anderson and Poullier 1999 give figures in nominal US dollars, and I have deflated by the US Gross Domestic Product, GDP, deflator). As a result of this growth, the G-7 countries in 1997 spent in real terms between 4 and 14 times more on health care per person than they spent in 1960. Because their economies did not grow nearly as rapidly, all the countries saw a rise in the share of GDP going to health care. By 1997 that share ranged from 6.7 percent in the UK to 13.6 percent in the USA.

Second, developments in economic theory, especially the growth of information economics, have aided the development of health economics. Third, although this is not really taken up below, the development of computational power has greatly facilitated empirical work by permitting analysis of large administrative databases. Finally, in several countries, especially the USA, the field has been generously supported when compared with most other subfields of economics, although not when compared with most natural or biomedical sciences.

1. Uncertainty, Medical Insurance, and Medical Care Services

The seminal article in health economics is generally considered to be by Arrow (1963). In explaining the institutions surrounding the delivery of medical care, Arrow emphasized two related features: the pervasiveness of uncertainty in medical care, and the asymmetric information between the physician and the patient. Uncertainty gave rise to a demand for insurance, but because insurance markets were seriously incomplete, nonmarket institutions evolved to compensate. In particular, medical ethics dictated that physicians were not to act in a narrow, profit-maximizing fashion, and the patient trusted that the physician was acting in the patient's interests. Much of what was to follow in

health economics over the next four decades flowed out of these notions.

The subsequent development of information economics in the 1970s stimulated developments in health economics; indeed, medical care was an example used in several of the early seminal articles in information economics (for example, Rothschild and Stiglitz 1976). These articles showed that if buyers in competitive insurance markets knew more about their risk than sellers, a market equilibrium would not exist and hence certain markets would not exist. One necessary condition for lack of equilibrium in the Rothschild–Stiglitz model was that the proportion of bad risks be relatively small, which is descriptively accurate about health insurance. Typically the highest five percent of spenders account for 50 percent or more of resource use (Berk and Monheit 1992). Relaxing the assumption of symmetric information between buyer and seller thus gave a theoretical rationale for Arrow's observation that insurance markets were often incomplete. It also gave a policy rationale for the public sector interventions in health insurance markets—or the direct provision of services by the public sector—that had by then occurred in every developed country.

Zeckhauser (1970) pointed out that health insurance—and risk-spreading arrangements more generally—inevitably created a second-best situation: although insurance offered protection against risk, it did so at the expense of increasing moral hazard. The traditional meaning of moral hazard in the insurance literature was failure of insured individuals to take preventive measures. In the case of medical care, that insured individuals might forgo prevention seemed of less concern because their health, including pain and suffering, was not insured. But medical care insurance typically reimbursed a certain proportion of spending rather than reimburse a lump sum contingent upon a certain event's occurring. Hence, moral hazard came to mean the additional consumption stimulated by the subsidy implied by insurance. Although the additional consumption was often construed as creating a dead-weight loss (Pauly 1968), this is not necessarily the case. One could want resources transferred to certain states of the world precisely so that one could consume medical care that would otherwise be unaffordable in those states (DeMeza 1983). As a result, the conventional test of a welfare loss from health insurance is whether a consumer, to insure a given state of the world, would purchase an actuarially fair insurance policy with an appropriate lump-sum reimbursement (Goddeeris 1984). Any willingness to pay on the part of others (i.e., an externality) should also be added.

There is, however, a literature in health economics that rejects the conventional test of a welfare loss from insurance for various reasons. Two prominent reasons given in this literature are that the observed demand curve does not reflect the preferences of an informed consumer (about which more below) or that income should not affect the delivery of medical services

(Williams and Cookson 2000). The applicability of the conventional test thus remains a controversial issue.

The understanding of how the health insurance contract itself affects health care and even health has progressed over several years. Following Zeckhauser, many early US studies focused attention on the extent of the moral hazard introduced by health insurance, or more concretely the demand response of the consumer to more or less generous insurance coverage. Indeed, the RAND Health Insurance Experiment, one of the largest social science projects to date, was in effect a controlled trial that was in part aimed at quantifying the consumer's demand response to varying levels of coverage (Newhouse and the Insurance Experiment Group 1993). (The results of this experiment are covered below.)

In addition to specifying the price to the consumer or the degree of subsidy, the health insurance contract also specifies the terms at which the insurer would reimburse the supplier. (Terms must also be specified when the government is a direct provider.) In many cases the supplier agrees to accept the insurer's terms as payment in full and does not bill the consumer an additional amount; indeed, in some instances, such as in Canada, billing additional amounts to the consumer is illegal.

Numerous studies have showed that the amount paid to the supplier, especially the physician, affects the quantity of services, holding constant the price paid by the consumer or patient (for example, Rice 1983). These studies have given rise to a lengthy debate among health economists about whether supplier-induced demand rendered standard demand theory, which postulated an exogenous set of consumer preferences, inapplicable to medical care.

The dominant empirical evidence purporting to show that supplier-induced demand violated standard theory was that the volume of health-care services often rose when physician fees were reduced. This was sometimes interpreted as physicians' delivering more services in order to maintain their income, and was referred to as the target-income hypothesis. But it subsequently was shown that this behavior could be accommodated by a standard neoclassical model, provided the physician's utility function was assumed to include total income, work effort or leisure, and the degree of inducement (the latter was assumed to be negatively valued) (McGuire and Pauly 1991). Under these conditions, if the cut in fees implied a large enough cut in income, the physician would increase inducement and services delivered would rise, but if the reduction in fees had only a modest effect on income, services would fall. (In the former case an income effect would dominate a substitution effect, and conversely in the latter case.) This modification, although potentially leaving the construct of a demand curve intact from the point of view of positive economics, left the applicability of conventional welfare economics on shaky ground.

The role of the physician as an agent for the patient gave rise to a literature that emphasized altering financial incentives facing physicians to improve the trade-off between risk spreading and moral hazard. Specifically, it was proposed to put the physician (or other supplier such as a hospital) at some risk for the quantity of services used by a group of patients (Ellis and McGuire 1986). Fee-for-service reimbursement of the physician, with fees set in an administrative transaction between the insurer and the physician, was thought to contain economic rents in many cases, with a resulting incentive for the physician to overprescribe services and procedures. For if fees were set at marginal cost there would be no incentive to overprescribe, and no concern about supplier-induced demand (Pauly 1980). Thus, the use of two-part pricing, wherein the physician (or other supplier) received a lump sum for each enrollee—a capitation—as well as a diminished fee, could in principle reduce the moral hazard from rents in fees without increasing the financial risk borne by the patient. (But some cost sharing on the demand side would still presumably be useful to address the patient's incentive to seek care in the first place.) Of course, if the consumer were well informed and could monitor the services delivered, the basis of payment to the physician, capitation, or fee-for-service, would not matter, but this was a strong assumption. Indeed, what the consumer often wanted from the physician was diagnostic information. The principle of a two-part payment could be extended to other kinds of services, for example paying a lump sum for each hospital admission, with perhaps additional payments for very expensive cases, rather than a varying amount for each admission, depending on the exact services delivered. This latter example shows that the fee portion of the payment could in principle be paid in nonlinear fashion.

The importance of pricing in affecting supplier behavior has blossomed in the USA with the development of managed care (Glied 2000). Health-maintenance organizations, which provide all necessary medical services in return for a monthly premium, had existed since the 1930s. Until the 1980s, however, they had a small market share (under 10 percent). But as medical capabilities and the resulting costs of health care rose, the scale of moral hazard and potential welfare loss of the then dominant insurance form rose concomitantly. Probably as a result, starting in the mid-1980s managed care grew to dominate the US market, in part because it was seen as a set of techniques to reduce the moral hazard without increasing the financial risk on the consumer.

Managed care consists of two broad techniques. The first is financial incentives to physicians, usually groups of physicians, to reduce services. A common form of such incentives is capitation, but there are also various kinds of risk-sharing arrangements with payment according to whether utilization is over or under a target. The second technique is command-and-

control-type regulation, such as utilization review or prior authorization of hospitalization, in order to reduce the delivery of low-valued services. Baumgardner (1991) showed how, as the technical capabilities of medicine increased, command-and-control techniques could become more valuable in addressing moral hazard.

But capitation had a downside as well. Because in practice the same capitation amount was paid for patients whose expected costs varied, there was an incentive to select good risks and avoid bad risks. This issue has been the subject of much analysis (Van de Ven and Ellis 2000). Some of the analysis stressed situations in which regulation prohibited charging different risks different amounts even when information was symmetric. Other analysis stressed asymmetric information and the attraction of sicker individuals to more generous benefits even if insurance plans made no active effort to discriminate among risks. The latter point of view gave rise to a literature on risk adjustment, meaning that an external party (government, an employer, a coalition of employers) would alter premiums facing consumers choosing among plans in accordance with the risk mix of their enrollees (Newhouse 1996, Van de Ven and Ellis 2000). After risk adjustment, plans that had a disproportionate number of bad risks would not be more expensive to the consumer than other plans.

The Rothschild–Stiglitz model of selection in insurance markets, which assumes asymmetric information, has been influential, but makes two predictions that do not correspond with experience. First, it predicts no pooling equilibrium (meaning heterogeneous risks purchase the same insurance plan). Second, it predicts that high-risk individuals can obtain the insurance they want, whereas low-risk individuals cannot. Real-world insurance markets obviously exhibit some pooling; furthermore, it is typically high-risk rather than low-risk individuals who have difficulty obtaining as much insurance as they want in competitive insurance markets. Newhouse (1996) showed that if it is costly for insurers to discriminate among varying risks or persons with varying expected costs, there will be some pooling of risks (there will be more pooling with higher costs of discriminating). Moreover, under these conditions it is high-risk rather than low-risk individuals who will not be able to buy all the insurance they wish. Although these predictions appear to accord better with reality, it is not clear that the magnitude of costs to insurers to discriminate among different risks is large enough to carry the burden assigned to them. Theoretical understanding of insurance markets remains imperfect.

If insurers (or health plans) compete for individual members, as is observed in the USA and in certain other countries (e.g., The Netherlands, Israel), competition will take place on risk type if premiums do not approximate expected cost at the individual level. In other words, if paid a uniform premium, it is in a

plan's financial interest to enroll relatively healthy persons and not to enroll the sick. A similar phenomenon can occur among physicians to the degree that they are reimbursed a fixed capitated amount per patient and are at risk for spending above that amount (e.g., primary care groups in the UK National Health Service). Selection based on expected costliness of patients implies that premium spirals may occur, in which certain plans are left with poorer and poorer risks, and ultimately may go out of existence (Cutler and Reber 1998). It also implies that prices quoted by health plans reflect the average enrollee risk in addition to any product differences that would affect cost for a given risk. In turn this means that prices facing an individual enrollee do not generally reflect the marginal cost of providing services to that enrollee, and that the allocation of persons to plans differs from that of a perfect market.

Remedying this situation by charging premiums geared to individual risk means an individual cannot avoid the financial risk of a deterioration in health if premiums are adjusted periodically, say annually, to reflect risk in the next period. For example, persons newly diagnosed with diabetes mellitus would face an increased premium and would thus bear the financial risk of contracting diabetes. In principle, the risk would be avoided if insurance policies paid a lump sum to an individual diagnosed with a disease at the time of diagnosis (Cochrane 1995). Such a feature is not observed, however, probably for the reason that health insurance tends not to be written as a fixed indemnity policy in the first place, namely that the large number of states of the world (i.e., the severity and combinations of various diseases) makes it impractical to enumerate the states. Furthermore, such insurance would fail to protect against the risk that a better but more expensive treatment will become available in the future, a common occurrence in medicine.

A monopoly public insurance program or the direct public provision of services effectively insures against the possibility of becoming a bad risk and also avoids the selection problem inherent in competitive arrangements, but potentially gives up whatever benefits in more favorable prices or quality may be available from competition. Moreover, it cannot readily cater to diverse preferences or willingness to pay for alternative treatments of varying expense. Also, even a monopoly insurance plan may leave competition among providers with which it contracts (e.g., physicians) and thereby introduce selection issues.

One middle ground between a monopoly insurer and competitive individual insurance markets is competition to insure groups of individuals who have formed for purposes other than obtaining health insurance (Diamond 1992). Provision of insurance through the place of employment, as is common in several countries, is one method of achieving this. Employer-provided insurance, however, breaks down

for small firms or the self-employed, as well as for individuals not attached to the labor market.

Another middle ground is so-called carve-out arrangements, whereby an employer or a public health insurance plan asks for competitive bids from suppliers of particular services such as mental-health services. A contract for the given service is then awarded to a single supplier, and the contract can be periodically rebid. For the service that is carved out, there is a single supplier to an entire group, but for services that are not carved out there can be competitive suppliers within the group. Carve-outs eliminate selection for the service that is carved out, but at the price of potential coordination problems among various suppliers. For example, it may be unclear whether a visit by a depressed patient who is complaining of fatigue should be charged to the supplier of carved-out mental-health services or the health plan that is responsible for all other health services.

Currently there is much interest in the consequences of different methods of reimbursing suppliers, especially physicians. The interest stems in part from the wide variety of methods used around the world, including fee-for-service, capitation (a fixed payment per period of time for 'necessary' services), and salary. Similarly, hospitals may be paid a fee for each detailed service, an all-inclusive fee per day, or an all-inclusive fee per admission. Several countries have changed their method of reimbursement (e.g., greater use of capitation in the USA). The consequences of different methods of paying providers will almost certainly be one of the main topics of research over the next several years.

2. Health

In 1972 Grossman developed a model that construed the demand for medical care services as derived from the demand for health, which he treated partly as an investment good and partly as a consumption good; for an exposition of the model and subsequent developments, see Grossman (2000). As an investment good, health care was assumed to increase the stock of health and thereby the flow of healthy days and productivity; as a consumption good, health care was assumed to improve well-being. Health, of course, was not traded in the market, but factors such as age and schooling altered the optimal level of health by altering its shadow price. Grossman's model, by emphasizing health rather than medical care as what was desired, was consistent with a stream of empirical work that sought to measure clinical outcomes of health care and did not simply take spending on medical services as equivalent to output. Starting from a different position, Sen (1992) has also emphasized the importance of health as a good in its own right.

The importance of health has given rise to two types of literatures in health economics, one on cost-effective

interventions to change health and the other on the determinants of health. One strand of literature evaluates various clinical interventions according to conventional economic criteria. Valuing health outcomes in dollar terms, however, is controversial; as a result, alternative methods for measuring benefits that are independent of willingness to pay have evolved. Two prominent methods are Quality Adjusted Life Years (QALYs) and Disability Adjusted Life Years (DALYs). These methods attempt to attach utility weights to various states of the world in order to compare them. In effect, they are measures of life expectancy adjusted for quality of life. For explications of methods and issues refer to Garber (2000).

It was natural for economists to study how additional medical services affected health outcomes. The RAND Health Insurance Experiment showed that free medical care induced participants to consume some 30–40 percent more services relative to a plan with a large deductible, but the additional services did little or nothing to affect the average person's health (Newhouse and the Insurance Experiment Group 1993). Such a finding was consistent with the prediction of a standard economic model, namely that ever-greater subsidies would lead to the consumption of ever-lower valued services. That additional services could have a small marginal effect on health, of course, is consistent with their having a large average effect; reducing medical services to zero could have catastrophic consequences.

Nonetheless, closer analysis of the experimental data suggested that the allocation of services by person did not fit the standard prediction. Fully insured consumers were more likely than those with cost sharing to receive services of substantial clinical value, which should have left them on average in better health, but they also were more likely to receive services of negative value (e.g., antibiotics for viral conditions). On average, the additional positive and negative services consumed by those with free care appeared roughly to offset, although for the poor who were chronically ill the additional services when care was free appeared to have a net benefit. In this group, of course, the prior odds that a given service would be beneficial rather than harmful was considerably greater.

The apparent misallocation of services to persons is consistent with one of the best established facts in health economics: there is enormous variation across areas—both small and large—in the delivery of various medical services, even conditioning on diagnosis (Phelps 2000). For example, rates of specific procedures per Medicare beneficiary in the USA generally varied by more than a factor of two from high to low across 13 large areas in 1981 (Chassin et al. 1986). And areas that had high rates for one particular procedure did not necessarily have high rates for another. Moreover, the percentage of 'appropriate' services in the various areas was roughly constant, rather than

declining in the areas with higher rates, and there were seemingly high rates of zero or negatively valued services in all areas, one-sixth to one-third for several procedures (Chassin et al. 1987). In other words, allocation of services to persons did not appear to be following the principle of maximizing health benefits in the population. Further studies have revealed high rates of zero or negatively valued services in other health systems as well (Brook 1993), which implies that the efficiency of health-care delivery worldwide may be well within the frontier.

In addition to the effect of medical services on health, economists have studied other determinants of health, in particular the consequences of various personal behaviors. The use of tobacco has probably been the most studied (Chaloupka and Warner 2000). Abuse of alcohol has also been studied intensively (Cook and Moore 2000). For both tobacco and alcohol, economists have shown that higher taxes reduce use substantially. In the USA, however, cigarette taxes are already at a level that roughly offsets the average and probably the marginal externality of smoking. By contrast, alcohol taxes are well below the average and probably the marginal externality created by excessive drinking (Manning et al. 1991).

Recently there have been a number of studies of the potential effect of income inequality on health outcomes, although most of these have been carried out by noneconomists. Many studies purport to show that increased inequality, controlling for the level of income, damages health, but there are issues as to which way causality runs and whether any inferences can be drawn from the aggregate data that many studies have employed. A useful review and critique is found in Smith (1999).

3. Policy Considerations and the Future

Health economists in several countries have been active in policy debates over financing medical services and measures to promote health. In some European countries, especially the UK, an important thrust has been to break apart the government role as both buyer and seller of services in order to promote competition on price among sellers. Similarly in the USA the spread of managed competition has been an effort to promote price competition among sellers of medical services (Enthoven 1988). The essence of managed competition is that a consumer should bear much or all of the incremental cost of choosing one health plan rather than another, which in turn motivates the health plan to seek economical suppliers of care.

The competition needs to be managed, however, so that it does not degenerate into a competition for good risks. As mentioned above, the 'manager' could be an employer, a coalition of employers, or government; in fact, all three are observed. Current techniques for

management or risk adjustment, however, are imperfect, explaining something less than half of the systematic or predictable variance across individuals in annual spending (Newhouse 1996, Van de Ven and Ellis 2000).

Although institutional arrangements in all countries attempt to control moral hazard, the efforts are imperfect for several reasons. First, medical knowledge is continually changing, so that what was thought to be the treatment of choice today may be discredited tomorrow. And sometimes the opposite happens as well. Because the spread of knowledge is imperfect, physicians may unwittingly be delivering a service that is known to be no longer effective or which is dominated by a newer service. Second, any efforts the physician makes to elicit the patient's preferences among alternative treatments may be imperfect. In extreme cases they may be futile, as in the case of a demented patient. As a result, the physician may give the patient a service a more informed patient would not have wanted or vice versa. Third, there is often lack of consensus about how health-care services should be rationed and in particular what role, if any, income should play (Garber 2000, Williams and Cookson 2000). Indeed, the advent of managed care in the USA and its effort at controlling moral hazard has led to a demand for 'patient protection.' In particular, under managed care arrangements patients have no ready way at the point of service to express the intensity of their preference or demand for a service. As a result, it is certainly possible that rationing would occur among highly valued services. Fourth, the degree to which others are willing to pay for an individual's treatment is variable across societies and across individuals. Improving methods for rationing services is likely to remain on many policy agendas for a long time.

One of the features of the late twentieth and early twenty-first century has been the aging of most developed countries. Several factors are contributing to this trend including increased life expectancy among those over 65, the post-World War II baby boom, and the ensuing baby bust. The result will be an increased demand for medical care (those over 65 typically spend from three to five times as much on medical care as those under 65) and an increased demand for personal care services as individuals become unable to live independently without assistance. Much of this demand will be financed from public sources, but the decline in fertility in developed countries means there will be more retired elderly per worker in most countries, and hence a greater tax burden for workers.

Historically, as noted above, real per capita medical care costs have gone up four percent or five percent per year in many countries over several decades. It is now generally accepted that this increase is mainly due to technological change or the increased capabilities of medicine (Newhouse 1992, Fuchs 1996). If this rate of increase in cost continues, medical care, much of

which is publicly financed, will consume an ever greater share of GDP. There is, of course, nothing inherently wrong with this, provided the benefits justify the costs, although the presence of insurance raises a question about whether, at the margin, the benefits do justify the costs. To the degree that the growth in costs is attributable to new capabilities, the issue is willingness to pay for those capabilities, both for oneself and others. Given the similar rates of increase in medical costs across countries with dissimilar institutions, there is some presumption that much of the increase is desired.

Continued biomedical research, especially the revolution in molecular biology and the mapping of the human genome, promise further technological change in medicine. Unfortunately, the implications of the change for cost are highly uncertain. Consequently, the future of health care and what of the increased menu of valuable services various societies will wish to purchase remains highly uncertain.

Health Education and Health Promotion

Health education is any combination of learning experiences designed to facilitate voluntary actions conducive to health (Green and Kreuter 1999). Health promotion is the combination of educational and environmental supports for actions and conditions of living conducive to health (Green and Kreuter 1999), thereby including health education. The two definitions represent a historical development in approach from more individual to more ecological where the role of the environment has acquired increased relevance in understanding and changing conditions for health. For this reason, we will use the term health promotion in the remainder of this article. Health promotion can be characterized by four other main developments: the need for planning, the importance of evaluation, the use of social and behavioral science theories, and the systematic application of evidence and theories in the development of health promotion interventions. Finally, we will describe recent developments in information technology (IT) and their effect on health promotion.

1. Health, Environment, and Behavior

In the ecological approach to health promotion, health is viewed as a function of individuals and the environments in which individuals are embedded, including family, social networks, organizations, and community and public policies. The relation between social economic status and health is a clear example of environmental influences on health. At the same time it also constitutes a major challenge. The central concern of health promotion is health behavior. However, health behavior refers not only to the individual's behavior but also to the behavior or actions of groups and organizations. Stress at work may be related to individual coping behavior, but also to managers' decision-making behavior (organization). Richard et al. (1996) describe the various environmental levels as embedded systems. They indicate that individuals exist within groups, which are in turn embedded within organizations and higher order systems. The individual is influenced by, and can influence directly or through groups and organiz-

ations, the higher order systems. The picture that emerges is a complex web of causation as well as a rich context for interventions. In the stress example, the individual as well as the manager will both be targets for health promotion interventions. Moreover, at the society level, the intervention may target politicians' decision-making related to a healthier organization of labor. We see managers and politicians as agents in the environment who serve as targets for health promotion interventions (Bartholomew et al. 2000).

2. Health Promotion Planning

Health promotion is a planned activity. The most widely used health promotion planning framework is Green and Kreuter's (1999) PRECEDE/PROCEED model (see Fig. 1).

The model begins on the right with the assessment of quality of life and health problems, changes in which should be the proposed outcomes of a health promotion intervention. It then guides the planner to assess the behavioral and environmental causes. In the behavioral assessment typically one asks what the individuals at risk are doing that increases their risk of death from the health problem. In the environmental assessment we ask what factors in the environment are related to the health problem directly or to its behavioral causes. In the previous subsection, it was explained how the environmental causes can be viewed as behaviors or actions at various environmental levels: groups, organizations, communities, and society.

In the next phase of PRECEDE/PROCEED, the determinants of the behavioral and environmental factors are assessed. Green and Kreuter (1999) describe determinants affecting behavior as predisposing, reinforcing, and enabling. Predisposing factors relate to the motivation of an individual or a group to act. Notice that the target may also be an agent in one of the environmental levels, such as a manager or a politician. These factors mostly fall into the psychological domain and include the cognitive and affective dimensions of knowing, feeling, believing, valuing. Reinforcing factors are those consequences of action that determine whether the actor receives positive (or negative) feedback and is supported socially after it occurs. Reinforcing factors thus include social support, peer influences, and advice and feedback by healthcare providers. Notice that the perception of social support would be a predisposing factor. Reinforcing factors also include physical consequences of the behavior such as well-being or pain. Enabling factors, often conditions of the environment, facilitate the performance of an action by individuals, groups, or organizations. Factors included are the availability, accessibility, and affordability of healthcare and community resources. Enabling factors also include new skills that a person, organization, or community needs to learn to carry out a behavioral or environmental

Figure 1
PRECEDE/PROCEED model (Green and Kreuter 1999)

change. Notice that self-efficacy expectations are a predisposing factor, the actual skills an enabling factor.

PRECEDE/PROCEED suggests that program planners start with the assessment of quality of life and health problems. In practice, that is a rare situation. Often health educators start somewhere within the model, depending on their task description or the specific moment in the ongoing health promotion planning process. For example, a health educator may be hired to develop a smoking prevention program for schools. We then enter the model at the behavior box. However, we first want to go back, to the right, and (re-)assess the quality of life and health problems as well as the behavioral and environmental conditions before we go on to the assessment of determinants of the behavior and environmental conditions and the development of the program.

The next phases of PRECEDE/PROCEED involve the administrative and policy assessment. The planner will now develop the plans into health education and other health promotion interventions, such as policy, regulation, or organization. The assessments include identifying barriers to overcome in implementing the program and policies that can be used to support the program. We then proceed to program implementation. Implementation is an essential element in the planning process. Without implementation, the intervention will not have any impact on determinants, behaviors, or health. The final phases of PRECEDE/PROCEED describe the evaluation levels: process,

impact, and outcome. Thinking about implementation and evaluation has to start as early as possible, not after the intervention development. In the Intervention Mapping protocol, anticipating implementation and evaluation are steps in the development process.

3. Program Evaluation

Even the best planned health promotion intervention may not have much effect. It is important to always evaluate the effect of an intervention, its impact and process. When the program has failed, we need to know why it failed. Rossi et al. (1999) suggest four levels of evaluation:

(a) *Program conceptualization and design* refers to the planning process and the use of theory and evidence in the development of the program.

(b) *Program monitoring* provides feedback on the actual implementation of the program and its reception by the target population.

(c) *Impact evaluation* is defined by Rossi et al. as the extent to which a program causes change in the desired direction. They use the word impact to make clear that the desired effect of a program may be defined at different levels, and often not at the health and quality of life level. It is useful to agree on the operationalizations of desired effects before the actual implementation of the program.

(d) *Program efficiency* evaluates the program in terms of costs and effects, such as cost-benefits and cost-effectiveness analyses.

Rossi et al. are very outspoken on when to evaluate and when not to evaluate: 'Clearly, it would be a waste of time, effort and resources to estimate the impact of a program that lacks measurable goals or that has not been properly implemented.'

Effect evaluation relies heavily on quasi-experimental designs (Rossi et al. 1999). The basic principle in effect evaluation is the random assignment of participants to the program group and a control group. Only then can we give a straightforward answer to the question if an intervention was successful. In health education practice the random assignment of individuals is often impossible. For instance, students from secondary schools cannot be assigned randomly to a school program or a control program, because most school programs are school-wide or at least class-wide. In that case, we ask various schools if they are willing to participate in the program, and we then assign schools randomly to the program condition or the control condition. A variety of quasi-experimental designs allow us to compare two or more groups that are as similar as possible. We have to expect that the groups are not completely equivalent on a number of relevant characteristics, and we cannot even assume that we know all the relevant characteristics. Statistically, we can control for most of these differences and levels, but only when we measure them before the program starts (see Bartholomew et al. 2000).

4. Social and Behavioral Science Theories

A health promotion program is most likely to benefit participants and the community when it is guided by social and behavioral science theories of health behavior and health behavior change (Glanz et al. 1997). Theory-driven health promotion programs require an understanding of the components of the theory as well as the operational or practical forms of these theories. Finding and applying relevant theories is a professional skill that health educators have to master (Bartholomew et al. 2000).

Notice that we assume that all theories are potentially applicable to all levels and also to adoption and implementation. The Theory of Planned Behavior, for example, is often applied to individual health behavior (Godin and Kok 1996) but also to politicians' behavior (Flynn et al. 1998) and to implementers' behavior (Paulussen et al. 1995).

The behavioral science theories that try to explain behavior and behavior change have two types of roots: health and health promotion in particular or behavior and behavior change in general (the last mainly being social psychological theories). Health and health promotion oriented theories are often related to perceptions of health risks, for example, the Health Belief Model (Sheeran and Abraham 1996, Strecher and Rosenstock 1997) or Protection Motivation Theory (Boer and Seydel 1996). Some other theories were developed in a health setting, but have evolved into a

general theory such as the Transtheoretical Model of Stages of Change (Prochaska et al. 1997) or Relapse Prevention Theory (Marlatt and Gordon 1985). Most general social psychological models were developed for a broad range of behaviors, but are easily applicable to health behavior and change. Some examples are Learning Theories (Westen 1996), Information Processing Theory (Hamilton and Ghatala 1994), Theory of Planned Behavior (Connor and Sparks 1996, Montano et al. 1997), Social Cognitive Theory (Bandura 1997), Goal Setting (Strecher et al. 1995), Attribution Theory (Weiner 1986), Self-regulatory theories (Clark and Zimmerman 1990), Social Networks and Social Support theories (Heaney and Israel 1997), Persuasive-communication Model (McGuire 1985), and Diffusion of Innovations Theory (Rogers 1995).

At the organizational level, health educators draw from various Organizational Change theories (Goodman et al. 1997). Typically we use constructs from these theories for considering policy development within organizations and for promoting program adoption and implementation.

At the community and society level, theoretical input can be found in the classic models of community organization and community development and the current perspectives being used for health promotion (Minkler 1997). Issues of power, participation, and goals, for instance, have received much discussion among health educators in recent years. In selecting the constructs to use for community change, planners must clarify their assumptions and values about the nature of the change process and select and implement strategies congruent with these. Finally, there are theories of policy making that have been used primarily at the national, state, and governmental level, such as Policy Window Theory (Kingdon 1995).

Theories are very important tools for professionals in health education and promotion. On the one hand, theories have become available to health promotion practice through textbooks such as Glanz et al. (1997) or Connor and Norman (1996). On the other, the application of theory has long been a challenge, for researchers as well as practitioners. Students of health promotion learn of theories and learn how to apply theories to well-selected practical problems. However, in real life the order is reversed: the problem is given and the practitioner has to find theories that may be helpful for better understanding or changing behavior (Kok et al. 1996). Recently, a protocol was published that describes a process for developing theory-based and evidence-based health education programs: Intervention Mapping (Bartholomew et al. 2000).

5. Intervention Mapping

Intervention Mapping distinguishes five steps: define proximal program objectives, select theoretical methods and practical strategies, design the program,

Figure 2
Intervention Mapping (Bartholomew et al. 2000)

anticipate adoption and implementation, and anticipate process and effect evaluation (see Fig. 2). Bartholomew et al. (2000) see planning as an iterative

process: two steps forward and one step back. Bartholomew et al. (2000) describe three core processes for Intervention Mapping, tools for the professional

health promoter: searching the literature for empirical findings, accessing and using theory, and collecting and using new data. From the literature search, a provisional list of answers is developed, which is often not adequate in finding solutions for the problem. The planner must go further to search for theory, using three approaches: issue, concept, and general theories approach. The issue approach searches the literature for theoretical perspectives on the issue. The concept approach begins with the concepts in the provisional answers, linking these concepts to theoretical constructs and theories that may be useful. The general theory approach considers general theories that may be applicable. Finally, it is important to identify gaps in the information obtained and collect new data to fill these gaps.

The first step in Intervention Mapping is the development of proximal program objectives, a crossing of performance objectives, determinants, and target groups. For instance, one proximal program objective for an HIV-prevention program in schools would be: 'adolescents (target population) express their confidence (determinant) in successfully negotiating with the partner about condom use (performance objective).' Performance objectives are the specific behaviors that we want the target group (or the environmental agents) to 'do' as a result of the program. For example, in the case of HIV prevention: buy condoms, have them with you, negotiate with the partner, use them correctly, and keep using them (Bartholomew et al. 2000). Determinants of behavior can be personal or external. Personal determinants are, for instance, outcome expectations, social influences, and self-efficacy expectations. External determinants are, for instance, social norms and support, and barriers. Target groups can be subgroups of the total group, for instance, men/women, people in different stages of change. Proximal program objectives are numerous and should be ordered by determinant. So we end this step with a series of lists, for instance, all proximal program objectives which have to do with skills training.

Intervention Mapping Step 2 is the selection of theoretical methods and practical strategies. The theoretical method is the technique derived from theory and research to realize the proximal program objective; the strategy is the practical application of that method. For instance, the method for self-efficacy improvement could be modeling and the strategy could be peer modeling by video. An important task in this step is to identify the conditions or parameters that limit the effectiveness of theoretical models, such as identification, observability, and reinforcement as necessary conditions for the effectiveness of learning by modeling.

Intervention Mapping Step 3 is the actual designing of the program, organizing the strategies into a deliverable program, and producing and pretesting the materials. In the example of HIV-prevention in

schools, the program comprised five lessons, an interactive video, a brochure for students, and a workbook for teachers (Bartholomew et al. 2000).

A solid diffusion process is vital to ensure program success. So, in Intervention Mapping Step 4, a plan is developed for systematic implementation of the program. The first thing to do, actually at the start of intervention development, is the development of a linkage system, linking program developers with program users. Then, an intervention is developed to promote adoption and implementation of the program by the intended program users. It may be clear that the anticipation of implementation is a relevant process from the very beginning of planning, not only at the end.

Finally, Intervention Mapping Step 5 focuses on process and effect evaluation. Again, this process is relevant from the start, not only at the end. For instance, 'adolescents express their confidence in successfully negotiating with the partner about condom use' is an objective, but is also a measure of that objective, that can be asked in pre- and postinterviews with experimental and control group subjects.

6. Recent Developments in IT

Mass media health promotion is able to reach large numbers of people, but a major weakness of mass media programs is their limited effect in terms of impact and outcome. However, more effective individualized health promotion is costly and time-consuming. Computer technology may help break several important barriers in health promotion related to individualization and program delivery. During the 1990s, health promotion researchers have been testing simple computer expert systems that enable the tailoring of communications to match certain characteristics that have been measured in individuals in the target group (Velicer et al. 1993, Brug et al. 1998, Dijkstra and De Vries 1999).

Velicer et al. define an expert system as a collection of facts and rules about something and a way of making inferences from the facts and the rules. The most common types of expert systems in health education are computer programs that are tailored to specific characteristics of the receiver. Thus, the expert system comprises one or more databases of messages based on theoretical constructs that vary as they apply to different characteristics of individuals, and on algorithms for matching the messages to individuals. The message channel could in general be anything that facilitates delivery of the message to the target: a report, a letter, computer-assisted instruction or any other channel. In the work of Velicer et al. (1993), messages were based on the Transtheoretical Model of Stages of Change and included processes of change tailored to the stage of the individual in regard to quitting smoking. Feedback included current status

and stage of change, current use of change processes, suggested strategies, and high-risk situations. Feedback was compared against a normative database as well as against participants' progress. All examples of computer-tailored health promotion in the literature are based on a similar configuration comprising (Brug et al. 1998):

(a) A theoretical framework and specification of relevant hypothesized determinants of the health behavior.

(b) Use of the determinant model to create a data collection tool and a series of messages that are tailored to these determinants.

(c) Several databases including, at least, a determinants file and a delivery message file.

(d) A set of decision rules and a tailoring program that executes these decisions.

(e) The actual communication messages.

(f) Delivery vehicles, such as a printed letter.

It is to be expected that computer tailoring will become more popular in the future and will also be applied using the Internet.

7. Conclusion

Health education and health promotion are planned activities. PRECEDE/PROCEED provides a very useful framework for the systematic planning of health promotion and Intervention Mapping provides a very useful protocol for evidence-based intervention development. Both models acknowledge the role of the individual as well as the relevant ecological levels in the environment.

Health, Global Budgets for

Introducing global budgets for health, i.e., setting prospective limits to expenditure on health care, is by definition the most effective means of controlling spending. If expenditure levels are fixed for the coming year or years, and if the limit is made to stick, then tautologically the rise in spending on health will be contained within the planned total. Not surprisingly, therefore, an increasing number of governments adopted this strategy in the 1980s, as a reaction to the largely unplanned and unanticipated rise in health care spending throughout the 1960s and much of the 1970s: what came to be known as the health care cost explosion. This article examines, first, the feasibility, form and effectiveness of this strategy in different health care systems; second, the conceptual and practical issues involved in fixing the global budget and then allocating it to populations or health care sectors.

1. Strategies and Mechanisms

In 1960, total health expenditure (privately as well as publicly financed) in the world's 18 richest countries—

those belonging to the Organisation for Economic Co-operation and Development—accounted for 4.2 percent of their combined gross domestic product (GDP). Ten years later, the figure was 5.8 percent, rising to 7.2 percent in 1980 (OECD 1987). Both the rate of increase, and the proportion of GDP devoted to health, differed among countries. Between 1960 and 1980, spending in the United States increased from 5.3 to 9.5 percent of GDP, rising to 10.7 percent by the mid-1980s, whereas the figures for the UK were 3.9 and 5.6 percent respectively, leveling out thereafter. From this flowed a widespread perception that spending on health was out of control, imposing damaging fiscal burdens on the economy and a consequent interest in mechanisms for halting, or at least slowing down, the seemingly inexorable rise.

The problem of ever-escalating costs could not be solved by invoking the usual market mechanisms and restraining demand by raising prices. Not only is health care financed predominantly through insurance schemes of various types; i.e., third parties rather than the consumers pay most of the costs. Equally, there is only limited scope for using co-payments or user charges to limit demand: the long-term effects on population health of deterring use may outweigh any short-term fiscal gains. Controlling the supply of health care thus seemed a more feasible and effective option, all the more so because of evidence that much of the demand for health care was generated by the system itself; i.e., was provider-driven. While it is consumers who make the initial contact with the health care system, it is the professionals who decide how they should be treated. And it is these decisions—about the number of tests to be carried out, the drugs to be prescribed and so on—which drive spending. Enter global budgeting.

Here the UK's National Health Service (NHS) was the paradigmatic case. Outside the communist bloc countries, the UK was the only health care system funded overwhelmingly by central government out of general taxation. In this it differed both from the tax-funded Scandinavian model, where both control and fiscal responsibility was divided between central and local government, and the social insurance based West European model, where responsibility was divided between central government and an often large number of insurance funds. In the UK, therefore, the Treasury controlled the fiscal tap, for both current and capital spending, to the health care system. Almost from the launch of the NHS in 1948, the system operated what in effect was a global budget; i.e., the Treasury set the limits of total spending for the next fiscal year. In turn, the UK's record suggested two conclusions. First, it appeared to demonstrate that global budgeting could restrain the rate of increase in health care expenditure: the UK continued, and continues, to be a restrained spender relative to other countries with a comparable national income. Second, it seemed to show that there was a direct relationship

between fiscal centralization and the successful operation of a global budget.

Both conclusions were borne out, if to a differing extent, as an ever higher proportion of countries adopted variations on the global budgeting theme in the 1980s and early 1990s as part of their strategies for cost containment. The rate of increase in health care expenditure, as a proportion of national incomes, did indeed slow down (Abel-Smith 1992, OECD 1992, 1994), and much of this could be attributed to the introduction of global budgeting. In all this, the USA was the most conspicuous exception; it did not introduce global budgeting and its spending on health care was almost 14 percent of GDP by the end of the 1990s (twice the UK figure). However, success did not necessarily correlate with fiscal centralization. Sweden not only halted, but reversed, the upward trend, even though its model of health care divides responsibility between central and local government: no doubt because the former carries by far the heavier fiscal clout. And the Netherlands, perhaps the most pluralistic variant on the European social insurance model, introduced global budgeting covering both the public and the private insurers (Maarse 1996) with the same set of fee schedules applying to both sectors.

This suggests that there are various mechanisms for achieving global budgeting—i.e., control of the supply side of health care—although the UK's single-payer model offers the most direct leverage. Without the simplicity of the UK model, these mechanisms vary with the nature of the reimbursement system used in different sectors of health care services and the political determination of governments to make their policies stick. In the case of the hospital sector, it proved relatively easy to impose global budgets (Glaser 1993). In the case of service payments for general practitioners or office-based specialists, controlling spending turned out to be less easy. Freezing the fee schedule tends to multiply activity as physicians safeguard their incomes by doing more. Here the strategy adopted was to impose a limit on the total amount to be paid out in fees, with retrospective downward adjustments of the payments to individual physicians if the total exceeds the target figure: Germany providing one such example, leaving responsibility for administering the pool to the medical profession (Schwartz and Busse 1996). And while the USA is a conspicuous failure in macro-terms, it has generated innovative models for microglobal budgeting; i.e., various forms of capitation payments to providers.

Systems also vary in the extent to which global budgets are underpinned by, or complementary to, other supply side measures. Some systems, such as that in the UK, control the production and distribution of the medical labor force. Most systems seek to control the number and distribution of hospitals and to exercise birth control over the diffusion of expensive new technologies. In the case of health care systems based on the social insurance model, govern-

ments can further buttress policy by regulating—in some instances freezing—the level of contributions charged by insurance funds, so controlling the flow of money into the system.

Global budgets have their pathologies as well as their advantages. By removing the incentive to maximize income by maximizing activity (possibly a desirable policy goal, since it also lessens the risk of overtreatment), global budgets for hospitals may also undermine the incentives to maximize efficiency (so leading to the undesirable policy outcome of queues for treatment). Hence Britain's brief experiment with a mimic market in the 1990s. This separated the purchaser and provider roles. Previously, health authorities had been responsible for managing hospitals and other services directly for the population within their geographical boundaries. Under the new system, they became responsible only for buying the necessary care from semi-autonomous agencies. Both before and after the changes, however, health authorities worked within budgets fixed by central government. The aim (never fully achieved) was to introduce an element of competition between providers—and thus provide incentives to greater efficiency—within the framework of a global budget for the NHS as a whole.

Some other issues also require noting. Global budgets for item-of-service payments raise awkward questions about the distribution of income between physicians: between those who maximize their activity and those within a fixed total who do not. Above all, global budgets tend to be associated with rationing: if the supply is limited, waiting lists may be the result. And while the phenomenon of rationing is far from exclusive to health care systems with global budgeting, it does raise questions about the adequacy of the budget level set.

2. Setting the Budget

The adoption of global budgets represents the pragmatic reaction of governments searching for policy instruments to restrain the growth of collective spending on health. A global budget for the health care system of a country is thus the byproduct of a government's decisions about priorities between expenditure on health and other programs competing for funds, between maintaining public services and cutting taxation. Its level reflects as much calculations of political feasibility—assumptions about how much spending can be restrained without provoking a political backlash from professional providers and the public—as calculations about what the appropriate level of spending on health should be. As such, it is an entirely atheoretical exercise. For no formula for determining a global budget, independent of the actual level of spending in different countries, has yet been devised: there are no agreed benchmarks against which the adequacy or otherwise of a given level of spending

can be assessed. Nor is it likely that such benchmarks can be devised, given the heterogeneity of the services produced under the 'health' label, the scope for substitution between them, and the productive factors involved and variations in productivity.

Global budgets are therefore best seen as history modified by politics, and often rationalized by appeals to demography. The inherited level of spending on health inevitably provides the baseline for setting global budgets. This is then modified in the light of factors either extrinsic to the health care system (usually the prospective capacity of the economy to produce extra wealth), or intrinsic to it (usually demography and the cost of technological innovation). The first strategy puts the emphasis on what a country can afford. The second puts the emphasis on what a country needs. Neither is as objective as it appears (Smee 1996). 'Affordability' is an elastic concept. And so is need. Even the most commonly used indicator of 'need,' the demographic structure of any given population, is problematic. For sure, people need more health care as they age. But projecting the cost of demographic change into the future assumes that patterns of both morbidity and service use will remain the same as in the past: a highly questionable assumption. And many of the same problems arise when it comes to apportioning global budgets, whether geographically or by health care sectors.

3. Dividing up the Budget

The issue of distributing global budgets geographically arises only in the case of health care systems—on the UK and Scandinavian models—where public agencies are responsible for delivering health care to a defined population. In these cases, the equity principle demands that resources should be distributed according to need. In the past, need was often equated with use: if use was high so, it was assumed, was need. But given increasing evidence that demand (or use) was strongly influenced by supply, emphasis has switched to devising other indicators. The demographic composition of the population provides, as noted above, the core of the various formulas that have been devised to allocate resources. Standardized Mortality Ratios are another. So is morbidity data, where available. Debate continues as to whether social deprivation is in itself a need indicator, over and above its contribution to the mortality and morbidity figures. In all this, need is, of course, a relative concept. That is, the various distributive formulas that have been developed purport to measure the needs of population A as against those of population B, not to measure the absolute level of provision that either requires.

In the case of the West European social insurance model of health care provision, the question of geographical distribution clearly does not arise. Re-

sponsibility for funding health care is divided between funds whose members—as often defined by occupation as by place of residence—do not necessarily live within the same geographical areas. However, some of the same distributional issues do arise. One frequent element in social insurance systems is a central pool of money which is then distributed to individual funds according to the risks that they carry. Designed to weaken the incentives of funds to discriminate against potential members who may—because they are older or sicker—require more expensive health care, risk compensation in turn means devising a formula for assessing relative need. This raises the same conceptual issues as devising a formula for distributing global budgets geographically and leads to many of the same solutions, notably heavy weighting for demographic factors.

Global budgets are, in most systems, also broken down by sectors for accounting and control purposes. Indeed, a national global budget may be the product of a step-by-step process of imposing expenditure limits on specific sectors; primary care, acute hospital care and so on. However, in this case there have not been—and probably cannot be, given the absence of a conceptual basis for such an exercise—any attempts to devise a formula for allocating funds between sectors. The sectoral distribution of global budgets, even more than the determination of their total, remains the product of history modified by incremental policy decisions.

Health in Developing Countries: Cultural Concerns

Human health and wellbeing worldwide are profoundly affected by complex interactions between economic, social, and political forces as well as by behavioral patterns and the application of technology (Wilkinson 1996). When considering health in countries around the world, use of the terms 'developed' and 'developing' countries implies a linearity of progress towards a condition that has been achieved by some countries but not others. It is clear that such a simplistic approach equating development with economic status in terms of average per capita gross national product (GNP) or the level of industrialization is both inaccurate and unhelpful. So-called developed countries may lack what many would consider very important aspects of development; for example, a sensitivity to the impact of consumption on ecology, or concern for the adverse effects of opulent and aggressive lifestyles on billions of people in other countries, or more obviously in relation to health, the achievement of universal access to health care. Similarly, some so-called developing countries are more developed than may be apparent from their economic status; for example in Kerala, India, the degree of social solidarity and health status achieved exceeds that expected from economic status alone—revealing the impact of human capital resources such as female literacy and empowerment.

A more sophisticated model of development (such as that used in the United Nations Human Development Report 1991) emphasizing achievements in health, education, female literacy, gender equality, and political liberty, more accurately reflects the real human development required. However, it should be acknowledged that even such development indices are incomplete, as they do not measure some important aspects of human flourishing. When comparing development and health in countries around the world, it is also necessary to appreciate that consumption patterns and the ways of life in industrialized countries

cannot become the norm for the whole world. For example, while the world's population has grown fivefold in the past 150 years, human consumption has increased 30-fold. The USA, with 5 percent of the world's population, accounts for 24 percent of annual global energy consumption compared to China with 20 percent of the world's population using 10 percent. Within health care, even a nation that spends \$4,000 per person per year on health care cannot afford to provide access for all citizens to all that modern medicine can offer (Iglehart 1999). Modern consumption patterns and health care practices are thus neither universalizable nor sustainable. Such considerations reveal the inadequacy of the terms 'developed' and 'developing' countries.

1. A Polarized World

While the twentieth century is considered by many to be the most successful in world history, with spectacular achievements in science, technology, and health care, the above considerations make it necessary to focus on the down side of progress—as reflected in widening disparities in economic and health status, the extent of expenditure on weapons of mass destruction, and the social construction of human rights abuses. Improvements in human health globally in the twenty-first century and achieving real development of all people throughout the world will be dependent on acknowledging such adverse features of modern life, and on developing new paradigms of thinking that will promote widespread human flourishing.

1.1 Economic Disparities

At the beginning of the twentieth century the wealthiest 20 percent of the world's population were nine times richer than the poorest 20 percent. This ratio has grown progressively—to 30 times by 1960, 60 times by 1990, and to over 70 times by 1997. The extent of absolute poverty has also increased. Today almost half the world's population lives on less than US\$2 per person per day and more than a billion people live on less than US\$1 per day. Tens of millions of people, including many children, die every year of starvation—in a world with enough food to feed all.

1.2 Disparities in Health and Disease

At the end of the twentieth century patterns of diseases and of longevity also differ markedly across the world. Of the approximately 52 million people who die each year, 17.5 million die of infectious and parasitic diseases (16 million of these—many in their youth—in

Table 1

Causes of death in 1997 by main causes and by level of development (The World Health Report 1997)

	Developed world (12 million deaths)	Developing world (45 million deaths)	World
Infectious and parasitic diseases	1 percent	43 percent	33 percent
Perinatal and maternal causes	1 percent	10 percent	8 percent
Cancers	21 percent	9 percent	12 percent
Diseases of the circulatory system	46 percent	24 percent	29 percent
Diseases of the respiratory system	8 percent	5 percent	6 percent
Other and unknown causes	23 percent	9 percent	12 percent

the developing world), 10 million die of diseases of the circulatory system (4.5 million of these in the developing world), and 6 million die of malignant diseases (3.5 million of these in the developing world) (see Table 1).

Among the poorest quintile of people in the world, 55 percent die of communicable diseases, as compared with 5 percent of the richest. The World Health Organization (WHO) estimated that in 1998, 11 million children and adults of working age died of six infectious diseases that could have been prevented at the cost of US\$20 per life saved. Poor countries bear over 80 percent of the global burden of disease in disability adjusted life years (DALYs). This burden is likely to increase as the epidemiological transition progresses, with added disability and suffering from noncommunicable causes of disability such as vascular disease, malignant neoplasms (especially of the lung associated with smoking), neuropsychiatric disease, accidents, and trauma.

Life expectancy at birth ranges from well over 70 years in highly industrialized countries to below 50 years in many poor countries. Wide disparities in life expectancy are also observed between rich and poor in rich countries. In sub-Saharan Africa gains in longevity achieved during the first half of the twentieth century are rapidly being reversed by the HIV/AIDS pandemic.

1.3 Mental Health

Improvements in physical health over the past 50 years have not been matched by improvements in mental health—even in developed countries. Mental illness accounts for 8 percent of the global burden of disease (measured in DALYs), and a further 34 percent of the global burden of disease is accounted for by behavior related problems such as violence, diarrhoeal diseases, AIDS and other sexually transmitted diseases, and

motor vehicle accidents and other nonintentional injuries (Desjarlais et al. 1995). The inadequacy of the knowledge base about mental disease (compiled almost exclusively in North America and Europe) to explain psychiatric diseases in other parts of the world poses formidable challenges for progress.

1.4 Militarization and the Social Construction of Human Rights Abuses

Industrialized countries spend on average 5.3 percent of GNP on the military but only 0.3 percent on economic aid to developing countries (Sivard 1996). The arms trade and its link to economic aid has contributed significantly to the escalating number of wars, conflict, and widespread torture since the Second World War which have rendered over 25 million people to refugee status and displacement—with profound disruptive effects on life and health. Global military expenditure in 1990 amounted to US\$1 trillion (Sivard 1996). The annual budget of the WHO is equivalent to 2.5 hours of global military expenditure. While money is always available to make war, it is less readily available to promote peace. Military expenditure has decreased in recent years, but released resources have not been channeled towards effective human development processes.

2. Relationship Between Economics and Health

It is now well established that there is a definite relationship between wealth/poverty and health/disease, although this relationship is complex and not linear. For example, one of the wealthiest nations in the world (the USA) has worse health statistics (infant mortality and longevity) than some other highly industrialized countries, and a particularly poor state

Figure 1

Distribution of economic resources (top bar), the burden of HIV/AIDS (middle bar) and world population (lower bar) in the world

Table 2

Health and other statistics in the 40 poorest countries in the world (WHO 1995)

Annual per capita GNP (US\$) ^a	168	282	404	570
Life expectancy at birth (years) ^a	47	51	56	60
Infant mortality rate per 1,000 live births ^a	126	112	90	70
Under 5 year mortality rate	158	169	132	109
Population access to safe water ^a	37%	53%	53%	63%
Population access to sanitation ^a	29%	26%	39%	48%
Population per physician (1970)	33,925	39,381	23,009	15,956

Average annual population growth ^a	2.7%	2.8%	2.6%	2.3%

^a 1991 data.

(Kerala) in India has achieved lower infant mortality rates and greater longevity than many wealthier nations (Wilkinson 1996). Both absolute and relative wealth affect health. Among the developed countries it is not the richest societies that have the best health, but rather those with the smallest income differentials between rich and poor (Wilkinson 1996). Despite the nonlinearity of the relationship between wealth and health, its existence underscores the need to see health and disease as intimately linked to social and economic conditions (Fig. 1).

Poverty (defined as lack of economic resources, lack of education, lack of access to basic life resources such as food water and sanitation, and lack of control over

the reproductive process) directly accounts for almost one-third of the global burden of disease. Poverty leads to poor health, which in turn aggravates poverty. Of the 40 poorest countries in the world, 11 have annual per capita GNPs ranging from US\$80 (Mozambique) to US\$210 (Sierra Leone), 10 from US\$220 (Bangladesh) to US\$340 (Nigeria), 9 from US\$370 (China) to US\$450 (Nicaragua), and 10 from US\$500 (Sri Lanka) to US\$600 (Zimbabwe) (WHO 1995). The relationship between income and some health indicators for these groups are shown in Table 2. Despite the difficulty in making accurate intercountry comparisons, it is clear that improvements in economic status are associated with better health statistics, and that

economic growth is necessary to improve the living conditions conducive to good health, independent of benefits that may arise directly from health care.

3. Health Care Expenditure

Since the 1960s, major advances in medicine and technology have been associated with escalating expenditure on their application in health care—most of this in highly industrialized countries. Annual per capita expenditure on health care ranges from \$4,000 in the US to less than \$5 in the poorest countries in Africa. Half the world's population lives in countries that cannot afford annual per capita health expenditures of more than \$5–10, and many people do not have access to even basic drugs. The WHO has estimated that in 1990 the annual cost of providing a basic package of public health and essential clinical services in a low-income country was at least \$12. In most such countries health care expenditure is typically less than \$6. Even though some parasitic diseases (for example, onchocerciasis, schistosomiasis, and lymphatic filariasis) could be controlled by mass treatment campaigns using inexpensive drugs, the infrastructure required to provide such coverage is inadequate. Effective treatment of diseases such as tuberculosis and leprosy, and HIV/AIDS requires more complex infrastructures than can be afforded on current health care budgets in poor countries.

In the 1990s, 89 percent of annual world expenditure on health care was spent on 16 percent of the world's population who bear 7 percent of the global burden of disease (in DALYs) and less than 10 percent of medical research expenditure was on health problems of the developing world. These are examples of global injustice that we should surely find intolerable if we have a real commitment to universal human rights and human dignity. Vaccine development programs and drug donation programs for poor countries, admirably promoted and supported by pharmaceutical companies, are necessary but insufficient responses to such injustices. Modest increments in economic status combined with a provision of a basic health care package have the potential to improve health in poor countries significantly. However, it should be noted that health is not merely a resource issue even in rich countries—as exemplified by comparative health statistics around the world (Wilkinson 1996).

4. The Global Political Economy and Health

The world at the end of the twentieth century is thus characterized by widening disparities in economic and health status (within and between countries), and by suffering, conflict, and alienation associated with pervasive social forces (Wilkinson 1996, Sivard 1996,

Benatar 1998). Erosion of the economy of many poor countries, under the impact of globalization and the 'debt trade,' has obstructed the introduction of effective forms of modern medicine into many poor countries and thus prevented achievement of widespread access to even basic health care for billions of people (Falk 1999). Third world debt requires special mention. The ways in which such debt have been created, the fact that third world debt is a small component of total world debt and can never be repaid, and that in sub-Saharan Africa four times as much is spent on debt repayment each year than on health and education combined, makes insistence on repayment unconscionable (Pettifor 1996).

The emergence of new diseases such as AIDS, that afflict predominantly those marginalized by poverty (80 percent of HIV-positive persons live in the poorest countries in the world), has been attributed to the social and environmental niches created by the nature of the global political economy and its ideology (Lee and Zwi 1996). Failure to appreciate such associations will result not only in failure to control such diseases as HIV/AIDS (as with tuberculosis in the past, Benatar 1995), but more importantly, will probably favor the emergence of new infectious diseases in the future. The changing spatial dimensions of human relations resulting from urbanization, migration, travel, ethnic conflict, and displacement of people and refugees, facilitates the spread of such diseases from which no one should feel immune.

5. Access to Health Care, and the Nature of Health Care Systems

Today many countries consider access to at least a minimum package of health care as a basic human right that nation-states should be committed to providing for their citizens. Some form of socialized and equitable health care is provided in all Western European nations and in Canada.

Medical care, delivered as a marketable commodity—albeit with considerable state assistance for the poor and the aged—is the example that has been set by one of the wealthiest nations in the world. However, this results in many citizens having inadequate access to health care. In considering how to overcome this, while recognizing that private/public alliances cannot be avoided and indeed may be beneficial, Buchanan has provided cogent arguments for the nine elements he considers essential for a just health care system. He argues further that achieving a just health care system as a cooperative between the public and private sectors requires an organization, such as the state, to act as a coordinator and guarantor of equitable access to care and fair distribution of costs. Such a balance between private and public medicine with appropriate coordination could over-

come the deficiencies of either system when one dominates (Buchanan 1995; see also Benatar 1996).

The effects of intensive privatization, aided and abetted by the structural adjustment programs promoted by the International Monetary Fund (IMF) and the World Bank, have been much more marked in poor countries, with severe adverse effects on health. Acknowledging the need for, and the right to, universal access to a basic health care package and achieving this goal pose challenges for the future. The WHO's renewal strategy for health-for-all places emphasis on equity, solidarity, and appropriate technical, political, and economic strategies that could promote health and sustainable health care systems as central to development. Here too an appropriate balance needs to be struck between public and privately funded medicine. How this balance can be struck and how health can be coordinated within an effective strategic alliance between many parties remain hotly debated subjects.

6. Traditional Healers

Despite the pervasiveness of Western influences, traditional healers have survived and play an increasing role in some countries. For example, while there are about 25,000 Western trained medical practitioners in South Africa, and Western medicine has a powerful foothold in this middle-income country, over 200,000 traditional healers carry out a thriving trade. Increasing contact and collaboration between Western medicine and traditional healers is being encouraged and the potential impact of their contributions to health, in particular through development of a primary health care approach, in many countries in Africa in the future should not be underestimated (Van Rensburg and Benatar 2000).

7. Prospects for the Future

As we stand at the threshold of a new era in which exponential increments in genetic information will be applied to medical practice, we need to contemplate whether such new power will be used for the benefit of all humankind or whether it will be reserved for the privileged. Acquiring a deeper understanding of the forces promoting health and diseases in developing countries needs to be coupled to a commitment to address these if health and human flourishing are to be achieved on a wider scale (Benatar 1999).

Health Insurance: Economic and Risk Aspects

Over the course of a year, individuals are at risk for a variety of unfortunate and unpredictable events, e.g., property damage due to fire or hurricane, property loss due to burglary, or physical and mental pain and suffering due to adverse health events. In most cases, affected individuals can purchase goods or services to replace the loss or to alleviate the adverse effects of an untoward event. In some cases, it is possible to reduce the probability that an adverse event will occur. In many instances, through the purchase of insurance, it is also possible to reduce financial loss associated with an adverse event. In general, people dislike risk and are willing to trade a small amount of money, in the form of an insurance premium, for protection against a potentially large loss in income. (Depending on what kind of health insurance system, particularly whether it is a private or public system, the payment can be

either a private insurance premium paid out of pocket or through a reduction in wages or a public premium in the form of taxes. For simplicity, we will refer to the payment as a premium. Similarly, the bearer of risk under insurance can be a private company or a public governmental body. We will refer to the bearer of risk as the insurer.)

This entry outlines the basic economic models of health insurance, emphasizing the relationship between risk and insurance demand. It also discusses the distortions in the market for health care services created by health insurance.

1. Risk and the Demand For Insurance

The relationship between risk and insurance demand is derived from the relationship between utility and wealth (for additional discussion see Arrow 1963). Utility is a function of wealth, with more wealth leading to higher levels of utility or satisfaction. Although utility rises with wealth, it is generally assumed to do so at a decreasing rate. This property is called diminishing marginal utility. Each incremental increase in wealth provides a smaller incremental increase in utility. It therefore follows that the gain in utility associated with any incremental gain in wealth is less than the loss in utility associated with an equivalent loss of wealth.

The property of diminishing marginal utility implies individuals are *risk averse*. That is, individuals would prefer to have any level of wealth with certainty than a gamble providing the same level of wealth on average. For example, a risk averse individual would prefer \$100 dollars with certainty as opposed to a gamble with a 50 percent chance of winning \$200 and a 50 percent chance of winning \$0. Risk aversion is an inherent property of a concave utility function. Because risk averse individuals prefer certainty, the premium they are willing to pay for an insurance policy that removes risk exceeds the actuarially fair premium (AFP) of the insurance, which is the amount that the insurer would have to pay out, on average, for this policy. The gap between the premium individuals are willing to pay and the AFP is termed the *risk premium* (Phelps 1997).

The risk premium allows insurers to cover expenses above the medical payout, e.g., claims processing. Several factors determine the size of the risk premium an individual will be willing to pay. First, risk aversion is likely to vary with wealth. For very different reasons, both individuals with very high and those with very low levels of wealth are less willing to pay a risk premium (Feldstein 1999). The marginal disutility of an incremental decrease in wealth falls at high levels of wealth, reducing any utility gain to avoiding risk. In contrast, the marginal disutility becomes very large at very low levels of wealth, making the opportunity cost of purchasing insurance too high.

Figure 1
Expected utility and risk

Second, the probability of a loss will influence the size of the risk premium. As the probability of the loss approaches 1, the willingness to pay for insurance rises, but more slowly than the increase in the AFP for that individual. Thus the risk premium falls. In the extreme case, when the probability of a loss equals 1, the risk premium goes to zero. In this case, there is no risk and individuals would not be willing to pay any risk premium. Similarly as the probability of a loss goes to zero, both the willingness to pay and AFP fall, but the willingness to pay falls faster and eventually the risk premium equals zero. Individuals would not pay for insurance if the probability of a loss equaled zero.

Third, the magnitude of the loss affects the risk premium individuals are willing to pay. A greater loss represents an increase in the variance of income. An individual will be willing to pay a higher risk premium for a higher cost illness.

The utility curve depicted in Fig. 1 can be used to analyze the demand for insurance described above. Throughout the analysis we assume individuals know the probability they will suffer a loss (or benefit from a gain). Because greater wealth leads to higher utility, the utility at point C, $U(C)$, is greater than the utility at points A or B. Diminishing marginal utility implies that if point B is equidistant from points A and C, the utility gained from moving from B to C is less than the utility lost from moving from B to A.

Consider an individual at wealth B evaluating a gamble with outcomes A and C, each of which has a 50 percent probability of occurring (e.g., tossing a fair coin). If point B is equidistant from points A and C, the expected wealth resulting from the gamble, i.e., where *on average* the individual could expect to be if tossing the coin, is the initial level of wealth, B. The expected utility of such a gamble, $EU(\text{gamble})$, is the probability weighted sum of the two outcomes A and C and, because each outcome has a 50 percent chance of occurring, can be determined by finding the midpoint on the chord connecting A and C. Because the utility curve is concave, even though the initial level of

wealth is the same as the expected wealth of the gamble, the utility of B, $U(B)$, will exceed the expected utility of the gamble, $EU(\text{gamble})$. This utility gain of avoiding risk is key to the demand for insurance.

Models of health insurance fit exactly into this model. For simplicity, assume a world in which there is only one type of adverse health event and spending in the unhealthy state is unaffected by the presence of insurance. Individuals are assumed to start with wealth level C and remain there if healthy during the year. If they suffer an illness shock, they will then spend $C - A$ on health care services. Assuming the probability of a loss is 50 percent, the expected loss is $C - B$. Expected wealth, under uncertainty, is B. Without insurance the individual would have expected utility of $EU(\text{gamble})$.

Now imagine individuals could purchase an insurance contract that would pay the costs of medical care in the event of an illness. With a 50 percent chance of each individual incurring the loss, the expected cost to the insurer of each enrollee is $C - B$. The AFP therefore is $C - B$. If individuals pay the AFP, their wealth level is B, regardless of whether the illness occurs. In other words, the risk of financial loss has been eliminated. The individual has turned a potentially large loss in income into a smaller known loss of income (in the form of the AFP). In this situation, the utility would be $U(B)$ because the income level B is achieved with certainty. As is clear from the figure, the individual prefers to purchase insurance relative to self-insuring. The amount of the utility gain is equal to the vertical distance between $U(B)$ and $EU(\text{gamble})$. The greater the concavity of the utility curve, the greater the risk aversion and the greater the utility gain from insurance.

The utility curve depicted in Fig. 1 also can be used to assess the amount that an individual would be willing to pay for insurance. Utility of a wealth level of x, with certainty, is equivalent to the expected utility of remaining uninsured (facing the risk of having a loss that leaves them at wealth level A). Thus an individual would be indifferent between being uninsured or paying a premium of $C - x$ for insurance. This premium is their maximum willingness to pay for insurance (WTP), with $C - B$ the AFP and $B - x$ the risk premium.

2. Moral Hazard

Up until now, the magnitude of the loss associated with an illness was not affected by the presence of insurance coverage for the desired medical care services. Substantial theoretical and empirical work suggests that this is not the case (Pauly 1968, Manning et al. 1987, Newhouse 1992). Specifically, because health insurance lowers the price of medical care services faced by the consumer at the time of purchase, individuals will often consume more care than they would if they paid the full price. The providers of this

Figure 2
Welfare loss and moral hazard

care are paid the full price, however, receiving out of pocket payments from the patient and reimbursement from the insurer.

The consequences of this behavior, known as moral hazard, depend in part on the difference between the cost of the care and the value individuals place on that care. Because individuals do not demand this same level of care without insurance, standard economic models assume that the value they place on the care is less than the full cost of that care. If this is true, insurance causes a loss in consumer welfare because of the insurance-induced increase in consumption, whose costs are passed back to the consumer in the form of higher insurance premiums. The welfare loss is thus incurred by the enrollee at the time the insurance premium is paid, not when care is received. This welfare loss accrues even if, as is the case in most complex insurance markets, the individual is not purchasing health insurance directly and may in fact not be aware of the welfare loss. In aggregate, adjusting for transfers between individuals, the amount paid through premiums exceeds the value of care financed by the insurance.

This analysis is depicted graphically in Fig. 2. The demand curve tells us how much medical care will be demanded for any given price. For example, assume the price of care, as paid to the provider of care, is denoted P^p . In this case, uninsured individuals would purchase q^* units of care. If insurance lowered the individual's out of pocket price to P^c , insured individuals would then consume q^{**} units of care.

The demand curve is taken as the measure of value because it also represents the maximum amount an individual would be willing to pay for any given quantity of care. For example the maximum amount an individual would pay for q^* is P^p . The overall value placed on all care up to any quantity is the area under the demand curve up to that point. For an uninsured individual, the value of care consumed would be the area under the demand curve up to q^* (ABq^*0). For

an insured individual, it would be represented by ACq^{**0} .

The total cost of care, paid by the individual and insurer, is the price paid to the provider times the quantity of services provided. In the case of an uninsured individual, it would be P^0 times q^* (P^0Bq^{*0}). Notice that the value of care to the consumer exceeds the costs of the care by the portion of the area under the demand curve not included in the box (P^0AB). This net value to the consumer is termed consumer surplus (CS).

If the individual purchases insurance and then increases consumption, the total cost of care increases to P^0Dq^{**0} . Notice the incremental cost of the care purchased, BDq^{**q^*} , exceeds the incremental value to the consumer, BCq^{**q^*} . The amount by which the incremental cost exceeds the incremental value represents the welfare loss (WL) of insurance and is represented by the triangle BDC.

At the time that care is consumed, the individual only pays a price of P^c , so the out of pocket cost is P^cCq^{**0} . The actuarial cost of the care to the insurer, however, is P^0DCP^c . It is this cost, not the out of pocket cost, that determines the AFP. As noted above, the welfare loss is thus incurred at the time of insurance purchase. If the demand curve were inelastic, that is, if the level of consumption were not very responsive to changes in price, the welfare loss would be relatively small. Consumers, if aware of the welfare loss, would prefer to consume less in exchange for an appropriately lower premium, particularly in cases in which the welfare loss is large (elastic demand).

There are three important assumptions that would affect the size of the welfare loss. First, the analysis assumes that individuals other than the patient receiving the care do not receive positive utility from that consumption. If this positive externality exists, the welfare loss is reduced. Second, the analysis assumes that the price paid to providers is equal to marginal cost (as would be the case if it were set in a competitive market). If the price were set in an imperfectly competitive market, so that it exceeded marginal cost, the welfare loss from a societal perspective would be diminished. Third, the preceding analysis assumes that income effects associated with paying the premium and the transfer of income from healthy to sick individuals have only small effects on the consumption of medical care. Nyman and Maude-Griffin (2001) suggests that if these effects are large, the welfare loss is considerably reduced.

Many different approaches might be taken to minimize the welfare loss associated with insurance. For example, increasing consumer cost-sharing for medical care services would reduce utilization but has the disadvantage of increasing the size of the financial risk faced by the consumer. Increasing provider cost-sharing through a variety of financial incentive systems would reduce utilization, but has the potential disadvantage of too little care being prescribed. Private

regulatory mechanisms, such as utilization review, can be implemented to constrain both where and what kinds of covered treatments an individual can receive. Managed care plans in the United States have been using these and other approaches to restrain use. In some cases, plans select providers whose preferred practice style leads to lower levels of utilization, particularly of higher cost alternatives. Some plans also educate both enrollees and providers to keep utilization below that which would otherwise occur. The extent to which various strategies are used will depend on the extent to which plans are in competition with other plans and the preferences of purchasers.

Nationalized systems can use similar strategies, limiting the resources available to provide care or providing financial and nonfinancial incentives to both providers and consumers to keep utilization at lower levels. Nationalized systems may also use their bargaining power to obtain favorable prices for medical care services.

3. Insurable Hazards

Given the analysis above, the theory of insurance would make several predictions regarding for which types of risks individuals would likely seek insurance coverage. First, they would seek insurance for services to treat events for which the probability of occurring is neither zero nor one. In other words, individuals would not want to buy insurance for protection against events for which they are not at risk, either because they know they will seek these services or because they know that they are at minimal risk of needing those services. Theory would predict that events with intermediate probabilities, that is, services with high-risk premiums, would generate the most demand. Thus the model would predict that most individuals would not purchase insurance to cover preventive services. The use of preventive services is not stochastic; that is, individuals know the probability of using these services in advance. Second, services that are costly would also have high risk premiums and would be attractive to insure. Third, individuals would not seek coverage for services for which demand is very elastic because such insurance would generate substantial welfare loss.

4. Adverse Selection

The preceding discussion was based on the utility curve for a single individual. To move the analysis to the market level, one must consider the behavior of many individuals, each with their own utility curve, initial wealth, and risk. Some individuals will be relatively low risk with low AFPs and others will be higher risk with high AFPs. Most models assume that individuals have more information about the risk that

they face than do the insurers. If an insurer were to base the premium it charged to a defined group of individuals on the estimated average AFP of all these individuals plus some mark-up, there would be some whose WTP was below the premium and others whose WTP was above the premium. If insurance purchase were voluntary, the individuals whose WTP was below the premium would opt not to purchase coverage, leaving a smaller pool of higher risk buyers. The average AFP for those remaining in the pool would rise. Of course as the AFP rose, the insurer would need to raise the premium in the next cycle. Some of the individuals who had remained in the first cycle would find the new premium above their WTP and would also opt out of buying coverage. This nonrandom selection out of the pool would result in an increase in the average AFP for the decreasing number of ever-higher risk individuals still interested in insurance.

Several papers outline scenarios in which insurance markets may collapse due to adverse selection (Akerlof 1970, Rothschild and Stiglitz 1976, Cutler and Reber 1998). In their seminal work, Rothschild and Stiglitz (1976) demonstrate that the set of policies that will be offered in the market is constrained by the ability of insurers to enter the market with new policies. This situation arises because insurers cannot perfectly ascertain the characteristics of the individuals they enroll. Certain policies cannot be offered in equilibrium because new insurers could enter the market and attract the lowest cost enrollees, leaving incumbent insurers with the higher cost enrollees, whose premiums do not cover their expected losses. In this environment, if an equilibrium does exist, it will be a separating equilibrium characterized by high risk individuals purchasing their most preferred actuarially fair policy and low risk individuals purchasing an insurance policy inferior to their most preferred actuarially fair policy, which will not be offered. Equilibrium is more likely to exist when there is a relatively large number of high-risk individuals and when the variation in risks is great.

Subsequent work indicates that the constraint on the set of policies offered depends on the equilibrium concept employed. Specifically, alternative equilibrium concepts can give rise to pooling equilibria (Wilson 1977) or even equilibria in which insurers may use profits on one product to subsidize losses on another (Spence 1978). All of the work in this area emphasizes the point that free entry into a market with asymmetric information limits the set of policies available because of adverse selection. Feldman et al. (1998) demonstrate that compulsory partial coverage may improve consumer welfare relative to a competitive equilibrium or compulsory comprehensive coverage.

Nationalized systems of insurance can reduce or eliminate adverse selection, depending on the degree to which coverage is compulsory and competition occurs within the system. Typically this would benefit

those with the highest expected expenditure, at the expense of those with less expected expenditures. The benefits of reducing adverse selection must be weighed against reductions in the ability of individuals to select their most preferred benefit design.

5. Empirical Evidence

5.1 Magnitude of Moral Hazard

The magnitude of moral hazard associated with the purchase of health insurance depends directly on the elasticity of the demand for medical care, i.e., how responsive consumers are to changes in the price. Manning et al. (1987) report estimates from a randomized trial indicating that the overall elasticity of medical care is -0.17 , that is, a 0.17 percent increase in utilization occurs for every 1 percent decrease in price. Demand for hospital services was estimated to be the least elastic (-0.14) and demand for well visits was estimated to be the most elastic (-0.43). These estimates are broadly consistent with other estimates derived from non-randomized settings (Feldstein 1999).

Estimated elasticities for other services tend to be somewhat higher than those for hospital and physician services. For example, elasticity of demand for pharmaceuticals has been estimated at about -0.40 (Smith and Garner 1974). Demand elasticity for nursing home care has been estimated at -0.76 (Lamberton et al. 1986).

5.2 The Demand for Insurance

The theory outlined above suggests that insurance demand is likely to be greatest for services with a high expected expenditure. In general, the evidence is consistent with the theory: services with a large estimated loss were more likely to be covered with insurance (Feldstein 1999). In addition, we would expect insurance demand to be greatest for services with highly inelastic demand. Again, evidence is consistent with theory. That is, the less price responsive the demand for the services, and therefore the smaller the moral hazard and associated welfare loss, the higher the level of insurance coverage (Phelps 1997).

Taken together, these factors explain much of the variation in service coverage witnessed among working adults in the U.S. For example, 76 percent of all employees participate in the medical care benefit offered by their employer, whereas only 59 percent participate in the dental care benefit, and 26 percent in the vision care benefit (USDOL, BLS, p. 6). Of those participating in the medical care benefit, 100 percent have coverage for hospital room and board, inpatient surgery, and inpatient physician visits; 85 percent have

coverage for home health care, 60–66 percent for well-baby care, physical exams, and hospice care, 52 percent for immunization and inoculation, and only 35 percent for hearing care (same source, p. 48).

Although measuring risk aversion is difficult, Barsky et al. (1997) used survey responses from the Health and Retirement Study regarding a respondent's willingness to take a new job with uncertain earnings to classify individuals based on their degree of risk aversion. They then related this measure of risk aversion to a variety of behaviors, including the purchase of health insurance. Stratifying by employment status (self-employed, employed, and not employed), they find that within each strata, the more risk averse respondents are more likely to purchase insurance.

5.3 Adverse Selection

Considerable evidence suggests that when given a choice individuals make health plan decisions based on their anticipated medical expenditures, thus generating nonrandom and, from the insurer's perspective, adverse selection. Much of the literature examines enrollment patterns when individuals face multiple insurance options that vary in terms of generosity. Even though a variety of data sources and methods have been used to investigate the self-selection into a range of plan options, the evidence suggests that adverse selection is quantitatively large (Cutler and Zeckhauser 2000).

6. Conclusions

Health insurance provides value to individuals by reducing the risk of a large financial loss associated with an adverse health event. This allows individuals to obtain medical care that they otherwise might not be able to afford. The payment from the insurer serves as a transfer of income to individuals who become ill.

However, if left unchecked, health insurance markets generate two deleterious effects. First, by lowering the patient's cost of consuming medical care, insurance leads to an increase in utilization (moral hazard). This increased consumption results in welfare loss. Second, insurance markets have a tendency to be unstable because of adverse selection. In the extreme, non-random selection could cause insurance markets to unravel, leaving some or all individuals uncovered and distorting the set of plans offered in the market.

Most health insurance systems, whether private or public, incorporate a variety of strategies to limit the welfare loss from the overconsumption of medical care and the effects of adverse selection. Inherently these strategies involve restrictions on individual behaviors.

The challenge in most systems is to mitigate the unwanted consequences of insurance as much as possible while still accomplishing the fundamental goal of reducing risk.

Health Interventions: Community-based

This article considers theories and methods underlying successful community-based health interventions, emphasizing four exemplars. Three exemplars relied heavily on modern means of mass communication and social marketing, relatively low-cost approaches with the potential to reach and change lifestyle behaviors of entire populations, in contrast to traditional individual or group counseling. One exemplar, studying alcohol-involved trauma, used community organizing for adherence to existing laws, rather than public education for behavior change. The article also describes barriers to change and lessons learned for future extensions of such endeavors.

By definition a community-based program is organized locally, achieving its goals through the community's institutions and communication networks. A community here is defined as a residential area with legally defined geographic boundaries, where a governmental system regulates certain local aspects of schools, businesses, transportation, policing, and recreational activities. A community is ordinarily last in a nation's regulatory chain, where education must ultimately occur, although for rural areas the *county* becomes the governing agent for education.

The relevance and intellectual context of community-based health education are addressed through these questions. (a) What is the rationale for community-wide interventions rather than in more limited locales, such as clinics, hospitals, work sites, or schools? (b) What theories, methods, and resources underlie success? (c) How does a community become committed to a novel health education campaign? (d) How can barriers to success be overcome in such interventions? (e) What roles do community activism, laws, and regulations play? (f) What is the future of community-based health education?

1. Rationale

Health education in schools, work sites, and clinics have a long history of individual success, but synergistic interactive effects can occur when they are imbedded in a total community campaign that adds inherently cost-effective mass media and environmental change (Schooler et al. 1997). Lifestyle changes, so powerfully influenced by custom and by the media in developed countries, cannot be countered effectively through simple means. Community-wide approaches fit the public health model because the traditional medical model can neither prevent most chronic

disease nor reach the entire population in need. The community provides influence through locally produced electronic and print mass media and through work sites, schools, medical and hospital settings, and social gatherings of many sorts. It offers opportunities for health-promoting regulations, such as providing opportunities for physical activity for all, school fitness classes, healthful school lunches, alcohol sales limits, and preventing tobacco product marketing to children (see *Health Promotion in Schools*).

Studies at the Stanford Center for Research in Disease Prevention (SCRDP) have shown that only multiple influences produce meaningful changes in the dietary, exercise, or tobacco-use behavior of adults, adolescents, and children. For adolescents, always resistant to health behavior change, the following influenced success: parent and teacher roles; school environments; amount and quality of school-based education on tobacco, fitness, and nutrition; peer influence; and amount and quality of community-wide health education. (Also, certain personal characteristics were influential, for example, self-efficacy toward one's behavior-change abilities; Fortmann et al. 1995.)

2. Theoretical Formulations

Community-based health education carried out by SCRDP and by some analogous projects have been guided by three major theoretical and management models (Flora et al. 1989).

(a) The community organization framework provides methods of identifying the health problem (and resources needed or available), mobilizing the community's opinion leaders and organizations, gaining populace support, forming coalitions, launching and maintaining education programs, achieving regulatory changes, and empowering communities to reach and maintain their goals.

(b) Social marketing provides methods of designing and sequencing messages for population subgroups based on their health needs, cultural attributes, social networks, media habits, and readiness for change.

(c) The mass communication-behavior change model describes theories underlying educational content, such as social cognitive theory (Bandura 1986) and methods of reaching and influencing the total population in multiple ways (see *Self-efficacy and Health*).

3. Intervention Principles, Methods, and Resources Needed for Success

3.1 Acceptance

Both relevant organizations and political and opinion leaders must be recruited into a coalition that sanctions any novel health education project. This

coalition must identify the health problem (needs assessment), provide a resource inventory, obtain populace support, and plan the intervention.

3.2 Comprehensive

Interventions must go beyond attempting to change knowledge, the usual goal of an educational system, by providing training in behavior-change skills. They must also go well beyond the individual, enlisting multiple community organizations in campaigns for change and seeking changes in the social environment and in regulations that promote access to the facilities and resources needed for healthful practices. Multiple communication channels (i.e., both mediated and face-to-face) are needed to reach different audiences, recognizing their preferences, stage of knowledge, and readiness for change.

A comprehensive intervention should involve schools, work sites, churches, and facilities for sport, recreation, and health. These organizations and others can serve as education conduits, with the community's electronic and print mass media organizations assisting in message design and delivery. The Internet provides a new channel, whose community education role is as yet poorly defined. Interactive computer learning, now becoming common in classrooms, can be designed for large groups—an emerging variant of mass media.

3.3 Variety

Comprehensiveness requires variety. For example, in tobacco control components of Stanford's CVD campaigns, local medical clinics, dental offices, pharmacies, and libraries distributed a low-cost skills-training Quit Kit; a local smoking cessation class, was shown on television; many newspaper articles and columns appeared; a local business supported costs of a smoking cessation contest; and all newspapers and electronic media 'cross-advertised' activities designed for mass audiences.

3.4 Integration

Success requires an appropriate mix and sequence of programs delivered through varied channels. This integration, with goals set in advance and goal changes based on early results, is analogous to a commercial marketing campaign, hence the term 'social marketing.'

3.5 Message Design and Audience Segmentation

Social marketing requires message tailoring to fit each subgroup's needs and preferences, taking into con-

sideration cultural differences, learning styles, and preferred learning sites. A message sequence should increase awareness, then, increase knowledge, and last, increase motivation and provide training in the skills needed for adoption and maintenance of a new behavior (Bandura 1986). Electronic media can carry out the first two parts of this sequence and stimulate use of the more information-dense print media of newspapers and booklets, which are inherently more effective in skills training than are electronic media (Flora et al. 1997).

Messages must be clear, focused, and salient. Salience requires broad reaching media, arousing interest and awareness—topics must break through passive indifference engendered by the information overload of many societies and become 'on the public agenda.' Given the large advertising budgets of today's mass media, health agencies' messages must be of sufficient production quality to compete for the public's attention.

3.6 The Message Must be Effective

Behavioral research confirms the rather self-evident rule that 'learning by doing' is more effective than 'learning from observing' (modeling a behavior), and both are more effective than an 'information-only' approach that changes knowledge alone. These principles are contained in Bandura's social cognitive theory, which posits that guided practice in a new behavior can lead to increased self-efficacy and to greater behavior change (Bandura 1986). Thus, 'knowledge-only' campaigns have been found less effective than those that apply Bandura's recommendations (see *Self-efficacy and Health*).

3.7 Intervention Dose

The dose needed depends on many factors: lesser amounts are needed in smaller communities, at earlier stages in a country's adoption of a 'health innovation,' and when the advocated behavior change is reasonably simple (such as mammography and hypertension screening and immunization campaigns). Clearly, more complex changes are needed in individuals and in society's norms to alter eating or exercise patterns or to control tobacco use. Complexity in respect to nutrition arises from many sources, including longstanding cultural beliefs and practices; entrenched methods in agriculture, food production, and retailing; advertising of 'unhealthful' foods; and the advent of widespread fast-food chains that are dominated by commercial interests unresponsive to local demands and needs.

Few projects have measured intervention dose. One excellent method records the total number and duration of messages distributed over a defined time period, albeit with a defect due to lack of message

quality measures (Farquhar et al. 1990). However, even this rough method, were it widely adopted, would be of great value to public health practitioners.

3.8 Role of Activism and Advocacy

Successful community-based health education requires effective leaders, community activists with the courage and charisma to advocate health innovations. Waves of advocacy filtering down from international, national, state, or provincial sources can wash up on the shore of an inert community to provide a local activist leader with the popular support to 'fight city hall' or other entrenched bureaucrats who defend the status quo. Tobacco control in Australia and the US provide examples. National and state advocacy groups with access to mass media created a strong mass movement for change, allowing advocates to enlist popular support for local tobacco control measures. In both California and Australia's State of Victoria this popular support led to statewide increases in tobacco taxes, with some retained for education against tobacco, a measure that had been resisted by state legislators who had long been influenced by tobacco lobbyists—an example of community activism filtering up the chain to a higher political level (Catalonia Declaration 1996).

3.9 Role of Policy, Laws, and Regulations (PLR)

Local actions can affect alcohol and tobacco sales and create environments that improve nutrition and enhance physical activity. However, national, state, or provincial actions can magnify local PLR and education efforts on topics such as tobacco taxation, automobile seat-belt laws, food and drug safety, school nutrition, school physical activity policies, and (in the United States) laws on firearms. As described in Section 4.8, widespread popular attitude changes in numerous communities can also affect the political process at the state or federal level.

4. History of Comprehensive Community Health Education

The history since the 1970s is restricted largely to 13 formal research projects designed to affect CVD risk factors. They involved entire populations of at least one education community, compared with at least one control community. Three of the four exemplars to follow are drawn from these 13 projects. Dissemination into practical applications of community organizing and mass communication technologies, derived in part from these research projects, occurred throughout many parts of the world.

4.1 The First Two Exemplars: The First Decade

The first and second exemplars, Stanford Three-community Study (TCS), in three small agricultural marketing towns in California (total population 45,000), and the North Karelia Study (NKS), in two adjoining predominately rural Finnish counties (North Karelia population about 180,000), each began in 1972. TCS, the first Stanford project, was carried out from 1972–75 in both English and Spanish, comparing effects of mass media alone in one community and mass media plus 10-session risk reduction classes for high-risk adults in a second, with a third as a control (Schooler et al. 1997). Groups exposed to varied education amounts showed a dose-response change in smoking, blood pressure, and blood cholesterol, with a proportionately larger effect in the Spanish-speaking residents than in the Anglo majority. (This minority population outcome required a compensating increase in intervention resources.) A composite CVD risk reduction of about 23 percent and 30 percent occurred in the mass media—only and mass media—plus classroom conditions, respectively. Thus, a relatively modest amount of mass media (about 30 television and radio 'spots,' weekly newspaper columns on heart health, and four separate mass mailings of booklets) was sufficient to change the population's body weight, cholesterol and blood pressure levels, and smoking prevalence. The education followed Bandura's principles but adapted to the mass media (as was also the case with exemplars two and three).

NKS, evaluated two, matched, rural Finnish counties that contained many villages with farming and lumbering as the main occupations. North Karelia (about 180,000 population) received an education campaign that began in 1972, continuing to the present. After 5 years, CVD risk factor changes comparable to the TCS occurred, and significant net reductions in CVD events occurred (Schooler et al. 1997). This study was marked by extensive community organizing, resulting in strong partnerships with residents and their organizations. The NKS influence on its country's policies was unparalleled among the CVD projects, providing its most important lesson—that a well executed project led by respected scientists can move an entire country. As examples, Finland's food and agricultural industries made large changes: Fertilizers were supplemented with selenium (a substance low in Finland's soil that is needed for health), milk pricing was changed (based on protein instead of fat content), programs were created to replace dairy farms with berry farms, a new canola industry replaced jobs lost in dairying, and increased production of low-fat foods occurred (Catalonia Declaration 1996).

In 1972 population-wide nutrition change and smoking cessation interventions were an innovation internationally, which may partly explain the success of these two pioneering programs (TCS and NK).

4.2 Early International Diffusion, 1977–1983

Studies patterned after the TCS done in Italy, Australia, Switzerland, and South Africa all had significant risk factor changes, adding evidence for the effectiveness of the TCS model (Farquhar et al. 1991).

4.3 The Second and Third Decades: Projects Begun in the 1980s and 1990s

The third exemplar is the Stanford Five-city Project (FCP) (USA). Its intervention phase from 1980 to 1986 extended TCS methods to larger populations (total population of about 360,000) with multifactor CVD prevention directed at two northern California cities. There were three control cities (Farquhar et al. 1990). It differed from TCS in greater use of community organizing and in greater collaboration with the communities' health, media, and education organizations in planning and implementing programs. It was similar in generous use of mass media, both print and electronic (63 percent television and 36 percent print). It was unique in measuring total dose of education (about 5 hours/year and about 100 episodes of exposure/year to all forms of media and classroom education).

FCP's initial year of television messages (defined as 'high reach/low involvement') stimulated the public's use of print media, which supplied more effective skills training than television (Flora et al. 1997). Results were comparable with the TCS (about a 15 percent fall in composite risk of CVD), with a major impact on blood pressure (Farquhar et al. 1990). Health bureaucracies, usually timid, should gain courage from the FCP's 'David and Goliath' demonstration that only 3 hours/year of high-quality television health education can counteract the public's exposure to about 100 hours/year of television advertising devoted to unhealthy nutrition. Although all preceding CVD studies showed effects in small towns and/or rural districts, FCP showed benefit in cities (with populations as high as 100,000). Also, these effects occurred despite the advent (at least in the state of California) in the 1980s of dual working families and increasing public use of fast food, factors that made achieving nutrition-behavior change more difficult.

FCP's modest resources and greater effects, as compared with some comparable projects, support the benefits of the skills training aspects of Bandura's social cognitive theory. Perhaps the most practical lesson to policymakers is that adult residents saved 30 times more money from their decreased cigarette purchases (\$120/adult/year) than the cost of the campaign (\$4/adult/year)—savings retained by the community. Lastly, the communities adopted FCP's technologies, later applying them to seat-belt promotion and violence and adolescent pregnancy prevention.

Other successful CVD projects, both large and small, occurred in these decades in the US, Sweden, Denmark, Canada, the Czech Republic, and China. Also, World Health Organization-sponsored projects began in about 23 other countries (Schooler et al. 1997). In all instances, they borrowed heavily from the experiences of the three exemplars and in many instances received training from either the Stanford or the North Karelia groups.

4.4 Community Projects in Other Health Topics

Interventions on alcohol, mammography, tobacco control, motor vehicle injuries, and HIV/AIDS are prominent examples of other community-based projects, but with fewer well-controlled studies than in CVD. One of these, Preventing Alcohol Trauma (PAT), is the fourth exemplar. This 5-year study of three US communities showed a 10 percent decrease in alcohol-related traffic injuries and a 50 percent decrease in adolescent alcohol use (Holder et al. 1997). Coalition building and organizational behavior change among the police, alcohol sales outlets, and alcohol servers were the main interventions. The public responded to a fear, instilled through publicity, of the penalties of greater enforcement of existing laws on underage alcohol purchases or drinking and driving. Therefore, in contrast to the three CVD exemplars, PAT showed that major public education is not needed for large public behavior changes. PAT estimated a cost saving of \$2.88 for every dollar invested, a number close to that found in many work-site health promotion studies. PAT found their communities had the required infrastructure for the campaigns, requiring only training provided by one indigenous community coordinator, a part-time clerk, an imaginative plan, and the will to proceed.

TCS, the first, and PAT, the fourth exemplar, are opposites: TCS had a maximum of mass-media education and a minimum of organizing, whereas PAT had the opposite. Thus, either model works, but to change complex behaviors, one needs sophisticated behavior-change methods, such as those adapted from Bandura (see *Self-efficacy and Health*). If fear of arrest for breaking existing laws on alcohol use suffices to change personal drinking-and-driving habits, then the education process is simpler.

5. Lessons Lead to a 'Master Plan'

A five-step approach emerges from these studies.

(a) Define the problem. Does the community need a health education campaign? A decision can be made from national or local survey data.

(b) Organize the community, creating a campaign that includes education, continued organizing, training of community organizations, empowerment of the public and the community's organizations, and future

maintenance of programs developed during an initial phase of about 2 years.

(c) Implement an intervention, delivering 3–5 hours of education exposure/year for 2 years, using initially about 50 percent television to arouse interest, followed by about 25 percent from more specific print media (emphasizing newspapers, if available) and 25 percent from community events and programs (such as health fairs, contests, and classes).

(d) Institutionalize programs. The community becomes a demonstration project, with its 'empowered' organizations functioning as health promotion resource centers for a wider region.

(e) Use the new community resources and its residents' potential power to advocate for local, regional, and national governmental regulations and laws that will increase local intervention effects and extend them beyond the community.

Any individual or organization that wishes to engage in community-based health education should gain courage from the words of Margaret Mead, as quoted in the closing passage of the Catalonia Declaration (1996, p. 75), 'Never doubt the capacity of a few dedicated individuals to change the world, in fact, it is the only way it ever has.'

6. Barriers and Challenges

A healthy city has been defined by the absence of crime, crowding, and poverty and by the presence of educated residents and enlightened (and trained) organizations. Together these lead to a community empowered to solve its social problems (i.e., to increase its social capital) (Travers 1997).

Considering barriers, MacIntyre (2000) found Glasgow's environmental factors to be major barriers to healthful exercise behavior. Certain macro-economic factors inherent in globalization, such as capital flight and increased wealth and income gaps, have been described as barriers to planned change (Bezruchka 2000, Cahill 1983). All such barriers threaten community stability, inhibiting greatly the success of health promotion attempts. However, wise compensatory resource allocation can overcome many barriers, as was shown in the Hispanic minority of the TCS. Therefore, the challenge for the future is: Responsibility for success in community-based health interventions lies with the interventionist, not with the community's residents!

7. Conclusions

Three decades of the 'total community' health education approach strongly support the feasibility, at relatively low cost, of achieving transfer of public education technologies to a community's infrastructure (public health, media, schools, etc.), resulting in significant changes in health habits of populations.

Although most studies derive from small communities, recent successes in Tianjin (China), a city of 400,000 (two exemplars examined populations of > 100,000), suggest that the model also works in large populations (Schooler et al. 1997). Organizing and educating communities requires advocacy, activism, coalition building, and leadership; success is enhanced by regulatory change. Theory matters: when the population gains self-efficacy through education, the result—community efficacy—enhances capacity to change institutional policy and practice, thus maintaining community change.

Science cannot serve society if its evidence for educational benefit is ignored. This is not a new concept. As written over 2,000 years ago, 'If a virtuous and learned scholar aims to influence the people as a whole, one must first educate the people' (Legge 1983).

Health Outcomes, Assessment of

Health is probably the most valued human asset. In fact, studies on the preference for different states of being show that virtually everyone rates health as most important. Despite the perceived importance of health, health status has remained difficult to define. There are two common themes in definitions of health. First, premature death is undesirable, so one aspect of health is the avoidance of mortality. The health status of nations is often evaluated in terms of overall mortality rates or infant mortality rates. Second, quality of life is also very important. Disease and disability are of concern because they affect either life expectancy or life quality. For example, cancer and heart disease are the two major causes of premature death in the United States. In addition, disease or disability can make life less desirable. A person with heart disease may face restrictions in daily living activities and may be unable to work or participate in social activities. Even relatively minor diseases and disabilities affect quality of life. A cold, for example, may interfere with the ability to concentrate, work, or attend school. The cold, however, lasts only a short time. A chronic disease, such as arthritis, may affect the quality of your life for a long time (Brown et al. 2000).

Within the last few years, medical scientists have come to realize the importance of measuring patient-reported health. Many major diseases, including arthritis, heart disease, and diabetes, or digestive problems are evaluated in terms of the degree to which they affect life quality and life expectancy (Koloski et al. 2000). One can also evaluate treatments for these conditions by the amount of improvement they produce in everyday life. The Food and Drug Admin-

istration now considers patient-reported outcomes in their evaluations of new products and nearly all major clinical trials in medicine use quality of life assessment measures. Several approaches to health outcome measurement will be reviewed. Chapter 130 by O'Boyle covers quality of life measures in more detail.

1. Historical Perspective

For many years, researchers and clinicians have struggled to reach consensus on the measurement of health and health outcomes. Different definitions emphasize related, but divergent, concepts. Some terms used to describe health are positive concepts, such as wellness or normality. Other definitions emphasize negative concepts, such as disability and illness. Much of the debate has centered on whether health is a continuum. Are disability and illness distinct from health, or are they opposite ends of the same continuum? (Patrick and Erickson 1993).

Because the concept of health lacked conceptual clarity, the World Health Organization (WHO) proposed a comprehensive definition of health in their charter document. Health was defined as, '... a state of complete physical, mental, and social well-being and not merely the absence of infirmity' (World Health Organization 1948). Since the introduction of this definition there has been some convergence of thought. It is now widely recognized that health has multiple dimensions. Further, it is now accepted that measures of mortality alone cannot summarize the health status of populations (Field and Gold 1998). However, there is still considerable debate about what constitutes health and health status.

Some of the debate about the definition of health originates from sociologists. From the sociological perspective, illness represents deviation from society's standards for physical and mental well-being. Often, this deviation is recognized when individuals cannot perform activities usual for their social roles. In addition to observable functioning, illness may cause reports of symptoms of pain and these deviate from society's norms on wellness. Parsons defined illness as '... a state of disturbance in normal functioning of the total human individual including both the state of the organism as a biological system, and/or his personal and social adjustments' (Parsons 1951, p. 431). For Parsons, health represented the capacity to perform valued tasks.

The traditional biomedical model is predicated on finding a specific biologic problem and repairing it. In contrast, measures of health outcome consider benefit from the patient's perspective. Successful treatments are those that improve the quality of life or extend life. Most surgical interventions are justified on the basis of saving lives. However, the great majority of surgical procedures have no effect on life expectancy. For

example, four of the most common indications for surgery in the United States are transurethral resection prostatectomy (TURP) for benign hyperplasia of the prostate (BPH), extractions of cataracts, joint replacement for severe osteoarthritis of the knee or hip, and hysterectomy for diseases of the uterus. Although, it is often argued that these procedures prevent deaths, reviews of the evidence suggest that these procedures are rarely performed to extend life expectancy. In each case, however, the surgery may lead to improvements in functioning or the reporting of symptoms. For example, TURP may reduce the symptom of urinary frequency in men. Cataract extraction may help older patients function better with reading, night-driving, and other activities of daily living. Joint arthroplasty may increase mobility for older patients. For most of these cases, traditional physiological measures are limited as outcome assessment. Patients seek these procedures because they want relief of symptoms. Outcomes assessment must consider whether the symptoms are, indeed, relieved. Ultimately, measures of health outcome can be used to evaluate the benefits of treatment from the patient's perspective.

2. Assessment of Health Outcomes

Methods of assessment of health-related quality of life represent at least two different conceptual traditions. One grows out of the tradition of health status measurement. Several efforts to develop measures of health status were launched in the late 1960s and early 1970s. All the projects were guided by the World Health Organization's (WHO) definition of health status. The projects resulted in a variety of assessment tools, including the Sickness Impact Profile (Bergner et al. 1981) the Quality of Well-Being Scale (Kaplan et al. 1996) the SF-36 (Ware and Gandek 1998) and the Nottingham Health Profile (Lowe et al. 1990). Many of the measures examined the effect of disease or disability on the performance of social roles, the ability to interact in the community, and physical functioning. Some of the systems have separate components for the measurement of physical, social, and mental health. The measures also differ in the extent to which they consider subjective aspects of life quality (Brown et al. 2000).

Perhaps the most important distinction between methods to assess quality of life is the contrast between psychometric and decision theory approaches. The psychometric approach attempts to provide separate measures for the many different dimensions of quality of life. Perhaps the best known example of the psychometric tradition is the Sickness Impact Profile (SIP). The SIP is a 136-item measure that yields 12 different scores displayed in a format similar to an MMPI profile (Bergner et al. 1981).

The decision theory approach attempts to weight the different dimensions of health in order to provide

a single expression of health status. Supporters of this approach argue that psychometric methods fail to consider that different health problems are not of equal concern. A runny nose is not the same as severe chest pain. In an experimental trial using the psychometric approach, one will often find that some aspects of quality of life improve while others get worse. For example, a medication might reduce high blood pressure but also produce headaches and impotence. Many argue that the quality of life notion is the subjective evaluation of observable or objective health states. The decision theory approach attempts to provide an overall measure of quality of life that integrates subjective function states, preferences for these states, morbidity, and mortality.

3. Common Methods for the Measurement of Quality of Life

A variety of methods have been proposed to measure quality of life, but we cannot review and critique them all here. Instead, we present some of the most widely used psychometric and decision theory based methods. Readers interested in more detailed reviews should consult Walker and Rosser (1993) and McDowell & Newell (1996). Quality of life measures are also covered in Chapter 130 (by O'Boyle).

3.1 Psychometric Methods

(a) *SF-36*. Perhaps the most commonly used outcome measure in the world today is the Medical Outcome Study Short Form-36 (SF-36). The SF-36 grew out of work by the RAND Corporation and the Medical Outcomes Study (MOS) (Ware & Gandek 1998). Originally, it was based on the measurement strategy from the RAND Health Insurance Study. The MOS attempted to develop a very short, 20-item instrument known as the Short Form-20 or SF-20. However, the SF-20 did not have appropriate reliability for some dimensions. The SF-36 includes eight health concepts: physical functioning, role-physical, bodily pain, general health perceptions, vitality, social functioning, role-emotional, and mental health (Kosinski et al. 1999). The SF-36 can either be administered by a trained interviewer or self-administered. It has many advantages. For example, it is brief, and there is substantial evidence for its reliability and validity. The SF-36 can be machine scored and has been evaluated in large population studies. The reliability and validity of the SF-36 are well documented (Keller et al. 1999, Scott-Lennox et al. 1999, Stewart and Ware 1992, Ware and Gandek 1998).

Despite its many advantages, the SF-36 also presents some disadvantages. For example, it does not have age-specific questions and one cannot clearly

determine whether it is equally appropriate at each level of the age continuum. The items for older retired individuals are the same as those for children (Stewart and Ware 1992). Nevertheless, the SF-36 has become the most commonly used behavioral measure in contemporary medicine.

(b) *Nottingham Health Profile.* The Nottingham Health Profile (NHP), is another profile approach that has been used widely in Europe. One of the important features of the NHP is that the items were originally generated on the basis of extensive discussions with patients. The NHP has two parts. The first includes 38 items divided into six categories: sleep, physical mobility, energy, pain, emotional reactions, and social isolation. Items within each of these sections are rated in terms of relative importance. Items are rescaled in order to allow them to vary between 0 and 100 within each section. The second part of the NHP includes seven statements related to the areas of life most affected by health: employment, household activities, social life, home life, sex life, hobbies and interests, and holidays. The respondent indicates whether or not a health condition has affected his or her life in these areas. Used in a substantial number of studies, the NHP has considerable evidence for its reliability and validity.

An important strength of the NHP is that it is based on consumer definitions of health derived from individuals in the community. The language in the NHP is simple and the scale requires only a low level of reading ability. Psychometric properties of the NHP have been evaluated in a substantial number of studies. However, the NHP, like most profile measures, does not provide relative-importance weightings across dimensions. As a result, it is difficult to compare the dimensions directly with one another (Lowe et al. 1990).

3.2 Decision Theory Approaches

Within the last few years, interest has grown in using quality of life data to help evaluate the cost/utility or cost-effectiveness of healthcare programs. Cost studies have gained in popularity because healthcare costs have grown so rapidly in recent years. Not all healthcare interventions equally return benefit for the expended dollar. Objective cost studies might guide policymakers toward an optimal and equitable distribution of scarce resources. Cost-effectiveness analysis typically quantifies the benefits of a healthcare intervention in terms of years of life, or quality-adjusted life years (QALYs). Cost/utility is a special case of cost-effectiveness that weights observable health states by preferences or utility judgments of quality. In cost/utility analysis, the benefits of medical

care, behavioral interventions, or preventive programs are expressed in terms of years of life adjusted for reduced quality of life or quality-adjusted life years (QALYs).

If a man dies of heart disease at the age of 50 and we expected him to live to age 75, we might conclude that the disease precipitated 25 lost life-years. If 100 men died at age 50 (and also had a life expectancy of 75 years), we might conclude that 2,500 (100 men $\times$ 25 years) life-years had been lost. Yet death is not the only relevant outcome of heart disease. Many adults suffer myocardial infarctions that leave them somewhat disabled for a long time. Though still alive, they suffer diminished quality of life. Quality-adjusted life-years take into consideration such consequences. For example, a disease that reduces quality of life by one-half will take away 0.5 QALY over the course of each year. If the disease affects two people, it will take away one year (2×0.5) over each year. A medical treatment that improves quality of life by 0.2 for each of five individuals will result in the equivalent of 1 QALY if the benefit persists for one year. This system has the advantage of considering both benefits and side effects of programs in terms of the common QALY units.

The need to integrate mortality and quality of life information is clearly apparent in studies of heart disease. Consider hypertension. People with high blood pressure may live shorter lives if untreated, longer if treated. Thus, one benefit of treatment is to add years to life. However, for most patients, high blood pressure does not produce symptoms for many years. Conversely, the treatment for high blood pressure may cause negative side effects. If one evaluates a treatment only in terms of changes in life expectancy, the benefits of the program will be overestimated because one has not taken side effects into consideration. On the other hand, considering only current quality of life will underestimate the treatment benefits, because information on mortality (death) is excluded. In fact, considering only current function might make the treatment look harmful because the side effects of the treatment might be worse than the symptoms of hypertension. A comprehensive measurement system takes into consideration side effects and benefits and provides an overall estimate of the benefit of treatment (Russell 1986).

Of the several different approaches for obtaining quality-adjusted life years, most are similar. The three most commonly used methods are the EQ-5D, the Health Utilities Index (HUI) and the Quality of Well-being Scale (QWB).

(a) *EQ-5D.* The approach most commonly used in the European community in the late twentieth century was the EQ-5D. This method has been developed by a collaborative group from Western Europe, led by Paul Kind and associates, known as the EuroQol group

(Kind 1997). The intention of this effort was to develop a generic currency for health that could be used commonly across Europe. The concept of a common EuroQol was stimulated by the desire for a common European currency—the Euro dollar. The original version of the EuroQol had 14 health states in six different domains. In addition, respondents placed their health on a continuum ranging from death (0.0) to perfect health (1.0). The method was validated in postal surveys in England, Sweden, and the Netherlands. More recent versions of the EuroQol, known as the EQ-5D, are now in use in a substantial number of clinical and population studies (Gudex et al. 1996, Hurst et al. 1997). Although the EQ-5D is easy to use and comprehensive, there have been some problems with ceiling effects. Substantial numbers of people obtain the highest possible score.

(b) *Health Utilities Index*. Another approach has been developed in Canada by Torrance et al. (1996). This method, known as the Health Utilities Index (HUI), is derived from micro-economic theory. There have been several versions of the measure, typically identified by 'Mark.' The HUI Mark I was developed for studies in the neonatal intensive care unit. The measure had 960 unique health states. In 1992, the HUI Mark II was developed and included 24,000 unique health states. The HUI Mark III, released in 1995, had 972,000 health states. Eight components of the HUI Mark III include vision (six levels), hearing (six levels), speech (five levels), ambulation (six levels), dexterity (six levels), emotion (five levels), cognition (six levels), and pain (five levels). Multiplying the number of levels across the eight dimensions gives the 972,000 states.

Using multiattribute utility scaling methods, judges evaluate levels of wellness associated with each level of each domain. A multiattribute model is used to map preference for the 972,000 possible states on to the 0.0 to 1.0 continuum. The HUI has been used in many population and clinical studies. For overall health status, men obtain higher scores early in the life cycle. However, after about the age of 45, women obtain higher scores and this difference grows systematically through the remainder of the life span (Kaplan and Erickson 2000).

(c) *Quality of Well-being Scale (QWB)*. A third method, known as the Quality of Well-being Scale integrates several components into a single score. First, patients are classified according to objective levels of functioning. These levels are represented by the scales of mobility, physical activity, and social activity. Once observable behavioral levels of functioning have been classified, each individual is placed

on the 0 to 1.0 scale of wellness, which describes where a person lies on the continuum between optimum function and death.

To accomplish this, the observable health states are weighted by quality ratings for the desirability of these conditions. Human value studies have been conducted to place the observable states onto a preference continuum, with an anchor of 0 for death and 1.0 for completely well. Studies have shown that the weights are highly stable over a one-year period and that they are consistent across diverse groups of raters. Finally, one must consider the duration of stay in various health states. Having a cough or a headache for one day is not the same as having the problem for one year. A health measure must take these durations into consideration. Using this information, one can describe health-related quality of life in terms similar to years of life. For example, one year in a state assigned the weight of 0.5 is equivalent to 0.5 of a quality-adjusted life-year.

3.3 Cost-effectiveness Evaluations

Utility-based measures of quality of life are often used to evaluate the cost-effectiveness of health-care programs (Kaplan et al. 1997). For example, one study using the QWB showed a new medication for patients with arthritis produced an average of 0.023 QALY per year, whereas a new medication for AIDS produced nearly 0.46 of these units per year. However, the benefit of the arthritis medication may last as long as 20 years, ultimately producing $0.023 \times 20 \text{ years} = 0.46$ year. The AIDS treatment produced a benefit for only one year, so its total effect was $0.46 \times 1 \text{ year} = 0.46$ year. In other words, the general system allows the full potential benefits of these two very different treatments to be compared (Kaplan et al. 1995).

QALYs are generic measures of life expectancy with adjustments for quality of life (Gold 1996). QALYs consider both benefits and side-effects of programs in terms of the common outcome units. Although QALYs are typically assessed for patients, they can also be measured for others, including care givers who are placed at risk because they experience stressful life events. The Institute of Medicine recommended that population health metrics be used to evaluate public programs and to assist the decision making process (Field and Gold 1998).

In addition to health benefits, programs also have costs. Resources are limited and good policy requires the allocation of resources to maximize life expectancy and health-related quality of life. Thus, in addition to measuring health outcomes, costs must also be considered. Methodologies for estimating costs have now become standardized (Gold 1996). From an administrative perspective, cost estimates include all costs of treatment and costs associated with caring for any side

effects of treatment. From a social perspective, costs are broader and may include the costs of family members staying off work to provide care. Comparing programs for a given population with a given medical condition, cost-effectiveness is measured as the change in costs of care for the program compared with the existing therapy or program, relative to the change in health measured in a standardized unit such as the QALY. The difference in costs over the difference in effectiveness is the *incremental cost-effectiveness* and is usually expressed as the cost/QALY. Since the objective of all programs is to produce QALYs, the cost/QALY ratio can be used to show the relative efficiency of different programs (Gold 1996).

Some traditional interventions, such as bypass surgery for one-vessel coronary heart disease, may cost as much as \$700,000 to produce a QALY. Screening programs, such as mammography, may also require many resources to produce a QALY. On the other hand, public health programs such as pneumonia vaccines for the elderly or laws requiring children to be in infant seats and adults to be in seat belts in motor-cars may produce a QALY at a very low cost. It might be argued that programs to the left of the pay line should be funded, but those with cost/QALY ratios to the right of the line should be examined more carefully.

4. Disease-specific Measures

This chapter has focused on generic measures of health outcome. These measures can usually be applied to any age, gender, or ethnic group. In most cases age and gender-related norms are available. However, there are a significantly larger number of situation-specific measures. Some of these measures are appropriate for a particular age, gender or ethnic group. For example, several measures are designed specifically to assess health outcomes in children. Most often, the measures are disease-specific, meaning that they are designed to assess outcomes of a particular health problem. Validated measures of health outcome are available for illnesses such as arthritis, diabetes, heart disease, kidney failure, and virtually every other major health condition. Two examples are the Arthritis Impact Measurement Scale (Meenan 1982) and the UCSD Shortness of Breath Questionnaire used in studies of patients with emphysema (Eakin et al. 1998).

The Arthritis Impact Measurement Scales (AIMS) is a health index designed at the Multipurpose Arthritis Center at Boston University. It is intended to measure physical health and social well-being for patients with rheumatoid arthritis (Meenan 1982). The resultant scale includes 67 items, with questions about functioning, health perceptions, morbidity, and demographics. The AIMS contains scales for mobility,

physical activity, social activity, activities of daily living, depression and anxiety and arthritis-related symptoms. In effect, it is an adaptation of an early version of the QWB (Eakin et al. 1998), with a series of items designed to tap more specifically the effect of arthritis upon functioning and the quality of life. Factor analysis of the AIMS has produced three subscales: physical function, psychological function, and pain. Most current applications of the AIMS use composite scores for these three areas.

The University of California, San Diego, Shortness of Breath Questionnaire (SOBQ) includes 25 items that evaluate self-reported shortness of breath during the performance of various activities of daily living. Evaluations of the measure show it highly correlated with other quality of life measures such as the Quality of Well-Being Scale and the Center for Epidemiologic Studies Depression Scale. The measure has high internal consistency ($\alpha = 0.96$) and is significantly correlated with performance measures such as the distance that can be walked in six minutes (Eakin et al. 1998).

5. Summary

The assessment of patient-reported experience has become a standard component of health outcome evaluation. There are several important distinctions between commonly-used approaches. Generic measures are used to evaluate the health outcome for any illness or disease of state. Generic measures can typically be classified as derived from psychometric or decision theory. Psychometric approaches include the Sickness Impact Profile, the SF-36, and the Nottingham Health Profile. Decision theory approaches are used to estimate outcomes in terms of quality-adjusted life years (QALYs). Methods used for this purpose include the EQ-5D, the HUI, and the QWB. Disease-specific measures are available for a wide variety of health conditions. Although disease-specific measures may be more sensitive for outcomes of a particular condition, they cannot be used for cross-illness comparisons or for cost-effectiveness analysis. The assessment of health outcome is a rapidly-developing field and we anticipate major new developments over the next decade.

Health Policy

In Western industrialized nations, the term health policy has come to mean government policies that subsidize and regulate the *economic* relations between patients, insurers, and health care providers—doctors, hospitals, pharmacies, pharmaceutical companies. Within this general framework—an economic model of medicine—the role of government in health care varies considerably from country to country and has been the subject of considerable and continuing political contestation. In order to understand these differences, one must return to the political circumstances that led to the enactment—or rejection—of specific health programs.

1. Types of Health Policy

The role of government in health care may be classified according to methods of financing health care provision. Governments may subsidize medical treatment by providing for tax exemptions for medical expenditures. They may provide government subsidies to private insurers. They may provide health insurance coverage by creating government insurance programs. Or they may provide health services through government-employed doctors and government-owned hospitals. Because each type of financing has implications for the role of government in regulating the medical market, government financial provisions in the health area can be ranked from less to more

invasive: tax expenditures are considered the least interventionist form of health policy; government health services are considered the most interventionist.

1.1 Government Subsidies

Tax deductions for medical expenditures were generally introduced after the Second World War, and were often the result of political conflicts preventing a more ambitious role for government in health, such as the failure of the Truman national health insurance proposal of 1948 in the United States. A policy of tax expenditure impacts the medical market by reducing the costs of health care to the consumer. This financial incentive allows governments to promote health policy goals, for example, by deciding which types of medical treatment will be deductible, or which types of insurance benefits qualify as tax exempt. Tax deductibility has been an important element in the spread of health insurance coverage as part of collective bargaining agreements since the 1940s, although the current trend is towards reduction rather than expansion of insurance benefits provided by employers.

A second form of government financing for health care is the payment of *subsidies* to insurance carriers. This policy dates from the mid-nineteenth century and was a reaction to the growth of voluntary mutual aid societies (also known as friendly societies or sickness funds) that provided their members with death and sickness benefits (cash payments to cover the costs of burial and income loss during illness, respectively). Typically, governments provided the mutual societies with a fixed subsidy per member. In return, the societies were required to follow specific financial practices—for example to build up larger financial reserves—and to provide medical benefits in addition to cash payments. In addition, political authorities used financial resources as a means of political control, monitoring the activities of the societies, and sometimes intervening in the selection of the members of the societies' governing boards, as was the case in nineteenth century France, Italy, and Belgium.

1.2 National Health Insurance

Under national health insurance programs, governments provide *compulsory* health insurance to all or parts of the population. Historically, such programs were first introduced to provide insurance to industrial workers at the end of the nineteenth century, with Bismarck's social insurance laws of 1883 as the first example (see *Social Security; Welfare State, History of Social Insurance: Legal Aspects*). Over the course of the twentieth century, compulsory health insurance programs have been expanded to cover ever greater portions of national populations—hence the term 'national.' National health insurance programs are in

place in most of Europe, Latin America, Canada, Australia, and Japan. When the entire population is covered as a right of citizenship, these programs are said to be universal. Nevertheless, while the term 'national health insurance' connotes the compulsory provision of health insurance to broad sectors of the population, there is no generally accepted definition for the portion of the population to be covered or for the exact benefits to be provided. These are matters of political negotiation and political choice.

National health insurance programs provide governments with greater incentives and instruments for regulating the medical market than programs of government subsidies. Government decisions determine who is to be publicly insured—often defined by income or age limits, or by specifying occupational groups, such as farmers, salaried employees, civil servants, or the unemployed, that are to be compulsorily insured. These decisions, in turn, set limits to the market for private insurance. National health insurance programs may be directly administered by government agencies, or by independent insurance carriers, often the voluntary mutual aid societies or nonprofit group plans that existed prior to the government program. In either case, however, governments regulate benefits, conditions of membership, portability of benefits, and contribution rates. Rather than paying a premium for their insurance coverage, citizens are said to pay a contribution, one which is often collected in the form of a payroll tax, as part of the nation's social insurance or social security system. Employers are generally required to pay for half or more of the insurance contribution for their employees. Consequently, many public insurance programs provide for some representation of these contributors on the boards of the insurance carriers, a practice that has been termed 'self-administration'.

The regulation engendered by national health insurance is not limited to citizens and insurers. Political decisions—often the result of negotiations between representatives of providers and insurance authorities—determine the specific treatments and medications that will be covered by a particular national health insurance program, as well as the price that may be charged. Governments may simply set maximum fees to be charged to national health insurance patients, or they may negotiate fees with representatives of medical or hospital associations. These lists of negotiated fees are known as fee schedules. Hospitals or doctors may be required to accept the national health insurance fee as payment in full, and thus prohibited from adding surcharges (balance-billing or extra payments).

Because government price controls may be circumvented by increasing the volume of services, newer methods of cost containment have been developed. Case-based payment or diagnostic-related groups remunerate hospitals a fixed sum per patient with a particular diagnosis rather than reimbursing the full

costs of treatment for a specific individual. In this way, providers are given an incentive to reduce the volume (and hence the costs) of treatment. The global budget bases hospital payments on a larger entity. Either a department or even the entire hospital will be given a yearly (or quarterly or semi-annual) budget, within which the hospital managers may allocate funds at their discretion. In the area of pharmaceuticals, common cost-containment measures include the development of positive (allowed) and negative (prohibited) lists of prescription drugs, as well as efforts to negotiate directly with manufacturers to obtain discounts on pharmaceutical and other medical products. In order to reduce the volume of prescriptions, some national health insurance authorities have introduced economic monitoring of physicians (reviews whereby physician behavior is compared to statistical averages) and prescription budgets for physicians. Further, many national health insurance programs rely on cost-sharing on the part of patients to reduce the demand for health services.

1.3 National Health Services

In a national health service, governments provide health services directly. Citizens are guaranteed a range of health care benefits, which are generally provided at no or at low cost at the time of treatment. Medical benefits are typically financed by tax revenues (although there may be a health insurance component as well) and provided under government auspices. Just what this 'public' provision is to entail, however, is highly controversial. In the British National Health Service, founded in 1948, and in Sweden, a country that can be considered to have a *de facto* national health service, the overwhelming majority of hospitals are government owned, and hospital doctors are paid a full-time salary. In Southern Europe (Italy, Portugal, and Spain), the more recently created national health services have incorporated privately-owned hospitals, such as those owned by churches and social security institutions, into the public service on a contractual basis. Within national health service hospitals, patients may or may not be allowed to pay additional monies for treatment in a 'private' bed or private room. Similarly, hospital doctors (especially chiefs of staff) may or may not be allowed to treat 'private' patients for additional fees.

The outpatient or ambulatory sector has traditionally been a battleground for the demarcation of the public-private boundary. Local health clinics or hospital outpatient departments compete with private office practice by providing health treatments at virtually no charge through doctors that are paid on a salaried basis. Even in private offices, doctors in national health services are often under contract to the government, and paid according to fee schedules or on

a capitation basis (a set fee per patient per year). Efforts to pay private office practitioners a yearly salary for their national health service work have generally failed in market economies. In state socialist countries, on the other hand (China, Cuba, the former German Democratic Republic, and the former Soviet Union, for example), health care was long provided through government hospitals and outpatient clinics (polyclinics or Ambulatorien) that employed doctors as salaried civil servants.

In comparison to systems of government subsidies and national health insurance—both of which increase the demand for health services—national health services provide governments with relatively effective tools of cost-containment and health planning. Particularly in a system such as the British, where health expenditures are financed by the national government and the national health budget constitutes a hard constraint on health spending, less regulation of providers has been necessary to hold expenditures in check. Moreover, centralized public authority for investment decisions has facilitated national planning for medical technology and the regionalization of the hospital system. These policies limit and guide the distribution of expensive technologies, such as nuclear-magnetic-resonance-imaging devices, and create a division of labor among hospitals, with more highly-specialized personnel and equipment concentrated at regional centers (see *Health Care Technology*). As expenditures are curtailed, however, waiting lists and complaints about the quality of services may arise.

1.4 Health Policy Issues

From this description, it is clear that the relationship between state and market has been a central issue of health policy. But, while this division dovetails neatly with political ideologies—and hence with political discourse—it is too simplistic for describing the complex mixture of private and public provision and financing of health care in place today. Even in relatively 'market-oriented' systems, government financing and regulation of health care is extensive, including funds for hospital construction and research, as well as a myriad of regulations governing health insurance, hospitals, and medical equipment. Furthermore, health care decision-makers—whether public or private—are turning increasingly to quite similar policy instruments. Private insurance companies, hospital corporations, and planners interested in regulating the private market promote managed care and managed competition that involves the same budgetary controls, fee schedules, and salaried employment that have been developed to contain costs under national health insurance and in national health services. On the other hand, government health systems now strive to use market incentives and increasing

competition to improve the quality, responsiveness, and efficiency of public systems in programs of public competition and internal markets. Consequently, terms like 'socialized medicine' and 'medical rationing' are better considered as political slogans than as accurate descriptions of health policy. The public component of medical care is very large in all countries—and has been so historically—and efforts to influence the distribution of health care services are prevalent throughout both the public and the private sectors. Instead, the politically more neutral monopsony (or existence of a single buyer) may better capture differences in health systems. To the extent that purchasing power becomes concentrated, the buyers of health care can exert more leverage over the providers. This tendency is at the root of conflicts between providers, such as doctors, and the organized buyers of medical services—private insurance companies, voluntary mutual aid societies, hospitals, and governments.

In sum, health policy entails government's pursuit of three goals through both public and private means: the provision of citizens with access to health care; the assurance of the quality of health care; and the control of the costs of health care. Because it is virtually impossible to meet these three goals simultaneously, health policy will continue to be contested. (See also: *Health Care Systems: Comparative; Health Care Delivery Services; Health Care Markets: Theory and Practice; Health Economics; Managed Care; National Health Care and Insurance Systems; Health Care, Rationing of*.)

2. Determinants of Health Policy

2.1 Public Health Provision

Conflicts over the role of the state in medicine go back as far as the Reformation. At that time, responsibility for health care was divided among an assortment of authorities with overlapping and contradictory jurisdictions. Medical services were delivered by a diversity of practitioners, with widely varying degrees of training, and through a range of institutions, including the Catholic church. In their quest for external and internal sovereignty (see also *Absolutism, History of and Policy History: Origins*), monarchs such as Henry VIII of England or Gustav Wasa of Sweden appropriated hospices along with other Church lands, and began to offer health services under government auspices. Particularly in countries with an absolutist tradition, the rise of the nation state (see *Nations and Nation-states in History; State Formation; State and Society; State, Sociology of the; State, History of*) was associated with an expansion of military medicine, and the establishment of public health officers as well as government bureaucracies for tracking contagious

diseases. In Russia, the state established public health clinics called *Zemstvos*; in many other countries, public health centers were blocked by medical opposition. By the end of the nineteenth century, governments throughout the West had acknowledged some role for the state in the provision of health services, but its scope varied widely.

2.2 The Medical Profession

Political authorities also interceded in the relationships between churches, universities, and medical corporations by giving government approval to specific institutions of medical training and licensing, and, in some cases, by outlawing alternative practitioners. The Royal College of Physicians of London, for example, was granted a charter in 1518 to license physicians. This charter did not interfere, however, with the rights of Cambridge and Oxford universities or ecclesiastical authorities. As in many European countries, three strata of practitioners co-existed: the academically-trained physicians; the more practically-trained surgeons—who had originally been associated with barbers, and whose development was linked to military medicine, like the *Feldshers*, *Wundärzte*, and *Fältskäraren* on the Continent; and the apothecaries—who, expanding their trade to prescribing medicines, had split off from the grocer's guild in 1617. The medical profession was not unified until the Medical Act of 1858, which provided for a General Council of Medical Education and Registration, composed of representatives of the medical corporations and the universities, that was to supervise medical education and register holders of medical licenses. All previous licensing bodies could continue to grant degrees, but there were no restrictions on who could practice medicine other than penalties for improper use of a medical title.

The process by which specialized routes of training and barriers to entry were established has been called professionalization (see *Medical Sociology; Professions, Sociology of; Professionalization/Professions in History*). In some countries, such as Spain and Sweden, professional unification came earlier than in Britain, and professional monopoly was 'tighter,' as unlicensed practice was actually outlawed. In many cases, liberal ideology—with its stress on free markets, individual freedom, and a minimal state—was a barrier to professionalization. In the United States and Switzerland, liberal and democratic ideals precluded medical licensing, limits on medical school admissions, and even prohibitions on medical quackery until well into the twentieth century. In Prussia, the liberal Berlin Medical Society opposed the introduction of mandatory licensing in 1869, which led to a system of state certification for doctors with no penalties for unlicensed practice when Germany was

unified. In France, the revolution (which firmly placed hospitals in the hands of the state) led to new laws that annulled the *ancien régime* requirement of a university degree for the practice of medicine, outlawed medical associations and abolished the university medical faculties, as well as a host of special rights and privileges granted to various subgroups of the profession. Only at the end of the nineteenth century was medical monopoly firmly re-established in France and placed under the jurisdiction of the state universities, without a role for professional bodies. Perhaps for this reason, professional organization in France has been weak, although medical monopoly is strong (see also *Western European Studies: Health*).

2.3 Medical Associations

One can distinguish between several different types of medical organization. Medical corporations, like the British Royal Colleges or the German *Bundesärztekammer*, are professional bodies with legal jurisdiction over medical licensing and professional ethics. Medical societies are associations formed for the purposes of disseminating medical knowledge, and have often founded medical journals. Despite their efforts to maintain some distance from economic and political issues, they have also promoted the interests of their members. Medical associations and medical unions are most directly involved with economic negotiations and lobby efforts, having been founded explicitly as interest associations. In addition, some nations require doctors participating in national health insurance schemes to belong to associations that represent doctors in bargaining with health authorities, such as the *Kassenärztliche Bundesvereinigung* in Germany. Separate organizations often exist for hospital doctors and for various medical specialties. Medical licensing is now only rarely left to medical corporations, but specialty licensing is often left to specialty societies, which may explain their high membership rates and influence.

Professionalization and the development of medical organizations both spurred and was spurred by the expansion of the market for medical care. By defining medicine as a distinct body of knowledge—in order to gain public legitimacy for professional privilege, on the view of some interpretations—medical professions promoted the demand for their services. As governments acknowledged these claims to expertise, they moved to provide medical services to the public, turning increasingly to programs of medical insurance to supplement direct public provision. To be sure, these policies of state medical care were not motivated purely by health policy concerns—the fear of working-class unrest and the need for healthy soldiers were just as important. Indeed, the voluntary mutual societies themselves were not formed solely to provide sickness

and death benefits, but instead served as a way to form associations at a time when many working-class organizations were prohibited by various anticombination acts. In any case, the provision of medical benefits through state-subsidized mutual associations and compulsory health insurance plans further stimulated the formation of medical associations, as doctors sought to prevent the development of disadvantageous working conditions.

2.4 Professional Autonomy

The increasing prevalence of collective payment for medical services stimulated normative and theoretical discussions about the relationship between public service and professional freedom (see for example the debate between Harold Laski and T. H. Marshall described in Marshall 1964 [1939]). Freidson's seminal work defines the key feature of professional freedom as 'technical autonomy.' Occupations that have been able to convince the public that their practitioners are privy to indispensable knowledge gain a privileged position, defined by the exclusive competence to judge professional work. Whereas Freidson specifically states that economic autonomy ('control over the socioeconomic terms of work,' 1970, p. 25) has nothing to do with professional freedom, this has been a central issue in health policy. Medical associations across Western Europe and North America fought for economic autonomy, arguing that economic freedom such as the right to set fees and receive private patients was a precondition of therapeutic freedom (the physician's ability to choose freely among medical therapies) and of the right of patients to a 'free choice of doctor.' As private medical practice has become subject to burdensome government regulation and corporate management controls, however, some argue that physicians are better off in national health systems, where more generalized budgetary controls obviate the need for such detailed micromanagement, preserving a greater degree of clinical autonomy (the ability of physicians to make individual medical decisions).

2.5 The Politics of Health

National health policies are thus the result of centuries of political conflict over the proper role of government in health. Both governmental decisions and those made in private negotiations have influenced the complex set of institutions and regulatory framework that governs contemporary health care financing and provision. In order to make sense of these patterns, scholars have turned to some of the same sociological and political theories that have been applied to the politics of the welfare state (see *Social Welfare Policy*:

Comparisons; Welfare State, History of). The development of different national health policies has been understood in terms of differences in: leading political ideologies and political cultures; social structure and class relations; state traditions and state structures; left and right political representation; national political institutions. A particular focus of the study of health politics has been the issue of professional dominance, that is, whether the medical profession as the sole experts qualified to deliver medical services can parlay their professional expertise into sufficient political power to dominate health policy decisions.

2.6 Future Challenges

Because of its historical development, health policy has been focused very much on the role of nation-states in facilitating and regulating medical services that are provided by national medical professions. This traditional definition now faces two central challenges: the internationalization of the economy, and the revolution in molecular biology. Internationalization poses a challenge to national institutions and programs of health care. Not only the free movement of persons and services across borders, but the tremendous international differences in access to medical treatment, highlighted by crises such as the Aids pandemic, cannot be easily addressed through national health policies. Nor is the Western-industrial approach, which is focused on individual medical services, necessarily appropriate for the problems of the developing world.

Even more profound, perhaps, are the implications of the cracking of the genetic code. Discussions about whether the goal of health policy should be to provide access to medical services or whether investments in public health—hygiene, vaccines, and nutrition—might not have more impact on the health states of populations have been perennial, to be sure. Nevertheless, the discovery of the genetic basis for disease poses a new threat both to the position of doctors as the holders of medical expertise and the role of curative medicine. Furthermore, the potential for genetic engineering, and even the development of more effective pharmaceuticals through recombinant DNA methods, entails tremendous ethical and cost problems.

Health Professionals, Allied

Health care services experienced remarkable growth in the latter half of the twentieth century in industrialized countries. Advances in medical science and technology, the expansion of health insurance, the aging of the population, increased public expectations and disposable income, and expanding social definitions of the boundaries of medical care all contributed to increased utilization of health services and changing patterns of care. These changes fostered the development of an expanded division of medical labor in which allied health professionals emerged to complement and compete with physicians in the provision of a broader array of health services. Globalization of health care has fostered renewed interest in strengthening the roles of allied health providers in developing countries and in the post-Soviet states in order to increase access to primary medical care and improve population health.

1. The Changing Context of Health Care

Health and medical services have undergone dramatic change since the mid-twentieth century. Medical care has become more specialized while also expanding in scope. At the beginning of the twentieth century, physicians accounted for about one in three healthcare workers; by the 1980s the comparable ratio was about 1 in 16 (Mechanic 1983). Health care occupations are highly sex-segregated with most nonphysician occupations dominated by women. Indeed, in many parts of the world physicians are also predominantly women reflecting societal sex role links between women and caring/health functions.

1.1 Changing Disease Patterns

Advances in medical science including antibiotics and vaccines as well as improved standards of living contributed to shifting the burden of illness from acute, infectious illnesses to chronic conditions. While advances in modern medicine have produced important treatments for chronic illnesses, most have resulted in 'halfway' technologies that extend life but do not cure the underlying disease (Thomas 1977). Examples include long-term renal dialysis for the treatment of kidney failure and, more recently, anti-retroviral drugs that extend the lives of people with acquired immunodeficiency syndrome (AIDS). Chronic conditions are accompanied by a myriad of functional limitations and social support needs that fall outside the conventional definition of medical practice. Nurses, social workers, occupational therapists, physical therapists, and other nonphysician health

professionals have demonstrated interest and expertise in helping the chronically ill and frail elderly manage the sequella of chronic conditions and medical treatments, thus creating new roles for themselves in the medical division of labor.

1.2 Medicalization of Problems of Everyday Living

The successes of modern medicine in treating life-threatening illnesses have resulted over time in the redefinition of a range of health-related issues and problems of everyday life as medical concerns. The boundaries of medicine have expanded to encompass health promotion, diet and exercise, child rearing, school performance, occupational health, and a wide array of personal and social problems. Medicalization of problems of everyday living lend legitimacy to social interventions (such as behavior control of disruptive school children), allow those seeking help to adopt a socially sanctioned sick role (Parsons 1951), and provide access to health insurance funds for financing treatment. Physicians are not well suited by interests or training to providing quasimedical social services, thus opening up new roles for allied health professions including social workers, psychologists, and chiropractors, as well as a myriad of new occupations such as personal exercise trainers and weight loss consultants.

Indeed, physicians have continued to pursue more specialized medical training and practice as help-seeking patterns in the general population have redefined the boundaries of medical care to encompass a much broader array of health concerns. Thus, in addition to the expanded opportunities afforded the allied health professions, alternative and complementary health practitioners such as naturopaths, acupuncturists, and herbalists have grown in number and availability. In 1997, American consumers paid an estimated \$27 billion for unconventional therapies, which is roughly comparable to out-of-pocket expenditures for physician services (Eisenberg et al. 1998). Increasingly, conventional physician-dominated settings, including prestigious teaching hospitals, are establishing alternative and complementary health clinics employing nonphysician providers.

1.3 Organizational Changes Conducive to Expansion of Nonphysician Professions

Professions routinely aspire for full control over well-documented jurisdictions in which workplace authority is secured formally through legislation or courts of law and validated by public opinion (Abbott 1988). Physicians have successfully defended their dominance over the medical division of labor through legislative

and legal actions, controlling referral patterns, and by limiting direct access to health services payments (Sage and Aiken 1997). Yet, nonphysician health professions are constantly seeking to define themselves, grow, survive, and contest with medicine within an organizational environment that is continually subject to change due to exogenous social and technological trends.

The organizational context of medical practice changed substantially in the latter third of the twentieth century. The corporatization and consolidation of health services resulted in loss of autonomy for physicians (Starr 1982), but new opportunities and a more favorable environment for the allied health professions. Managerial priorities on cost containment gave allied health professions their first opportunity to compete with physicians on the basis of price and client satisfaction, and they have been successful on both.

1.4 Rapid Growth of Nonphysician Clinicians

The changing nature of health care and its organization has resulted in the rapid growth of allied health professions even in a context of a rapidly increasing physician supply. An analysis of growth of nonphysician clinicians in the USA revealed that the aggregate number of nonphysician clinicians in 10 disciplines (nurse practitioners, physician assistants, nurse-midwives, chiropractors, acupuncturists, naturopaths, optometrists, podiatrists, nurse anesthetists, and clinical nurse specialists) doubled between 1992 and 1997, and was expected to increase by two-thirds more by 2005 (Cooper et al. 1998). These 10 occupations were selected for study because they most overlap the scope of medical and surgical services provided by physicians. The growth of allied health professions is not unique to the USA, and evidence of expansion of nonphysician clinicians can be found in many industrialized countries and also in the developing world as health care becomes an increasingly global enterprise.

1.5 Globalization of Health Services

Global trade and business interests have increasingly impacted upon health services and health care personnel through cross-national commercial ventures, trade agreements affecting the movement of workers across national boundaries, and international aid activities. The North American Free Trade Agreement (NAFTA), linking Mexico, the USA, and Canada, and the European Union (EU) created the impetus to begin reconciling the training and practice of health professions across countries (Freeman et al. 1995). Health services is a major vehicle for transforming economic markets in the now independent states of the former Soviet Union, and many Western concepts of organization and financing of health services, and

education of medical personnel are being introduced (Mossialos and McKee 1998/99). The growing threat of new emerging infectious diseases in parts of the developing world has attracted international attention and focus on strengthening public health and primary care in poor countries (Institute for the Future 2000). Since the health workforce is the infrastructure upon which health services initiatives are built, global initiatives inevitably impact on the education and composition of the medical workforce.

2. Nursing

Nursing is the largest of the health professions. Nursing historically has been closely tied to the profession of medicine, and the boundaries between the two have blurred over time in interesting ways. Nurses now participate in activities that in the past were the sole domain of physicians, such as physical examinations, diagnosis, treating illness, and prescribing drugs. The obverse is also true. Physicians have claimed jurisdiction over some types of services provided routinely in the past by nurses, as in the case of attending at normal births (Fagin 1990), and provision of anesthesia for surgery which only since the 1980s has become a physician specialty (Bankert 1989).

Expanded roles for nurses is a global phenomenon. The USA has led in developing expanded roles for nurses in care exploiting high technology (Fairman and Lynaugh 1998) and in independent practice roles in ambulatory care with the development of advanced practice nurses (Mezey and McGivern 1999). Other countries are now following similar patterns. British nurses have been granted wider authority by the National Health Service to prescribe drugs (Norman 2000). Canada is training nurse practitioners based on the US model of advanced practice nursing. Role expansion for nurses is occurring in a context of sufficient or excess supply of physicians, suggesting that nurses are not substituting for physicians as much as they are responding to a broader definition of health and medical care and market forces that provide new opportunities for role expansion for nonphysicians.

2.1 Historical Perspectives

Modern nursing dates back to mid-nineteenth century England when hospitals were disorganized, unsanitary, staffed by unskilled and undisciplined workers, and were generally held in low esteem. Only the destitute sought help in hospitals, except in times of war. Florence Nightingale, a wealthy and educated English woman, accepted the challenge of bringing order to military hospitals during the Crimean War and in doing so began a social experiment that would change the nature of hospitals around the world. Nightingale identified trained nurses as the vehicle for transforming hospitals but she recognized that nurses capable of skilled work and responsible ward man-

agement would have to be recruited from the better-educated classes. To legitimize the work of nursing to more highly educated women, she drew on the well-respected traditions of religious education and military-style authority. Young nurses motivated by a sense of dedication and service to mankind worked long hours for few economic rewards under strict discipline with total obedience expected (Abel-Smith 1960).

Nightingale combined her vision of order and management led by trained nurses, with the opportunity created by the Crimean War and her social position and statistical prowess to forge a new future for hospitals. Florence Nightingale, while well known as the founder of modern nursing, was also among the first to use proportional statistics (Cohen 1984). By tracking deaths by cause in military hospitals in Crimea she demonstrated that more soldiers died of hospital environmental causes than of injuries received in battle. Her volume, *Notes on Hospitals*, has been reissued in several versions as an example of one of the first medical outcomes studies (Rosenberg 1989).

2.2 Vestiges of History in Contemporary Nursing Roles

Nursing's history leaves a legacy that gives contemporary professional nurses special legitimacy in the medical division of labor, and a high level of public trust. However, that same legacy creates substantial barriers to the continued evolution of the profession of nursing in contemporary health care. Nursing developed as an ancillary occupation supportive to physicians. Nurses gained much of their professional status and public legitimacy from their close association with physicians. The subordinate status of nursing relative to medicine in the medical labor hierarchy, however, has hindered their quest for greater autonomy (Friedson 1970). The dominance of medicine over nursing is often cited as the archetype of settlement of competing occupational jurisdictional claims by subordination (Abbott 1988). Medical dominance over nurses is linked to the organizational frame of the modern hospital where the majority of nurses practice and where physicians exercise considerable professional authority. Indeed, nursing's quest for professional autonomy was not realized to any great extent until they began to practice in larger numbers and in a broader array of roles outside the hospital.

The association of early nurse training with religious orders has reinforced a continuing expectation of service and charity. These attributes are no longer valued as highly in Western culture, and no longer serve as sufficient motivating forces to recruit and retain professional nurses in today's world. Despite a shift from caring and nurturing functions to more technological responsibilities akin to those associated with male roles in other occupations, nursing has

retained a feminine image and is thus subject to sex-role stereotyping and sex discrimination in professional relationships and labor practices. The large-scale entry of women into the labor force and into higher education has facilitated the advancement of nursing by increasing the absolute number of nurses, raising overall educational levels, and broadening scope of practice. However, women now have many more career options than in years past and nursing is attracting a smaller share of new career aspirants as suggested by a steady rise in the average age of practicing nurses (Buerhaus et al. 2000). Prospects for attracting enough qualified nurses to meet projected future demands for health care are uncertain, which poses a threat to the professional advancement of nursing. In the past when the supply of nurses has been insufficient to meet market demand, nursing has been vulnerable to the substitution of less-educated personnel and pressures to lower educational standards.

2.3 Nursing Education

The education of professional nurses has undergone a dramatic transformation since the 1970s that is still underway world-wide (Lynaugh and Brush 1996). Nursing education developed in hospital apprentice-like programs with a large service component. Indeed, until the Great Depression forced many graduate nurses into hospital employment, hospital nursing care was supplied largely by students in training. Leaders in American nursing advocated early in the twentieth century the standardization of nursing education within institutions of higher education. The Flexner Report of 1910 had brought about similar reform in medical education in the USA. The analogue of the Flexner Report for nursing, known as the Goldmark Report, was published in 1923 and recommended the baccalaureate degree as the minimum entry-level educational requirement for professional nursing. Subsequent reports and commissions supported the recommendation culminating in the American Nurses Association in the late 1970s setting 1985 as the target year for requiring the baccalaureate degree. While progress has been made toward the goal of baccalaureate education for nurses, the new century dawned without this goal having been achieved in the USA, although other countries including Australia, New Zealand, Iceland, Chile, and United Kingdom have implemented an academic degree requirement for new entrants into nursing.

Friedson (1970) described nursing as an incompletely closed profession because of its inability to set a minimum educational requirement. Three generic types of education programs prepare professional nurses: three-year hospital diploma programs, two-year associate degree programs, and four-year college/university programs. Neither employers nor legal practice acts distinguish between professional nurses by type of education. The proportion of US nurses

trained in hospital diploma programs declined from over 80 percent in 1960 to less than 8 percent in 1996. Community college programs instead of baccalaureate education replaced the diploma programs and now train over 60 percent of US nurses (Aiken and Gwyther 1995). By 1996, only about 40 percent of US nurses held a baccalaureate or higher degree, and 10 percent held master's or doctoral degrees (Moses 1997).

3. Nurse Practitioners and Physician Assistants

Nurse practitioners, also known as advanced practice nurses, and physician assistants are two relatively new additions to the medical division of labor, both originating in the USA in the 1960s. Nurse practitioners represent more of an evolution in the profession of nursing than a distinct new occupation while physician assistants constitute a new allied health profession.

Nurse practitioners (NPs) are registered nurses with advanced clinical training (Mezey and McGivern 1999). In the USA a master's degree is required for certification in advanced practice nursing. Nurse practitioners provide generalist care including routine physical assessment, treatment of uncomplicated episodic illness, continuing care for persons with stable chronic conditions, and acute care in hospital settings. Nurse midwives, a type of advanced practice nurse, provide routine obstetrical care including normal deliveries as well as routine health care for women. Nurse practitioners have successfully defined a legal scope of autonomous practice although attempts by physicians to exert control over their practice and remuneration is a continuing source of conflict (Sage and Aiken 1997).

Physician assistant (PA) education is generally 24 months in length. Programs exist in four different academic pathways: certificate programs, associate degree programs, bachelor's degree programs, and master's degree programs although the PA component is the same regardless of degree level (Hooker and Cawley 1997). A major difference between physician assistants and nurse practitioners is that physician assistants have accepted a legally dependent role working under the direction of a physician while nurse practitioners have fought for and obtained a legal scope of practice that does not require physician supervision (Sage and Aiken 1997).

3.1 Historical Context

While nursing's history and evolution is strongly tied to the development of the modern hospital, nurses have a long and distinguished history in public health and home care, settings in which they exercised considerable autonomy and professional leadership. Lillian Wald invented the term 'public health nurse' in 1893 to describe a role for nurses that was a com-

bination of health promotion, illness care, and social reform (Buhler-Wilkerson 1993). Public health nursing and public health in general underwent substantial erosion in the USA with the rise of health insurance after World War II. However, the foundation for the emergence of nurse practitioners was the legacy of public health nursing.

The evolution of expanded roles for nurses and the development of physician assistants is often linked to a perceived shortage of generalist physicians in the USA in the 1960s and the market demand for physician substitutes. In the case of nurse practitioners, however, these factors created a favorable environment for expanding the scope of nursing practice that had long been advocated by nursing's leaders and that was exemplified by the early public health nurses. Thus, nurse practitioners, while often considered new allied health professionals, are really not new at all but nurses with legally sanctioned expanded scope of practice including some domains formerly controlled solely by physicians, such as drug prescription authority (Lynaugh and Brush 1996, Mezey and McGivern 1999). While educational and legal requirements for advanced nursing practice vary across countries, there is a global trend to replicate the successful US model (Fagin 1990, *British Medical Journal* 2000).

The origins of the new occupation of physician assistants in the USA stem from the return to the civilian workforce of military medical corps personnel in the 1960s at a time of a perceived domestic physician shortage. Most initial recruits to physician assistant programs were experienced medical corps personnel and the initial training programs were short-term on-the-job training. While the profession was predominantly male in its inception, it is now almost equally male and female, and the most recent graduating classes are over 60 percent female (Hooker and Cawley 1997). The early programs were located at medical schools but did not have academic standing or lead to degrees. Over time, degree-granting programs have been incorporated into schools of allied health.

Nurse practitioner education was rapidly incorporated into the large existing university-based infrastructure of schools of nursing. Enrollments in nurse practitioner programs grew steadily and by 1996 over 70,000 nurses in the USA had formal preparation as nurse practitioners, primarily at the master's level (Moses 1997). There was no comparable existing educational infrastructure for physician assistant education, and thus their numbers have grown more slowly than those of nurse practitioners, reaching 29,000 in 1997 (Cooper et al. 1998).

3.2 Practice Issues

A large research literature has developed on the safety and effectiveness of care provided by nurse practitioners and physician assistants. The Office of Tech-

nology Assessment of the US Congress conducted a synthesis of research published through 1985 and concluded that nurse practitioners and physician assistants working within their areas of competence provided comparable care to that provided by physicians, and in some aspects of care, such as patient satisfaction, nurse practitioners and physician assistants had better outcomes than physicians (Office of Technology Assessment [OTA] 1986). A special issue of the *British Medical Journal* (2000) reports similar findings from four randomized clinical trials evaluating care provided by nurse practitioners in the UK.

Competing jurisdictional claims between professions are unlikely to be solved by scientific evidence. Indeed, no matter how many studies have been undertaken including randomized controlled trials (Mundinger et al. 2000), many physicians have not accepted nurse practitioners (Kassrer 1994, Sox 2000). The opposition of physicians notwithstanding, the market demand for nurse practitioners has grown steadily in the USA, a trend that appears to be spreading to other countries (Norman 2000).

4. Other Allied Health Professionals

Over 200 different occupations and professions comprise the allied and auxiliary health care workforce. In the USA, this broad category accounts for 60 percent of the nation's 10.5 million health care workers and includes personnel who provide therapeutic, diagnostic, informational, and environmental services across the full array of health care delivery settings (Ruzek et al. 1999). The non-nursing allied health occupations are diverse in roles, functions, and education (Hamburg 1975). Many of these occupations are products of the twentieth century, having evolved in response to demands created by new technologies and niche roles created by changing patterns of medical care. Some of the alternative and complementary medicine occupations such as acupuncturists have roots in cultures that predate the development of modern Western medicine but are nevertheless considered newcomers within the Western division of medical labor (Eisenberg et al. 1998).

Education, work setting, and license/regulatory requirements vary vastly across the allied health occupations. Some fields require six months to one year training and are institutional on-the-job training programs, while others are university based. Physical therapy (PT) and occupational therapy (OT) are illustrative of the allied health professions that emerged primarily in the twentieth century.

4.1 Roles and Work Settings

Physical therapists plan and administer treatment to relieve pain, improve functional mobility, maintain cardiopulmonary functioning, and limit the disability of people suffering from physically disabling injury or

disease. Approximately one-third are employed in hospitals; other major employers include rehabilitation facilities, home health agencies, nursing homes, school systems, and clinics. About 20 percent of physical therapists are in private practice.

Occupational therapists promote learning of skills necessary to perform daily tasks, diminish or correct pathology, and promote and maintain health. Occupational therapy focuses on both mental and physical disabilities. About 60 percent of occupational therapists work with people with physical disabilities. Some specialize in particular age groups such as the elderly or children. Occupational therapists working with the mentally ill or disabled in institutional and community-based settings typically provide activities that help mentally ill and disabled people learn to cope with daily stresses and manage their work and leisure time more efficiently (Institute of Medicine 1989). Most occupational therapists are employed by healthcare organizations and private practice is not common.

4.2 Evolution of Occupational and Physical Therapy

Occupational therapy traces its origins back 200 years to a French physician's observation that mental patients given menial tasks to perform improved in functional capacity faster than those who were idle. In the USA at the end of the eighteenth century, physician Benjamin Rush introduced work as a treatment for mentally ill patients at Philadelphia's Pennsylvania Hospital, and in 1906 the first training course for occupational therapists was established in Boston (Institute of Medicine 1989). World War I created a demand for rehabilitation of large numbers of injured soldiers, which served as a major impetus for expanding the scope of practice of occupational therapy to physically as well as mentally disabled persons, and for establishing the new occupation of physical therapy.

4.3 Education and Characteristics

Not surprisingly, given the growth impetus for physical and occupational therapists associated with the two World Wars, the early recruits to both occupations were predominately women. Over time both have remained predominately female occupations, although 25 percent of physical therapists are men compared with 5 percent of occupational therapists and 6 percent of nurses. The first training program in physical therapy in the USA began in 1917 as a short course for women aides. The success of these aides in the aftermath of World War I resulted in federal funding to increase the supply of therapists during World War II through accelerated programs to train college graduates in related fields such as physical education for roles in therapy. University-based degree-granting programs in physical therapy were

established concurrently. Physical therapy has thus been a university-based educational program almost from its inception.

Since 1979, the American Physical Therapy Association has advocated graduate level preparation for the profession. As of 2002, the Association will no longer accredit baccalaureate professional programs and is moving to master's and doctoral level professional education. While practitioners with a baccalaureate degree may still practice, the purpose of the change in accreditation is to shift the educational patterns for future cohorts. Physical therapy does not support career mobility from the physical therapy aide category to the professional category and has established non-overlapping educational requirements for the two groups thus avoiding the problem nursing has faced. Physical therapy has also developed viable options for private practice, which allows the occupation to continue to evolve independently, to some extent, from institutional managerial control of salaried practice. Physical therapy is considered to be more visible and autonomous than occupational therapy for these reasons (Institute of Medicine 1989).

Occupational therapy in many ways more closely resembles nursing in its composition and education than physical therapy, perhaps because its roots are in the nineteenth century with nursing and its knowledge and intervention domains are less discrete than physical therapy. The first formal 'professional' standards for education in occupational therapy were established in 1923 as 12-month training programs for high school graduates, in contrast to physical therapy, which moved directly to university-based education. There are presently two educational levels for practice: technical training at the two-year associate degree level and professional education at the baccalaureate degree for registered occupational therapists.

Occupational therapy has had difficulty attracting students reportedly because of its focus on mental health services, which are highly stigmatized, and poorer remuneration opportunities than alternative fields such as physical therapy. In 1995, there were 54,000 registered occupational therapists compared to 102,000 physical therapists in the USA (Bureau of Labor Statistics 1996).

5. Global Perspectives

Developing countries, which contain 84 percent of the world's population, account for only 11 percent of the world's health professionals (Schieber and Maeda 1999). Physicians, the most expensive category of health personnel, are often in relatively generous supply compared to nurses and allied health personnel in countries with modest annual health expenditures. An imbalance in the ratio of physicians to allied health workers has a number of consequences including excess expenditures on secondary and tertiary care leaving inadequate resources for primary care and

public health as well as geographic imbalances in health care because physicians tend to locate in urban areas. The range in the ratio of nurses to doctors is enormous across countries: from one doctor to three or four nurses in northern European countries, to one doctor to 1.5 nurses in south-eastern Europe, and from one nurse to two doctors in Argentina, to one nurse to five doctors in Pakistan (Bankowski and Fülöp 1987).

Allied health workers provide much of the medical care in poor countries but are in short supply and often poorly trained. The potential of nurses and nurse midwives to improve access to and quality of health care in developing countries is well recognized. However, many countries have insufficient resources to create employment opportunities for qualified nurses (Bankowski and Fülöp 1986). Thus, nurses trained in developing countries migrate in substantial numbers to more affluent countries. Additionally allied health workers with some medical training such as feldshers in Russia are also in short supply because of the practice of admitting experienced health care workers to physician training programs (Ryan and Thomas 1996).

Developing countries tend to emulate the medical care systems in industrialized countries by building hospitals, purchasing technology, and training large numbers of physicians. Ultimately the prospects for improving health in the developing world are in investments in frontline allied health workers, primary care, and public health and safety.

Thus, nursing and other allied health occupations have good prospects for future growth in developing countries as well as in the sophisticated and highly technological health systems of industrialized countries.

Health Promotion in Schools

Health promotion in schools is a topic of both practical and empirical interest. Schools which provide comprehensive school health promotion programs are more effective in encouraging children to adopt health-enhancing behaviors and in reducing health-compromising behaviors than schools that provide health education alone. Research into the effectiveness of comprehensive school health programs provides evidence of the positive influence that such programs can exert on student health behaviors. However, conditions that enable effective school health promotion programs to be initiated and maintained depend on several school organizational and program implementation factors.

1. Changing Concepts of Health Promotion

The meaning of health and health promotion have been transformed over the 1990s. Influenced by the World Health Organization (WHO), health is seen as more than avoiding illness. Similarly, health promotion involves more than helping people to choose healthy lifestyles.

Health promotion in the USA, Canada, and Western Europe has been influenced by WHO concepts contained in the Ottawa Charter for Health Promotion (1986). Health is viewed as a resource of daily living, a positive concept emphasizing social and personal

resources, as well as physical capacities. Responsibility for health rests not only with the health sector, but includes building healthy public policy, creating supportive environments, strengthening community action, developing personal skills, and reorienting health services. Accordingly, health promotion professionals are expected to work for health through advocacy, enabling individuals, and mediating among diverse sectors. Developments since the Ottawa Charta suggest increasing awareness of the role values play in health-related activity as well as increasing emphasis on social justice, reducing inequalities, and enhancing social cohesion. The Jakarta Declaration on Health Promotion in the 21st Century (1997) finally outlined priorities for promoting social responsibility for health, increasing investments for health development, increasing community capacity, empowering the individual, and securing an infrastructure for health promotion.

Currently, the ever-widening gap between rich and poor is an issue of great concern, and compelling evidence confirms that exclusion, both societal and material, is highly linked to health problems. The potential effects of inequalities on the health of populations have first been stressed by The United Kingdom Charta for Health Promotion, followed by reports from Canada and the US which reported profound variation in health and well-being between poor and nonpoor children. Health inequalities exist in level of mortality and morbidity, accidents and injuries, risk behavior, mental health, school achievement, and family violence. These differences have traditionally been interpreted in terms of risk behaviors resulting from lack of education, and material deprivation. Yet, careful analyses indicate that most of the variance in health outcomes among differing social classes is not accounted for by lifestyle factors. Recent analyses challenge the 'risk group' metaphor, showing that American and European children and adolescents in high-risk settings (low income families, high unemployment of the caregivers, poor neighborhoods) were in poorer health than those living in wealthier settings.

2. Health-promoting Programs

Numerous health-promoting programs have been published; the focus diverges with some publications emphasizing public health concerns and other reflecting an education perspective. In addition, the programs vary with respect to age range, comprehensiveness, theoretical background, and the importance of evaluation. While some studies comprised primarily of survey data, others examine the effect of intervention programs. Several papers incorporate a substantial body of epidemiological and demographic data as basis for their conclusions. Most discuss policy options and recommendations. Thus, substantial vari-

ation exists with respect to such factors as level of detail, use of research data, intended audience, and political viewpoint.

Rather than giving an overview of the current state of research in school-based health promotion (see David and Williams 1987), in the following, some examples of comprehensive programs will be given, prominent trends will be presented, and, finally, frequent domains in health promotion programs will be evaluated.

To date, not many prevention and intervention programs have incorporated the important developments in health promotion values and principles. The Dartmore Health Promotion Study (McIntyre et al. 1996) is one of the rare programs that coordinated school health instruction, health services, and a healthful environment to enhance the program's effect on the health of the heart and mental health of children in grades four, five, and six. Several studies suggest that children are not engaging in physical activity of sufficient length and intensity to improve cardiovascular fitness; during adolescence, the amount of physical activity further decreases. This has resulted in the development of community-wide Youth Exercise Promotion in order to prevent heart diseases and to influence blood pressure in pupils with risk for hypertension.

To give an example, the CATCH (Child and Adolescent Trial for Cardiovascular Health) is the most comprehensive multilevel program which has been extensively evaluated (Perry et al. 1997). The interventions targeted changes at the school level (food services offerings and minutes of class time devoted to physical activity) and at the student level (psycho-social factors, dietary behaviors, physical activity levels, smoking intentions, physiological indicators). The CATCH interventions consisted of: (a) Eat Smart, a school food service program to provide children with meals reduced in fat and sodium; (b) Catch PE, to increase the amount of time students spent in physical activity at school and for other times of the day; (c) Hearty Heart and Friends, 15 classroom lessons to teach dietary and physical activity information through a series of stories; and (d) Family Fun Nights, during which pupils and family members participated in 90 minutes of games, fitness-related activities, and healthy snacks.

Generally, health promotion programs have been confined to highly selective programs designed to identify specific health risks, such as tobacco smoking, alcohol consumption or drug use, and to train health-promoting behaviors, for example with respect to prevention of HIV. Most of these programs are designed for late childhood and early adolescence and pursue multiple strategies for preventing health damage, including more traditional strategies (for example, teaching drug information and/or general communication and problem-solving skills) and approaches based on the social influence model (which emphasizes

strategies for identifying and resisting social pressure to use drugs or alcohol). Time reserved for cognitive instruction was usually low, with most curricula ranging between 5 and 15 lessons. Although the overall cognitive progress in most programs was impressive, this was not sufficient to produce corresponding reduction in use of alcohol, drug or nicotine. Mostly, the effects were stronger and longer lasting for girls than for boys. Frequently, developmentally relevant variables are incorporated, for example increasing peer pressure or a risky lifestyle during adolescence. Resistance-Skill Training(s), however, was not always found to be effective strategies for preventing the onset of alcohol, drug or tobacco use; sometimes counterproductive effects were found.

Health promotion in middle schools is a neglected area, although the middle school years are a time of increasing risk for negative health related outcomes. Health promotion in the middle school mostly focuses on two approaches, a social decision approach (e.g., teaching strategies and skills that help children to make favorable decisions when confronted with health damaging situations and offers) and social skills training (in which children are prompted, coached, and guided to practice using the skills). These approaches are based on the observation that children are unlikely to retain and use information conveyed solely through formal lessons; they need opportunities for reinforcement and practice. Further, not many health promotion or health education programs are developed for elementary school children. The Claxton Elementary School Health Program (Landis and Janes 1995) is one of the rare examples. In this project, school administrators, parents, and local physicians worked together to discover what types of healthy and unhealthy activities children and parents are engaged in, and identified which health problems are of greatest concern to parents and teachers.

Professionals in school health education have frequently emphasized parent and family involvement in school health education. Unfortunately, preparing prospective educators for such involvement often has been overlooked. Teacher training for involving families in school health education were designed to provide staff members with the background necessary to incorporate family involvement concepts and activities into their classes. This may include, for example, (a) newsletters to provide information about health and the school health program to family members, (b) family calendars about quick activities—less than five minutes—that families can do daily, and (c) information about children's books, television programs and movies that address health topics.

Recently, the interaction with families of high-risk children became a major focus, particularly in settings outside school. The Triple P Program, for example, aims at helping parents of kindergarten children with sleeping and eating disorders to cope with these

challenges by developing positive parenting attitudes and behaviors. Although it targets categorical symptoms rather than their common antecedents, it is highly valuable for preventing more severe future health problems in offspring.

To summarize, health promotion and education programs focus on late childhood and adolescent subjects and target problem behavior (which is highly inter-related such as drug and alcohol use) and unhealthy life styles (with respect to nutrition and physical activity). Stress prevention programs or programs teaching functional coping skills are less frequently applied. Most programs are centered in and around schools, but preventive approaches sometimes reach out to families with preschool children at risk

3. Evaluation of School-based Prevention and Intervention Programs

Quantitative research summaries are needed to deal with questions such as the relative efficacy of prevention and intervention programs with different aims and program orientations. In assessing program outcomes, five criteria should be met: (a) the use of appropriate comparison groups; (b) the use of appropriate pretests, post-tests, and follow up assessments; (c) examining research attrition; (d) the validity of dependent variable assessments; and (e) the use of statistical procedures appropriate for program evaluation research. In the following, quantitative reviews of prevention and intervention programs targeting adolescent drug use, smoking, and alcohol consumption were presented. They represent a new approach in that program classification schemes were used to categorize outcome, which were then employed in a quantitative meta-analysis of study effect size, based on the above criteria.

3.1 Meta-analyses of Smoking Prevention Programs

A substantial number of research report evaluating programs designed to prevent adolescent smoking have been published in the 1980s and 1990s. A very important set of questions deals with: (a) how successful these programs have been in general; (b) whether programs of different orientation show different levels of success; and (c) what variables, in addition to program orientation, may account for different levels of success. The meta-analyses conducted by Bruvold (1993) was based on 94 separate intervention studies published between 1970 and 1990. These studies evaluated school-based programs designed to deter adolescents from smoking tobacco products and were screened for methodological rigor. Each study reviewed was independently evaluated on the five methodological criteria detailed above. Forty-eight studies with adequate and defensible method-

ology were included in the meta-analyses. Program classification revealed four different types of orientation of the prevention program: (a) rationally-oriented information approach; (b) developmentally-oriented affective education; (c) social norms-oriented alternatives; and (d) social reinforcement-oriented social pressures approach. The rational model supports traditional classroom interventions where information about the short- and long-term health effects of tobacco is didactically presented. Reinforcement, social norms, and developmental interventions have two features in common: all are relatively new, and all were developed because of dissatisfaction with the uncertain effectiveness of the traditional didactic approach. Weighted average effect sizes were computed for all 48 better methodology studies for knowledge, attitude, and behavior, respectively. Positive results with similar high effect sizes for knowledge were found in programs with developmental, social norms, and social orientation. Results for attitude were generally not as positive. Programs classified primarily as social reinforcement-oriented seem to have had the most impact on attitudes, followed by those classified primarily as developmental. This suggests that newer orientations were more successful in modifying attitudes than more traditional rational approaches. Behavioral effect sizes were found to be largest for interventions with a social reinforcement orientation, moderate for interventions with either a developmental or a social norm orientation, and small for interventions with the traditional rational orientation. Altogether, the results of this meta-analysis suggest that rational orientation had very little if any impact on behavior and attitudes, and that the developmental and social reinforcement orientation revealed similarly positive effects on attitudes and behavior. Not much difference, depending on program orientation, emerged with respect to the cognitive outcome.

3.2 Comparison of Tobacco and Alcohol Intervention Programs

Frequently, school-based interventions were designed to deter children and adolescents from starting to consume alcohol and tobacco, and to convince those already consuming these substances to stop or reduce consumption. Bruvold and Rundall (1988) conducted a meta-analysis on those programs that combined tobacco and alcohol prevention. Again, they classified the programs according to their theoretical orientation into rational, social reinforcement, developmental, and social norms. In addition, the major methodological requisites for research evaluating school-based tobacco and alcohol interventions detailed above were applied to the studies incorporated in the meta-analysis. Altogether, 19 studies were found which had a control or comparison group, reported attrition rate, employed pretest, post-test and follow-up measures,

and used adequate statistical analyses. A very consistent result was that the intervention program, based upon the rational model produced fewer positive behavior and attitude effects but more positive knowledge effects than those in which the rational model was *not* dominant. Knowledge effects were consistently positive over all studies reviewed, but attitude effects were mixed, some positive and some negative. For smoking behavior, the effect size was satisfactory for long- and short-term measures, but behavioral results for alcohol were meager for long- and short-term measures. Thus, while the alcohol interventions had an effect in the desired direction on alcohol consumption, the average impact was not as large as that for smoking.

3.3 Effectiveness of Drug Abuse Resistance Education

School-based drug prevention programs have been an integral part of the US and European antidrug campaign during the 1980s and 1990s. Although programs have proliferated, Project DARE (Drug Abuse Resistance Education) is the most widely implemented school-based, drug use prevention program in the United States, and has been adopted by approximately 50 percent of school districts nationwide. The drug prevention curriculum offers 17 lessons, usually once a week, and is applied in elementary schools, as well as in junior and senior high schools. Lessons focus on teaching pupils the skills needed to recognize and resist social pressures to use drugs. In addition, lessons focus on providing information about drugs, teaching decision-making skills, building self-esteem, and choosing healthy alternatives to drug use. Didactics include lectures, group discussion, question and answer sessions, audiovisual material, workbook exercises, and role playing. Ennett et al. (1994) used meta-analysis to review methodological rigorous evaluations of short-term effects. The DARE effect size for drug use behavior was very low across the studies. For all outcomes considered, the DARE effect size means were substantially smaller than those of programs emphasizing social and general competencies and using interactive techniques. Considering the enormous amount of public funding for DARE, the short-term effectiveness of DARE for reducing or preventing drug use behavior can not be considered as satisfactory.

4. Implications for School Health Programs and Personnel

The School Health Education Evaluation indicated that for school health education to promote health for children, schools should devote at least 50 hours of classroom time each year to health instruction. How-

ever, in many industrialized countries, particularly in southern and eastern Europe, these standards are not met (Takashini and Hamburg 1997). Limited resources, including curricular time, make it unlikely that health promotion in schools will realistically increase in strength. Thus, it is important to develop more efficient ways to promote children's health, for example by adding complementary interventions to school health education from other sources.

Meta-analyses of more recent school-based studies show that it is necessary to carefully evaluate the programs. Overall, improvements of methodology and conceptualization of programs is noticeable, but still a need exists to upgrade substandard procedures regarding experimental attrition and establishing the validity of dependent variable measures. Further, there is a need for developing program intervention models that clearly and fully follow tenets of the guiding theory. In addition, prevention and intervention programs which have been designed and evaluated so far are largely confined to certain age groups (frequently to adolescents) and limited to the treatment of problem behaviors (such as drug, alcohol, or tobacco use). The health needs of younger ages, for example preschool children or children from grades one to five, are largely neglected.

Based on the recent developments of health promotion values and principles detailed in the Jakarta Declaration, health promotion in schools should acknowledge societal factors such as inequalities and poverty as important determinants of health in children and adolescents. Health promotion in schools therefore has to incorporate the community level of life quality in designing programs. School health personnel need to deal with issues that influence children and youth's health, but is beyond the traditional focus of health education and behavior change. They need to assess the quality of life as it is perceived by children and adolescents, and identify the specific needs of individual children. Then, community-based action can be developed to address these issues.

Health Psychology

Health psychology can be defined as the application of psychological knowledge and methods to the study, prevention, and management of physical diseases and disorders. Evident in this definition is the fact that health psychology is both a science and an applied discipline intended to promote human welfare. However, unlike many psychological disciplines, such as clinical or counseling psychology, health psychology addresses issues of physical rather than mental health. Emotional adaptation and mental health are considered in health psychology only to the extent that they influence—or are influenced by—physical health and illness (Schwarzer and Gutiérrez 2000).

The formal emergence of health psychology in the 1970s was influenced by a variety of factors. By that time, for industrialized nations infectious illnesses such as smallpox and influenza were no longer the leading cause of death. Through advances in basic biomedical science and its application in public health, vaccines, antibiotics, and acute clinical care, infectious illnesses had been replaced by several chronic diseases as the leading sources of morbidity and mortality. Cancer, coronary heart disease, cerebrovascular disease, and diabetes differ from infectious diseases in three fundamental ways that assured the emergence of health psychology. First, these illnesses are influenced by behavior. Daily habits or 'lifestyle' factors are

major contributors to their development and course. Second, unlike the acute crisis of infectious illness, chronic illnesses have far-reaching impacts on emotional, social, and vocational adaptation over long periods of time. Finally, behavior change is a key component of care for such conditions. Hence, behavior plays a prominent role in the development, impact, and management of the current major health threats in industrialized nations, making psychological research and practice essential in comprehensive medical research and care. This is the case for our most common chronic diseases, such as cancer and heart disease, and for more recently emerging diseases such as HIV/AIDS.

1. History, Foundations, and Related Disciplines

The emergence of health psychology was made possible by a variety of developments at the interface of behavioral and biomedical science. The work of Walter Cannon, Hans Selye, and other physiologists working in the 1930s, 1940s, and 1950s described physiological changes induced by environmental stressors and negative emotions (e.g., the 'fight or flight' response). This identified a pathway through which psychological factors could impact physical health. Shortly thereafter, epidemiologists determined that several behaviors—notably smoking, excessive intake of fat and calories, and low levels of physical activity—were risk factors for the subsequent development of cancer and cardiovascular disease. Elsewhere, psychologists were beginning to explore the application of learning principles to the treatment of physical conditions, as in the seminal work by Neal Miller on the operant conditioning of physiological responses and the work of William Fordyce on the use of behavioral contingencies in the management of pain and disability. At the same time, clinical psychologists—led primarily in the United States by Joseph Matarazzo—were beginning to establish research and clinical roles within academic medicine through appointments to medical school faculties and the establishment of related academic medical departments and services.

In response to a variety of government and organizational initiatives, health psychology became a recognized subdiscipline in the late 1970s. For example, it was established as a formal division within the American Psychological Association in 1978, and the first health psychology handbook was published in 1979 (Stone et al. 1979). At the same time, an interdisciplinary field—behavioral medicine—was established, sharing the focus on behavior in the development, prevention, and management of medical conditions (Schwartz and Weiss 1978). Although most health psychologists view themselves as engaging in behavioral medicine, that field includes concepts,

methods, and professionals from medicine, public health, and other disciplines. Hence, health psychology is a component of this broader field. Because health psychology addresses the impact of behavior on health beyond its role in established disease and disability, its emergence represented a departure from older fields such as medical and rehabilitation psychology. The former refers traditional clinical psychological services (e.g., assessment, consultation, and psychotherapy) within medical settings, whereas the latter refers to similar services and research in the context of physical disabilities (e.g., spinal cord or brain injuries).

The biopsychosocial model is a conceptual cornerstone in health psychology and behavioral medicine. In the traditional biomedical model which underlies much of modern medical research and practice, disease is seen as stemming from disordered biological systems. Aberrations in biochemistry or physiology cause disease, alter its course, and are intervention targets. Psychological or social factors are seen as largely irrelevant. In a landmark paper, Engel (1977) articulated the biopsychosocial model as an alternative. Here biological, psychological, and social processes are seen as inter-related influences on and effects of health and illness. The onset, course, and treatment of illness is best understood as involving each of these interacting, reciprocally determined levels of analysis.

Current research in health psychology consists of three general topics. The first—health behavior and prevention—focuses on the determinants of behaviors that influence disease (e.g., diet, exercise, smoking), and the effectiveness of interventions to reduce these risks. The second—stress and illness—focuses on direct connections between psychological processes and the development of illness. Rather than the intervening effects of habits and lifestyle factors, this research examines the impact of environmental stress and related personality and social processes on psychobiological mechanisms and the pathophysiology of disease. The third research area—the psychosocial impact and management of illness—focuses on the emotional and social consequences of illness and psychological interventions intended to improve adjustment and supplement traditional medical care.

2. Health Behavior and Prevention

Decades of epidemiological research have demonstrated the impact of daily habits on health (see *Health Behaviors*). A variety of conceptual models have been developed to describe the determinants of these behaviors, and thereby provide targets for interventions intended to reduce health risks (Armitage and Conner 1999). For example, the health belief model suggests that several cognitive factors influence health behav-

ior: the value or importance an individual places on health; beliefs about vulnerability conferred by a specific behavior; beliefs about the severity of the related illness; the individual's beliefs about the effectiveness of a behavior change in reducing risk; and a view of the relative costs and benefits of that change. From this perspective, interventions designed to increase the perceived importance of good health, strengthen the belief that a specific behavior impacts health, make clear the severity of the disease or condition to be prevented, emphasize the risk reducing impact of behavior change, and make salient the relative benefits of this change in promoting more healthy lifestyles. Based on this and closely related models of health behavior, interventions ranging from individual counseling to national advertising campaigns have been developed.

Other models of health behavior describe the adoption of a healthier lifestyle as a cyclical process, in which people consider and initiate behavior change, often revert to less healthy habits, and perhaps later renew their efforts (Weinstein et al. 1998). Different interventions may be optimal at different stages in this process. Informational strategies derived from the health beliefs model may be best for individuals who are in the earliest stages, either before or as they begin to consider a change in lifestyle (see *Health Behavior: Psychosocial Theories*). In contrast, active planning about the nature of 'high risk' situations where a return to old habits is likely and rehearsal of strategies for avoiding or managing such relapses may be useful after they have initiated changes. A specific health behavior change can also be addressed to many different intervention levels. For example, to increase regular physical activity, individual level counseling can be supplemented by small group or organizational level interventions such as couple, family, or workplace programs. Further, public policy level interventions can be effective, such as taxes to increase the cost of cigarettes or the construction of public recreational facilities.

For many health behavior changes, the biological level of analysis is a critical consideration. Nowhere is this more evident than in the case of smoking cessation. It has become quite clear that nicotine is an addictive component of tobacco, and that habitual smoking can be seen, in part, as the self-regulation of this addictive agent. Hence, nicotine replacement therapy (e.g., nicotine gum or trans-dermal patches) is a valuable addition to psychological or behavioral approaches.

The biopsychosocial approach to health behavior change is also evident in our current understanding of the nature and treatment of obesity. Body weights 25 percent or more above normal are associated with increasing risk of diabetes, high blood pressure, coronary heart disease, and stroke. Further, in industrialized countries, the prevalence of obesity is increasing. Vulnerability to obesity is influenced by

genetic factors. There are several likely physiological 'sites' of these genetic vulnerabilities, including resting metabolic rate, the degree of weight gain in response to overfeeding, and the location of fat deposition in response to excess energy intake. The energy balance model identifies two additional influences on obesity—the amount of energy (i.e., calories) consumed and the amount expended. Simply, individuals gain weight when the amount of energy consumed exceeds energy expended. Hence, caloric restriction (i.e., dieting) and increased energy expenditure through physical activity are critical determinants of obesity and essential components of treatment. However, larger sociocultural and economic factors also affect obesity. In industrialized nations, the availability of high-fat, energy-rich foods has increased dramatically in recent decades, and levels of leisure time and work-related physical activity have decreased. Especially for the genetically vulnerable, this sociocultural and economic context for the individual's energy balance can be a 'toxic environment' promoting obesity (Hill and Peters 1998). Hence, our understanding of health behavior influences on obesity is facilitated by the comprehensive perspective of the biopsychosocial model.

Smoking and obesity are very difficult to treat in adulthood, even with multicomponent, multilevel interventions. Research and practice on health behavior and prevention has begun to address the prevention of unhealthy behavior. That is, rather than focus on improved methods of smoking cessation and weight loss in adults, more attention has been paid recently to methods of preventing smoking and obesity in childhood and adolescence, and on the modification of these and other risk factors in youth. This trend has necessitated a developmental view of health habits and behavioral risk factors, as well as age-appropriate interventions at the individual, family, school, and community levels. Even though the modification of health behaviors in adulthood remains a priority in health psychology, early prevention is likely to become more widespread in the future.

The emergence of health psychology and its focus on health behavior change preceded by only a few years the identification of Acquired Immune Deficiency Syndrome (AIDS) and the HIV infectious agent. Quickly, epidemiological and clinical research identified intravenous drug use and unprotected sexual activity as primary risk factors. As a result, health psychologists have been closely involved in efforts to prevent HIV infection (see *HIV Risk Interventions*). As in other health behavior change efforts, multiple levels of intervention have been employed. Individual level programs include educational interventions based on the health behavior model and related approaches such as enhancing the individual's skill in negotiating condom use during intercourse. Community level approaches have focused on changing norms regarding sexual behavior and advocacy of 'safer sex' by

visible members of high-risk communities. Institutional approaches have involved increased access to clean needles for drug users.

3. Stress and Disease

A second major focus of research and practice in health psychology involves the impact of stress, negative emotions, and other psychosocial factors on the development of physical illnesses (see *Stress and Coping Theories*). In contrast to the effects of health behavior described above, this area addresses more direct connections between mind and body. In the general view guiding this research area, the stresses and strains of everyday life exact a toll on the individual's physiology. Accumulated over many days, months, or even years, such physiological changes can initiate, hasten, or exacerbate the development of illness. Further, some characteristics of the individual's personality or social environment can make them more or less susceptible to these psychological influences on disease.

A growing array of environmental and personality characteristics have been identified in epidemiological research as risk factors for physical illness and premature death. For example, individuals who are socially isolated or report low levels of available social support are at increased risk of cardiovascular disease, cancer, and premature death (House et al. 1988). High levels of job stress also place people at greater risk of illness (Schnall et al. 1994), as does the chronic stress of caring for seriously ill family members (Schulz and Beach 1999). Individuals who are prone to anger and hostility are at increased risk of developing cardiovascular disease and dying prematurely, as are people who report symptoms of anxiety, depression, pessimism, and hopelessness (Smith and Gallo 2001).

People who are socially isolated, experiencing high levels of job stress, or prone to negative emotions may be more likely to smoke, overeat, consume too much alcohol, or avoid regular exercise. These health behaviors could account for some of the effect of the social environment and personality on health. However, the association of these psychosocial risk factors with subsequent morbidity and mortality remains significant even when the effects of health behavior are controlled (Adler and Matthews 1994). The prevailing view in this research area is that the physiological effects of stressful environments and negative emotions are the link between psychosocial risk factors and subsequent disease. These mechanisms are best understood in two general pathways—the effects of stress on the cardiovascular system (Rozanski et al. 1999) and its effects on the immune system (Kiecolt-Glaser and Glaser 1995).

Environmental threats and demands evoke transient increases in heart rate, blood pressure, and concentrations of various hormones (e.g., epinephrine,

norepinephrine, cortisol, etc.). In human and animal research, over time these stress-induced physiological changes appear to promote more enduring levels of high blood pressure, and initiate and hasten the development of atherosclerosis in the coronary and carotid arteries. Atherosclerosis in these sites increases the risk of coronary heart disease and stroke, respectively. Environmental stressors and the brief physiologic changes they evoke can also precipitate acute manifestations of cardiovascular disease (e.g., temporary reductions in oxygen supply to the heart muscle) among individuals with pre-existing atherosclerosis (Rozanski et al. 1999). Further, psychosocial risk factors identified in epidemiological studies as risk factors for cardiovascular disease tend to be related to this psychophysiological mechanism. For example, social support generally reduces the magnitude of these stress-induced physiological reactivities (Uchino et al. 1996), and personality characteristics associated with increased risk of cardiovascular disease such as hostility are associated with more pronounced cardiovascular and neuroendocrine reactivity (Smith and Gallo 2001). Additional evidence of this mechanism comes from nonhuman, primate models of environmental stress, individual differences in social behavior, and the development of atherosclerosis. For example, subjected to the chronic stress of being housed with new cage-mates every few weeks, socially dominant but not subordinate male monkeys develop more severe atherosclerosis than when they are left in stable, less stressful housing conditions. Presumably, the recurring threats to status among dominant animals and the effort required to reassert status evoke physiological reactivity. Further, this effect can be prevented when the input of the sympathetic nervous system to the heart is blocked pharmacologically (Manuck et al. 1995). That is, reduction of the usual cardiovascular 'fight or flight' response through pharmacologic blockade prevents the otherwise unhealthy effect of psychosocial factors on atherosclerosis. Such findings provide the outlines of an answer to age-old questions about the influence of the mind on the body, and suggest that stress reduction could be useful in the treatment of cardiovascular disease. Interventions designed to reduce psychological stress have been found to produce beneficial effects on the health of patients with coronary heart disease (Rozanski et al. 1999).

A variety of illnesses from the common cold to some forms of cancer are influenced by the immune system, as is the rate at which wounds heal. The immune system is a complex set of structures and processes, the overall function of which is to identify and destroy foreign bodies (e.g., viruses) and aberrant cells (e.g., malignancies), and to facilitate repair of damaged tissues. Reductions in immune system functioning render the individual more susceptible to conditions it otherwise controls. A growing body of evidence suggests that environmental stress and factors that

influence the individual's susceptibility to stress impact immune functioning (Rabin 1999). Factors as diverse as the stress of final examinations to marital discord have been found to reduce immune functioning. This interdisciplinary field, psychoneuroimmunology (PNI), is the second area in which the study of mind-body connections is quite advanced. Nearly all of the psychosocial variables identified in epidemiological research as risk factors for disease have been found to be related to immune functioning (Kiecolt-Glaser and Glaser 1995).

Health behaviors might be responsible for some effects of stress on immune functioning. Smoking, inactivity, poor diet, and even sleep deprivation can produce deficits in immune functioning, and are therefore plausible links between stress and immune functioning. However, as in the case of research on cardiovascular disease, statistical control of health behaviors does not eliminate the effect of life stress and chronic negative emotions on immune functioning. As described above, environmental stress and negative emotions are associated with heightened circulating levels of several neuroendocrine factors such as cortisol and catecholamines. These neuroendocrine responses can disrupt immune functioning. It is not clear that the type and degree of immune disruption produced by stress is sufficient to account for the effects of such psychosocial risk factors on the development and course of even minor illnesses, let alone conditions as serious as cancer. Further, although some studies have demonstrated that stress-reducing interventions can have positive effects on immune functioning even among high-risk groups such as individuals with HIV, the evidence of substantial health benefits of interventions based on the PNI literature is preliminary. Nonetheless, the sophistication and clinical implications of this research area are growing rapidly.

4. Psychosocial Aspects of Medical Illness and Care

The third major topic in health psychology involves the psychosocial impact of acute and chronic medical illness, and the usefulness of psychological interventions as adjuncts to standard medical care. Some research is intended to identify the type and extent of psychosocial impacts of medical illness such as pain, disability, emotional distress, and disruption of personal relationships. Other work seeks to identify modifiable psychosocial influences on these outcomes (e.g., social support, coping styles, etc.), as well as psychosocial influences on the disease process itself (e.g., depression). Such studies can guide the development of psychosocial interventions. Although the patient is typically the focus of such interventions, some are directed at family members, caregivers, or even members of the healthcare team.

An early example of this topic was Irving Janus's psychological study of surgical patients. Based on patient interviews, Janus described a curvilinear association between the patient's anxiety before an operation and subsequent physical recovery. Those with moderate levels of presurgical anxiety experienced the least pain and the most rapid recovery compared to patients with very low or high levels. Janus argued that moderate anxiety facilitated the 'work of worry,' helping patients to develop realistic expectations and prepare to cope with later discomfort. In contrast, patients with high levels of preoperative anxiety were too distressed to engage in adaptive preparations, and patients with very low levels preoperative distress were not sufficiently motivated to prepare. Decades of subsequent research have indicated that presurgical anxiety is related to postoperative recovery in a simple linear manner (i.e., greater preoperative distress is associated with slower and more complicated recovery), providing the impetus for now routine psychological preparation of patients undergoing many potentially stressful medical procedures (Contrada et al. 1994). The provision of social support and information, hypnosis and relaxation therapies, and rehearsal of distraction and other coping strategies have been found to be effective in reducing emotional and physical discomfort, reducing medical complications, and accelerating wound healing and recovery after invasive diagnostic procedures, chemotherapy, childbirth, and even open heart surgery (Kiecolt-Glaser et al. 1998). In the case of young children, interventions intended to reduce parents' distress can facilitate the child's recovery, presumably by enhancing the parent's ability to comfort the child. These interventions are cost effective; interventions as brief as 30 minutes can reduce the length of hospitalizations by a day or more (Devine 1992). Research in this area suggests it is important to match interventions and the patient's coping style. Additional information is useful for patients who prefer involvement in their care, whereas training in distraction is best for patients who manage stress with avoidance.

Chronic illnesses such as coronary heart disease, cancer, and diabetes create many burdens for patients. These conditions pose the threat of further limitations and early death, often are associated with discomfort, disrupt social and vocational functioning, and involve unpleasant medical interventions and demands for patient behavior change. These threats to quality of life are in and of themselves important targets for health psychology interventions. However, emotional distress and poor adherence to prescribed medical regimens can contribute directly to poor medical outcomes. Interventions to facilitate coping with chronic disease, managing unpleasant symptoms, and making necessary changes in health behavior can improve functioning among these individuals and in some cases improve prognoses (Compas et al. 1998, Dusseldorp et al. 1999). For some diseases (e.g.,

essential hypertension, diabetes), behavioral interventions for changes in diet, increased physical activity levels, weight loss, and adherence to medical regimens are particularly effective, as these patient behaviors are key components of medical management. The patient's success in implementing and maintaining these behavior changes is a central determinant of health (see *Chronic Illness, Psychosocial Coping with*).

In other conditions (e.g., arthritis, headache, chronic back pain), psychological interventions are useful additions to standard care. Stress management, training in pain coping techniques, reinforcement for increasing levels of physical activity, and interventions designed to improve adaptive communication in couples and families have been found effective for reducing pain and reliance on pain medication, and in increasing functional activity levels (Compas et al. 1998). HIV/AIDS poses nearly all of these challenges in that patients are faced with a life-threatening and sometimes disabling disease, painful and distressing symptoms, and the necessity of adherence to complex medical regimens. Behavioral interventions to reduce stress, control unpleasant symptoms and treatment side effects, and improve adherence are valuable additions to HIV/AIDS care (Sikkema and Kelly 1996).

5. Emerging Challenges and Opportunities in Health Psychology

The rapid growth and evolution of health psychology seems likely to continue. Developments in basic and applied research in each area of the field have included many contributions to our understanding of health and illness, and to efforts to prevent and manage illness. Three factors are likely to shape health psychology in years to come. First, rising costs of medical care will continue to encourage the development of effective methods to prevent illness, maximize the benefits of care and limit its costs, and reduce the economic impact of illness. Although psychological interventions face growing competition from traditional medical services in a tightening climate in healthcare financing, effective interventions of any type will be well received.

Second, all areas of medical science and practice, including health psychology and behavioral medicine, must increase attention to the nature and management of health problems across diverse segments of the population. The growing concern with women's health and the health of ethnic minorities are obvious examples of this issue. Behavioral influences on health, the impact of illness on psychosocial functioning, and optimal intervention strategies in prevention and management are likely to vary across these groups. More recently, it has become clear that socioeconomic status is also a critical consideration. Within indus-

trialized nations, socioeconomic status is related to health and life expectancy. Health behavior, environmental stress, and access to medical care are important factors in this association (Adler et al. 1993). Hence, research and applied agendas in health psychology are likely to shape and be shaped by the emerging emphasis on the socioeconomic gradient in health. Of course, behavioral issues are no less important in the health of poorer nations, and an emerging 'world health' perspective will identify new roles for health psychology.

Finally, advances in basic and applied medical science will continue to shape health psychology. For example, developments in medical imaging have made it possible to study the impact of stress and other psychological factors on disease in more definitive ways. The revolution in medical genetics is making it possible to study gene behavior and gene environment interactive effects on disease more precisely, and may create the opportunity to focus behavioral risk reduction on those at greatest risk. The development of the artificial kidney and organ transplantation procedures created the need to understand the psychosocial aspects of new medical technologies. Similarly, advances in genetic testing to assess risk of illnesses such as cancer have created a new area of psychosocial research. The last three decades of theory, research, and practice in health psychology have produced remarkable growth and innovation. Although the future is difficult to predict, it appears to hold even more progress and impact for this recent variety of social and behavioral science.

Health Research, Qualitative

Qualitative health research is social research that uses qualitative methods to study problems in health, illness, and medicine. These methods include participant observation, in-depth interviewing, document analysis, and focus groups. The data collected are qualitative in nature including fieldnotes, open-ended interviews, narratives, text, organizational documents, and news and media excerpts. The data are usually in text form, but also may be visual or pictorial, and are analyzed by a variety of strategies (see Miles and Huberman 1994, Strauss 1987).

Qualitative health research is distinguished from quantitative and clinical research. Quantitative health research typically utilizes some kind of numerical data (e.g., from censuses, surveys, or experiments) and relies on statistical techniques for analysis. Clinical research is usually based on patient populations and is conducted as an adjunct to the delivery of medical care, focusing on clinical (e.g., treatment) problems. Some clinical research may use qualitative data, but typically qualitative health research does not focus on clinical or medically defined problems.

1. Background and Context

The roots of modern qualitative research can be found in early twentieth century social science (Vidich and Lyman 1994). While anthropologists had used ethnographic field work to study nonliterate and tribal cultures, sociologists at the University of Chicago in the 1920s pioneered using participant observation studies for examining aspects of urban and industrial societies (Bulmer 1984). Very little of this early fieldwork focused on health or medicine, although the classic study of *Middletown* did devote a chapter to it (Lynd and Lynd [1929] 1956).

During the 1950s and 1960s a new generation of University of Chicago trained sociologists including Everett Hughes, Anselm Strauss, Howard S. Becker, Eliot Freidson, Julius Roth, and Fred Davis, among others, laid the groundwork for the modern development of qualitative health research (Charmaz and Olesen 1997). This research was characterized by ethnographic approaches and the use of qualitative data, especially from interviews and observation, focusing on the subjective and interactional aspects of social life.

Early studies focused on medical education, organization of health care, medical institutions (especially hospitals), doctor–patient interaction, and death and dying. Several of these studies, especially by Becker et al. (1961) and Glaser and Strauss (1967) contributed significantly to the development of more rigorous and systematic data gathering and analytic methods.

Others like Goffman's (1961) *Asylums* became classics in the field.

In the latter years of the twentieth century qualitative health research prospered and continued to evolve. While social scientific research on health and medicine was dominated by quantitative studies, qualitative studies first found an intellectual niche and later flourished.

While sociologists pioneered qualitative health research, other disciplines adapted it to their own research needs. Anthropologists, who had long used qualitative methods, began to focus more research on modern societies and conducted studies on ethnicity, illness, and health care in community settings (Good and Good 2000). Qualitative studies permeated nursing research, in part because of the development of a nursing Ph.D. program at the University of California, San Francisco by Anselm Strauss and his colleagues. Feminist researchers have used qualitative methods for research on gender and health, reproductive issues, care-giving and care-receiving (Olesen 1994). Beginning in the late 1960s, British academics adopted qualitative methods to conduct research in health and medicine. In ensuing years it was adopted by researchers in France, Australia, Germany and other countries (Anderson and Bury 1988).

Qualitative methods are now well established in social scientific health research. Any number of useful primers for qualitative research now exist (e.g., Lofland and Lofland 1995), as well as compendiums for more advanced researchers (e.g., Denzin and Lincoln 1994, Hammersley and Atkinson 1995). Several journals feature qualitative studies, especially *Sociology of Health and Illness*, *Medical Anthropology Quarterly*, *Health*, and *Qualitative Health Research*. Dozens of health-related books based on qualitative data from researchers in several fields appear each year.

2. Types of Qualitative Methods

2.1 Participant Observation

Participant observation is the classic form of qualitative research. In this mode, the researchers collect observational data by observation in a situation or organization, after gaining access to their research sites. The balance between participation and observation varies, depending on the researcher and the site. The goal of the research is to understand the situation from the perspective of the participants and gaining this type of social scientific empathy can be a lengthy process. Participant-observers take fieldnotes based on their observations, which become the core data and the basis of their analysis and report. Observation is often combined with informal and formal in-depth interviewing to broaden data sources.

Participant observation is very labor- and time-intensive, but allows a close-up view of social life. In health research it has been used with great benefit for

the study of medical education (Becker et al. 1961), the delivery of health care (Zussman 1992), uses of medical technology (Timmermans 1999), professional-patient interaction (Waitzkin 1991), patient and self-help groups, alternative health care, and interaction among professionals (Bosk 1979).

2.2 In-depth Interviewing

In-depth interviewing is a central method of qualitative data collection, characterized by the researcher asking respondents a series of open-ended questions or raising topics for discussion. This is contrasted to survey interviewing, where researchers use mostly fixed-response questions (e.g., yes or no, multiple choice, Likert scale questions). Many researchers see in-depth interviewing as a 'guided conversation,' lasting perhaps from 15 minutes to many hours. While some use a fixed list of questions, others prefer to have an interview guide of topics, and then allow respondents to present their view or 'tell their story.' In either case, the goal here is to obtain narrative or textual data in the respondent's own words. Some studies are longitudinal and conduct several interviews with the same subjects of a period of time. Researchers often use tape recorders or similar devices and then transcribe the tapes into written textual data.

Researchers need to be careful to construct their interview guides so as not to unnecessarily bias the data. Questions should be asked in as neutral a form as possible and interviews should take place in a situation that is comfortable for the researcher and the respondent. One of the benefits of this kind of interviewing is that it allows the researcher to be sensitive to respondents and adjust the interview to new paths in the research inquiry.

The number of respondents in such studies varies greatly. Some studies use just a few selected respondents and interview them in great detail and depth. At the other end of the spectrum, some studies use a randomly selected sample of hundreds of respondents, each of whom is interviewed (in this case, usually by members of a research team). Most frequently, in-depth interview samples range from 20 to 100 respondents, depending on research question and the researchers' resources.

In-depth interviews have been used to study experience of illness and disability; patient and/or family view of treatment or care giving; health care providers' views of their work; the development and dilemmas in health careers; biographical perspectives on health and illness; and medical issues like adherence, seeking care, use of services, and quality of life (e.g., Conrad 1985, Kleinman 1988, Schneider and Conrad 1983).

2.3 Focus Groups

Since the early 1980s, focus groups have come into fashion as a method for collecting qualitative data,

adapted from marketing research. Focus groups are a collection of people who meet together with the investigator to discuss some topic or issue. Depending on the research topic, the members of the focus group may be already acquainted or unknown to each other, may or may not have direct experience with the topic at hand, and the groups may be of different sizes and composition. Typically, focus groups are small (five to 10 members) and meet from a single to a few occasions with the researcher. The researcher proposes the question or topic and then lets the group discuss it; depending on varying strategies, the leader may guide groups' discussion toward the topic of interest or let the group take its own course. The conversation is usually tape-recorded and then transcribed.

One advantage of focus groups is that they are a very economical method of collecting data. Several well-designed focus groups meeting for a couple of hours each can produce interactive data representing dozens of people. Compared to interviews, focus groups allow for considerable interaction among participants and thus resemble a multifaceted conversation. However, focus groups are artificial occasions, created by the researcher, and thus may not very well reflect everyday life, tend to remain on a superficial level, and are constrained by the group experience.

Focus groups are useful for discovering what a range of views are on different issues, what people's reactions are to certain topics or stimuli (e.g., type of drug or treatment); how people discuss health issues collectively; and to get a sense of the experience related to an illness, care-giving situation, or some other health-related matter (e.g., Kerr et al. 1998).

2.4 Documents

Some qualitative health data comes from sources other than observation, interviews, and focus groups. Most of these data come in the form of some type of document. This can range from governmental or 'official' documents, to organizational memos, to patient records, to news media stories, to personal letters and diaries. They can include pictorial or visual documents but are usually in some form of text. Such documents are ubiquitous to our modern world and are common in health settings and related to health issues.

Document analysis may be used as an adjunct to other methods such as participant-observation or may be the central data of a research inquiry. In some studies the data are collected very systematically, with a rigorous sampling strategy and a tight coding scheme; in other studies, often with limited and scarce data, the data collection is more of a convenience sample meant to illustrate some empirical or conceptual point. In most cases, for textual materials, one of several forms of qualitative content analysis is used to analyze the data. Often the documents can be

analyzed with the same strategies used for other qualitative data.

One advantage of documents is that they already exist and are available if one can get access to them. However, documents were created for other purposes than research and thus may not contain all the information an investigator requires or may represent more the view of the producer than reflect the reality of the situation.

Document analysis has been used to examine the emergence of medical conceptions in the professional literature, the changes in official statements about an illness or treatment, the news media's coverage or depiction of a health problem, an organization's statements about operation or purpose, or the content and presentation in patient records.

3. Qualitative Analysis

Qualitative analysis tends to be inductive rather than deductive. Instead of working from specific hypotheses and with predetermined codes, the researcher codes the data while or after it has been collected. Coding schemes can often be very complicated but are key to the data analysis (see Lofland and Lofland 1995, Strauss 1987).

Once the data are coded, researchers use qualitative analytic strategies such as 'grounded theory' (Glaser and Strauss 1967) to develop a substantive and a conceptual analysis. Grounded theory is a strategy that uses elaborate coding and continuous comparison to develop the analysis, allowing the categories to 'emerge' from close reading and analysis. An important aspect of qualitative analysis is the development of concepts, abstractions from the data that can be used to generalize the findings to other situations or cases. Examples are Glaser and Strauss's (1964) concept of 'awareness contexts' which they developed to understand the different situations and stances around information about dying, and Conrad's (1985) 'self-regulation' as an alternative to the commonly held notion of 'noncompliance.' Qualitative studies rarely claim to develop entire theories but at their best create insightful and useful conceptual understanding of aspects of the empirical world.

The best qualitative health studies enlighten the substantive issue at hand by the application or development of a conceptual analysis. If qualitative studies are to be case studies, the researchers must ask, what is it a case of? This will necessitate a conceptual or theoretical abstraction from the particulars of the case.

4. Contributions of Qualitative Health Research

Qualitative health studies have made important contributions to our knowledge. By insisting that researchers stay close to the data in their analysis and by

emphasizing first-hand data collection, qualitative studies have enlightened areas around health and health care. Qualitative studies are well suited to examining the social context of health care, organizational culture (Anspach 1993), the impacts of technology on patients (Timmermans 1999, Baszanger 1998), bioethics in medical care (Bosk 2000), the experience of illness (Conrad 1987, Anderson and Bury 1988), the functioning of medical organizations (Zussman 1992), and the process of medical education (see Hafferty 2000). Many important studies on patient experience and professional–patient interaction are qualitative (see Conrad 1987, Waitzkin 2000).

For many health issues, qualitative studies provide a unique ‘insider’s approach’ to studying a problem. In their review of ethnographic studies in medical sociology, Charmaz and Olesen (1997) conclude that qualitative studies have contributed in six ways: (a) maintaining a critical focus on the institution of medicine; (b) bringing subjective experience into medical sociology; (c) providing empirical corrections to public, professional, and sociological assumptions about medical care and health and illness; (d) challenging accepted ideas in subfields of medical sociology; (e) deepening other social scientific analyses; and (f) extending the range of medical sociology.

Qualitative research usually stands on its own but can also be used in conjunction with quantitative research; typically, either the quantitative or qualitative research predominates. For example, quantitative research can be used to set the context of a qualitative study or qualitative data can be used as cases to illustrate quantitative findings. True integration of qualitative and quantitative data is achievable although difficult (e.g., Broadhead and Heckathorn 1994).

Qualitative health research is most often of the ethnographic or analytically descriptive form described here. But other varieties have developed, including conversational analysis (e.g., Frankel 1984), narrative research (Kleinman 1988) and biographical reflection (Zola 1982). While these are not discussed separately here, they have also made important contributions to health research.

5. Critiques of Qualitative Health Research

There are several critiques of general qualitative research that also apply to qualitative health research. Since most such studies are of specific sites or nonrandom samples, the question is often raised about how generalizable findings are from the case to the larger population. Generalizability in this sense of sampling is a concept derived from quantitative studies that is often misapplied to qualitative studies. Most qualitative studies attempt to examine social processes that can be revealed by a close investigation and analysis, and it is the processes, not the site or sample, that may be generalizable. Another critique, which

frequently is a self-critique, is that qualitative researchers rarely tend to study ‘up.’ That is, investigators tend to study on their own social level or below, but rarely study the ‘seats of power.’ In health, that means we have many studies of patients, doctors, and health service organizations, but few studies of health insurance organizations, the medical industries, or the high level policy makers. This is in part a problem of access, and, it can be said, true of quantitative social scientific studies as well.

In the late 1980s, a number of scholars advanced the so-called postmodern critique of ethnography, calling into question the authority of the research and researcher and creating what some have called ‘the crisis of representation’ of qualitative research (see Denzin and Lincoln 1994). These critics argued that ethnographies are stories (even ‘fictions’) and narratives rather than authoritative representations of reality. The postmodernist emphasis on the validity of multiple perspectives rather than privileging the authors’ authority and singular truth raises significant questions about data collection, presentation, and validity of research. Some critics even suggest social scientists should abandon the pretense that ethnography adequately represents the ‘real world.’ Postmodernism’s disenchantment with ‘realism’ is not evident in most qualitative health research. Most of the research data are still realist tales (Van Maanen 1988), albeit more reflexive and circumspect than the qualitative research of earlier decades. Qualitative research remains accepted as a social scientific method of investigating social reality.

Having survived challenges from quantitatively oriented disciplines and criticisms from postmodernists, social scientific qualitative health research is by now well-established. New data sources like the Internet, an increasing number of computer-based analytic packages, and adoption of the method by more academic disciplines should allow for continued expansion and development of qualitative health research in the twenty-first century.

Health Risk Appraisal and Optimistic Bias

1. Importance of Health Risk Perceptions

Perceptions of health risks influence the actions people take to prevent illness and injury, the decisions they make to seek medical care, their choices among treatment options, and their adherence to treatment requirements. Public controversies over the risks that may be created by government and corporate actions are also familiar. During these controversies, scientists and members of the public frequently disagree, demonstrating that laypeople do not passively accept the risk judgments of experts.

These various reasons suggest that it is important to understand how risk perceptions are formed, how accurate they are, and how they influence decisions and behavior. Furthermore, as research continues to identify new risks and 'risk factors' (attributes of individuals or environments that alter a person's likelihood of harm), the need grows to explain this information clearly so that individuals can make better decisions about their health. Such education about risk is the goal of the specialty called 'risk communication.'

2. Defining 'Risk' and 'Risk Perceptions'

Before pursuing this topic it should be mentioned that the term 'risk' is used in several different ways. Sometimes 'risk' is used synonymously with the word 'hazard', denoting a specific undesirable outcome. In this sense, cancer, the common cold, and automobile accidents are all 'risks.' 'Risk' is also used as a synonym

for 'probability', referring to the probability (or likelihood) of the undesirable outcome. Thus, one can speak of the risk that a person will develop cancer. 'Risk' is frequently used in still another way, as a synonym for 'danger' or 'threat' (for example, 'How risky is smoking?'). The term 'risk perceptions', then, is a general term that refers to the various beliefs that people hold about health and safety hazards.

3. How do People Think about Risk?

3.1 Dimensions of Hazards

Hazards have many dimensions. According to classical theories of decision-making, the key attributes of a hazard are the probability that it will occur and the severity of the undesirable consequences should it occur.

Pioneering research by Lichtenstein et al. (1978) demonstrated that laypeople are also influenced by hazard attributes that are not so obviously important. When scientists are asked about the riskiness of different illnesses and technologies, their judgments strongly reflect the number of people who die annually from each one, thus reflecting both seriousness (deaths) and likelihood (number of events in a particular population). Lay judgments are only moderately related to the number of fatalities. In addition, laypeople respond to whether the risk is familiar or unfamiliar, manufactured or natural, voluntary or involuntary, and other factors. Summarizing the many attributes that influence risk perceptions, researchers have suggested that lay judgments of risk reflect two main dimensions, the extent to which the hazard is perceived to be known or unknown and the extent to which it is dreaded or not (Slovic 1987).

Leventhal and colleagues suggest that each person copes with illness threats in accord with their own 'common sense' model of that illness (see *Illness Behavior and Care Seeking*). These models involve five attributes: the identity of the risk, its timecourse (e.g., chronic vs. acute), its consequences, its causes, and its potential cure or control (Leventhal et al. 1992).

The preceding perspectives emphasize various hazard attributes. Another approach emphasizes the interconnections among the hazard properties. Beliefs about the cause of an illness, its prevalence, routes of exposure, and personal risk are all important, but it is also important to know how they are related to one another. Misunderstandings about the causes and prevalence of hazard, for example, may result in misperceptions about the likelihood of victimization. These different aspects of knowledge and belief are viewed as a 'mental model' that describes both the separate pieces and the connections between these pieces (Bostrom et al. 1992).

3.2 Hazard Probabilities

Much attention has been given to how people think about hazard probabilities. (Apparently researchers think that hazard severity is a simpler issue, for this topic has received little attention.) Although proportions (e.g., '0.25'), percentages (e.g., '25 percent'), and odds (e.g., '1 in 4') are the units used by scientists to measure probability, there is abundant evidence that laypeople have great difficulty understanding and using such information. For instance, people sometimes give a higher probability to the likelihood of dying of breast cancer than to the likelihood of developing breast cancer. Thus, the ability to recite the correct percentage, rate, or odds should not be used as the criterion to decide whether people truly understand the probability. Except for percentages given in weather forecasts, the public is rarely exposed to probability statistics, so it is not surprising that many people find numerical information about hazard probabilities unhelpful.

Some evidence indicates that people find verbal designations of probability (e.g., 'small chance of happening') to be easier to use and to better reflect their own views than numerical risk measures (Diefenbach and Weinstein 1993), but people vary greatly in the numbers they associate with particular verbal labels, making the conversion of numbers to words highly subjective. Expressions of probability in terms of odds (e.g., 1 in 50 chance) are especially disliked by laypeople.

Because it seems impossible to navigate an uncertain world without forming estimates of the likelihood that particular events will occur, we tend to assume that people must form and encode judgments of hazard probabilities. In fact, it is possible that people rarely do encode such information. Instead they may generate risk judgments from past experiences and from their own implicit theories as needed. It is also possible that people store in memory only very crude probability information (e.g., no chance, small chance, large chance, certain) and never use the finer distinctions that concern scientists and policy makers.

Because social comparison is a central feature of human existence, in everyday life people may find it more natural to make decisions on the basis of risk comparisons than on beliefs about absolute probability (the likelihood that an event will occur). Thus, a woman's interest in preventing heart disease may depend less on her beliefs about her absolute likelihood of a heart attack (e.g., 40 percent chance) than on her belief that her risk is greater than the risk of her friends. She may also compare one risk (e.g., heart disease) with another (e.g., cancer).

4. Goals of Risk Perceptions

Obviously, accurate risk perceptions can help people make appropriate decisions about actions to avoid

illness or injury. However, accuracy is only one of the goals guiding people as they formulate their risk judgments (Kunda 1990). Risk perception is not an unbiased appraisal of information, but an attempt to seek the most comforting view of one's personal vulnerability that fits within the bounds of the evidence. Beliefs about our vulnerability to harm can lead to positive or negative emotions (pleasure about successfully avoiding harm; anxiety about potential illness or disability). Perceptions of vulnerability can also affect our feelings of self-esteem (see *Vulnerability and Perceived Susceptibility, Psychology of*). Since we want to believe that we are intelligent, competent, and foresighted, to admit that our actions place us at greater risk than our peers would be a threat to our self-esteem. Thus, minimizing negative affect and maximizing self-esteem are also goals of risk perceptions, and these goals may be at variance with the goal to be accurate.

5. Optimistic Bias

This bias in risk perceptions is revealed especially clearly when people are asked to compare their risks with the risk of the rest of the population. Whatever they may believe about the risk of others, they tend to believe that their own risk is less (Weinstein 1987). For example, when people are asked how their risk of a particular illness compares with the risk of others of the same age and sex, many claim to have below average risk and few admit to having above average risk. Across a variety of hazards, it is typical to find 40–70 percent of a group asserting below average risk; another 30–50 percent saying that their risk is average; and less than 10 percent acknowledging that their risk is above average. Obviously, this distribution cannot be correct. The 'average' person has, by definition, an 'average' risk. So when the people who claim below average risk greatly outnumber those who say their risk is higher than average, implying that the average person is below average in risk, something must be wrong with their risk judgments.

Optimistic bias is not just denial, a blanket defense against anxiety. If it were, we would expect to find the greatest optimism among hazards, such as cancer, that generate the most fear. The amount of optimistic bias (that is, the extent to which people claiming below average risk outnumber those who say their risk is above average) does vary from hazard to hazard (Weinstein 1987), but it is not related to the severity of the hazard. Instead it is greatest for events that are believed to be preventable by individual action and events with which people have little personal experience. Bias is especially great if people think that vulnerability appears early, leading them to conclude that if they have not experienced the problem so far, they are free from risk.

The belief that we are less at risk than others is apparently reassuring, since people resist attempts to correct their misperceptions. Most interventions designed to eliminate bias in comparative risk judgments—for example, having people think of the ways in which the negative event could happen or think of the precautions that they have not taken—have proved unsuccessful (Weinstein and Klein 1995).

It may appear obvious that underestimating risk will expose people to unnecessary harm. However, a different view of this issue, known by the label 'positive illusions,' suggests that optimistic biases are really adaptive (Taylor and Brown, 1988). It points out that people who are overly optimistic about their ability to fight off the AIDS virus, for example, may be encouraged to maintain a healthy lifestyle and to bear with burdensome treatments. Thus, even if the perception of resistance is false, it may support other actions that are themselves beneficial. Although definitive evidence is lacking, it seems likely that underestimations of personal vulnerability decrease interest in prevention, especially when people see themselves as members of a group that does not need to be concerned about the risk, but optimism about surviving a life-threatening illness can help patients avoid depression and hopelessness (Wood et al. 1985).

6. Effects of Risk Perceptions on Health-related Behaviors

Perceived probability and/or perceived severity occupy an important role in nearly all theories that are used to explain the health-related behavior of individuals (see *Health Behavior: Psychosocial Theories*). The literature on health behavior generally supports the idea that increases in perceived risk increase precautionary behavior (Janz and Becker 1984), but there are also numerous instances in which risk perceptions and behavior turn out to be unrelated.

This should not be surprising. There are many factors other than risk perceptions that influence behavior, and people who think that they have a high risk may nevertheless doubt their ability to carry out precautions or the efficacy of the precautions. In addition, most health behavior studies have used correlational research designs, which are problematic for examining risk perception–risk behavior linkages. Finally, as mentioned earlier, experimental interventions may fail to alter peoples' perceptions of their invulnerability.

The link between perceptions and action may depend on the type of action. Precautions that prevent a health problem from occurring (such as vaccinations) should reduce both perceived risk and worry about that risk. In contrast, being tested for the presence of an existing health problem (as in cancer screening) offers the immediate potential of extremely distressing information, especially if the problem is

difficult to treat, so high perceived risk may be associated with high fear. The links between risk perceptions and different types of action still need to be elucidated.

Health: Self-regulation

Many health conditions are caused by risk behaviors such as problem drinking, substance use, smoking, reckless driving, overeating, or unprotected sexual intercourse. Fortunately, human beings have, in principle, control over their conduct. Health-compromising behaviors can be eliminated by self-regulatory efforts, and health-enhancing behaviors such as physical exercise, weight control, preventive nutrition, dental hygiene, condom use, or accident-preventive

actions can be adopted instead. Health self-regulation refers to the motivational, volitional, and actional process of removing such health-compromising behaviors in favor of adopting and maintaining health-enhancing behaviors (see *Health Behaviors*). Health self-regulation encompasses a broad range of social cognitions and behaviors that are subject to developmental changes. This article, however, is limited to models that address the current debate within the discipline of health psychology, excluding the larger fields of social and developmental psychology (Baltes 1997, Baumeister and Heatherton 1996, Brandtstädter and Greve 1994, Carver and Scheier 1998).

1. Health Motivation Factors

Before changing their habits, people need to become motivated. This is seen as a process towards an explicit intention (e.g., 'I intend to quit smoking this weekend'). Three variables are considered to play a major role in this process: (a) risk perception, (b) outcome expectancies, and (c) perceived self-efficacy (Bandura 1997, Carver and Scheier 1998, Conner and Norman 1996).

Perceiving a health threat seems to be the most obvious prerequisite for the motivation to remove a risk behavior. If one is not aware at all of the risky nature of one's actions, motivation cannot emerge. Usually, people are aware of some level of risk although the accuracy of their perception may be biased. When it comes to a comparison with similar others, one's view of the risk is somewhat distorted ('Compared to others of my age and sex my risk of getting lung cancer is low/medium/high'). This has become known as the 'optimistic bias' (see *Health Risk Appraisal and Optimistic Bias*). Nevertheless, persons also acknowledge some degree of risk when confronted with objective data. There is a realistic component that keeps the positive illusions in leash. For example, smokers not only know that smoking can cause adverse health in others, they also perceive that they are more at risk themselves for lung cancer and other diseases than nonsmokers.

Risk perception has two aspects: perceived severity of a health condition and personal vulnerability toward it (see *Vulnerability and Perceived Susceptibility, Psychology of*). The first refers to the amount of harm that could occur, and the second pertains to the subjective probability that one could fall victim to that condition. Thus, it has been recommended that people should be informed about the existence of a health risk, and moreover, that they should imagine themselves as possible victims if they do not take the necessary precautions.

Fear arousal is an emotion that can accompany risk perception. Scaring people into health behaviors, however, has not been shown to be effective. In general, initial risk perception seems to be advan-

tageous to put people on track for developing a motivation to change, but later on other variables are more influential in the self-regulation process, such as outcome expectancies, self-efficacy, and behavioral intentions.

People not only need to be aware of the existence of a health threat, they also need to know how to regulate their behavior by understanding the contingencies between their actions and subsequent outcomes. These *outcome expectancies* are influential beliefs in the motivation to change (Bandura 1997). A smoker may find more good reasons to quit than good reasons to continue smoking ('If I quit smoking then I will save money'). This imbalance does not lead directly to action but it can help to come up with the intention to quit. The pros and cons represent positive and negative outcome expectancies that are typical in rational decision making. However, such contingencies between actions and outcomes need not be explicitly worded and evaluated, they can also be rather diffuse mental representations, loaded with emotions. Outcome expectancies can also be understood as methods, or means-ends relationships, indicating that people know proper strategies to produce desired effects.

Moreover, the efficacy of such a method has to be distinguished from the belief in one's personal efficacy to apply the method. *Perceived self-efficacy* (Bandura 1997) portrays individuals' beliefs in their capabilities to exercise control over challenging demands and over their own functioning (see *Self-efficacy and Health*). Self-regulatory strength (Baumeister and Heatherton 1996) is a similar notion of one's capacity or stable resource to cope with demands. These beliefs are critical in approaching novel or difficult situations or in adopting a strenuous self-regimen. People make an internal causal attribution when imagining their behavior (e.g., 'I am certain that I can quit smoking even if my friend continues to smoke'). Such optimistic self-beliefs influence the goals people set for themselves, what courses of action they choose to pursue, how much effort they invest in given endeavors, and how long they persevere in the face of barriers and setbacks. Some people harbor self-doubts and cannot motivate themselves. They see little point in even setting a goal if they believe they do not have what it takes to succeed. Thus, the intention to change a habit that affects health is to some degree dependent on a firm belief in one's capability to exercise control over that habit (see *Control Beliefs: Health Perspectives*).

2. Self-regulatory Efforts

Changing one's health behavior is considered to be a difficult self-regulation process. After people have become engaged in a goal they need to prepare action and, later, maintain the changes in the face of obstacles and failures. Thus, goal setting and goal pursuit can be understood as two distinct processes, the latter of which requires a great deal of self-regulatory effort.

The process of self-regulation can be subdivided into sequences such as planning, initiation, maintenance, relapse management, and disengagement although these are not perfectly distinct categories. Plans specify the when, where, and how of a desired action, and carry the structure of 'When situation S arises, I will perform response R' (Gollwitzer 1999). People take *initiative* when the critical situation arises and give it a try. This requires firm self-beliefs to be capable to perform the action. People who do not hold such beliefs see little point in even trying.

The adoption and *maintenance* of the health behavior is not achieved through an act of will but involves the development of self-regulatory skills and strategies. This embraces various means to influence one's own motivation and behaviors such as the setting of attainable, proximal subgoals, creating incentives, drawing from an array of coping options, and mobilizing social support. Action control processes include focusing one's attention on the task, while avoiding attention to distractors, resisting temptations, and managing unpleasant emotions. Perceived self-efficacy is required to overcome barriers and to stimulate self-motivation repeatedly.

Competent *relapse management* is needed to recover from setbacks. Some people rapidly abandon their newly adopted behavior when they fail to get quick results. When entering high-risk situations (e.g., a bar where others smoke), they cannot resist due to a lack of self-efficacy. The competence to recover is different from the competence to initiate an action (Marlatt et al. 1995). Restoration, harm reduction, and renewal of motivation are serviceable strategies within the context of health self-regulation.

Disengagement from the goal can be evidence for lack of persistence and, thus, indication of self-regulatory failure (Carver and Scheier 1998). But in the case of repeated failures, disengagement or scaling back the goal might become an option which can be adaptive, depending on the circumstances. For example, if the goal was set too high or if the situation has changed and become more difficult than before, it is often not worthwhile to continue the struggle. In the case of health-compromising behaviors, giving up is not a tenable option. Better self-regulatory skills have to be developed and unique approaches to the problem need to be taken. The experience of failure can be a useful learning experience to build up more competence, on the condition that the individual makes a beneficial causal attribution of the episode, and practices constructive self-talk to renew the motivation.

3. Models of Health Behavior Change

In health psychology (see *Health Psychology*), models are built to describe, explain, and predict how people become motivated to change their risk behaviors, and how they become encouraged to adopt and main-

Figure 1

A social-cognitive process model of health self-regulation (Schwarzer 1992, 1999)

tain health actions (see *Health Behavior: Psychosocial Theories*).

3.1 The Transtheoretical Model of Behavior Change

Stage theorists have made an attempt to consider process characteristics by including the postintentional phase. The *Transtheoretical Model of Behavior Change* (DiClemente and Prochaska 1982), for example, has become the most popular stage model. Its main feature is the implication that different types of cognitions may be important at different stages of the health behavior change process. It includes five discrete stages of health behavior change that are defined in terms of one's past behavior and future plans (precontemplation, contemplation, preparation, action, maintenance). For example, at the precontemplation stage, a drinker does not intend to stop consuming alcohol in the future. At the contemplation stage, a drinker thinks about quitting sometime within the next six months, but does not make any specific plans for behavior change. At the preparation stage, the drinker resolves to quit within the next six months. The action stage includes individuals who have taken successful action for any period of time. If this abstinence has lasted for more than six months, the person is categorized as being in the maintenance stage.

The model, which also includes self-efficacy and other relevant features, has been applied successfully to a broad range of health behaviors, with particular success for smoking cessation. However, it has been argued that the notion of stages within this theory might be flawed or circular, in that the stages are not genuinely qualitative, but are rather arbitrary distinctions within a continuous process. Instead, these 'stages' might be better understood as 'process heur-

istics' to underscore the nature of the entire model. That is, the model can serve as a useful heuristic that describes a health behavior change process which has not been the major focus of health behavior theories so far. In redirecting the attention to a self-regulatory process, the transtheoretical model has served an important purpose for applied settings. The postintentional, preactional phase ('preparation') may be the most challenging stage for researchers and professionals because it is exactly in this phase where an intention is or is not translated into an action—depending on the circumstances. Planning and initiative, but also volatility, hesitation, and procrastination characterize this phase. The identification of stages has been shown to bear important implications for treatment. Interventions have been tailored to communicate stage-matched information to smokers who were in different motivational stages (Dijkstra et al. 1998).

3.2 The Health Action Process Approach

The *Health Action Process Approach* (HAPA model; Schwarzer 1992, 1999) suggests a distinction between preintentional motivation processes and postintentional volition processes. Within these two phases, different patterns of social-cognitive predictors may emerge (see Fig. 1).

In the initial *motivation phase*, a person develops an intention to act. In this phase, *risk perception* is merely seen as a distal antecedent within the motivation phase. It may include not only the perceived severity of possible health threats but also one's personal vulnerability to fall prey to them. Risk perception in itself is insufficient to enable a person to form an intention. Rather, it sets the stage for further elaboration of

thoughts about consequences and competencies. *Outcome expectancies* operate in concert with *perceived self-efficacy*, both of which contribute substantially to the development of an intention, whereas this pattern may change later in the postintentional stage (Schwarzer and Renner 2000).

After goal setting, people enter the postintentional stage or *self-regulation phase* in which they pursue their goal by planning the details, trying to act, investing effort and persistence, possibly fail, and finally recover or disengage. The guiding principle here is that each substage advances from the previous one and is, in addition, facilitated by perceived self-efficacy. Thus, at each point there are two predictors, namely the successful completion of the previous substage in conjunction with an optimistic sense of control over the next one. Risk perception and outcome expectancies are no longer of much influence when goals have been set and when it comes to predicting actual behaviors. Certainly, there may be various influential factors in the self-regulation phase, but according to the present knowledge, stage progression and self-beliefs appear as the most parsimonious and powerful set of predictors (Bandura 1997, Schwarzer and Renner 2000).

This health behavior change model is regarded as a heuristic to better understand the complex mechanisms that operate when people become motivated to change, when they adopt and maintain a habit, and when they attempt to resist temptations and recover from setbacks. It applies to all health-compromising and health-enhancing behaviors and could be extended to behavior change in general (see Conner and Norman 1996 and Weinstein 1993 for other models).

4. Future Directions

Health self-regulation encompasses a broad range of cognitions and behaviors. Research is needed to identify the key variables and the essential mechanisms that operate in this process. Certainly, different perspectives lead to an emphasis on different variables and mechanisms. A social psychological perspective would underscore social influence and the social context of self-regulation. A life-span developmental perspective would accentuate personal history, life events, as well as gains and losses. The present health psychology view pertains to rather short time periods that are typically involved in coping with addictive behaviors and in thorny cessation attempts. In the last two decades, social-cognitive prediction models had been preferred to explain the mechanisms of health self-regulation. These approaches are being replaced now by stage models that imply a cycling and recycling process of individuals across two or more stages. This advance in the field has led to some difficulties and controversies. One refers to the demand for parsimony because variables become easily inflated. For example,

the Transtheoretical model includes five stages and 10 processes. According to the present view, it is suggested to reduce the motivation stage to only three predictors and the self-regulation stage to only two components: stage progression and self-beliefs appear as the most parsimonious set of components. Further elaborations, however, are required and could benefit from other fields, in particular from relapse prevention theory (Marlatt et al. 1995) and self-regulation theories (Baltes 1997, Baumeister and Heatherton 1996, Brandtstädter and Greve 1994, Carver and Scheier 1998, Karoly 1993).

Health Surveys

Information collected by health surveys is used by public health officials to plan, conduct, and evaluate programs; by elected officials to inform policies and legislation; and by researchers to understand the health status of the population, the determinants of health, and the health care system. While such surveys are sponsored and carried out by many private entities, core information is generally obtained through relatively large, multipurpose, government-sponsored data collection systems; these will be the focus here, although most of the issues discussed pertain to all health surveys.

The World Health Organization definition of health as a state of physical, mental, and social well-being and not merely the absence of disease or infirmity provides the starting point for health surveys. The multidimensionality of this definition requires different survey methodologies. Since health is both a biologic and a social construct, health surveys must reflect this duality. Major topics to be covered include aspects of survey design, conceptualization and measurement of health status, determinants of health, summary measures of health, health care utilization and health behaviors. The effect of recent technological advances on data collection methods are discussed as are the growing opportunities for data linkage and the future challenges of providing access to data while protecting confidentiality and privacy.

In the late 1990s, 9.2 percent of the United States population reported they were in fair or poor health; 14 percent of children under 18 years of age had no health insurance coverage; 79 percent of children 19–35 months old were up to date on immunizations; 25 percent of adults were smoking cigarettes; and 24 percent were hypertensive (National Center for Health Statistics, NCHS 1999). Such information is used by public health officials to plan, conduct and evaluate programs; by elected officials to inform policies and legislation; and by researchers to understand the health status of the population, the determinants of health and the health care system. Information on the health of a population can be obtained through a variety of data collection approaches; health surveys represent one mechanism.

While such surveys are sponsored and carried out by many private entities, core information is generally

obtained through relatively large, multipurpose, government-sponsored data collection systems; these will be the focus here, although most of the issues discussed pertain to all health surveys. These surveys are used to profile the health of the population, to track demographic shifts and trends, and to monitor change in health and health care. In addition, the data are also used to investigate epidemiologic relationships between risk factors and health outcomes and to provide information for prevention, evaluation, research, planning, and policy. Many nations include the conduct of general purpose health surveys in their statistical systems. Table 1 provides a list of countries and the title and year of their most recent general health survey (CDC, NCHS 1999). It is tempting to directly compare the results of these surveys, but cross-national cultural differences and variation in the nature of health care systems as well as in survey designs must be taken into account when making international comparisons.

1. Definition and Operationalization of Health

The World Health Organization definition of health as a state of physical, mental, and social well-being and not merely the absence of disease or infirmity provides the starting point for health surveys (WHO 1948). However, because this definition is broad, complex, and multidimensional, it is difficult for any single survey to collect all the needed information. Depending on the specific objectives of a particular survey, there will be variation in the universes from which the samples are drawn and in the health and health-related information obtained. Since health is both a biologic and a social construct, health surveys must reflect this duality. In fact, these inter-relationships between the biological and social aspects of health are often best approached through health surveys, and advances in technology have made it increasingly possible to incorporate direct measures of biologic aspects of health into more traditional surveys.

2. General Design Issues

Health surveys can either obtain information directly from individuals (the subject or an informant) or can rely on administrative records. A wide range of sampling methodologies, sampling frames, and data collection strategies are used depending on survey objectives and the characteristics of the area in which the survey is done. Countries that have universal health care with centralized administrative systems can utilize designs that would be inappropriate in countries with less well-developed or decentralized health care systems. The simplest sampling scheme is a simple random sample of a population obtained from a complete and up-to-date list such as from a census of

the population or a centralized health care system. In the case of surveys of persons, if such lists do not exist, area sampling can be used with clustering to reduce costs. In order to be able to report information on subpopulations of interest as defined by geography and/or demographic, socioeconomic or health characteristics, designs often include oversampling of these groups. It is often necessary to incorporate screening into designs to achieve this objective. Information can be obtained either by mail, by phone, by in-person interview, or by some combination of modes depending on the ability of the researchers to contact the population using these means. The latter two modes can also incorporate computer-assisted technologies, and the use of the Internet for the administration of health surveys is being investigated.

In general, obtaining information directly from the survey subject provides more reliable and valid health data. However, this is not universally true and depends on the nature of the information sought and the characteristics of the subject (Moore 1988). For example, while accurate information on risk behaviors among adolescents can probably only be obtained from the adolescent in a private environment, adolescents are not good reporters of health care utilization or household income. Even more problematic is the situation where a health condition does not permit a subject to respond for him- or herself. Since eliminating the subject from the survey would seriously bias the results, a proxy respondent is often used.

While necessary, the use of proxy respondents does introduce a source of error into health surveys, particularly longitudinal surveys. Obtaining information on the relationship of the proxy to the subject as well as the conditions leading to the use of a proxy can reduce this error. In other cases, subject reporting is fraught with a great deal of measurement error. For example, information on the characteristics of an insurance plan is usually better obtained from the insurer rather than the person holding the insurance. Finally, reliable assessment of specific types of morbidity, risk factors, and mortality requires direct measurement through physical examination or access to administrative records from health care providers.

Many health surveys limit their population of interest. For example, it is common for health surveys to only include the noninstitutionalized population. The dramatic differences in the living conditions of the institutionalized and noninstitutionalized populations make it difficult to design survey methodologies that would apply in all situations. The military population is also often excluded from general health surveys. The scope of the universe needs to be clearly defined, especially if populations that differ in their health status are omitted—such as persons residing in nursing homes.

When obtaining information directly from the population is inefficient or would result in either poor data quality or high costs or both, an alternative is to

sample from existing records that were created for other purposes. Information on health care utilization for specific conditions is more easily obtained from hospital or provider records than from a population sample given the relative rarity of the phenomena of interest. The vital statistics system can also be considered a survey of administrative/legal records for the purpose of describing the health of the population. Administrative systems, in addition to providing basic health information, are often used as sampling frames for population based surveys. They are very attractive for this purpose as they eliminate the need to identify members of the population who have the characteristics of interest.

3. Content

Information collected on health surveys can be divided into three general types: (a) health status; (b) determinants or correlates of health including health behaviors; and (c) health care utilization. In addition, information is also collected on demographic and socioeconomic factors that affect health. For illustrative purposes, examples will be provided from two major health surveys conducted in the United States by the National Center for Health Statistics, CDC: The National Health Interview Survey (NHIS) (<http://www.cdc.gov/nchs/nhis>), and the National Health and Nutrition Examination Survey (NHANES) (<http://www.cdc.gov/nhanes>). Many statistical agencies work closely with counterparts in other nations in the design of their health surveys, thus, many observations regarding the NHIS and NHANES apply to similar surveys in other countries. Attempts to standardize various parts of health surveys have increased in recent years.

The NHIS is a principal source of information of the health of the civilian noninstitutionalized US population. Conducted annually since 1957, the NHIS currently collects information through computer assisted in-person interviews from approximately 40,000 households covering 100,000 people. Conducted about once a decade, NHANES is based on detailed physical examinations in addition to in-depth interviews. A nationally representative probability sample of the US civilian, noninstitutionalized population is interviewed at home and then invited to visit a Mobile Examination Center (MEC) for a standardized physical examination of about four hours, including a physician's exam, physical measurements, blood and urine tests, and nutritional assessments.

4. Overall Health Status

As noted above, health status is a multidimensional concept, requiring multiple indicators and multiple methodologies for adequate measurement. Several

different indicators of health status are usually included in health surveys, including single summarizing measures; questions relating to disease incidence and prevalence; and questions relating to functioning (physical, cognitive, emotional, and social). Health status measures also vary by whether they are based on objective information obtained from standardized examinations or medical records or from information obtained from the individual or a proxy. To be most effective, individual health surveys should capture a variety of aspects of health status so as to provide a more comprehensive and complete assessment of health status than would be possible from any single strategy. Measures of health status should also be constructed to be useful in epidemiologic analyses of risk factors as well as for monitoring trends.

The subject's self-assessment of his/her health status as excellent, very good, good, fair, or poor is a popular summary indicator of health status. This measure has been shown to be highly correlated with other measures of health status and is predictive of mortality and admission to long-term care facilities (Idler and Angel 1990). However, this measure can be problematic when used to monitor change over time. The means by which individuals evaluate various aspects of health have been shown to be affected by contextual parameters. Implicit in self-perceived health status is the individual's evaluation of his/her health status against some unstated standard. Societal norms act to define the standard, but the norms and the standards change in response to a variety of conditions. The reporting of general limitation of activity has also been shown to be affected by changes in such things as the criteria used by government agencies in determining eligibility for disability benefits (Wilson and Druny 1984). Thus, observed changes in the indicator may not reflect changes in underlying health status.

5. Medical Conditions

A variety of approaches can be used to measure disease incidence and prevalence including: diagnosis by a health care provider; symptomatology (if an appropriate symptom battery exists); or medication use. Additional information of interest related to conditions includes date of onset, the use of health care services, and the impact of the condition on the individual's ability to function. Severity of condition is often inferred from the type of medications or health care services used or the nature of the impact of the condition. In examination surveys, diagnostic testing adds to the information available on the prevalence of conditions. Most important, direct physical exams allow for the measurement of previously undiagnosed conditions.

A major issue in the collection of condition data is the number of conditions to be considered. Condition checklists can be used to obtain information on a great

number of conditions, but in most cases, only a minimal amount of information on any given condition is collected. In addition, long checklists are difficult to administer and result in reporting errors. However, the use of comprehensive lists does allow for the ascertainment of co-morbidities. An alternative is to obtain more detailed information on a select group of conditions. Criteria such as the prevalence of the condition or the potential impact for the individual and the health care system are used to select the target condition. In the NHIS, for example, information is obtained for adults on heart disease, diabetes, cancer, pulmonary diseases, depression, and arthritis.

Some surveys, such as the NHIS (until 1997 when a major questionnaire redesign was fielded), limit their focus to conditions that result in the receipt of medical care or in activity restriction, thus placing more emphasis on the impact of the condition than on the fact that a diagnosis had been made or symptoms reported. This provides a somewhat more concrete referent for the questions being asked which should result in improved data validity and reliability. However, limiting the definition of health problems to those that result in behavior such as seeking care or restricting activity is more appropriate when ill health is primarily the result of acute conditions where onset is clear and there is a closer association between the condition and the behavior. As a result of the 'epidemiologic transition,' acute conditions have given way to chronic conditions as the major sources of morbidity. Chronic conditions are more difficult to diagnose, and longer periods are spent in the disease state both prior to and after diagnosis. As a result, the collection of information on symptoms takes on greater importance when investigating chronic conditions that may or may not have been diagnosed. Diagnostic examination or testing is necessary for some important conditions (e.g., hypertension, cancer) which may be asymptomatic in their early or less severe stages.

Requiring that health care use or activity limitation be present in identifying conditions also makes it difficult to investigate social correlates of health status since the definition incorporates a social dimension. Access to sick leave or affordable medical care may be limited by social or economic factors. Persons who do not demonstrate the required behaviors because of these social factors will not be considered as having a health condition.

Examination surveys like the NHANES provide a complementary mechanism for obtaining information on conditions. Self-reported information, similar to that collected on the NHIS on self-perceived health status, disease symptomatology, physician diagnosis, and level of functioning, is obtained from in-home or MEC interviews. In addition, the results of the physical exam, and of the blood and other tests, can be used to objectively measure health status. For example, information on diagnosed diabetes is

obtained from the interview, and information on undiagnosed diabetes is obtained from blood tests. Information on functional limitations related to diabetes (e.g., vision and mobility problems) coupled with similar information available from the other components of the NHANES allows for a detailed characterization of an individual's health status. The information is also used for the investigation of risk factors for disease and for monitoring of functional outcomes.

Information on conditions can also be obtained from surveys of health care providers (hospitals, private physicians, hospital outpatient departments, emergency departments, ambulatory surgery centers, and long-term care). Sampling frames of providers must first be developed. Random samples of discharges, stays, or visits are then selected from the records of a random sample of providers. Information on conditions is routinely found on the medical records in addition to other descriptive information concerning the patient and the encounter. Such survey designs are generally used to obtain information on health care utilization and the health care system, but the information available can be used to study conditions that are associated with medical care.

Health care or provider surveys offer an independent assessment of disease prevalence by approaching the problem from the provider side rather than the patient side. Health care surveys are particularly important since they obtain information on rare conditions that would not be picked up in population based surveys. They also provide larger sample sizes than would be obtained in surveys such as the NHIS and the NHANES. While information is collected on all conditions for which health care is obtained, the nature of the information available is limited to that which would routinely be obtained from records. In addition, the event (e.g., the discharge), rather than the person, is the unit of analysis. For example, while it is possible to estimate the number of hospital stays associated with hip fracture, it is not possible to estimate the number of persons with hip fracture even if one could assume that all hip fractures were admitted to the hospital. An enhancement to health care surveys would be to follow patients after the health care encounter.

Cause of death statistics obtained from a vital statistics system also provide essential information on medical conditions. While not error free, a great deal of effort is put forth to standardize the collection and coding of cause of death (<http://www.cdc.gov/nchs/icd9>).

6. Functioning

An important component of health status concerns functioning—physical, cognitive, emotional, and

social. While conditions relate more to the biologic aspects of health, functioning moves more into the social realm. Information on functional status can be ascertained through objective tests but is most often obtained through direct reporting by the individual or a proxy. Information on functional status encompasses a wide range of activities from the very basic such as raising an arm to the more complex such as working and going to school. Obtaining information on functioning is complicated by the fact that performance is affected not only by physiologic abilities but by the environment as well. A person's ability to walk may be impaired by a condition that leads to weakened muscles, but with the use of braces or a wheel chair along with appropriate accommodations in the physical environment (e.g., ramps), that individual is mobile and able to carry out appropriate social roles. For some purposes, information is needed on functional ability without the use of assistance of any type. In other cases, functioning ability as measured by usual performance is important. In any case, questions must be specific concerning how performance should be measured. A large number of question batteries have been developed to measure function (McDowell and Newell 1996). Some use only a few questions, focus on the more complex social roles, and do not differentiate between different aspects of functioning (physical, cognitive, emotional, or behavioral). Others are quite lengthy and obtain detailed information on a wide range of activities both with and without assistance.

In the NHIS, information is obtained on limitation of activity (i.e., the subject's ability to perform age-/sex-appropriate roles such as working, going to school, keeping house), activities of daily living (e.g., bathing, dressing, toileting, eating, and transferring), and physical functioning (e.g., walking, bending, and standing). Information is also obtained on the conditions causing the limitation. A subset of the NHIS functioning questions is provided in Table 2.

As for self-perceived health status, measures of functioning are affected by contextual parameters as well as unstated standards against which respondents compare their own functioning. The less explicit the referent standard, the more likely that the response will be affected by external factors. For example, no explicit standard is provided when asking subjects if they are limited in the kind or amount of work they can do. Responses to this question will be affected by the kind of work that the individual thinks he or she should be doing as defined by their own expectations and by the requirements set by government agencies such as disability programs as well as by more objective states of health. This is less of a problem if one is interested in monitoring the impact of health on work. However, it is much more of a problem if the aim is to understand and monitor a more objective measure of health.

Many health surveys are limited to the noninstitutionalized population and therefore do not include

Table 2

Examples of questions on functioning from the National Health Interview Survey

Family members under five years of age	Are/Is {fill in name of child} limited in the kind or amount of play activities he/she/they can do because of a physical, mental, or emotional problem? Is {subject name} able to take part at all in the usual kinds of play activities done by most children {subject name}'s age? Do any of the children under 18 in this family, {fill in names of children under age of 18} receive Special Education or Early Intervention Services? Has a doctor or health professional ever told you that {subject name} had Mental Retardation or any other developmental delay? Has a doctor or health professional ever told you that {subject name} had Attention Deficit Hyperactivity Disorder (ADHD), Attention Deficit Disorder (ADD), Mental Retardation, or any other developmental delay.
Family member between the ages of 4 and 17	Do any of the children under 18 in this family {fill in names of children under age of 18} receive Special Education or Early Intervention Services?
Family member older than 17 years of age	Do you now have any health problem that requires you to use special equipment, such as a cane, a wheelchair, a special bed, or a special telephone? By yourself, and without any special equipment, how difficult is it for you to walk a quarter of a mile—about 3 city blocks, walk up 10 steps without resting, stand or be on your feet for about 2 hours, sit for about 2 hours, stoop, bed, kneel, or reach up over your head? (each asked separately) By yourself, and without using any special equipment, how difficult is it for you to use your fingers to grasp or handle small objects, lift or carry something as heavy as 10 pounds such as a full bag of groceries, push or pull large objects like a living room chair? (each asked separately) By yourself, and without using any special equipment, how difficult is it for you to go out to things like shopping, movies, or sporting events, participate in social activities as visiting friends, attending clubs and meetings, going to parties, do things to relax at home or for leisure (reading, watching TV, sewing, listening to music ...)? (each asked separately) Because of a physical, mental, or emotional problem, {do/does} {you/anyone in the family} need the help of other persons with personal care needs, such as eating, bathing, dressing, or getting around inside of the home?

Table 2
(Continued)

{Do/Does} {you/subject name} need the help of other persons with bathing or showering, dressing, eating, getting in or out of bed or chairs, using the toilet, including getting to the toilet, and getting around inside of the home? (each asked separately) Because of a physical, mental, or emotional problem, {do/does} {you/anyone in the family} need the help of other person in handling routine needs, such as everyday household chores, doing necessary business, shopping, or getting around for other purposes? Does a physical, mental, or emotional problem now keep {you/any of these family members} from working at a job or business? {Are/Is} {you/anyone in the family} limited in any way because of difficulty remembering or because {you/they} experience periods of confusion? What condition or health problem causes you to have difficulty with activities/these activities? How long {have/has} {you/subject name} had this condition?

those segments of the population in poorest health or with the highest level of functional limitations, such as those in long-term care settings. Special studies of these populations can be carried out and there should be some attempt to combine results from the non-institutionalized and long-term care populations (<http://www.cdc.gov/nchs/about/major/nnhsd/nnhsd.htm>, <http://www.cds.duke.edu/text/nltcs.html>). Changes in the delivery of long-term care with the expansion of transitional establishments have made this an even more important issue for survey designers.

7. Determinants of Health

Health surveys generally include measures of risk factors, health behaviors, and nonhealth determinants or correlates of health such as socioeconomic status. The range of measures that can be included is wide and varies by survey. Basic demographic and socioeconomic variables are usually included (i.e., age, race/ethnicity, education, income, urbanicity, region). Tobacco use, alcohol use, diet, and physical exercise are common health behaviors. In order to identify causal relationships between determinants and outcomes, longitudinal designs are needed. The value of health surveys would be increased by the inclusion of

a broader array of potential determinants of health (biologic, psychological, and social).

8. Summary Measures of Health

There has been considerable interest in the development of summary measures of health in order to more easily characterize and monitor the health status of a population and for use in cost-benefit and cost-effectiveness analyses. There is also increasing interest in developing basic health status indicators comparable to the economic indicators currently in use. These indicators would be used to monitor the effects of public policy and to identify areas where interventions are needed. An overall health measure is very appealing in this context. Many health surveys include the information necessary to calculate the summary measures that have been developed. One such approach is to use a measure of morbidity or health status to transform life expectancy into healthy life expectancy. Examples include Disability Free Life Years, Healthy Life Expectancy, and Years of Healthy Life. Constructs such as these combine measures of the different aspects of health into a single number using a conceptual model that views health as a continuum. The health states along the continuum are assigned numbers that represent the values that either society as a whole or individuals place on that health status. Various methods have been used to determine

the values of the different health states. These measures are used to modify duration of life (Erickson et al. 1989).

9. Health Care Utilization

The use of the health care system is a major dimension of health. Information on utilization and related characteristics such as health insurance are collected from person-based surveys and through surveys of administrative records. In person-based surveys, respondents are asked to recall the number of contacts they have had with various health care providers and the nature of the provider and the contact. Information on the receipt of particular services, such as immunizations or mammography, is also obtained. This is often difficult for respondents. Research has shown that reporting of doctor visits drops off considerably when the recall period extends beyond two weeks (Edwards et al. 1996). To address this recall problem, some surveys such as the Medical Expenditure Panel Survey (MEPS) ask respondents to keep detailed diaries of their medical care contacts, obtain the name of the provider, and then contact the providers (with the subject's permission) to verify the self-reported information (Monheit et al. 1999). Information on utilization can also be obtained from surveys of providers, usually providing more accurate information on the nature of the contact, including the reason for the contact and the services provided. Surveys of providers can also yield valuable information on the structure of the health care system itself and how the characteristics of the system affect access to care and the cost of care.

10. Longitudinal Designs

Most health surveys use a cross-sectional design which provides data for the calculation of population averages and is most appropriate for monitoring changes in health over time. A cross-sectional design is not appropriate for investigating causal patterns or for documenting transition probabilities from one health state to another where change at the individual level needs to be measured. A solution would be longitudinal studies which are expensive and more complicated to field. One alternative is to transform cross-sectional studies into longitudinal studies by linking information from mortality records to the survey data. The United States has developed a National Death Index which allows investigators to track the vital status of their study cohorts by matching identifiers to a complete listing of death certificates. Using a probabilistic matching algorithm, information is provided on the fact, date, and cause of death (<http://www.cdc.gov/nchs/r&d/ndi>). Cross-sectional surveys also can form the baseline cohorts for future active longitudinal follow-ups (US DHHS 1987). These

longitudinal activities present extensive opportunities for understanding the relationship between risk factors and disease outcome as well as the natural history of disease. Generation and analysis of such longitudinal data is greatly facilitated in countries (e.g., Sweden) where various governmental information systems and surveys can be linked.

11. Technological Advances

Advances in technology have affected the conduct of all surveys. Computer-assisted telephone and personal interviewing have allowed for increasing levels of complexity of survey administration. Errors associated with keying and coding have been replaced by errors associated with programming. The use of these technologies has resulted in the need for longer lead times prior to fielding a study but has reduced the time from the end of data collection to the availability of results.

The increase in electronic as opposed to paper files has greatly expanded the opportunities for linking data from various sources. Ecological or contextual information about the geographic area in which survey respondents live can now be linked to the survey data. This has the advantage of allowing researchers to address different levels of analysis. Survey data can also be augmented with administrative data from mortality files and from health care providers. In addition to reducing survey costs, this often leads to data of improved quality.

12. Methodological Research and Analytic Techniques

The quality of health survey data has been greatly increased by methodological research on survey techniques (Bradburn and Sudman 1979, Fowler 1995, Lessler and Kalsbeek 1992). A major advancement has been the development and application of cognitive methods for questionnaire construction (Sirken et al. 1999). Drawing from the field of cognitive psychology, cognitive research laboratories have been established and can investigate how respondents perceive and answer questions. Another fruitful area of research involves studying the behavior of both interviewers and respondents within the social context of the interview situation (Cannel et al. 1977). A more structured approach to the errors found in health surveys will enhance data quality. The results of this research will lead to improved design that minimizes error but will also lead to ways to adjust for known errors in the analysis and interpretation of results (Jabine 1987).

Advances have also been made in the development of appropriate analytic tools for use with health survey data. These include methods to account for such issues as survey nonresponse and complex survey design. As

it is possible to collect data of increasing complexity, it will be necessary to develop the analytic approaches appropriate for the collection methods used (Korn and Graubard 1999, Biemer et al. 1991, Groves and Couper 1998, Rubin 1987).

13. Privacy and Confidentiality

For ethical reasons and in order to obtain high response rates and valid information, most health surveys closely guard the information provided by respondents. In some cases, the requirement to protect confidentiality is legislatively mandated. This is particularly important for health surveys, given the personal nature of the information collected. Confidentiality can also be protected by not releasing data that could identify a respondent. Most survey sponsors subject files that are to be released for public use to rigorous disclosure review. The risk for inadvertent disclosure has increased in recent years. It is no longer necessary to have access to large mainframe computers to utilize survey data, much of which are provided on the Internet or on CD-ROMs. In addition, databases not related to the survey data, but which can be used to identify individuals in the survey data files, are more available and more easily accessible.

It is the potential linking of survey data to these external databases that increases the risk of disclosure, and the risk increases with the amount of information that is available. The ability to link external data to survey responses presents an analytic breakthrough as the utility of survey data can be greatly increased through the appropriate linkages, however, this ability also greatly increases the risk of disclosure especially when the linkages are done in an uncontrolled and inappropriate way. The increased sensitivity to issues of privacy in many countries, especially as related to health care, is affecting how confidential data are being protected. There has been a decrease in the amount of data that can be released as public use files. Other mechanisms are being developed so that access to data can be maximized while protecting confidentiality. The use of special use agreements, licensing and research data centers are examples of these approaches (Journal of Official Statistics 1998).

Hebb, Donald Olding (1904–85)

Donald Hebb was responsible in no small part for the profound change in psychological outlook that emerged in the 1950s. His influence on the field of cognitive neuroscience is still apparent.

1. Education and Early Life

Hebb was born, the eldest of four siblings, on July 22, 1904 in Chester, Nova Scotia. Both his parents were physicians. He was educated at home until the age of eight by his mother, using Montessori methods. He then attended the local school, which he hated.

Hebb's ambition as a young man was to become a novelist. He graduated from Dalhousie University (Halifax, Nova Scotia) in 1925 with a BA in English and philosophy. While awaiting inspiration for the 'Great Canadian Novel' he returned to his village school as a teacher. In search of experience he spent the next summer as an itinerant farm worker in western Canada and tried, unsuccessfully, to get a job as a deckhand in Vancouver.

In 1927 Hebb was back East, teaching at a Montreal high-school. Becoming interested in Sigmund Freud's ideas, he applied to McGill University to study psychology part time. The next year he was appointed principal of an elementary school and enthusiastically set about instituting and testing new teaching methods. In 1930 he was bedridden for a year with a tubercular hip, during which time he conceived a theory of how spinal reflexes might be learned *in utero*. This formed the basis of an MA thesis, now lost. Hebb (1980) later described it as nonsense.

In 1932 Hebb began doctoral research, still part-time, at McGill. The experiments, which involved conditioning dogs, were supervised by Leonid Andreyev, a former student of Pavlov, but Hebb soon became disillusioned with the technique and when his first wife was killed in a motor accident he abandoned the research.

Hebb enjoyed teaching and administration and was tempted to make a career of being a headmaster. He finally chose to continue his studies, however, and in 1934 he was accepted as a student at the University of Chicago by Karl Lashley, whose book, published a few years earlier (Lashley 1929), had established him as the pre-eminent physiological psychologist of the period.

Hebb spent a year in Chicago where, in addition to his close association with Lashley, he attended lectures by Wolfgang Köhler, Paul Weiss, C. J. Herrick, and the statistician L. L. Thurstone. Then Lashley accepted the offer of a professorship at Harvard and Hebb accompanied him. He was granted a Harvard PhD in 1936 for research on the effects of early experience on vision in the rat.

2. Montreal Neurological Institute

After a post-doctoral year of research with Lashley, Hebb was awarded a two year Fellowship to study mental changes resulting from brain operations at the newly established Montreal Neurological Institute (MNI). The operations were mostly frontal and temporal lobectomies performed by Wilder Penfield to combat epileptic seizures. Hebb made what is probably the first observation of a visual deficit after human right-temporal lobe removal. To his surprise he found no measurable effect of frontal lobectomy on standard measures of intelligence (Hebb and Penfield 1940). Attempts to understand this result lay at the foundation of much of Hebb's later work.

3. Primate Research with Lashley

After his MNI Fellowship, Hebb obtained a post as Lecturer at Queen's University (Kingston, Ontario). There he devised a variable rat-maze so that he could continue his brain lesion research using rats. In 1942 Lashley offered him a five year Fellowship to study effects of brain lesions in chimpanzees at the Yerkes Laboratories of Primate Biology, Florida. Partly because of his heavy teaching load at Queens, he accepted it.

The project was to study the effects of brain lesions on intelligence and emotion in chimpanzees. Lashley was to work on intelligence tests, Hebb on tests of emotion, but no lesions were made before 1947 when Hebb's Fellowship ended. Hebb did, however, assemble a good stock of chimpanzee stories that contributed to the great popularity of his subsequent lectures, and in the intellectually stimulating surroundings he wrote his most influential work, *The Organization of Behavior*, which was published in 1949.

4. McGill Once More

After World War II, the McGill psychology department had dwindled to one part-time child psychologist, so in 1947 Hebb was one of four psychologists who were recruited to rebuild the department. The next year he was appointed chairman.

Having made a highly successful foray into the world of science, Hebb returned to teaching and administration with enthusiastic vigor. He taught the introductory course to overflow classes for the next 25 years, and wrote three editions of a highly respected textbook. He also conducted a seminar for all incoming graduate students, which gave him the opportunity to coach them in the presentation of succinct and closely timed talks, as well as to instill a thorough understanding of a range of theoretical issues. To test some predictions of his theory, he supervised research on early learning in rats and dogs, and effects of sensory deprivation on human thought processes.

In later years Hebb received many honors; he was President of both the Canadian (1952) and the American (1960) Psychological Associations. He was elected a Fellow of the Royal Society of London (1966), a Foreign Associate of the National Academy of Sciences (USA), and an Honorary Member of the American Academy of Arts and Sciences. In 1970 he was appointed Chancellor of McGill University. In 1974 Hebb retired to his family home in Chester Basin and became active in the psychology department at Dalhousie University, where he was appointed Honorary Professor. He published his last monograph, *Essay on Mind* in 1980 and died in Halifax on the 20th of August, 1985 of heart failure during hip-replacement surgery.

5. Hebb's Contributions to Neuroscience

During his years as a graduate student Hebb learned the hard way what was wrong with contemporary psychology. At McGill, as is evident from the topic of his Masters thesis, he flirted with the extreme empiricism then rampant in North America. Influenced by Boris Babkin and Leonid Andreyev, students of Pavlov, he passed through a Pavlovian phase. When he moved to Chicago he entered the Gestalt enclave of Wolfgang Köhler and Karl Lashley; and at Harvard he encountered the historian, Boring, who taught him what psychology had been like before the Behaviorists. Sooner or later, for reasons that are cogently presented in the first few chapters of *The Organization of Behavior* (Hebb 1949), he turned against all the established schools of psychology.

Because of his research on cortical lesions and his neural theories, Hebb is often labeled as a physiological psychologist, but his interests were really much broader. *The Organization of Behavior* was an important catalyst, aiding the revival of cognitive psychology, and although he was a zealous proponent of the idea that the brain is the organ of mind, Hebb's interest in neurophysiology took second place to his interest in thinking and other aspects of behavior. In his hands neurologizing was a tool to restore respectability to the study of mental functioning in psychology.

As a psychologist, Hebb was frustrated by the behaviorists' refusal to acknowledge such important processes as attention, expectancy, and thought, lest they should be accused of vitalism. Hence his eagerness to show that those mental processes could be performed by an entirely material brain. He based his neural model as far as possible on established physiological principles, but neuroscience was on the brink of a revolution and many of those principles were soon to be revised.

For example, Eccles, whose defense of the electrical theory of synaptic transmission Hebb had embraced, recanted and demonstrated excitatory and inhibitory

chemical synapses. Furthermore, the behavioral importance of subcortical structures such as the reticular arousal system, the amygdala and the hippocampus became clearer, and improved staining techniques revealed a much more complex visual system than was known to Hebb. The fact that these revelations had almost no effect on the impact of Hebb's book shows to what extent the psychological implications of his neurologizing outweighed the underlying physiology. By proposing a material basis for concepts, Hebb demolished barriers to the study of cognitive processes that the behaviorists had erected a generation earlier. In his Presidential address to the Experimental Psychology Division of the American Psychological Association in 1954, Hebb introduced the reticular activating system into his model to extend his explanation of emotion, but apart from that he did little to revise the theory in the light of new neuroscientific data.

His most famous contribution to neuroscience was not based on neurophysiological research, it was inferred from behavior. Most physiologists thought that learning synapses were strengthened by use, but Hebb along with other psychologists realized that association involved at least two activities. Thus he postulated that learning changes at synapses require simultaneous firing of both presynaptic and postsynaptic neurons. Synapses with properties similar to those postulated were subsequently identified experimentally and are now known as Hebb synapses.

Hebb held strong views about the 'nature-nurture' question. After his early gyrations he adopted the unassailable position that both inheritance and experience are totally necessary for intelligent behavior, using the analogy of area as the product of length and breadth. Of course, one may still be interested in whether an area is square, long and narrow, or short and fat. In spite of Hebb's bipartisanship, his concept of the development of vision was long in the 'nurture' dimension. Hebb's visual cortex bore a strong resemblance to Locke's *tabula rasa*.

Thus, Hebb assumed that neurons are randomly connected in the newborn visual cortex. With experience, synapses are strengthened between neurons activated simultaneously by sensory input, producing groups of connected neurons (*cell assemblies*) that then represent the input. Hebb further postulated that a complex figure elicits a series of eye movements, thereby activating a succession of associated cell assemblies that Hebb called a *phase sequence*.

Anatomical diagrams of the cortex suggested to Hebb that cell assemblies consist of networks of closed loops. This led him to speculate that once a cell assembly is activated impulses continue to circulate around the loops for some time (reverberation), constituting a short-term memory. In this way Hebb explained the persistence of an idea or mental image in the absence of the corresponding object. Today, short-term memory may be explained more plausibly by

persistent chemical traces, but Hebb never abandoned his reverberation theory, which still dominates the thinking of many neural model builders and neurophysiologists who study the visual system.

According to Hebb, the impulses reverberating around the cortical loops of an activated cell assembly produce synaptic changes that bind the neurons together more permanently. This explains long-term memory. Ideas arouse other ideas by association, thus cell assemblies must acquire associations with each other whenever they are active at about the same time. Hebb never satisfactorily explained how, after linking in this way, they avoid merging to become bigger cell assemblies.

The capacity to explain intention, attention and other mental processes was an important goal of Hebb's theorizing but one that, in *The Organization of Behavior*, he was content to achieve in principle rather than by rigorous neural modeling. Short-term expectancy and attention were explained in terms of the phase sequence getting ahead of the sensory input. Thus a previously experienced sequence of stimuli sets up a central process that facilitates cell assemblies in advance of the sensory input they represent. Hebb postulated higher order central processes that facilitate more extended sequences. In much of his writing Hebb treats the cell assembly as equivalent to an idea; its neural basis is tailored to fit behavioral observation.

6. Summary

The Organization of Behavior is now a classic. Half a century after it was written it is still frequently cited. Many psychologists regard it as the herald of an era of cognitive research that blossomed in the 1950s. Hebb's ideas about the representation of concepts and their associations with each other are the common currency of almost all present-day psychologists, even those who prefer to ignore the brain, but devotees of neural networks and neurophysiologists studying sensory systems are those who most often refer explicitly to his theory.

After Hebb left Lashley's 'think tank' in Florida and took up his duties as chairman of the McGill psychology department, most of his energies turned to building and running a strong department there, including teaching. Although Hebb took every opportunity to promote neurologizing in psychology, he showed little further inclination to keep pace with the rapid advances in neuroscience or to make any major changes to his neural theory.

Apart from his own characteristically stylish and witty account (Hebb 1980a), there have been several more recent commentaries that complement this entry for those who wish to learn more about Hebb's life and work. These include nine essays in his honor, written by former students and edited by Jusczyk and Klein (1980), and a delightful chapter by Stephen Glickman (1996) which accurately portrays the man and his

achievements. Fentress (1999) and Klein (1999) edited a special issue of the *Canadian Journal of Experimental Psychology* that contains a further collection of papers on Hebb and on research inspired by his ideas. Orbach, a student of both Hebb and Lashley, published a book (1998) in which the contributions of his two mentors are discussed and compared.

Hegel and the Social Sciences

G. W. F. Hegel (1770–1831), born in Stuttgart, achieved his full fame in Berlin between 1818 and 1831 as a professor of philosophy. Much of his fame rests

on the posthumously edited and published lectures on the philosophies of art, religion, and history, along with his epochal book of 1807, the *Phenomenology of Spirit*. However, despite Hegel's immense influence on modern thought, he has remained one of the most controversial and difficult to interpret philosophers of the modern period. It is nonetheless widely agreed that Hegelian-inspired theories of society rest on certain fundamental theses: first, they give fundamental priority to the 'totality' of social life over more individualist accounts; second, such theories claim that we can only understand the kinds of demands social life makes in terms of its historical embeddedness; and, finally, such theories claim that there can be no value-free approach to history and society. There is, however, not nearly as much consensus as to what each of these general claims meant for Hegel or about what follows from them. In some interpretations, Hegel has been taken as an ominous figure, a kind of dark warning for modern academics to stay away from metaphysics; in other interpretations, Hegel is taken as one of the original theorists of European modernity and as an ongoing source of insight and inspiration.

Although part of the difficulty of interpreting Hegel has to do with his notoriously obscure style and his sometimes ferociously idiosyncratic jargon, much of the difficulty has to do with how one is to take his statements about the role of mentality (*Geist*, perhaps better rendered in English somewhat artificially as 'mindedness') in nature, society, and history (and often one's interpretation of that depends how one understands Hegel's ultimate stance toward religion). This is also tied into Hegel's general holism, the thesis that the politics, art, religion, and economy of a society are so intimately related to each other that not just any concatenation of such practices and institutions is compatible with any others, and that the point of such practices and institutions is to provide the vehicles through which a way of life can collectively reflect on and become self-consciously aware of what ultimately matters to it. In Hegel's own lifetime and afterwards, people took his holism more or less in one of two ways: either as a grandly metaphysical statement about an absolute reality (called *Geist*, mindedness) that assumes different forms in history and which progressively reveals itself to itself; or as a more normative account of agency that does not invoke that kind of metaphysical entity acting behind the scenes to explain things.

To understand what is at stake in that debate, one must at least have some idea of the rather heated atmosphere present in German philosophy at the time in which Hegel came to prominence.

By the end of the eighteenth century, Kant's critical philosophy had changed the very terms of debate in Germany, and while certainly not everybody became a Kantian, almost all aspiring philosophers in Germany felt that they had to come to terms with Kantian

thought. Kant had, according to his own description of things, essentially demolished the longstanding feud between empiricists—those who believed that science was only a sophisticated and methodical purification of our more ordinary responses to the givens of experience—and rationalists—those who thought that Galilean and Newtonian physics showed that the mind was capable of mathematically articulating the structure of the universe independent of experience. Kant argued that there were no givens of experience at all, that our conscious experience of the world always involved an active and spontaneous 'taking-up' of that experience (a rationalist theme), although our activities of 'taking-up' experience depended for that experience for its empirical content (an empiricist theme). He also argued that in the moral realm, we are completely self-legislating; there are no givens within human nature or in the cosmos at large that can determine what may count as a moral principle for us. The reality of this radical human spontaneity and freedom was secured, so Kant had argued, by distinguishing between the way in which we necessarily had to describe and order our experience of the world and the way that the world existed in itself independent of any description we might give it. We could never know, in Kant's famous phrase, the way things were in themselves, only the way in which they necessarily appear to us. Thus although we had to appear to ourselves as standing under deterministic natural causal laws, we also had to postulate for practical reasons the necessity of our freedom as we were 'in ourselves,' even though we could never theoretically demonstrate the existence or lack of existence of such radical freedom.

For Hegel's generation, who had come to believe, however indistinctly, that they were leading unprecedented lives and for whom the French Revolution was the defining event, Kant's philosophy of freedom and spontaneity had an electrifying effect. Kant's immediate successors were also convinced that the outstanding problems with his own solution called for an effort to 'complete' the project he had begun. This took the forms of attempting to establish Kantianism on better foundations, or of focusing on the way in which Kant had (or should have) rejected all forms of 'givenness' in epistemology and morality, or of showing how Kant's own dualisms were to be reconciled by showing them to be only mutually conflicting 'appearances' of some deeper underlying 'absolute' reality that itself was only to be apprehended through some non-discursive act of intellectual intuition. The latter turn was famously carried out by Hegel's old friend, F. W. J. Schelling, who crafted an entire theory of nature and mind as modes of appearance of the 'absolute,' or as the way the absolute gradually realizes itself in history. (In part, much of the debate about Hegel's philosophy has since centered on just how 'Schellingian' or 'non-Schellingian' his thought really was.)

In much of his writing prior to the 1807 *Phenomenology of Spirit*, Hegel had worried about what shape a 'modern' way of life would take and in particular what role religion, especially a reinterpreted form of Christianity, might play in such a modern way of life. Throughout his development, however, he held fast to the post-Kantian notion that the modern, post-revolutionary world was something qualitatively new and demanded a 'new sensibility' appropriate to itself. To that end, Hegel's 1807 *Phenomenology* was intended to demonstrate what would be required of 'we moderns' if we to conceive of our lives without any secure, 'given' foundations. In his *Phenomenology*, Hegel sarcastically characterized Schelling's notion of the Absolute as 'the night in which all cows are black,' signaling his rejection of the idea of an absolute reality that is beyond all conventional descriptions and differentiations and which can only be grasped in some non-discursive mode. So Hegel argued, rejecting all 'givens' and affirming Kantian notions of spontaneity implied there could be no inherently privileged viewpoint without at the same time also implying that we were stuck with any kind of pure relativism about viewpoints.

In an early chapter in the *Phenomenology* (drawing on some themes taken from Fichte and Schelling), Hegel constructed an imaginary encounter between two agents, each thinking of himself as seeking only to satisfy the desires given to him by organic life. To the extent that each agent legitimates his own judgments about what is valid for him only in light of locating himself within the totality of 'life' and its demands, he demands of the other that the other recognize his point of view as authoritative, that he may do what he pleases to satisfy his own desires, even to use the other to get what he wants. In making that demand, though, each finds that it is not 'life' itself that is setting the terms of judgment but his own self-conceived project for his life, of his bestowing on *his* desires a prior claim to satisfaction over the desires of others. Each thus demands 'recognition' from the other of the authoritativeness of his own point of view—not merely that he has pressing desires but that he determines which desires and whose desires have a legitimacy to satisfaction. Those reciprocal and incompatible demands necessitate a struggle for such recognition, and to the extent that one of the parties decides that his own self-conception is more important than life itself and is willing to risk his life to secure the authoritativeness of his self-conception, it becomes a struggle to the death.

If in such a struggle for recognition, one of the combatants out of fear for his life submits to the other's demand for recognition, he then enters into the relationship of servitude to that other, who now becomes the 'master.' The vassal then comes to judge the validity of his own desires, tastes, and plans in terms of how they fit into the master's point of view. Or, as Hegel put it, the vassal's own *self-relation* is now mediated through an 'other.' Through the discipline of

his work for the master, the 'vassal' comes to distinguish more clearly between his own subjective point of view and a more impersonal, normative point of view represented by the master. The master's point of view represents the 'totality' in terms of which the vassal must orient himself. However, as only a particular point of view whose sole claim to authority has to do with its ability to force itself on the vassal, it cannot ultimately sustain any normative allegiance to itself. As the vassal reflects on his status, he comes to understand the sheer contingency of the master's hold on him, and the master comes to understand that the recognition he requires from the vassal is only compelled, not the free recognition he requires.

Self-consciousness in Hegel's scheme thus only comes about through struggles over mutual recognition. To be self-conscious in Hegelian terms is thus not to have some inner sensation of oneself or merely to be consciously alive; it is rather to locate oneself and others (and similarly be located by others) in a complex 'social space' of norms, commitments, entitlements, and the like, and for both parties to act in light of that mutual self-locating and being located. This conception of self-consciousness as emerging only in mutual recognition and of its being the result of a struggle turned out to be one of Hegel's most enduring and widely interpreted legacies. Although others had often made claims about the inherently social nature of man, Hegel was the first to make this claim about the very structure of reasoning and agency itself. Each agent needs the other not to help him satisfy some given desire but to *be* an agent at all. Agency is thus itself a reciprocally conferred social *normative status*, not a metaphysical *fact* about people: to be an agent is to be the kind of organic creature that binds himself to and is held by others to epistemic, practical, even religious and aesthetic *responsibilities*. We become agents, almost paradoxically, by treating each other as agents.

The rest of the *Phenomenology* presented a historical account of how various modes of sociality—of complex reciprocal holding of self and others to basic authoritative norms—have failed to be able to sustain themselves and became thereby unlivable, compelling their participants to come to recognize that they had over time failed to sustain their own status as agents and (without intending it) had come to require of themselves a different form of collective life. In such transitions, what had seemed like an 'absolute' point of view had turned out to be incoherently unlivable or to be only the point of view of some particular group, and its capacity to sustain allegiance to itself unraveled. In those terms, Hegel reinterpreted not only the great transition from the ancient to the modern world but also certain particular historical transitions such as that from ancient Greece to Rome or from the aristocratic society of the *ancien régime* to the moralistic society of postrevolutionary Europe. Each such transition came to be understood as part of the

development of reason itself, of what counted as a basic norm and therefore what counted as agency itself. This was in Hegel's account not the development of a latent capacity somehow already present within us but which was only gradually actualizing itself nor was it the result of any kind of natural law compelling such historical movement, as it were, from the outside; it had to do with the inherent difficulties involved in binding each other to certain types of norms and in the way in which we came to be required to hold ourselves to different norms—that is, in *being* certain types of agents—and in the specific ways being those types of agents had failed and quite unintentionally resulted in different collective ways of being agents.

In his own lifetime and until today, people have tended to read Hegel's philosophy of history in the *Phenomenology* as a kind of story about how some appropriately grand absolute reality (identified with mindedness itself, *Geist*) gradually develops itself and actualizes its own potentiality by using various world-historical individuals and nations as a way to follow its own destined path of maturation. However, Hegel himself argued that the sense of destiny in history had nothing to do with laws of history or any such grand metaphysical scheme but with the ways in which human agents can understand the kind of agents they concretely *are* only in light of the kinds of options that their history has opened up for them. The realization that that there is no grander show behind the curtain of appearance pulling the strings for us, either in the form of historical laws (metaphysical or material) or in the form of gradual actualizations of longstanding latent potentialities, is itself distinctly modern and, as an *unsurpassable* form of self-understanding, as marking perhaps *the* decisive event in human time, is itself *absolute*. It also represents, so Hegel thought, the human community coming to a more adequate collective self-consciousness about the kinds of norms to which it had committed itself and to which it had to keep faith; and, quite famously, Hegel held that art, religion, and philosophy are to be understood as historically embedded social practices whose underlying point has to do with the manner in which they embody a way of life's concrete reflection on who they have come to be and on the matters that have come to be authoritatively valuable for them.

The different ways of taking Hegel's thought also apply to the different interpretations given of his mature work in social and political philosophy, the 1820 *Elements of the Philosophy of Right*. Although the book was unfairly criticized both during and after Hegel's lifetime as a mere 'apology' for Prussian absolutism, it was actually an attempt on Hegel's part to articulate the rational form of the kind of reformed, modern European state that modern reformers like Baron von Stein, and later, Prince von Hardenberg, had tried to establish in Prussia. The core idea of the book is that what counts as 'right' in general is what is necessary for the realization of freedom.

Hegel thought of freedom, though, not as the exercise of some special form of causality (as Kant had done) but as a kind of 'self-relation,' as having one's actions come from oneself (always though in terms of such self-relations being mediated by relation to like-minded others); and, quite radically, Hegel held that for 'we moderns,' freedom involves being held to norms that are rationally redeemable. The opposite of such freedom is to be pushed around by factors or considerations not really our own but stemming from something else that we cannot rationally redeem (for example, brute desires or mere social conventions). In Hegel's almost paradoxical way of putting it, one can be an agent only by being recognized as an agent; the conditions of agency are the social conditions under which such agents can reciprocally hold themselves and each other to being certain kinds of agents.

For agents to be free, they must be able to practically reason about their activities, and that requires that they have some conception of some 'good' that they are seeking to actualize. Hegel wished to argue that all genuine practical reasoning has as its major premise some statement about what is ultimately good and best, and when an individual acts rationally, he acts on the basis of some (again, perhaps sometimes implicit) deliberation about what is necessary for him to achieve what is good and best for himself.

For 'we moderns,' that good must be that of 'freedom,' but stated so abstractly, it seems to offer little guidance for deliberation on what would be required to achieve such 'freedom.' To that end, Hegel argued, in the modern world, the realization of freedom must be articulated into three more determinate spheres, which he characterized as 'abstract right,' 'morality,' and 'ethical life' (*Sittlichkeit*). Each of them embodies a way in which very specific institutions and practices underwrite and sustain the ways in which our freedom is actualized in that each of them provides individuals with more concrete, specific first premises about 'the good' (freedom) on the basis of which they may then rationally deliberate what they are required to do.

If we are to have any concrete first principles for moral reasoning, therefore, we must grasp them not as specifications of some 'master rule' but as elements of a social *practice*, ways in which we prereflectively learn to orient and move ourselves around in the social world. Hegel called this sphere, 'ethical life,' *Sittlichkeit*. 'Moral' individuals exercising their 'abstract rights' to life, liberty, and property require a location in these kinds of social practices, which embody within themselves determinate conceptions of what is 'ultimately best,' namely, as the way in which individuals exercise their rights, manage their moral obligations, and come to be 'at home' in the social world by virtue of acquiring a kind of 'ethical virtuosity' in being brought up and socialized in these practices. *Sittlichkeit* thus provides us with determinate principles and a kind of practice-oriented ethical 'know-how,'

and such institutions and practices form what Hegel called 'concrete universals.'

There are three such institutionalizations of *Sittlichkeit* in the modern world, each serving to give individuals a concrete specification of these final goods upon which they can then rationally deliberate. These are the modern family, civil society, and the constitutional state. Together they form a social 'whole' in terms of which individuals orient themselves and which reconciles them to modern social life, gives them good grounds for believing that modern life really is, although imperfect and finite, nonetheless for the best.

Since the modern state appeals to neither God nor natural law for its legitimacy, it must appeal to some sense of what a 'people' collectively establish as rational. This drives political philosophy into a philosophy of history, which, so Hegel argued, demonstrates that from the vague intimations in the ancient eastern states that 'one' (the emperor, the pharaoh) is free, and from the Greco-Roman political conceptions that 'some' (aristocratic males) are free, history has culminated in the modern world's recognition of the principle that 'all' are free. This, Hegel argued, is the *meaning* of world history, and Europe has been its penultimate staging ground. European culture, with its inherent sense of 'negativity,' self-doubt, and skeptical questioning, has by virtue of the kind of culture it is, propelled itself progressively to abandon those criteria, whose lack of rationality made itself manifest until in the modern period it has come to recognize, at least implicitly, that freedom has always been its collective goal, and that such freedom can only be vouched for in an institutional setup much like the one outlined in the *Philosophy of Right*. Freedom itself is thus reinterpreted as a kind of social norm, a historical *achievement*, not the better realization of a potency that, for example, the Greeks also possessed but failed to actualize. (In a completely empty sense of 'potentiality,' such capacities were, of course, always empirically present exactly in the sense that, for example, empirical science or abstract art has always been a human possibility. The kind of 'potency' that is being realized is more like that involved in a narrative than it is like an orthodox Aristotelian realization of a potentiality.)

After his death, in the rather tense atmosphere in Berlin in the 1830s and 1840s, there was a lot of pressure to interpret Hegel in either conservative or progressive terms. The 'July Monarchy' in France and the subsequent revolutionary upheavals in other parts of Europe (along with social unrest throughout Germany) made the ruling authorities anxious while raising the hopes of the reformers. There was a line of thought, especially popular among liberals, to the effect that a kind of historical law was at work that mandated countries to pass through a revolutionary upheaval, establishment of a republic, years of war, and then roughly fifty years later to settle into a constitutional monarchy (first in England, later in

France); on that view, England represented the end-point of modernity, France was almost there, and progress seemed to call for the establishment of constitutionalism in Germany by revolution if necessary; many of Hegel's own students enthusiastically embraced this view of the 'law' of history (despite Hegel's own rejection of such a view). His school thus split famously into 'right' and 'left' Hegelians. The 'right' Hegelians made Hegel into more of a Schellingian and had him espousing a view of history that basically endorsed the (non-constitutional) Prussian monarchy as metaphysically destined, as the only form of social organization compatible with the necessary structure of the cosmos. The 'left' Hegelians, led first by Hegel's friend and follower, Eduard Gans, tended to stress the elements of work and recognition as accomplishing the necessary historical tasks. In the hands of later 'left' Hegelians, however, such as Ludwig Feuerbach, the question began to be raised as to whether it was necessary to have any kind of 'absolute' at all. If history was a matter of labor and recognition, and people's labors were always socially and therefore materially mediated, then why could Hegelianism not be turned into something more like sociology, or into some form of empirical social theory?

The young Karl Marx, coming to maturity in this left-Hegelian atmosphere, transformed Hegel into a materialist thinker. (He was helped in this endeavor by the deservedly forgotten H. M. Chalybäus's characterization of Hegel's thought as following the strict scheme of thesis/antithesis/synthesis, a bowdlerization that has been applied ever since.) Eschewing all talk of the 'absolute' and of 'mindedness,' Marx read into Hegel a kind of evolutionary doctrine of the gradual realization of human capacities that were themselves historically mediated and were themselves the achievements of labor and struggle. The material conditions of life—both its organic demands for sustenance and its social demands for the organization of labor and distribution of wealth—set the terms in which people interact with each other. Hegel's doctrine of the 'struggle for recognition' thus became shorn almost completely of its epistemological bearings and became a doctrine of materialist social reality and history. In the writings of the mature Marx, this was complemented by a theory of how human consciousness is itself socially mediated and is therefore dependent on the ways in which that society is structured, particularly in terms of the relevant forces of production in society and the patterns of ownership of the means of production. Famously, Marx also transformed Hegel's philosophy of history into a set of dialectical laws to the effect that revolutions come about when the forces of production and the relations of production come into irrevocable conflict with each other. Hegel had argued that history was not best understood as a matter of divine providence, natural law, or even as the consequence of the decisions of

great men, but rather as a kind of broad scale drama of people collectively trying to come to terms with the people they had come to be in terms of the norms to which they had collectively bound themselves; Marx transformed that into a broad scale story about the ways in which human societies are organized around key material matters such as the production of the necessities for organic and social life, and he held that these follow a law-like pattern in a manner analogous to natural events.

Like Hegel, though, Marx thought that one had to understand social and political phenomena as a whole, even if he ascribed more or less independent importance to the facts about ownership of the means of production; and like Hegel, he put great emphasis on how a given social formation understands itself—what it basically values and counts as authoritative for itself, even though there too he ascribed a more or less independent value to the economic organization of society in determining how such communities arrive at this kind of collective self-consciousness. Marx's own ideas about the historical destiny of the proletariat, of course, went far beyond anything to be found in Hegel's thought. (Later 'Western' Marxists such as Georg Lukacs tried to synthesize Marx's and Hegel's alternative understandings of historical development.)

Simultaneous with Marx's materialistic development of Hegel's thought, there were ongoing 'liberal' developments of Hegel's views. Lorenz von Stein (whose impact on Marx is difficult to prove but who developed certain key 'Marxist' ideas before Marx had developed them himself) developed a kind of liberal post-Hegelian theory of society and history in the 1840s and 1850s through a series of historical writings on the social and political developments in France from 1789 to 1848. Stein argued that 'society' (*Gesellschaft*) had come to assume a prominent role in modernity such that one could best understand the way in which a people comes to reflect on itself not in terms of a 'people' or a 'nation' but in terms of the way in which the 'social' has in modernity separated itself from the 'familial,' the 'political,' and even from 'religion' to make itself central to modern life. The basic norm of freedom had historically generated a sense of individualism that, together with the emerging industrial revolution, made 'social' matters (and, more specifically, economic matters) absolutely central to modern forms of self-understanding. In particular, notions of 'possession' and 'property' assumed all the more importance in the self-understanding of such modern individuals; in 1842 Stein argued that a new social class, the 'proletariat,' had thus emerged within modern 'society,' and the tensions emerging between propertied owners and unpropertied proletarians was to be the central social issue of modern times; since the propertied classes and families would quite naturally seek to take over state power for themselves, it was crucial to construct Hegel's notion of the political state around an idea of a socially oriented state that would

secure the fair distribution of the basic goods of society for all its members. (Like Hegel, Stein also thought constitutional monarchy was consistent with such a state.) Retaining the Hegelian emphasis on the 'totality' and the ways in which collectivities understand themselves, Stein nonetheless transformed Hegelian idealism into a kind of quasi-empirical sociology and sociological theory of history; the dynamics of social change and contemporary social structures were to be understood historically in terms of the different modes of self-understanding at play in them; the crucial role of the economy in modern self-understandings was not a timeless natural law (as with Marx) but the result of the kind of self-understandings that modern individualism and industrial society had given rise to. (The next step, although Stein himself did not take it, was to transform Hegel's notion of social practices of family, society, and state into a theory of social *roles*. Hegel's own conception of agency as itself a reciprocally conferred normative status opened the way to understand social action in terms of the more theatrical notion of role-playing, since for Hegel there is no self 'behind' or 'beyond' the deeds that express the norms to which we mutually bind ourselves.) Hegel's own more philosophical worries about how, if all knowledge is socially embedded, the thinker could be in a position to know that or to truthfully assert it were also absent in Stein's transformation of Hegelianism into sociology.

In sum: for Hegel, mindedness, *Geist*, formed a sphere distinct from nature without itself being any kind of non-natural thing; indeed, *Geist* was, for Hegel, no *thing* at all but instead a socially mediated normative status. Hegel's view, moreover, toward the incipient social sciences of his own time was, on the whole, positive; he seemed to think, for example, that Adam Smith and the other Scots had made economics into a science. There is no reason for a Hegelian to deny that there are many interesting causal facts or correlations about societies that can be discovered and established only by empirical investigation. (Thus, the post-Hegelian distinction between the 'understanding' appropriate to the human sciences vs. the 'explanation' appropriate to the natural sciences would be viewed by Hegelians as yet another inadequately dualistic approach.) However, Hegel's key idealist notion—that we best understand societies by understanding how they collectively interpret themselves and the kinds of authoritative values to which they bind themselves and with how those acts of mutual binding must be understood historically—remains forever at odds with all doctrines that posit that some set of basic, natural facts fully determine how we are to understand the course of human events (such as the overall material geography of a place, as the vastly influential historian, Ferdinand Braudel, has argued). Such natural facts, while clearly forming the context in which such collective attempts at self-interpretation occur, cannot fully determine those interpretations. To understand

those interpretations, we must understand why that way of life came to regard those specific norms and not others as binding for them, and to understand that, we must understand how such commitments emerged as necessary in light of the way in which past attempts at collective self-definition had proved themselves to be unlivable. Underlying that is the 'Idea,' as Hegel put it, of freedom, of humanity realizing its destiny in a way of life whose members could be at home in the social world they create, although of course never under the conditions chosen by themselves. For Hegel, all social science only made sense as a smaller part of a larger story about modernity's coming to terms with the radical sociality of our own mindedness and with our very modern awareness of modernity's decisive rupture in human time.

Hegel, Georg Wilhelm Friedrich (1770–1831)

1. Biographical Data

Hegel, Georg Wilhelm Friedrich the philosopher was born on August 27, 1770, in Stuttgart (Germany), and died on November 14, 1831, in Berlin. In 1788, Hegel, son of a medium-grade civil servant, entered the Protestant Seminary in Tübingen, where he won the friendship of his roommates Hölderlin and Schelling. He held a ducal scholarship for studying Theology and Philosophy at the University of Tübingen. After graduating in 1793, he earned a living as a private tutor in patrician families, first in Bern, Switzerland (1793–1796), and then in Frankfurt (1797–1800), where he regularly met Hölderlin. At the beginning of 1801, Hegel joined Schelling in Jena and qualified for lecturing with his habilitation thesis *On the Orbits of the Planets*. While at Jena (1801–1806), Hegel published his *The Difference Between Fichte's and Schelling's System of Philosophy* (1801). In the years 1802 and 1803, his essays *The Relationship of Skepticism to Philosophy*, *Faith and Knowledge*, and *On the Scientific Ways of Dealing with Natural Law* came out in the *Critical Journal of Philosophy*, which he copublished with Schelling. The major work of this period was, however, the *Phenomenology of Spirit* (1807), which was intended to be the first part of his system of philosophical science.

After the Battle of Jena, Hegel, having no income, took over as editor of a newspaper in Bamberg in 1807 and one year later he became principal of a secondary school in Nuremberg. There, Hegel married Marie von Tucher with whom he had two sons. During the Nuremberg period, Hegel published his *Science of Logic* in three volumes (1812, 1813, and 1816), the first of which, the *Doctrine of Being*, reappeared in heavily revised edition in 1832. In 1816, Hegel was finally granted the privilege of earning a secured income as a full professor in Heidelberg. In 1818, owing to the personal intervention of Minister Altenstein, he became Fichte's successor in Berlin.

From 1816 on, Hegel published—apart from several minor writings—the *Encyclopedia of Philosophical Science* (1817 in Heidelberg, and in two greatly enlarged editions 1827 and 1830) as well as his *Elements on the Philosophy of Right* (1821). His lectures on Esthetics, the History of Philosophy, and the Philosophy of History and Religion were not only attended by students but also by members of the Berlin society hungry for education. Until the mid-1940s, Philosophy in Germany could not be exercised without taking a position on Hegel's philosophy. Moreover, his philosophy influenced the formation of those special sciences, which Dilthey later called '*Geisteswissenschaften*.' Soon after Hegel's unexpected death, his school split into different wings as a consequence of

philosophical disputes on religion. In 1837, David Friedrich Strauss classified this splitting into the left (e.g., Karl Marx), the right (e.g., Friedrich Wilhelm Hinrichs), and the central (e.g., Karl Rosenkranz).

2. Aspects of his Philosophy

2.1 Interests of the Young Hegel

The young Hegel studied the ancient authors, the literature of the Enlightenment and above all Kant's critical philosophy (see *Kant, Immanuel (1724–1804)*), Rousseau's works on cultural criticism and theory of politics (see *Rousseau, Jean-Jacques (1712–78)*) as well as the dispute on Spinoza, which had been initiated by F. H. Jacobi. Furthermore, he enthusiastically paid close attention to the course of the French Revolution. At that time, he mainly worked on three questions. Firstly, how must a national religious education be conceived for it to strengthen the motivation for ethical and political action? This question had strongly suggested itself after Rousseau had failed to come to a convincing result concerning the question: which type of religion can be legitimated from the political point of view of a rational community? In his works on religion and ethics, Kant had then shown that a conflict is avoidable between religious and ethical duties on the one hand and religious and political duties on the other. Therefore, what mattered was to translate the idea of such a union of all those duties into an educational program.

Hegel, Hoelderlin and Schelling devoted themselves to finding a corresponding way of life, which they called 'invisible church.' Related to these interests is the second, historical question: what explains the fact that Christian faith developed into a 'positive,' authoritarian religion, which became a tool for despotism to misuse? It was the strategic behavior of the scientific community that gave rise to the third question. In the mid-1990s, the theological Orthodoxy of Tübingen began to misuse Kantian philosophy in an attempt to justify anti-liberal church dogmas in a new manner. This led to the question: how can Kant's critical philosophy be protected argumentatively from such a dogmatic misuse? From his penetrating critique, first of Kant's doctrine of postulates, emerged a system of philosophy in the end whose position may be called 'speculative idealism.' But it did not replace his original interests. Indeed, this system was to provide for their answers.

2.2 Phenomenology of Spirit

The *Phenomenology of Spirit* (PS) exhibits the 'way of despair' which 'natural consciousness' has to go in

order to justify its knowledge under the conditions set forth by the conscious contrast constitutive of itself: its own subjectivity—made into a first principle—in opposition to the objectivity not reducible to it. On the way, it becomes clear that the knowledge intended by various shapes of consciousness does not satisfy its own, immanent truth criteria. For example, it is regarded as impossible to guarantee the intended immediate knowledge of perceptual data by means of indexical references alone ('sense-certainty'). This self-examination is the first step of the procedure. In a second step, 'we,' who contemplate consciousness philosophically, have to identify this negative result—taken positively—with a new shape of consciousness. The self-examination is not complete until the contrast of subject and object has been overcome and the contents of the consciousness fulfill its truth criteria. Hegel calls this ultimate shape of consciousness 'absolute knowing,' which is at the same time an undeveloped knowing of the Absolute.

Apart from the much discussed chapter 'Lordship and Bondage'—which exhibits how two people self-consciously struggling for recognition end up developing the specific shape of intersubjectivity of lordship and bondage—the chapters on practical reason, spirit, and religion of the PS should be of some interest to the social scientist. The chapter on *Reason* exhibits that any effort of self-actualization—i.e., gaining pleasure, making inner laws universally valid, and spreading virtue—must necessarily fail. Even a self-conscious practical reason cannot reach its goal of self-actualization if it merely advances the concealed Good of the world instead of rearranging the world in the first place.

The chapter on *Spirit* contains the doctrine of the basic convictions of a society concerning the purpose of society or its central elements. The internal problems of occidental societies—exhibited in their historical order—transformed them into one another, so that—in them—the Spirit reached new basic convictions about itself. The relevant problems, however, are not those which an objective observer of a later stage in history can discover, but those which the members of the societies in question could experience themselves.

In the chapter on *Religion*, Hegel carries out a similar analysis for the religions in history. As Max Weber after him, Hegel believed that the religions above all—*qua* their internally developed convictions—promoted a process of rationalization in world history (see *Weber, Max (1864–1920)*), a process which Hegel comprehended as an advance in the consciousness of freedom. For him, Christianity was the religion, which first gave effect to the principle of subjectivity and thereby pushed through the consciousness that all men as men are free. At the end of the PS it is supposedly possible to expose a concept of cognition based on the historical experiences which natural consciousness has made in the course of

history of occidental societies and religions. This concept, which Hegel called ‘absolute knowledge,’ has the process of these experiences as its contents and the type of rules concerning the transformation of the shapes of consciousness as its form. It is the purpose of this knowledge to promote humanity, which, in turn, Hegel determines to be the process ‘to press onward to agreement with others’ at the end of the preface to the PS. The knowledge arrived at in the PS, however, so far only concerns the historical genesis of the present as an epoch which has to bring out humanity. In order to satisfy this demand, knowledge of what emphatically *is* has to be acquired, too. (Preface to the Philosophy of Right.) Since the PS has shown that certain fundamental concepts are the central constituents of each shape of consciousness, Hegel conceives of a doctrine of such ‘determinations of thinking’ in his *Science of Logic*: It has to examine whether these determinations are true for themselves.

2.3 Science of Logic

To logically unfold the absolute knowledge developed in the PS is what Hegel declared to be ‘proper metaphysics.’ It is its task to settle an adequate concept of philosophical recognition and thereby of itself (‘absolute Idea’). To fulfill this task it primarily criticizes the aims at knowledge of pre-Kantian metaphysics and Kant’s transcendental philosophy. In the *Science of Logic* (SL), which is this metaphysics, the traditional concepts of Metaphysics and Logic incapable of defining a concept of the Absolute are improved in an iterated process: abstract understanding begins with determining the traditional concepts in a way that makes them as distinct as possible from other concepts and hence suitable to define the Absolute. In a second step, dialectical reasoning demonstrates that no concept, however well determined by understanding, can be distinguished even from its opposite, and demands to skeptically suspend any judgment in the face of this negative result. But then, speculative reason identifies this negative result with a new term of the history of philosophy, which the understanding tries to determine again (see Sect. 2.4). Since the results of the first two steps are included in the new concept, the concepts of the SL become richer in content in the process. Once dialectical reason cannot find an opposite concept anymore, the process reaches its end. Hegel calls the ultimate concept ‘absolute idea,’ which is at the same time the concept of the philosophical recognition carried out in the SL (Fulda 1991).

In the final step, this concept is arrived at by overcoming the dualism of our theoretical epistemic attitudes (‘Idea of Truth’) and our practical ones (‘Idea of the Good’). In these attitudes of finite recognition—paradigmatically conceived of by Kant as theoretical and practical reason—we regard the

world as being a well-structured touchstone of our knowledge, but also as insignificant and worthless in the face of the Good which lies only in the will of the perceiver. The concept of the absolute idea is intended to deliver us from this conflict between our references to the world. But in order not to give rise to a new conflict between the finite knowledge (prescientific and of the special sciences) and philosophical recognition, Hegel required translation rules mediating between both types of attitudes (see Sect. 2.4) and obliged philosophical recognition of the Real to demonstrate the correspondence of its results to ‘empirical appearances’ (see Sect. 2.4). According to Hegel, a philosophy of the Real also depends on integrating new expressions from other sciences to denote the developed concepts. To that extent recognizing the Real is underdetermined by the SL, and a philosophy of the Real as well as Logic itself depends on the status quo of human knowledge.

2.4 Philosophy of the Real

The *Encyclopedia of the Philosophical Science in Outline* was meant to instruct the students who attended Hegel’s lectures, and therefore only contains the rudiments and basic concepts of all philosophical sciences. The logic outlined above makes up the first part of the *Encyclopedia*, the second and third parts being the philosophy of Nature and Spirit. It is primarily through these two parts that we have access to Hegel’s philosophy of the Real.

2.4.1 Philosophy of Nature. In his philosophy of Nature Hegel tries to answer the question of how we can overcome the duality of our theoretical and practical interests concerning Nature and thereby satisfy our needs without turning Nature—and thereby aspects of ourselves—into the Other per se, which would merely become controlled by technology. This philosophy looks for a third way between the modern objectification and quantification of phenomena in the natural sciences on the one hand and a romantic subjectification of Nature on the other. In doing so it does not, however, regard itself as competing with the natural sciences, but rather tries—on the basis of the results of scientific research—to conceive of Nature as an idea in which we can finally recognize ourselves.

2.4.2 Philosophy of Spirit. In so far as Hegel gains his concept of Spirit from his doctrine of living natural beings, which contrasts the sphere of Spirit from that of Nature, he tries to overcome Descartes’ dualism between *res cogitans* and *res extensa* in his whole

Philosophy of Spirit, without, however, reducing the phenomena of one sphere to those of the other.

In particular, Hegel teaches in his *Doctrine of the Subjective Spirit* how the subjective spirit of individuals rises step-by-step from its embodiment (Anthropology) and its object-boundedness (Phenomenology) towards higher cognitive and volutative competencies which culminate in the knowledge of and will to its own freedom (Psychology). In the first part, the *Anthropology*, the phenomena to be comprehended are e.g., dreaming, habits, aging, gestures, and mental disorders, while the *Phenomenology* treats the different levels of consciousness of objects. Sensory consciousness, perceptual consciousness, and comprehending consciousness are all subsumed under the heading ‘consciousness,’ since these forms of consciousness do not imply any knowledge the subject has of itself. Under the heading ‘self-consciousness’ are reviewed those forms into which some knowledge of the subject of consciousness of itself necessarily enters (desire, social approval). Finally, ‘Reason’ is the consciousness of objects, in which it is comprehended that knowledge of general objects is only possible when the subject understands that the functions of his subjectivity constitute these objects in the first place. In conclusion, the higher cognitive performances (intuition, recollection, imagination, memory, and thinking) and volutative ones (practical emotions, instincts, arbitrary acts, and striving for happiness) are discussed in *Psychology*. Within the ‘free spirit,’ the highest form of the subjective spirit, the attitude is reached and comprehended in which an individual knows of itself that it is only free and can only realize its freedom when it has overcome the dualism of interests which are merely of a theoretical or practical nature.

The *Doctrine of the Objective Spirit*, which Hegel has also worked out as *Elements of the Philosophy of Right* (PR), comprehends the objective institutions in themselves, which men who know of their freedom give themselves—right in a narrower sense (property, contract, punishment of felonies), moral norms of acting individuals who strive towards the individual or collective Good (*Moralität*), and the forms of social life in family, civil society, state, communities of states, and world history (*Sittlichkeit*). In order to accomplish this project, Hegel did not try to set up as large a set of consistent principles as possible, but instead conceived of concepts adequate to the subjects in question. The adequacy of the concepts is to be achieved by penetrating the fundamental conceptual material of effective norms and existing convictions of common sense and thus correcting the concepts.

Hegel’s analysis of civil society has been especially influential (see *Marx, Karl (1818–89)*). According to this analysis, modern society tends to accumulate great wealth in the hands of a few, alienate workers in the working processes from their products and from themselves, press large parts of the population below

the subsistence level, undergo times of over- and underproduction, form global markets, and colonize other countries (Elements of Philosophy of Right (PR)). But at the same time, civil society implements institutions to administer justice, provide for the common welfare, and unite people in trade associations and municipalities. These institutions of society and others of the state make comprehensible how civil societies can develop and stabilize themselves in spite of their inherent tendency to crises. In his doctrine of state, Hegel tried to comprehend institutions which represent the general interests of a rational community and enforce them in the face of the special needs of estates and individuals of the civil society. So the state becomes the authority which alone can guarantee the ‘concrete freedom’ of the individual of self-determination.

According to Hegel, world history, the doctrine of which makes up the final part of the PR, is constituted by the state. The principle organizing world history is the ‘world-spirit,’ the process of the developing consciousness that all men are free. In this history, several states have made—to Hegel’s mind—decisive contributions to this progress at certain times. In these Periods, Hegel thought, they have the right—and indeed, the power—to politically and organizationally establish and expand a new principle. France was an example of Hegel’s time: a country which had carried out a progress in the consciousness of freedom in its Revolution and had expanded this new order through the Napoleonic Wars in great parts of Europe. Since the doctrine of the objective Spirit did not reach the highest form conceivable of freedom, Hegel’s philosophy of spirit does not end with it, but rather with the doctrine of the absolute spirit.

Hegel’s *Doctrine of the Absolute Spirit* is a doctrine of the three leading forms of culture in which men have at all times tried to understand what is significantly true and who they are within the whole of actuality that depends on such a ‘Truth.’ According to Hegel, these forms are art, religion, and philosophy. However, they have not always had the same importance since the time they came into being. Each form rather has its particular period in which it becomes the model form to exhibit the Truth. Hegel believed that for the ancient Greeks, art was the medium through which they best understood themselves and were able to express what they cherished most. For the Christians, religion was the best form for men to represent their relation to the Truth and the Truth itself. Both forms, however, have the drawback that their means of explication are at most somewhat discursive—or, indeed, not at all. It is the purpose of philosophy as a science to conceive the content of Christianity’s true representations in an argumentative discourse and thereby to gain insight into the deepest reasons for which men come to agreement with each other and afford a stable basis for their life with each other. Therefore, Sect. 2.4 closes with a concept of phil-

osophy, which is also to justify in retrospect the recognition carried out in the system of the philosophical sciences.

3. Some Lines of Reception in the Social Sciences

Karl Marx is the most prominent recipient of Hegel's philosophy in the domain of the social sciences; therefore, see *Marx, Karl (1818–89)*.

3.1 Lorenz von Stein (1815–1890)

Lorenz von Stein was one of the most politically influential Hegelians among the theoreticians of society in the nineteenth century. With his diverse writings on modern society, he influenced central economic terms of Marx' theory (e.g., surplus value, and accumulation) on the one hand, and considerably influenced Bismarck's social policy on the other. In the sciences, however, he was almost forgotten when Positivism became dominant. It was not until the 1920s that he was studied by theorists of public and constitutional law (Rudolf Smend and Carl Schmitt), a discussion that was continued in the German debates on the principle of the welfare state after the second World War (Stein 1972). Stein took up the question posed in Hegel's doctrine of '*Sittlichkeit*': how must a state be structured for the principles of the French Revolution to be realized considering the conditions of the industrializing society? He regarded the political constellation of his times as an unavoidable antagonism between the civil society based on the satisfaction of individual needs and the state aiming at general freedom. To his mind, this antagonism leads the propertied to try to occupy all state functions through unequal elections, in order to prevent the socioeconomical rise of the nonpropertied. Therefore, Stein thinks it to be the duty of a legitimate state and his institutions (monarch, officials, army) to implement social reforms resulting in a rise of the non-propertied to the economical level necessary for them to participate in the process of forming a public will. In addition to this, the state should counteract the inequalities of the civil society by introducing universal and equal suffrage and guaranteeing basic rights. To this extent, Stein's doctrine of the state—like Hegel's—aims at more than just the guarantees of the liberal constitutional state, because it does not confine itself to the task of protecting the freedom of the individual from the state, but instead goes further to protecting the political freedom of the individual against the inequalities of the civil society through the state.

3.2 St. Louis Hegelians

This American philosophical school was founded by William Torrey Harris (1835–1909) and Hans Conrad

Brokmeyer (1828–1906). After the Civil War, this school was institutionalized by the foundation of the *St. Louis Philosophical Society* (1866) and the *Journal of Speculative Philosophy* (1867), the first philosophical journal in the USA. In contrast to the Transcendentalists at Yale and many of the German intellectuals, questions concerning religion did not play an important role for the St. Louis Hegelians. Instead, questions concerning social justice in a modern society were central for them. In addition to this, another one of Hegel's basic interests became important again, on which, however, Hegel had only remarked in passing in his systematic works: how must a pedagogy be in order to make the individuals growing up able to competently participate in forming modern society? Besides being influenced by Hegel, Denton Snider (1841–1925) and Thomas Davidson (1840–1900), two St. Louis Hegelians, were also influenced by the pedagogy of the German Friedrich Froebel (1782–1852) when they realized several educational projects: the *Communal University* in Chicago, the *Chicago Kindergarten College*, the *Goethe School* in Milwaukee, and the *Breadwinner's College* in New York City, which was devoted to the education of the working class. In 1889, Harris became the United States Commissioner of Education. Brokmeyer played a key role in the Constitutional Convention of Missouri in 1875, which guaranteed the right to education for all aged six to 20. Besides these important roles of the St. Louis Hegelians in the formation of the modern educational system of the USA, the *Journal of Speculative Philosophy* offered a platform for the publications of important American philosophers such as John Dewey, William James, Charles S. Peirce, and Josiah Royce. Beyond offering this platform, they successfully animated the study of Hegel's philosophy (Flower and Murphy 1977).

3.3 Wilhelm Wundt (1832–1920)

Wundt is commonly regarded as the founding father of Psychology, which established itself as a science around the beginning of the twentieth century. In 1879, Wundt founded the first psychological laboratory of the world in Leipzig, Germany, where he mainly studied sensations and feelings by employing experimental methods. This foundation also became influential outside Germany due to the many visits of foreigners—especially American students and scientists (see *Hall, Granville Stanley (1844–1924)*). Although Wundt often mocks at the methodology of Hegel's philosophy, he explicitly praises Hegel's achievement of 'granting the right to exist to all 'things in themselves,' whether they are to count as metaphysical borderline concepts or as practical postulates' (Wundt 1911, p. 736). Without this basis, it would have been impossible for Wundt to pursue Psychology as an empirical special science, because the soul would have been withdrawn from the applic-

ability of methods borrowed from the natural sciences, as long as it were conceived of as an independent substance removable from the body (Descartes) or were postulated as such on practical grounds (Kant). Hegel, on the other hand, 'has regarded the individual soul as the immediate relationship of the experiences of the soul, as a piece of that infinite reality of the world spirit, which still draws only on its very own actual reality to obtain all that it means' (Wundt 1911, p. 736). So Wundt arrives at the conclusion that Hegel 'had also declared the liberty of Psychology when it proclaimed for all that all mental coming into being—and, therefore, all happening in the soul as well—is actuality, is immediate experienced reality, and that essence and appearance of the Spirit are one and the same, and only mean something different in so far as we comprehend the essence as the relationship of the appearances which is correctly recognized' (Wundt 1911, p. 737; own translations) (see for more *Wundt, Wilhelm Maximilian (1832–1920)*).

3.4 George Herbert Mead (1863–1931)

The posthumously published book *Philosophy of the Present* (1959) primarily promoted an interpretation of Mead's thinking that considers the last phase of it as on the way towards a speculative metaphysics of Hegel's kind. This is surely exaggerated. It is nevertheless possible to prove that Mead named Hegel as an inspirer of his own thoughts throughout his working period. Hegel's philosophy especially stimulated the scientific program of the young Mead. His early outline of a program of philosophical disciplines puts forward two main tasks of Psychology, one of which was inspired by Hegel's PS: Psychology is to give 'an analysis of the objective world in terms of the consciousness of the objective individual' (Mead 1900, p. 12). In pursuing this task, Hegel—according to Mead's view—e.g., proved that the organization of different characters, which constitute 'social objects,' comes from 'our mutual relations' (Mead 1903, p. 106). In contrast to the explaining and describing Psychology, Logic is a normative science (Mead 1903, p. 107), into which 'the general theory of the intelligent act as a whole would fall,' and which is as such of Hegel's kind (Mead 1900, p. 2). However, apart from this praise, Mead also continued to criticize Hegel's doctrines throughout his life: e.g., he falsely subsumed Hegel under the philosophy of romanticism, which, to his mind, only discussed the rationalization of bygone attitudes—quite contrary to the orientation towards the future of the American society and philosophy. Nevertheless, Mead praises Hegel's philosophy of history as '[t]he most grandiose attempt to combine the three great motives of speculation (that of Greek contemplation, that of the church's plan of salvation, and that of experimental science)' (Mead 1964, p. 505) (see *Mead, George Herbert (1863–1931)*).

3.5 Juergen Habermas (1929–)

In his essay *Can Complex Societies Form a Rational Identity?* (Habermas 1976), which Habermas chose as the basis of his speech on the occasion of accepting the Hegel Award of the city of Stuttgart, Germany in 1974, he explicitly classifies his proposal as standing in the tradition of Hegel's and Marx' thinking (p. 118). Although his interpretation of Hegel's answer to the question posed in the title of his essay is affirmative in many points, Habermas mainly criticizes—firstly—that for Hegel, 'only the idea of freedom' is to be conceived as a constituent of modern consciousness. In addition to this, 'the unrestricted objectifying thinking and a radical orientation towards the future' are also constitutive for it (p. 105). Therefore, Hegel did not succeed in abolishing the threefold division between the modern subjectivity and external nature, society, and inner nature (p. 102) in *all* respects. Habermas objects, second, that modern society did not gain its rational identity in the constitutional state; and he objects, third, that philosophy is unable to exhibit this identity as rational for all individuals—as religion has done in the past (p. 106 ff.). It is Habermas' opinion instead that modern societies could gain their rational identity in 'the consciousness of the general and equal opportunities of participation in leaning processes of forming values and norms' (p. 119) by realizing communicative structures 'by themselves,' in whose 'autonomy' alone a new collective identity can crystallize 'today' (p. 120; own translations). Critical remembrance of tradition, science, philosophy, and art propose rival identity projections (p. 121). However, Habermas seems to have partially taken back his criticism of Hegel with his concept of 'constitutional patriotism' (Habermas 1990). In addition to this, his interpretation of the rational function of Right to deliver moral discourse (Habermas 1996) can be understood as a continuation of Hegel's thoughts on the relationship of '*Moralität*' and '*Sittlichkeit*.'

M. Wildenauer

Hegemony: Anthropological Aspects

1. Introduction

By the time anthropologists discovered Antonio Gramsci's idea of hegemony in the late nineteen eighties, it had been reworked by others so that it

barely resembled Gramsci's. Although anthropologists cite Gramsci's *Prison Notebooks* (1971) when they refer to hegemony, most are inspired by revisionist interpretations of hegemony.

2. Hegemony

Hegemony is the central idea among many by which Antonio Gramsci established a humanistic, neo-Marxist approach to revolutionary change. Instead of subordinating the superstructure of ideas to the force of the economic base, Gramsci empowered the influence of ideas over Marxism's economic determinism. At the core of Gramsci's methodology is the dialectical relationship between hegemony (consent–support) and domination (coercion–force). His primary theoretical concern was how to resolve this contradiction, for in political practice one is always tempered by the other. He tried to reach resolution in part by redefining hegemony.

Lenin defined hegemony as domination. Gramsci redefined it as an *intellectual and moral leadership* directed by contradictory political and cultural agents and organizations he called *organic* and *traditional* intellectuals. Organic intellectuals represented the interests of working classes. One of their tasks was to make the proletariat aware of capitalist domination and exploitation. Traditional intellectuals represented the interests of the bourgeoisie. One of their tasks was to quell counter-hegemonic resistance to capitalism.

More than other Marxist thinkers, Gramsci recognized the significance of culture in revolutionary practice. Gramsci defined culture as 'the exercise of thought, the acquisition of general ideas *the habit of connecting cause and effect* ... enlivened by organization' (Kurtz 1996a, 1996b). Culture was central to Gramsci's political strategy. He argued that culture was a political product of intellectuals, for another of their tasks was to develop the people's culture through education and ideological indoctrination. Traditional intellectuals worked to convince people of the virtues of capitalism and obtain their consent to capitalist rule. Organic intellectuals worked to help people develop an alternative to a capitalist culture. Among other strategies, Gramsci suggested how organic intellectuals might use popular cultural forms and signs to marshal working class revolutionary energies, depose capitalism, and construct a unitary proletarian culture.

3. Revisionists

Of the many works that explore Gramsci's thinking (Kurtz 1996a), anthropologists rely largely on those of Williams (1977) and Laclau and Mouffe (1985).

Williams is concerned with the relationship between culture and hegemony. He argues that hegemony goes beyond culture, is synonymous with culture, serves as a form of 'cultural domination,' and, as a structure of cultural forms, provides a repository for traditional values. But, by equating hegemony with tradition, Williams divests it of Gramsci's political specificity.

Laclau and Mouffe are concerned with the heterogeneous social organization of contemporary capitalist nations. They equate hegemony with ideology grounded in discourses by which oppressed categories in capitalist societies—women, gays, ethnic categories, and the like—can be made aware of their oppression. For Laclau and Mouffe hegemony (read ideology) provides the 'organic cement' of political formations that will transform western capitalism into a 'radical socialist democracy.'

These authors appropriated Gramsci's idea of hegemony and made themselves its authority, yet little that they say corresponds to Gramsci's idea of hegemony. They also ignore the role of intellectuals in political practice. Still, the beauty and bane of their interpretations are the extent to which hegemony becomes amenable to diverse interpretations by anthropologists, but sometimes at the cost of the political intent with which Gramsci imbued it.

4. *Anthropology and Hegemony*

Anthropologists were attracted to the idea of hegemony for several reasons. It provided a neo-Marxist approach that complemented the idealist orientation among anthropologists who emphasize the power of ideas over material forces; it provided a new way to explore political relationships; it enabled reconsideration of old ideas, such as culture. Above all, it was thought provoking. Consequently there is little consistency regarding how anthropologists use it.

Most often anthropologists use hegemony as a trendy buzz-word that dilutes the concept's power. The idea of hegemony becomes more complicated when anthropologists use it seriously to analyze political relations. Only rarely do anthropologists use Gramsci's definition of hegemony to explore relations of domination and subordination. Instead, most anthropologists cite Gramsci, if only in passing, as the source of the idea of hegemony. Then they relegate his idea of hegemony to a secondary status and make it a point of departure to use or develop other interpretations of hegemony (Kaplan and Kelly 1994, Kurtz 1996a).

As a tool for analysis, anthropologists most often equate hegemony with a political force in society which usually emanates from those in power. Some anthropologists use revisionist ideas of hegemony to focus on other of Gramsci's ideas, such as *common sense* (peoples' awareness of their condition) (*Amer-*

ican Ethnologist 1993). However they approach hegemony, anthropologists infer that a hegemony of the proletariat to counter domination is rare (*American Ethnologist* 1993, Kurtz 1996b).

When anthropologists explore the relationship between hegemony and culture, it is Williams' ideas of hegemony and culture, not Gramsci's, that informs these explorations. Others use Laclau and Mouffe's idea of hegemony as ideology in conjunction with Williams' ideas of hegemony as culture and tradition to rework Gramsci's ideas. In these instances anthropologists become the source and authority of new ideas of hegemony. Almost no anthropologist places either hegemony and domination or traditional and organic intellectuals in the dialectical context that Gramsci thought to be important in hegemonic encounters.

This diversity of application of hegemony by anthropologists can be explained by their frequent argument that Gramsci did not define hegemony clearly. It is true that Gramsci's *Prison Notebooks* are fragmentary and open to interpretation. But anthropologists also do not read the *Notebooks'* informative footnotes, Gramsci's preprison writings, or the authoritative exegeses of his work. As a result they privilege others' interpretations of hegemony. Regardless how anthropologists define and locate hegemony theoretically, it is most applicable to two related concerns: the consequences of state and colonial policies and political relations of domination and subordination.

4.1. *State-Colonial Policies*

Only a few anthropologists apply Gramsci's formulation of hegemony to explore the impact of colonial policies. Carstens (1991) used Gramsci's idea of hegemony to account for how unequal relations between dialectically opposed intellectuals, British missionaries and Okanagan Indian chiefs, changed Okanagan culture and relegated the Indians to an inferior economic status in contemporary Canada. Kurtz (1996b) extrapolated from Gramsci's idea of hegemony to develop the idea of *hegemonic cultivation* to explain why political leaders strive to instill an ideology of work in their political communities and why resistance to these efforts is rare.

More commonly, analyses rely on Williams' idea of hegemony as cultural domination. Fox (1989) used Williams' idea of hegemony as culture to explore how cultural meanings arose in colonial India and compelled colonizer and colonized to conform to certain behaviors. Contrary to Williams, hegemonic agents are central to Fox's idea of hegemony. He demonstrates how intellectuals continually experiment with existing cultural meanings which both enable and constrain resistance to colonial rule. But hegemony is not a source of revolutionary change for Fox. Instead,

as Williams' cultural domination, hegemony continues to subordinate behaviors to the meanings it encodes.

In analyzing cultural confrontations in colonial South Africa, the Comaroffs (1991) emphasize Williams' ideas of hegemony as tradition, and Laclau and Mouffe's idea that discourse has the power to transform indigenous culture. For the Comaroffs, hegemony represents a tradition which, through discourses, acquires an ideology that helped to reorganize indigenous South African societies in accord with colonial rule. Ideology, not hegemony, provided the force of change. As tradition, hegemony had power only to shape actions, perceptions, and changes to the extent that it provided the source of new ideological challenges to existing traditions. As a process, hegemony (read tradition) is reproduced by its interplay with ideology into a functionalist 'hegemonic order' that provides a repository from which cultural forms may be created through the discursive power of ideology.

4.2 Domination and Subordination

Anthropologists who analyze the impact of state and colonial policies on anthropological subjects do not ignore the relationship between resistance and domination. Domination and subordination are implicated in almost all application of hegemony. But anthropologists who emphasize these relations explore them largely in post colonial and authoritarian societies, such as Sri Lanka and Bolivia, through ideas of hegemony that are largely of their own making. They agree only that hegemony is always a process.

Among these explorations hegemony is perceived as a *synthesizing principle* for welding class interests into a coherent world view (McDonogh 1991). In another context hegemony is a *social process* embedded in discourses aimed at instilling an ideology of nationalism (Brow 1988). The persistence of patron-client relations is maintained by hegemony identified as a *force* that maintains a social structure through the cultural shaping of experience (*American Ethnologist* 1993). Hegemony, conceived as a *historical moment*, explains how a ruling class shapes perceptions of ideas, such as female beauty, to legitimate their rule over the working class (*American Ethnologist* 1993). Some anthropologists load the idea of hegemony with an array of theoretical considerations. In one instance, hegemony functions as the source of *education* for Gramsci's idea of 'common sense' (Woost 1993). In another it represents an ongoing *formative process* that may promote resistance to domination (*American Ethnologist* 1993).

Most anthropologists who consider the role of agents in these relations emphasize the role of elites, and argue that proletarian agents are not very effective in developing counter-hegemonies. Even those few anthropologists who emphasize the role of working

class intellectuals in confrontations with elites conclude that proletarian intellectuals have little impact on changing the sources of rule and domination. As Laclau and Mouffe suggest, this is because the proletariat is too alienated and submerged under a dominant culture and rule. A logical consequence of this tendency is to privilege hegemony as tradition and render it apolitical.

Although anthropologists use hegemony as understood by others than Gramsci, and often in more convoluted fashion, they tend to agree on what could only be disheartening to Gramsci: the hegemonic impact of colonial and some contemporary governments has sufficiently restructured the culture and society of subordinate peoples that counter-hegemonies to domination are difficult to attain. Hegemony, however conceived, seems to accommodate best the interests of the elites.

5. The Future of Hegemony in Anthropology

The concern of anthropologists with the idea of hegemony peaked in the early 1990s. Now hegemony is firmly ensconced in anthropological discourse and theoretical orientations concerned with culture, structuralism, a poststructuralism *cum* postmodernism, even a revised historical materialism that objectifies ideas as material forces. Regardless how anthropologists conceive hegemony, it holds a privileged place among a cadre of non-materialist, neo-Marxist anthropologists and provides them a humanistic methodology to explore novel cultural and political relations. The collapse of the Western European and, more recently, Soviet empires and the energy of the expanding world capitalist order have produced global disjunctions in social, cultural, economic and political relations. To explain these epiphenomena, anthropologists are likely to continue to develop creatively the explanatory power of the idea of hegemony.

Hegemony: Cultural

The concept of 'hegemony' has provided one of the most influential theoretical frameworks in contemporary cultural and media studies, and Marxist intellectual work in particular. While imprisoned by Mussolini's Fascist regime in the 1920s and 1930s, the Italian Marxist Antonio Gramsci developed the concept of hegemony to address the question of why the working class failed to make a communist revolution in the advanced capitalist countries despite Marx's prophecy. By 'hegemony', Gramsci (1971) intended to conceptualize the pivotal role of cultural persuasion in acquiring, exercising, maintaining, or challenging power without resorting to physical coercion. Stated briefly, the concept of hegemony refers to a historical process in which a dominant group exercises 'moral and intellectual leadership' throughout society by winning the voluntary 'consent' of popular masses.

1. The Concept of Hegemony

The concept of hegemony can be more effectively understood when it is compared to Gramsci's notion of 'domination,' as each term represents a different kind of power. Whereas domination rests on a dominant group's coercion of the less powerful, hegemony relies on a dominant group's ability to procure subordinate groups' consent to the existing social order. Domination belongs to the state, which Gramsci called 'political society,' and is equipped with instruments of coercion such as the police and armed forces. In contrast, hegemony takes place in the realm

of private institutions—including those outside of the spheres of economic production and the state, such as families, churches, trade unions, and the media—which Gramsci called 'civil society.' Gramsci attributed the political stability and obedience of the working class in Western European countries to the hegemony built into the vigorous civil societies of those countries. Consent and coercion always coexist, but typically, dominant groups in contemporary capitalist societies rule through hegemony unless severe social and political crises require directly coercive interventions.

1.1 The Concepts of Consensus and Historical Bloc

The essence of the concept of hegemony lies in the idea of subordinates' consent. According to Gramsci, the consent of subordinates is constructed when a dominant group's particular world view is accepted by the subordinate groups as their world view, and thus the dominant group's interests appear to be the interests of the society at large. As a result, the dominant group is seen as entitled to its ethical and intellectual leadership and arises as a hegemonic group in a particular historical period. Moral and political authority legitimated by popular consent characterizes hegemony as power from below, distinguished from power wielded by coercion or by manipulation from the top down.

However, the paradox of subordinates' consent to their subordination in the long run raises suspicions about the nature of popular consent (Lears 1985). Indeed, some critics of the concept of hegemony have questioned how subordinates can give consent to what will adversely affect their interests unless they are self-deceived in false consciousness. The very idea of 'false consciousness' threatens to undermine the concept of hegemony in at least two ways. First, if one accepts the idea of false consciousness as the basis of popular consent, subordinates' consent is the outcome of sheer manipulation, and Gramsci might be accused of elitism for his implicit assumption that the popular masses are dupes. Alternatively, if one rejects the idea of false consciousness by arguing that people know the purpose of their actions and consistently base their actions on rationally determined self-interest, then the consensus may represent genuine or true consensus. Then, the characteristic of hegemony as dominance over subordinates would be invalidated, and their actual grievance or resistance may slip from view.

Both Jackson Lears (1985) and Stuart Hall (1996a) responded to this dilemma by rejecting the binary opposition of false and true consciousness in understanding the nature of consent. They instead embraced Gramsci's idea of 'contradictory consciousness' grounded in 'common sense.' According to Gramsci, common sense as everybody's spontaneously arrived

Gramsci's concept of hegemony has been continually reinterpreted and applied to different areas of cultural and media studies, depending on the immediate social and cultural questions of theorists in specific social and historical contexts. However, all research relying on the concept of hegemony shares a common pursuit in criticizing culture as a source of control, and, simultaneously, in envisioning it as a source of resistance.

S. Kim

Heider, Fritz (1896–1988)

Fritz Heider was born in Vienna on February 19, 1896, spent his childhood in Graz, and received a classical education at the official state Gymnasium. Unable to serve in the army during World War I because of the loss of vision in one eye due to an injury during his childhood, he entered the University of Graz (where ironically at one point he studied depth perception). He did not have a professional goal in mind, and in the European tradition attended a wide range of lectures open to all University students. His interests eventually centered on the study of philosophy and psychology (in opposition to the pursuit of architecture desired by his more practical father).

As a student, Heider met Alexius Meinong, an influential figure in European philosophy, who suggested the topic of Heider's doctoral thesis with the obscure question: 'Why do we say we see the house, rather than saying that we see the sun, for the reflected rays of sunlight are the stimuli that actually strike the eye?' In discussing this problem, Heider distinguished between 'thing,' or the objective structure in the environment, and 'medium,' or that in the environment providing information about the object. This theme reappears in much of his work on person perception. He believed in a 'real' world, with the task of the observer being to come to know this reality. In Graz, Heider was also influenced by the psychologist Vittorio Benussi, one of the first people to publish experiments in the field of gestalt perception.

After finishing his dissertation, written during 1919, Heider worked for a year as an applied psychologist. But he soon became restless and moved to Berlin. At the suggestion of Bernussi, he made contact with the psychologists at the University of Berlin. An air of excitement permeated the Berlin Department of Psychology. The lectures in perception, especially those of Max Wertheimer, were very popular among students and intellectuals. There was a feeling that Gestalt principles would have an important influence on the development of psychology. Heider attended the lectures of Wertheimer, as well as those of Wolfgang Köhler. He found many Gestalt concepts, such as laws governing 'unit formation,' useful in his later work in person perception and interpersonal relationships. He also formed a lasting social and intellectual

friendship with Kurt Lewin, at that time a younger member of the Berlin faculty.

After Berlin came the *Wanderjahre*, a period when Heider spent a good deal of time meandering and reading philosophy, especially Spinoza and Nietzsche, as well as psychology and literature. Then, in 1927, he became an assistant to Wilhelm Stern at the University of Hamburg. In 1930, supported by a recommendation from Stern, Heider took leave from Hamburg to accept what he thought of as a one-year position with the Gestalt psychologist Kurt Koffka, who was on a research fellowship at Smith College in Massachusetts, USA. Heider's principle work was at the Clark School for the Deaf, where Grace Moore was also a member of Koffka's research group. They were married shortly thereafter and Heider remained in the USA.

Heider settled at Smith College as an Assistant Professor until 1947, where he combined research at the school for the deaf, teaching, and raising three sons. In 1947, he accepted an offer from the University of Kansas as Professor of Psychology. Roger Barker, the new Chairperson of the Psychology Department, had brought with him a group of people like himself who had been closely associated with Kurt Lewin. Then, with the aid of Beatrice Wright, Heider completed his long-awaited book, *The Psychology of Interpersonal Relations* (1958). A number of awards followed, including the Distinguished Scientific Contribution Award from the American Psychological Association. Fritz Heider died in Lawrence, Kansas, on January 2, 1988 at the age of 92. He was a gentle man with a sly twinkle in his eye, shy and introspective, with a love of art and literature, and a wide-ranging intellectual curiosity.

1. Scientific Contributions

Unlike other influential psychologists, Heider published few articles, did little experimental work, had few students, and was removed from the mainstream of American psychology. He apparently sought neither power nor fame. Nonetheless, his book *The Psychology of Interpersonal Relations* (1958), published when he was 62 and nearing retirement, had enormous impact. In this work, Heider applied the laws of the perception of physical objects and events developed by Gestalt psychologists to the perception of persons and their actions. Synthesizing object and person perception is one of Heider's important scientific accomplishments.

1.1 Balance Theory

Two central and associated thematic statements were most fully articulated in *The Psychology of Interpersonal Relations* (1958). One of these relates to the

concept of balance. Balance theory as formulated by Heider should be considered within the context of Gestalt views regarding the perception of objects. Gestaltists contended that there is a tendency toward simplicity in the perceptual system such that simple structures are preferred. For example, faces are perceived as symmetrical although this is not exactly the case, and even when a circular form is not quite closed, it is nonetheless perceived as a circle. Furthermore, parts of a system become organized and the groupings form a particular structure in an uncontrollable and inevitable manner. For example, two similar objects in close proximity to one another are joined to form a unit, as in the following example: ** ##. In the perceptual field, organisms impose particular arrangements.

Heider reasoned that object configurations, including social objects, could be classified into those that are in a balanced or in an imbalanced state. Balanced states are preferred to imbalanced states because they form 'good' figures or simple structures. For example, in a two-person system, if a likes b and b likes a, then the system is in balance. But if a likes b while b does not like a, then there is disequilibrium—imbalance exists and there is a force to change in the direction of balance. This can be brought about by changing attitudes toward the other, misperceiving the sentiments of the other, changing the attitudes of the other, and the like.

Configurations with three entities, such as those involving two persons and an object, are more complex. If, for example, a likes b as well as object x (e.g., the elected president), then if b does not like x, the situation is again imbalanced and a force will be created to bring the system into a state of equilibrium by, for example, a change in one's attitude toward b or toward x. In Heider's characteristic manner of integrating everyday observations, literary examples, and scientific analysis, he noted that many literary tragedies make use of balance principles (e.g., Romeo loves Juliet, Juliet loves Romeo, Juliet loves and obeys her parents, but her parents do not accept Romeo). An example of 'latent' imbalance, which contributed to the dramatic tension in Ibsen's *Wild Duck*, occurs when a scrupulous husband loves his wife who, unbeknownst to him, has engaged in a dishonest act for his benefit. Here we can see the relations between object perception, unit formation, the preference for particular arrangements, and social behavior.

Balance principles have been widely applied in the study of interpersonal relations, attitude change, social cognition, and other areas of research. They also provided a new approach in motivation inasmuch as motivation to change was derived from the configuration of cognitive elements, rather than from viscerogenic need states, which were involved in most studies of motivation. In accord with Gestalt principles, the whole pattern of the structure determines its motivational effects.

1.2 Causal Attributions

Causal attributions, or beliefs regarding the causes of events, were the second major focus in *The Psychology of Interpersonal Relations*. Attribution theory was even more impactful than Heider's balance ideas, and became the dominant theme in social psychology for nearly fifteen years, between 1970–1985.

Heider postulated that people are motivated to understand and to master their environment—understanding is adaptive and instrumental to future behavior, and also there is a basic curiosity and desire 'to know.' Understanding and mastery require knowledge of the causes of events.

Pursuing the distinction in his thesis between thing versus medium, Heider stated that we are often only in contact with immediate facts or raw data (the 'medium') but we search for the underlying core processes or dispositional properties to explain these facts (the causal 'things'). These perceived causes are generally enduring aspects of the world. Covariation information regarding the presence and absence of the inferred cause and the effect are important sources of causal knowledge. But when explaining the actions of persons, Heider reasoned that we often ascribe their behavior to some stable dispositional quality or trait, rather than to situational factors. The underestimation of the situation as a perceived cause of the behavior of others, and over-attribution to the person, subsequently was labeled 'the fundamental attribution error.'

Although the topics of balance and attribution have been treated separately in the psychological literature, Heider saw them as intertwined. He reasoned that balance principles guide causal attributions. Thus, we infer that a good act was done by a good person, and ascribe success more than failure to the self (the 'hedonic bias'), for in both of these examples the inferences result in balanced states or simple structures.

1.3 Scientific Method

The sources of Heider's ideas were largely observational and literary: he often relied upon 'thought experiments' in which interpersonal situations were imagined and altered in a systematic manner (e.g., assume Romeo does not like Juliet, or that Juliet does not care about her parents). The psychological consequences of these new cognitive configurations were then inferred. This method may seem atavistic given the movement of psychology toward an experimental science, but it proved fruitful for Heider.

Heider also made use of a second methodology: Examining common speech in order to capture *a priori* logical relations. Concepts such as belonging, benefit, harm, and sentiment were subject to his logical analysis. This was particularly the case regarding

perceptions concerning the causes of success and failure, where he articulated the relations between can and try as causal determinants of achievement outcomes. Because of his mental experiments (rather than manipulation of variables and responses by other), and the use of everyday language in his theoretical analysis, Heider is often labeled a 'naïve' psychologist. This characterization is not entirely correct inasmuch as his theoretical analyses embrace abstract principles that transcend any one concrete situation, providing laws that a layperson could not articulate.

2. Contemporary Relevance

As already indicated, attribution theory dominated social psychology in the 1970s. However, its influence did not end there. It remains a presence in social psychology and has made deep inroads as well in the fields of clinical psychology, motivation and emotion, cognitive psychology, educational psychology, and personality. Furthermore, it is almost impossible to discuss interpersonal relationships without making some reference to the concepts of balance or attribution. When assessing the contemporary impact of Heider, it must be recognized that this influence is now carried through more contemporary figures in social psychology who interpreted and elaborated Heider's ideas, while adding their own insights. Among the figures one generation removed from Heider are Edward Jones, Harold Kelley, and Bernard Weiner, three among the authors of the book: *Attribution: Perceiving the Causes of Behavior* (1972). More recently, other researchers two generations removed from Heider have, in turn, replaced these figures as leaders in their field.

What follows is a sampling of some of the attribution-related research areas outside of social psychology that can be traced to the foundation laid by Heider. Rather than assess the 'truth' of the various hypotheses that have been suggested, these are presented to show the presence of research activity stimulated by Heider's ideas.

2.1 Clinical Psychology

There is substantial research examining whether causal ascriptions are precursors to depression. It has been contended that when the causes of aversive outcomes are perceived as unchanging, unchangeable, and/or implicate the self (i.e., there is learned helplessness), then depression may follow. Furthermore, perceptions of the causes of dysfunctional symptoms by others may contribute to the course of the illness. Critical and hostile emotional expressions, spawned by causal beliefs that the other is responsible for the illness, affect the recidivism rates of schizophrenics as well as depressives.

2.2 Aggression and Prejudice

A number of different forms of aggression have been subject to attributional analyses. Some types of child abuse, wife battering, and marital hostility have been traced to the aggressor ascribing intentional misbehavior to the other (e.g., ‘My child refuses to obey me;’ ‘She purposely made me a bad meal’). In general, aggressive individuals tend to over-attribute intentionally to others when experiencing a negative outcome. Prejudice also is a product of (or may give rise to) different attributions for in-group and out-group members. For example, aggression by an out-group member may be perceived as controllable by others and intentional, thus producing further out-group derogation.

2.3 Coping

Following a negative life stressor, such as rape, unwanted pregnancy, or illness, there often is a search for causality (‘Why me?’). Some individuals ascribe the aversive event or outcome to their character (‘I am too impulsive’), whereas others place blame on a particular behavior (‘I was at the wrong place at the wrong time’). Those causal beliefs elicit different coping mechanisms, with the more adaptive behavioral blame resulting in active coping, whereas the less adaptive avoidance coping is in part evoked by attributions to properties of the self that are unchanging.

2.4 Motivation and Emotion

A large literature documents that attributions for achievement success and failure have important consequences on subsequent striving. Guided by the can/try distinction articulated by Heider, it has been found that attributions for failure to low aptitude are particularly debilitating, in contrast to ascriptions to insufficient effort, which promote action. In a similar manner, the belief that ability is changeable is more adaptive than the belief that one’s ability level is fixed. In addition, reactions of others are guided by beliefs about the causes of failure. Non-attainment of a goal because of lack of aptitude elicits sympathy and help from others, whereas failure due to low effort gives rise to anger and neglect.

A great deal of research under the rubric of appraisal approaches to emotion has contended that how one feels is determined by what one thinks. As intimated above, beliefs about the causes of events comprise an important aspect of this literature. For example, guilt is often preceded by the belief that one ‘could and should have done otherwise’ whereas shame often follows from the causal inference that the causes of

personal failure mark one as different from others and cannot be changed. Anger, sympathy, regret, and gratitude also are typically preceded by specific causal beliefs.

2.5 Cognitive Psychology and Psycholinguistics

Many researchers are examining the antecedents of causal beliefs, ranging from individual differences in cognitive preferences to the role of covariation information and the probabilistic co-occurrence of antecedents and consequences. Not all research attempting to understand the contents and process of causal inferences can be traced back to Heider. Nonetheless, some of this research is directly related to his thinking. Linguists have pointed out that verb forms also implicate causality. For example, the phrase ‘I admire him’ results in causality residing in the admired person, whereas ‘I hit him’ places causality in the person committing the act. Some people interested in gender issues have pointed out that journalists may influence lay causal beliefs when they state: ‘The flirtatious woman was raped by him’ as opposed to ‘He raped the flirtatious woman.’ In sum, it is evident from this very select review that, like his ideas about perceived interpersonal relations represented in balance theory, the understanding of perceptions of causality, represented in attribution theory, had a broad influence in psychology. Fritz Heider, an armchair psychologist with knowledge of philosophy and literature, and armed with theoretical acuity, has left a flourishing psychological legacy.

Helmholtz, Hermann Ludwig Ferdinand von (1821–94)

1. Life

Hermann Ludwig Ferdinand von Helmholtz was born in Potsdam, Germany on 31 August, 1821. His father taught humanistic subjects at the local gymnasium, and encouraged Hermann's keen interests in music and the arts generally, in enjoying nature, and in philosophy. At the gymnasium Helmholtz distinguished himself in every subject of study. Although his great intellectual love was physics, his father persuaded him that there was little call for professional physicists and that, moreover, he could not afford to send Hermann to university. Helmholtz thus enrolled (in 1838) at the Königlich-medizinisch-chirurgisches Friedrich-Wilhelms-Institut in Berlin, the Prussian military medical school. The school provided full support to its students in exchange for eight years of military service.

After graduating in 1842 and serving a year as an intern in Berlin's Charité hospital, Helmholtz served nearly five years (1843–8) in Potsdam as an army surgeon. The position afforded him much free time, and he spent it publishing papers in physiology and conducting research in physics. In 1848–9, he served as Johannes Müller's assistant and as an anatomy instructor in Berlin, before being released early from his remaining military obligations in order to begin an academic career as Extraordinary Professor of Physiology at the University of Königsberg.

While at Königsberg, Helmholtz invented the ophthalmoscope (1850). It soon revolutionized ophthalmology by allowing doctors to examine the living retina, and thus diagnose the eye far more thoroughly and help treat it for disease. It also led to Helmholtz's becoming a full professor, boosting his reputation among the Prussian educational authorities, and giving him a European-wide reputation. In 1855, he transferred to the University of Bonn, where he spent the next three years as Professor of Anatomy and Physiology. In 1858, he accepted Baden's offer to

become Professor of Physiology at the University of Heidelberg. A year after arriving there, his wife, Olga, died, leaving him a widower with two young children to raise. He soon married Anna von Mohl, with whom he had three children and who helped introduce him to the world of German high society. The university built him a new institute of physiology; he served as the university's prorector in 1862–3, and, more generally, became one of Heidelberg's stellar figures during its golden era.

With the establishment of the German Reich in 1871, the Prussian authorities were determined to reacquire Helmholtz as part of their effort to turn the University of Berlin into the centerpiece of German academic life. Helmholtz felt he could not refuse the call to Berlin, where he now became Professor of Physics and Director of the Institute of Physics. Prussia built him an entirely new physics building, the largest such in Germany; his institute became a mecca for German and foreign students alike. In going to Berlin, Helmholtz also left physiology and devoted himself almost exclusively to physics. In Berlin, Helmholtz became an even more prominent figure in German academic and intellectual life. Since the early 1850s, he had regularly been called upon to give popular lectures on science, which he continued to do throughout Germany and in Britain. His home became one of Berlin's leading *salons*. He regularly served the Prussian and Reich governments as a representative at national and international scientific meetings. In 1883, the German emperor ennobled him for his services. Four years later, he was appointed the founding President of the Physikalisch-Technische Reichsanstalt (PTR), a nonacademic government institute devoted to research in physics and technology, including the setting of physical standards and testing. He spent the last seven years of his life directing the PTR and pursuing theoretical physics. He died in Berlin on 8 September, 1894.

2. Scientific Contributions Pertinent to the Social Sciences

Helmholtz's contributions to science concentrated above all on physics and physiology. He produced over 150 scientific papers, which were reproduced in his three-volume *Wissenschaftliche Abhandlungen* (1882–95); a three-part *Handbuch der physiologischen Optik* (1856–67) that analyzed and synthesized the results of physiological optics; a pathbreaking musicological treatise, *Die Lehre von den Tonempfindungen, als physiologische Grundlage der Theorie der Musik* (1863); and a two-volume collection of some twenty-five popular and philosophical essays (*Vorträge und Reden*, 5th edn., 1903) on various aspects of science. The hallmarks of Helmholtz's efforts in science included a gift for generalizing and synthesizing results;

using the methods or results of one discipline to advance another; showing the importance of instrumentation and measurement for advancing science; turning philosophical problems into scientifically addressable questions; analyzing the epistemological foundations of science; relating science and art to one another; and popularizing science. Although Helmholtz was not a social scientist, several highly selective aspects of his work in physics and physiology merit attention for their pertinence to the social sciences, above all psychology.

2.1 *The Conservation of Energy and Socioeconomic Thought*

In the mid-1840s, Helmholtz and several other scientists sought to establish an ‘organic physics,’ i.e., to explain life processes exclusively on the basis of the laws of physics and chemistry, and thereby rid physiology of the vague notion of ‘life force.’ Helmholtz centered his early scientific efforts on the problem of heat and its mechanical equivalent. In 1847, he published his epoch-making conception of the principle of conservation of force. Although he was only one of several scientists in the 1840s who conceived of the idea of force conservation in physical or physiological systems, his presentation offered by far the most systematic, mathematical, and general account, thereby helping to unite various disparate branches of physics. The work was part of his larger program of providing a mechanical interpretation of nature, organic as well as inorganic. Nonetheless, Helmholtz never maintained that human beings, whom he believed to possess free will, could be understood solely in material and mechanical terms.

During the 1850s and 1860s several physicists transformed Helmholtz’s principle of force conservation into the first law of thermodynamics. This new energy-based physics and the associated concept of ‘work’ generally inspired a number of economic and social thinkers in the second half of the century. Thanks in good measure to Helmholtz’s work, physical scientists and social thinkers alike now unequivocally recognized the impossibility of perpetual motion. Social and economic thinkers began to see both the individual human body and socioeconomic systems in general in terms of individual or societal energy production, consumption, transformation, and output. Helmholtz helped give economists a greater sense of the importance of the conservation and general circulation of energy. His work in thermodynamics also helped deepen understanding of the human body as a mechanical system, a human motor. The new thermodynamic viewpoint helped give new meaning to the terms ‘work,’ ‘labor,’ and ‘value’ (see Rabinbach 1992, Mirowski 1989).

2.2 *Nerve–Impulse Measurements*

Helmholtz’s work on the propagation velocity of the nerve impulse spoke directly to the interests of the emerging set of experimental psychologists. In 1849–50, Helmholtz conducted a series of experiments on the propagation velocity in frogs, demonstrating that the impulse was propagated at a finite, and measurable, velocity. He and others saw that reflex nervous action could also be measured in humans, and that there was a small, noninstantaneous time interval between human thought and bodily response.

As a result, the mind–body problem took on a new dimension, and a vigorous program of stimulus–response studies in physiological psychology began. By implication, Helmholtz’s work provided a measure of a subject’s reaction time to sensory stimulation, e.g., to visual or auditory cues, to voluntary movements, and to the association of ideas. Wilhelm Wundt and others built on Helmholtz’s work by constructing methods for measuring the time intervals in thought processes. Helmholtz’s work, along with Gustav Theodor Fechner’s on psychophysical experiments, and Wundt’s mark an important milestone in the emergence of experimental psychology as a field. It meant that at least some psychological phenomena could be treated quantitatively and become the subject of laboratory research.

2.3 *Physiological Acoustics and Optics*

Beyond neurophysiology, Helmholtz’s importance to the emergence of experimental psychology lay generally in his work in physiological acoustics and optics, especially in his two great books, the *Handbuch* and the *Tonempfindungen*. These two books became the standard reference works for psychologists and others. Both had a similar structure: they first gave analyses of the physical aspects of their respective subjects, physiological optics and acoustics; then physiological analyses of the respective sensations of light and sound; and finally arguments for the importance of the psychological factor as mentally integrating sensations into experienced perceptions or sounds. In particular, Helmholtz believed that unconscious inferences transformed the physical and physiological sensations received by the bodily organs and nervous systems into perceptions. From birth onwards, the individual learned through empirical experience that certain types of behavior produced certain types of responses, which, in the course of time, the mind transformed into unconscious inferences.

Helmholtz’s work in physiological acoustics and optics began with his theory (borrowed from Müller) of specific fiber energies. Müller had maintained that the stimulation occurring in each type of sensory organ is responsible for a specific sensory experience; each type of sensory nervous system is qualitatively

different from the others. Helmholtz extended this theory for vision by claiming, as had Thomas Young before him, that there were three sets of optical nerve fibers, each of which provided its own specific nerve energy that corresponded to the primary colors. Similarly, he extended Müller's theory for hearing by maintaining there were several thousand specific auditory energies. He announced his so-called resonance theory of hearing in the *Tonempfindungen*, showing that the ear is a set of resonators that analyzes homogeneous sounds into their components. Although he thought that sensory processes of hearing and seeing were in good part mechanical ones, he did not think that sensations were copies, let alone mirror images, of the external world; rather, they were 'signs' of it. Although Helmholtz's theory of specific energies was modified or rejected by some, it came to constitute part of the foundations of experimental psychology.

2.4 The Nativist–Empiricist Controversy

Helmholtz was not only one of the two principal antagonists in the nativist–empiricist controversy over the proper foundations of vision research. He also coined the labels of these two fundamental positions and did much to shape the controversy between himself and Ewald Hering, and their respective followers. Although their differences were many, the two sides mainly disagreed on whether the eye possessed and required a mind to see. The controversy began in the 1860s and lasted until the 1920s, though in several ways it has continued down to the present.

In the *Handbuch*, Helmholtz labeled Hering and his followers 'nativists,' since they claimed that spatial perception was innate to newborns. By contrast, he called himself and his followers 'empiricists,' since they claimed that spatial perception was an acquired phenomenon, one that each individual gradually learns through daily experience and which requires the mediation of unconscious inferences. The two sides also disagreed about the receptor mechanisms affecting color vision, and about explanations for contrast phenomena, adaptation, optical illusions, eye movements, the constancy of color, retinal correspondence, and so on.

The controversy helped shape the intellectual substance and disciplinary formation of physiology and psychology. Experimentally minded psychologists like Carl Stumpf, Georg Elias Müller, and Franz Brentano opposed the empiricist view insofar as it employed unconscious inferences and so harkened back to psychology's roots in philosophy. On the other hand, nativism's stress on the biological foundation and explanation of perception threatened to replace psychology with physiology. Yet nativism also emphasized the role of phenomenological experience, and that appealed greatly to a number of experimental

psychologists, including Stumpf, Hermann Ebbinghaus, Oswald Külpe, Erich Jaensch, and David Katz.

3. Impact on Psychology and Beyond

Unlike Fechner and Wundt, Helmholtz had no desire to create a new, institutionally independent discipline of psychology. His contributions and overall importance to the discipline came largely (and indirectly) from his work in physics and physiology, and from his general prestige. His contributions to the 'New Psychology'—a movement that arose in Germany between 1860 and 1910 and that was associated with names like Wundt, Ebbinghaus, Külpe, and Stumpf—consisted largely in the observational and experimental study of, and speculation about, sensations and perceptions. The New Psychology in good measure replaced the older philosophical psychology, and in so doing adopted, adapted, or extended many of its methods and results from sensory physiology and psychophysics, not least those introduced by Helmholtz.

Helmholtz's work deeply influenced and must be seen against the emergence and course of the New Psychology. During the 1860s and 1870s, a number of psychologists aligned themselves with (sensory) physiology, and it was during these decades that Helmholtz had his greatest influence on the field. For example, Wundt, who was Helmholtz's assistant at Heidelberg, shared Helmholtz's empiricist theory of perception, and Helmholtz later drew on Wundt's work on vision for his *Handbuch* and supported him professionally. As advocates of psychology as an experimental discipline, they were allies. Yet there were also differences between the two: Wundt later rejected Helmholtz's mechanistic approach to sensation, the two men had a priority dispute concerning the theory of unconscious inferences, and Helmholtz criticized several of Wundt's views. The young Ebbinghaus was similarly influenced and supported by Helmholtz. Helmholtz's work on the measurement of the velocity of nerve impulse served as a starting point for Ebbinghaus's famous work on measuring memory. Helmholtz was one of Ebbinghaus's examiners for the right to teach at Berlin, where Ebbinghaus lectured in psychology (1880–94) and where Helmholtz supported him in other ways.

In 1890, when Ebbinghaus and Arthur König founded the *Zeitschrift für Psychologie und Physiologie der Sinnesorgane*, they included Helmholtz on their editorial board. The new journal played a leading role and constituted an important milestone in physiological psychology. Yet the discipline of psychology was itself changing: as it gradually separated from physiology, a number of its practitioners gradually abandoned its elementalist, sensory-based approach in favor of the phenomenalist approach of the

Gestalt psychologists (especially after 1920), who rejected Helmholtz's mechanistic approach to psychology and, like the nativists, his theory of perception. In short, from the 1890s psychology moved away from Helmholtz's views and gained a new sense of intellectual and institutional autonomy.

Helmholtz also had a strong impact on other young psychologists, two of whom warrant special mention. As a medical student and young doctor, Sigmund Freud was especially taken with the program of the 'organic physicists.' (He had once hoped to study with Helmholtz, though nothing came of this.) Freud sought to link neuropsychological to physiological phenomena, and his early psychological language is the language of physiology (e.g., that of 'energy'). He called Helmholtz 'one of my idols.'

Likewise the young William James had intended to study with Helmholtz but never did. He called Helmholtz 'immortal' and said that he was 'perhaps the first scientific genius now [in 1868] above ground.' Helmholtz's work and views on physiological psychology constituted an important source for James: as a young scientist, he assiduously studied Helmholtz's *Handbuch*, the *Tonempfindungen*, and the popular and philosophical essays. Helmholtz was one of the most-frequently-cited authorities in James's *Principles of Psychology*. Yet although James often cited him positively, especially as a source of empirical evidence, he rejected Helmholtz's notion of unconscious inference and his sensation-based theory of perception, and he found Helmholtz's mechanistic and mathematical predilections in science alien to his own. James wrote of the *Handbuch*: 'Can I find fault with a book which, on the whole, I imagine to be one of the four or five greatest monuments of human genius in the scientific line? If truth impels I must fain try, and take the risks. It seems to me that Helmholtz's genius moves most securely when it keeps close to particular facts.'

Beyond psychology, Helmholtz also affected several of the future leaders of the next generation of social science in ways that are perhaps impossible to state. The young Franz Boas had originally intended to become a physicist and to study with Helmholtz, but he soon turned away from physics and towards geography before settling on anthropology. (Helmholtz did, however, serve as one of Boas's examiners when he [successfully] sought to obtain the right to teach at the University of Berlin.) The young Wilhelm Dilthey was a frequenter visitor to the Helmholtz home in Berlin. Although Dilthey's holistic and dynamic theory of consciousness stood in sharp contrast to Helmholtz's sensationalist approach, he studied Helmholtz's writings carefully; considered Helmholtz's popular scientific essays as the best such set that had ever appeared in German; engaged him in friendly discussions of their philosophical differences; and graced his *Einleitung in die Geisteswissenschaften* (1883) with an opening quote from Helmholtz.

By the 1920s Helmholtz's substantive achievements and outlook had lost their attraction for some psychologists. Nonetheless, for many in Germany and abroad, Helmholtz still stood, as he did for Max Weber in 'Science as a Vocation' (1919), as a model scientific researcher. And as late as 1950, Edwin G. Boring, in the second edition of his monumental *A History of Experimental Psychology*, ranked Helmholtz, along with Darwin, James, and Freud, as one of the four most important figures in the history of psychology.

Hempel, Carl Gustav (1905–97)

Carl Gustav Hempel was a leading figure of the logico-empiricist movement that dominated much of American philosophy in the second third of the twentieth century, and has been a principal source of present day analytical philosophy. In the spirit of logical empiricism Hempel aimed at a scientific philosophy with the principal objective to arrive at a purely logical methodology of the empirical sciences, including the social sciences. His most important contribution in this respect is what can be regarded the first theory of scientific explanation. This theory is referred to as ‘the Hempel–Oppenheim model,’ the ‘covering-law model’ or the ‘standard model of scientific explanation.’ In his later years Hempel gave up the idea of a purely logical (i.e., syntactical and/or semantically) ‘rational reconstruction’ or ‘explication’ of basic methodological concepts like explanation, confirmation, law of nature, probability, type, etc. Both the internal failure of this program and the influence of Thomas S. Kuhn caused Hempel to acknowledge for a satisfying reconstruction of methodological concept also ‘pragmatic’ aspects of science in the sense of social and historical circumstances of its development.

1. Biography

Hempel was born on 8th January, 1905, in Oranienburg (near Berlin, Germany). He studied mathematics, physics, and philosophy at the universities of Göttingen, Heidelberg, and Berlin from 1923 to 1929. After graduation (*Staatsexamen*) that qualified him to teach in secondary schools (*Gymnasien*) Hempel went to Vienna to study with Moritz Schlick and, particularly, Rudolf Carnap. Both of them, together with the mathematician Hans Hahn and the economist Otto Neurath and others, had founded in 1923 the ‘Vienna Circle’ (*Wiener Kreis*), that was to become the nucleus of logical empiricism. After his return to Berlin in 1930 Hempel entered teacher’s training and teaching and worked at the same time with Hans Reichenbach, head of the ‘Berlin Group’ of logical empiricism, on a philosophical dissertation on the concept of probability. After graduation in 1934 Hempel preferred to leave Nazi Germany and went to Brussels to assist Paul Oppenheim, a private scholar, in carrying out philosophical research that related principally to concept formation in empirical science. In 1937 to 1938 Hempel worked for a year as research associate with Carnap in Chicago, and again went back to Brussels until he found a post of instructor at City College, New York in 1939. The academic year 1940 to 1941 saw him at Queens College, New York, from where he went as associate professor to Yale in 1948. In 1955 Hempel became Stuart Professor of

Philosophy at Princeton. After retirement at Princeton (1973) he worked as university professor at Pittsburgh University from 1977 until 1985. He died at Princeton on 9 November, 1997.

2. Major Contributions

Hempel has given important contributions: (a) to the rational reconstruction of methodological concepts, particularly the concept of scientific explanation; (b) to the ‘universality thesis,’ i.e., the thesis that the social sciences do not, and should not, use methods that are essentially different from the methods of empirical science; and (c) to concept formation and taxonomy in empirical science.

2.1 Scientific Explanation

Hempel reconstructs scientific explanations of concrete events in nature, history, and society as arguments, i.e. as logical deductions containing as premises (*‘explanans’*) at least one (general) scientific law L_1 , as well as initial and boundary conditions C_r , and as conclusion (*‘explanandum’*) the statement E describing the event in question. We thus obtain the following model of ‘deductive-nomological (*D-N*) explanation’

$L_1, L_2, \dots, L_n$	The <i>explanans</i>
$C_1, C_2, \dots, C_r$	[entails logically]
E	the <i>explanandum</i>

In case the *explanandum* contains essentially a statistical law (e.g., for all x : the probability of G , if F is given, equals r and as boundary condition that F is given for some b) the explanatory argument does not deliver a deduction of the *explanandum* statement E but rather gives inductive support for E , i.e., the *explanans* shows that E was to be expected with a certain degree r of probability. In simplified form (one statistical law, one boundary condition) we thus obtain the following model of ‘inductive-statistical (*I-S*) explanation’:

$p(G, F) = r$	The <i>explanans</i>
$F(b)$	[lends inductive support of probability r to]
$G(b)$	the <i>explanandum</i>

In the case of *I-S* explanation, one must further assume that the *explanans* is maximally specified, i.e., the *explanans* must contain all available information that is possibly relevant for the explanation of the *explanandum* E . Or, in other words, the *explanandum* must contain all pertinent statistical laws and those special facts that can be connected with the E -event by statistical laws. *I-S* explanations thus relate to the body of scientific knowledge at a given time, i.e., they

become ‘epistemically relative.’ The postulate of maximum specificity avoids the ‘explanatory ambiguity,’ i.e., the possibility to give acceptable *I-S* explanations based on true premises for mutually exclusive *explananda*.

In case one deduces as *explanandum* a general or a statistical law of lesser generality than the one(s) in the *explanandum* one obtains the reduction of a law or theory in the first case (e.g., explaining the law of free fall by means of the law of gravitation), and a deductive-statistical or *D-S* explanation of a statistical law by a more comprehensive statistical law in the second.

Originally Hempel claimed the structural identity of explanation and prediction. Later he had to admit that, although every adequate explanation is (under pragmatically changed circumstances) also a prediction, not every adequate prediction yields also an adequate explanation, for symptoms are often adequate for a prediction, but not for the corresponding explanation. So is, for example, a sudden fall of the barometer (together with suitable laws) sufficient for predicting a thunderstorm, but it does not explain it, since the fall of the barometer is not the cause of the thunderstorm, but rather a symptom of its arrival.

2.2 Unity of Science

Hempel claims the methodological unity of empirical science. With respect to scientific explanation this amounts to a universality thesis of scientific explanation: there is no essential difference between explanations in the natural sciences and those in psychology, the social sciences, or history. Explanations in these fields aim to show that the event in question was to be expected on the basis of antecedent and boundary conditions and general laws. In history those general laws are usually taken from psychology, sociology, economics, the natural sciences, etc. Hempel leaves the question open whether genuine historical laws exist. Normally explanations in history and sociology fail to include an explicit statement of the laws they presuppose. This failure is due to the fact that those laws are part of folk psychology and seem to be tacitly taken for granted. Apart from that it is difficult to formulate in a sufficiently exact way the underlying general assumptions about e.g., the outbreak and course of revolutions. Furthermore, most of the regularities in the social sciences are statistical. Therefore one can only expect explanation sketches in these fields.

The method of empathic understanding that is often claimed to distinguish the social from the natural sciences is neither sufficient, nor necessary for explanations in these fields. It is not sufficient, because the individual act of understanding is only a heuristic device in order to suggest general psychological hypotheses that might subsequently serve as explana-

tory principles in the case under consideration. It is not necessary, because a historian might well be able to explain the deeds of a paranoid historic personality by reference to the principles of abnormal psychology without being able to arrive at an empathic understanding of such a personality.

2.3 Concept Formation in Empirical Science

Hempel’s work on concept formation in empirical science originates in his early cooperation with Paul Oppenheim and consists basically in the application of principles of logical empiricism to the formation of scientific concepts. Hempel distinguishes: (a) classificatory; (b) comparative; and (c) quantitative concepts. These distinctions normally characterize at the same time the historical development of a science from its initial descriptive ‘natural history’ stages to its mature theoretical stages. Classification divides a given set or class of objects (e.g., human beings) into subclasses (e.g., beings that suffer from certain mental disorders). Each of these subclasses is defined by means of a certain concept (e.g., schizophrenia) that represents the complex of characteristics essential for the membership in that subclass. Hempel speaks also of ‘classificatory types.’ The elements of these subclasses are those individuals to whom the respective concept applies (e.g., schizophrenics). The characteristics that form the defining concept are ascertainable fairly directly by observation. Classificatory concepts as well as scientific concepts in general have to fulfil two requirements. They have: (a) to be objective; and (b) to have systematic import. Objectivity is attained first by using operational criteria and (often only partial) operational definitions in a large sense that includes observation as operational and second by eliminating criteria with valuation overtones. Scientific concepts have systematic import if they lend themselves to the formulation of general laws or theoretical principles. Whereas classificatory concepts are a yes-or-no affair, i.e., a certain individual belongs to some subclass or it does not, comparative concepts admit of more or less with respect to a certain trait (e.g., *x* is warmer than *y* with respect to cold-hot). They lead to (quasi)linear orderings as soon as one includes the relation of coincidence (e.g., *x* is equally warm as *y*). Hempel calls the extremes of such orderings ‘ordering types.’ The next step would consist in giving these linear orderings a metric and thus arriving at quantitative concepts (e.g., temperature).

For Hempel the ‘ideal types’ that have become popular in the social sciences since Max Weber are neither classificatory nor ordering types. Ideal types are interpretative or explanatory schemas that contain a set of empirical generalizations that establish subjectively meaningful connections between different aspects of some kind of phenomenon, e.g., purely

rational economic behavior, a capitalist society, a religious sect. Accordingly ideal types must rather be reconstructed not as concepts but as theoretical systems that are intended to provide explanations and therefore must contain testable hypotheses. Despite their lack of clarity and precision there thus are also with respect to ideal types no essential methodological differences between psychology or the social sciences and the corresponding methods in the natural sciences.

3. Influence, Impact, and Current Significance

Hempel's ideas constitute the mature form of logico-empiricist thinking. His work on scientific explanation 'stands out as the benchmark to which all subsequent studies of this topic must be referred' (Salmon 1998, p. vii). His reconstruction of concept formation in empirical science has become a sort of standard for objective procedures of concept formation. It has greatly influenced subsequent editions of the *Diagnostic and Statistical Manual (DSM)* of the American Psychiatric Association (Houts 2001). His later work reflects the openness of logical empiricism to new developments in the philosophy of science (particularly T. S. Kuhn's work) that put a strong emphasis on the historical and sociological ('pragmatic') factors of the development of science (Wolters 2000).

G. Wolters

Henry, Louis (1911–91)

Henry was born on February 19, 1911 and was 35 years old when he joined the newly created French Institut National d'Études Démographiques (INED) in 1946; he retired in 1973 and died on December 30, 1991. Most of his work was published under the auspices of INED, either in the journal *Population*, or in the Institute's monograph series. He was one of several retired artillery officers hired by INED because of their rigorous mathematical education at the national *Ecole Polytechnique*; others were Jean Bourgeois-Pichat and Sully Lederman, who would also leave their mark in the field, although they had no formal training in the social or historical sciences. Henry soon joined forces with Paul Vincent in the study of fertility, and this became his area of specialization. He made an early contribution to its measurement by inventing a new index, the parity progression ratio (Henry 1953). This is defined as the proportion of women with a particular number of children, or parity, who have gone on to have another child, and is computed on the basis of the number of children ever born recorded at a particular age.

Henry intended to go beyond the mere measurement of phenomena, and undertook to decompose reproductive processes into their component factors, what later became known as the proximate determinants of fertility. He decided to study the 'physiological' level of fertility, that is, the fertility that would prevail among married women or couples in the absence of deliberate efforts to limit their number of births; this he called 'natural' fertility. In a contemporary population, however, contraception and abortion that are subject to human decisions are widespread, and it becomes difficult to investigate physiological factors. In his quest to find reliable data on populations where family limitation was not practiced, Henry studied records from the European past, at a time when the recording of vital events was complete and accurate. He first used a series of genealogies on the ruling classes of Geneva, going all the way to the sixteenth century (Henry 1956); later he analyzed the parish records for a village of Normandy, Crulai, that had been extensively compiled by a local historian, Etienne Gautier (Gautier and Henry 1958). The records for Geneva demonstrated the sharp contrast between the

earliest marriage cohorts, where marital fertility by age seemed to be independent from age at marriage, and the later cohorts where the behavior of couples was clearly modified by the duration of their marriage and the number of children they had attained. It could be shown conclusively that the bourgeoisie of Geneva had adopted family limitation as early as the second half of the seventeenth century. In contrast until the end of the eighteenth century, Crulai, the first parish analyzed by the new method of family reconstitution that Henry had invented, showed the features of a regime of natural fertility, where parity does not affect a woman's subsequent behavior.

In a manual written with Michel Fleury (Fleury and Henry 1956), he laid out—to the minutest details—the rules for the processing of parish data. These rules have been followed faithfully by demographic historians, not only in France but also in other European countries such as England, where they guided the work of the Cambridge Group for the History of Population and Social Structure, and in Canada. Henry would publish another textbook on historical demography (Henry 1967). Moreover, applying the vast experience accumulated in his early parish studies, he initiated a study of rural France, using a representative sample of French parishes during the eighteenth century. He analyzed this material by aggregative methods, and for a smaller sample of parishes used nominal information to reconstitute families. The project provided the first national series of estimates of fertility, mortality, and nuptiality for a Western European country in the eighteenth century. This body of work makes Louis Henry the uncontested father of historical demography as it is practiced today.

Mining the past for data on populations that did not consciously limit their family size was initially only a tool towards measuring the physiological components of human reproduction. Henry identified the factors to be considered as fecundability, the probability that a conception would result in a live birth; the delay in the resumption of ovulation after a delivery or nonsusceptible period, and total or partial sterility. He provided estimates of the value of these parameters on the basis of his own historical studies of population, but also of various accurate measurements made on other selected populations. His work was picked up by English and American demographers and biometricians working on fertility models, and among them by Mendel Sheps and Jane Menken who edited a collection of translations from Henry's most important articles (Henry 1972.) The seminal importance of Henry's work was acknowledged by the Population Association of America when it made him the first recipient of the Irene B. Taeuber Award for Excellence in Demographic Research in 1977. Just before his death in 1991, the International Union for the Scientific Study of Population had named him its first Laureate.

The concept of natural fertility is often considered as one of Henry's most significant contributions to population studies. He did not invent the term, but he defined it rigorously and provided means to identify natural fertility regimes. It refers specifically to the behavior of married couples, and is therefore not affected by variations in the proportions married and the age at marriage. Natural fertility is compatible with behavior that may affect the levels of natural fertility (frequency of intercourse, length of breast feeding) or even with attempts to space birth that are not depending on parity. Although the notion remains controversial, it has been used widely in the study of the fertility transition, both in the West and in today's developing countries.

Hermeneutics, History of

The term 'hermeneutics' refers to the science, art, or technique of interpretation, paradigmatically of written texts but by extension of human actions and other social phenomena. In this extended sense, it has come to denote a variety of approaches in the social and behavioral sciences. The word refers to the Greek messenger-god Hermes, and reflection on the problems of interpretation and criteria for the truth, validity, or adequacy of interpretations, goes back to ancient Greek thought in the European tradition and a similar historical distance in the other world civilizations. We can consider this as the prehistory of hermeneutics, revived in the philological criticism of classical texts in the Renaissance, the interpretation

of Roman Law, the interpretation of the Bible in (especially Protestant) Christianity and the philosophical analysis of texts.

The systematization of hermeneutics occurred largely in German-speaking Europe in the course of the nineteenth century, although two earlier thinkers deserve particular mention. Johann Martin Chladenius (1710–59) published in 1742 a general account of interpretation which brought together traditional Aristotelian rhetoric and more recent Enlightenment themes, developing in particular the notion of point-of-view or perspective (*Sehe-Punkt*), crucial to later philosophy of history and social theory (Mueller-Vollmer 1985). Second, Giambattista Vico (1688–1744) formulated the basic principle that our knowledge of what we ourselves have made (individually or collectively) is different from what we have not made. The world of human society and culture is in some sense ‘our’ product.

This distinction, crucial to later hermeneutics and ‘hermeneutic’ social science, between what we know from the inside and what we know because we have learned about it is taken up in a rather more speculative form in Hegel’s differentiation between reason (*Vernunft*) and the understanding (*Verstand*), although the maker here is the world-spirit coming to recognize its own productions (including, ultimately, the world itself) and its learning processes as rational, in contrast to the essentially contingent states and relations found in nature and described by the mathematical and natural sciences. Something more like Vico’s idea returns again in the second half of the nineteenth century, when Hegel’s concept of objective mind is extracted from its surrounding developmental ‘grand narrative’ and treated more as a descriptive category.

It was Friedrich Schleiermacher (1768–1834), following Friedrich Schlegel, who consolidated hermeneutics in a systematic form, establishing the term understanding (*Verstehen*), which had been used by Chladenius and which has survived as standard usage in English-language social science discourse, and making it central to interpretation—understood as a more systematic activity. Interpretation here involves both the linguistic understanding of meaning and a psychological understanding of the author’s intention. Schleiermacher introduced the distinction between technical and more developed or speculative forms of interpretation and formulated the much-discussed principle that it should be possible to understand an author better than he understood himself. Schleiermacher’s contribution was made the central and culminating point of the account of ‘the rise of hermeneutics’ given by Wilhelm Dilthey (1833–1911), with whom hermeneutics becomes central to the self-definition of what he called the human sciences or *Geisteswissenschaften*. In these sciences, as Dilthey put it, the mental activity of humans and of some other animals, and its products, can be understood.

Dilthey and his contemporary, the philosopher of history J. G. Droysen (1808–84), developed what we would now call a research program for history and the other human sciences based on the distinctiveness of human psychic expressions and the understanding of those expressions. In a move that was to become a definitional feature of later interpretive social science, Dilthey, like Schleiermacher, emphasized the continuity between everyday understanding and more formal processes of interpretation. His distinction between the natural and human sciences was developed in large part in opposition to Comtean positivism, which had become influential, even in the German-speaking countries, by the middle of the nineteenth century. In a parallel, but more methodological formulation, two other neo-Kantian thinkers, Wilhelm Windelband and Heinrich Rickert, argued that the study of culture is essentially concerned with individual processes and relating them to shared human values, whereas the natural sciences are concerned with general laws about objects which are essentially remote from questions of value. We are interested, for example, in the French Revolution, not just as a member of a class of revolutions exhibiting certain common features (this would be, for Rickert, a natural-scientific mode of approaching it), but as a unique event embodying, and perhaps also violating, certain crucial human values.

This opposition between positivism and methodological dualism, and more particularly between causal explanation, analyzed in terms of universal regularities, and ‘understanding’ comes to structure the emergent human or social sciences, as the term ‘culture’ increasingly gives way to ‘society’ or ‘sociation’ (*Vergesellschaftung*). There is a fairly strong line of influence from Rickert to Max Weber, both directly and also through his friend Georg Simmel, who discusses our knowledge of the social world in terms that foreshadow social constructionist theory (see *Constructivism/Constructionism: Methodology*).

Max Weber’s personal development from economic and legal historian to sociologist continues the encounter between hermeneutics and the social sciences which had been a dominant feature of the late nineteenth century, and he also develops a middle position on the issue of methodological dualism, as he had earlier on the related opposition in economic theory (the *Methodenstreit*) between the pursuit of a systematic laws and a more interdisciplinary and historical approach. For Weber, as he put it in an early essay, ‘the course of human action and human expressions of every sort are open to an interpretation in terms of meaning which in the case of other objects would have an analogy only at the level of metaphysics’ (Weber 1975, pp. 217–8). He therefore later defines sociology, in the first sentence of his major work ‘Economy and Society,’ as a science which aims at an interpretative understanding of action in order thereby to understand its course and its effects.

Whether by this Weber means that explanatory understanding is itself a form of causal explanation, or merely complementary to it, the crucial point for him is that explanations of social phenomena must be both 'causally adequate' and 'meaningfully adequate.'

For Weber, then, our access to knowledge of the social world is importantly different from our knowledge of nature. However, it is not, in his view, any less objective. He heroically attempts to hold together Rickert's principle that our perspectives on cultural phenomena, and our knowledge of them, are shaped by values (based for Weber on ultimately ungroundable existential choices), with the idea that the social sciences can attain a bedrock of solid and 'value-free' knowledge which would have to be accepted, as he sometimes curiously puts it, 'even by a Chinese.' Weber insists that it is the intentions and purposes (subjective meanings) of human actors which define their actions and which therefore have to be understood by the historian or sociologist, but he moves rapidly to the construction of a system of ideal types of action-orientation less limited than that found in economic theory but still substantially dependent on it.

Weber's synthesis was pulled apart from both sides in the decades following his early death in 1920. At one pole, there was now a more stridently naturalistic and indeed reductionist variant of positivism: the logical empiricism of the Vienna Circle, in whose 'unified science' the statements of all sciences should be ultimately reducible to material-object language or to statements in physics; *Verstehen* was of no more importance, in Otto Neurath's vigorous formulation, than a good cup of coffee which sustains the social scientist.

From the other direction, Alfred Schutz initiated the tradition of social phenomenology, and what is often loosely called 'hermeneutics' in the context of the social sciences, with a book published in Vienna in 1932 with the title *The Meaningful Constitution of the Social World*. Schutz felt that the problem with Weber's ideal types was not that they were insufficiently scientific, but precisely the opposite: Weber was too quick to impose them on the phenomena he described, paying insufficient attention to their grounding in acts of typification performed by ordinary members of society. For Schutz, the social scientist is merely constructing second-order typifications based on those already carried out in the lifeworld. This theme was taken up by the phenomenologist Aron Gurwitsch in the USA, where Schutz had also settled, and by Peter Berger and Thomas Luckmann (1967), who finally put the term 'social construction' on the map, offering in the guise of a sociology of knowledge a paradigm more directly adapted to use in social research. By the time Schutz's first book was republished, in Germany in 1970 and in the USA in 1967, the way had been prepared by his own later work and by Berger and Luckmann (1967).

The middle decades of the twentieth century replay many of the debates which had dominated the second half of the nineteenth century. Droysen's complaint, in a letter of 1852, about the rise of what he called 'crass positivism,' and his crusade against it in a course which he taught from 1857 onwards, is echoed by antinaturalist social science just over a hundred years later. Social phenomenology also of course had affinities with the well-established minority North American tradition of symbolic interactionism, which also experienced a certain resurgence in the 1960s with, for example, the republication of the work of G. H. Mead and that of Herbert Blumer, and also the publication of various studies by Erving Goffman. But where the interactionists tended not to spend time on formal critiques of empiricism, Harold Garfinkel's ethnomethodology (Garfinkel 1967) was more aggressive. A former student of the structural functionalist Talcott Parsons, Garfinkel was led by his study of the deliberations of a trial jury to emphasize, like Schutz, the importance of practical reasoning in everyday situations. He showed that our drive to interpret leads us to impute a meaning even to random processes in the social world, as in one of his later experiments in which an interviewer playing the role of a counsellor replied to the clients' questions by a random 'yes' or 'no,' leading them into more and more contorted interpretative efforts. The production of meaning is at the same time the production of social order—Parsons' major concern. Unlike his former teacher, however, Garfinkel insisted that social actors are not simply bearers of their social roles ('cultural dopes'), but active subjects obliged to practice social analysis in order to function in everyday society.

Social phenomenology found a somewhat unexpected ally in a convergent move within analytic philosophy. Beginning on the margins of the Vienna Circle, Ludwig Wittgenstein came to abandon the simple conception of a picturing relation between propositions and the world, and was drawn into a more sensitive and holistic analysis of the practicalities of 'language-games' based on implicit rules and embedded in what he enigmatically called 'forms of life.' An important book by the Wittgensteinian philosopher Peter Winch (1958) drew the consequences for social theory, using Max Weber, as Schutz had done, as one of the foils for his argument. For Winch, knowing a society meant learning the way it is conceptualized by its members. He thus revived the central principle of nineteenth century German historicism, according to which every age must be understood in its own terms. Winch directly identified himself with the German idealist tradition by insisting that social relations are 'like' logical relations between propositions (1958, p. 126) as well as, more concretely, with an ethnographic field-work approach.

Hermeneutic theory itself also took a new turn with the 'philosophical hermeneutics' of Hans-Georg Gadamer (1900–), whose *Truth and Method*, published in

1960 and translated into English in 1975, insists, in opposition to historicist hermeneutics, on the practical dimension of interpretation, conceived in Heidegger's sense of an 'encounter' between the 'horizon' of the interpreter and that of the text itself. Gadamer's philosophical hermeneutics is thus conceived in opposition to the methodological emphasis of traditional hermeneutic theories and their concern with the accuracy of interpretation. Gadamer's aim is to describe the underlying process, an existential encounter between two perspectives or horizons of expectation, which makes interpretation possible in the first place. Understanding is not just a matter of immersing oneself imaginatively in the world of the historical actor or text, but a more reflective and practical process which operates with an awareness of the temporal and conceptual distance between text and interpreter and of the ways in which the text has been and continues to be reinterpreted and to exercise an influence over us. This effective history (*Wirkungsgeschichte*), which traditional historicist hermeneutics tends to see as an obstacle, is for Gadamer an essential element that links us to the text. Our pre-judgments or prejudices are what make understanding possible.

Although Gadamer has often stressed that his philosophical hermeneutics, with its origin in Heidegger's hermeneutic ontology, is distinct from hermeneutics as a technique of interpretation, his approach clearly poses a challenge to more traditional conceptions of hermeneutics. These differences are brought out in particular in Gadamer's exchanges in the 1960s with Emilio Betti. The alternative conception of the human sciences or *Geisteswissenschaften* put forward in Gadamer's work also made it central to Jürgen Habermas' reformulation of the logic of the social Sciences (Habermas 1983). Habermas welcomed Gadamer's critique of hermeneutic objectivism, which he saw as the equivalent of positivism in the philosophy of the natural sciences, and also his stress on the totalizing character of understanding. For Habermas, however, Gadamer's stress on the fundamental nature of language, expressed in his claim that 'Being that can be understood is language,' amounted to a form of linguistic idealism. Together with Gadamer's stress on the importance of tradition and his rehabilitation of the category of prejudice, this suggested an ultimately conservative approach which was unable to deal with the systematic distortion of communicative processes by relations of power and domination. Habermas and Gadamer debated these issues in the late 1960s and early 1970s (Bleicher 1980); more recent theorists have tended to stress the compatibility of hermeneutics and critical theory (see *Critical Theory: Frankfurt School*) in a conception of critical hermeneutics (Thompson 1981, Outhwaite 1987). More recently, Gadamer also engaged briefly with the French deconstructionist philosopher Jacques Derrida, whose conception of interpretation is more skeptical.

Habermas' version of 'critical theory' can be seen, along with critical realism and Anthony Giddens' structuration theory, as one of three particularly influential attempts in the final third of the twentieth century to reconcile, as Max Weber had done at the beginning of the century, the rival claims of explanation and understanding in the social sciences. Habermas, along with his close collaborator Karl-Otto Apel, argued for a complementarity between an empirical-analytic approach oriented to the explanation, prediction, and control of objectified processes and a hermeneutic approach concerned with the extension of understanding, in an emancipatory model of critical social science, instantiated by psychoanalysis and the Marxist critique of ideology, which aims at the removal of causal blocks on understanding. Much of this remains in his more recent theories of reconstructive science and communicative action.

Critical theory tends towards a dualism of natural and social science, but in an increasingly muted form. The assumption that opposition to positivism also entailed dualism or antinaturalism was however also put in question in the late 1960s and early 1970s by the realist metatheory of science developed by Rom Harré and Roy Bhaskar (1975). Both Harré and Bhaskar, like Habermas, were substantially motivated by the desire to undermine positivistic theories and approaches in the social sciences. Harré and Secord (1972) developed a philosophy for social psychology based on the work of the later Wittgenstein and the analytic philosophy of language practiced at Oxford by J.L. Austin. Ordinary language, they argued, is better suited to the description of the mental processes of social actors than apparently more scientific artificial terminology, and they drew attention to models of research practice of this kind in the work of Goffman, Garfinkel, and others.

Harré and Bhaskar were in any case interested in giving a more adequate account of science as a whole, in a world composed of relatively enduring structures and mechanisms. Some of these could be isolated in scientific experimentation, given the contingent existence of *Homo sapiens* and *Homo scientificus*. An important aspect of the realist programme developed by Harré, Bhaskar, and others was a conception of explanation as involving not an essentially semantic reduction of causal statements to general laws but a reference to the causal powers of entities, structures, and mechanisms. Causal tendencies might or might not be outweighed by countervailing tendencies, and two causal tendencies may neutralize one another, as do the centrifugal force of the earth's rotation and its gravitational attraction, with the convenient consequence that human beings and other animals are safely anchored to the earth's surface.

This and other features of realism meant that the whole issue of naturalism could be rethought. Human beings could be seen as having causal powers and liabilities, just like other entities; it no longer mattered

so much that their relations rarely sustained any universal generalizations of an interesting kind, but only sets of tendencies regular enough to be worth exploring. The fact that many of the entities accorded causal force in social scientific explanations were necessarily unobservable was not, as it was for empiricism, a problem of principle. And the understanding of meaning could, as Bhaskar put it, be seen as in some ways equivalent to measurement in the natural sciences. Finally, it seemed natural to include among the causes of human action the agents' reasons for acting—reasons which must be understood as far as possible.

The realist critique of traditional epistemology found an echo in social theory, notably in the work of Anthony Giddens, who had become similarly impatient with the residues of positivist social science as well as the more radical contentions of social constructionism. Giddens' conception of the 'duality of structure' was designed to replace the traditional dichotomies between theories of social structure and social change, the micro–macro divide, and between interpretive and more structural approaches. Approaches like these which aim to mediate between pure hermeneutics and more naturalistic conceptions of social science coexist, at the dawn of the twenty-first century, with more explicitly hermeneutic or phenomenological conceptions (see e.g. Soeffner 1989, Müller-Doohm and Jung 1993). Hermeneutics in a broader sense continues to exist as a major research tradition in the humanities, as well as a minority one in the social sciences (Shapiro and Sica 1984). More importantly perhaps, social scientists that would not sign up to an explicitly hermeneutic program have at least accepted the importance of hermeneutic issues.

Hermeneutics, including Critical Theory

1. Johann Conrad Dannhauer (1603–66)

The term 'hermeneutics' is generally defined as 'the science or art of interpretation.' Although it denotes a practice which stretches back to the Greeks, modern hermeneutics emerges in the seventeenth century with the publication in 1654 of J. C. Dannhauer's *Hermeneutica sacra sive methodus exponendarum sacrum litterarum*. The significance and novelty of Dannhauer's approach lies in the fact that interpretation is for him no longer treated simply as a tool for biblical exegesis or textual philologists, but as a universal phenomenon. Dannhauer was led to this conclusion by virtue of the fact that in the seventeenth century there was an enormous proliferation of texts in all disciplines due to

major innovations in the world of printing. Consequently, critical attention was now directed toward the various worldviews which were circulating in textual form, and away from those systems of belief which had hitherto escaped the scrutiny of a less than literate public. Knowledge was being construed as an activity which sought to penetrate behind appearances neither to ultimate reality, nor to a stable and immutable order of things, but as a practical mode of engagement with the texts and writings of those who had made popular the view that there was such an order. Hence, texts which had hitherto assumed divine status—such as the Bible—were now in open competition with multifarious other books and treatises. The veracity of any text depended, from a hermeneutic perspective, upon how well both it and its author withstood interpretative scrutiny.

Such a procedure did not seek to engender confusion or to render truth and meaning inaccessible. For Dannhauer, on the contrary, hermeneutics amounted to a ‘universal science’ which enables us to appraise the truthfulness of any discipline by clearing away prejudice and falsehood. As such, getting at meaning or truth requires an approach which is never content simply to take things at face value. The master of suspicion will see meaning as something to be disclosed through a recovery of an author’s intention, and not as something which can be grasped intuitively.

Dannhauer’s universal science of hermeneutic inquiry was a rudimentary attempt to come to terms with the uncertainties regarding the status of truth, knowledge, and meaning occasioned by the dawn of the Renaissance. By giving interpretation a central epistemic role, he anticipated what was to become a major philosophical school of thought.

2. Romantic Hermeneutics: Schleiermacher and Dilthey

Although Dannhauer’s significance ought not to be underestimated in the history of hermeneutic thought, much of what comes under the headings of ‘hermeneutics’ and ‘critical theory’ today has its direct antecedents in the eighteenth and nineteenth centuries. It is to scholars of the Romantic period, such as Friedrich Schleiermacher and Wilhelm Dilthey, that one must look in order to gain an understanding of the many contemporary movements which are classified as being largely hermeneutic in origin and ethos.

2.1 Friedrich Schleiermacher

Schleiermacher and Dilthey are usually credited with having made hermeneutic inquiry a central *philosophical* preoccupation. Schleiermacher (1768–1834) sought to advance Dannhauer’s attempt at a universal

hermeneutics by trying to identify what was common to the technical operations and apparatuses of both the philologist and classical exegete. Consequently, he disregarded subject matter—whether classical document or scripture—in an effort to pinpoint the fundamental and universal techniques or methodology of the interpretative process.

Schleiermacher concluded that any act of interpretation involved both a ‘grammatical’ and a ‘technical’ form: while grammatical interpretation tries to understand a document by studying the broader linguistic milieu from which it derives, technical (stemming from ‘*techne*’—meaning artistic creativity or making) interpretation, on the other hand, looks to the author and the author’s personality and unique genius as a means of understanding the text in question. While both types of interpretation are significant for Schleiermacher, he nevertheless insists that they cannot be carried out concomitantly. For to interpret grammatically is to focus attention on language *stricto sensu*, and not on the individual speaker as such; conversely, technical interpretation demands that the reader look to the peculiarities of a particular author, to the author’s style and use of expression. In the latter case, the general language used by the author is overlooked in favor of the *way* in which the author uses it.

For Schleiermacher, the ultimate task of the hermeneutic project is served best by this technical approach to questions of meaning and understanding. Truly to understand a text, the readers must strive to reappropriate its subjective dimension. They must endeavor, that is, to extrapolate from the document the individual author’s ‘psychological’ intentions and motives. In so doing, the readers seek to come to terms with the text’s central purpose and aims. Technical interpretation allows us to tap into the soul of the work in question.

As stated above, Schleiermacher considered his way of dealing with the complexity of texts as more than simply a means of alleviating the difficulties confronted by biblical exegetes and classical philologists. He followed Dannhauer’s lead in trying to identify a hermeneutic methodology (*Kunstlehre*), which would govern not only specialized interpretative procedures, but all forms of understanding. In so doing, Schleiermacher insisted that we must always begin by presupposing misunderstanding, that misunderstanding is not something which may bedevil our reading at some future point, but that which bedevils us at every stage of the interpretative process. Hence, in the words of Jean Grondin, Schleiermacher ‘universalizes misunderstanding as the situation and occasion of interpretation’ (Grondin 1994, p. 70). The prospect of their not having fully understood a work, in other words, is what persuades the readers to read and reread the subject matter, to assess and reassess their findings. Furthermore, to presuppose misunderstanding sharpens the interpreters’ acuity, in that such an approach

ensures that they will not take anything for granted; that the readers will always admit to the possibility of being disproved.

This is why technical interpretation is, for Schleiermacher, to be preferred over and above grammatical interpretation. For if misunderstanding is to be surmounted, there ought to be as complete a reconstruction of the authorial intention as it is possible to undertake. It is only by trying to stand in the shoes of the author that we can best understand the meaning and *raison d'être* of the text. Indeed, he goes further by suggesting that we ought not only understand as well as the author, but that we must, if we are really to reconstruct a foreign viewpoint, cultivate an even more profound understanding of the work than that possessed by its author. Such is the ultimate objective of all hermeneutic inquiry for Schleiermacher.

To understand a text more thoroughly than its author seems a strange ideal for someone who emphasizes so emphatically the fundamental role of misunderstanding. It should be read, however, as simply that—an *ideal*. Due to the fact that one can never assume that all misunderstanding has been eradicated, it is the duty of the reader to purvey ever more valid and fruitful interpretations of a work. Such an ideal provokes the reader to overturn previously held interpretations in favor of more plausible alternatives. The desire to know the author and the author's world better than the author is what prevents, in Schleiermacher's opinion, hermeneutic complacency. It is what drives and inspires the inquisitive reader who cannot settle for the commonly held interpretation.

Such attempts to penetrate behind the mind of an author through a technical interpretation of that author's work caused many to charge Schleiermacher with psychologism. While such a criticism is valid to the extent that Schleiermacher's hermeneutics did evince a tendency to reconstruct a psychological profile of the author, or to highlight the thought processes which led certain authors to write as they did, it could be argued alternatively that such a procedure was a nascent attempt to crystallize what was to become the bedrock of all subsequent hermeneutics—the recreation of an imaginary dialog with those of our past in an effort to make sense of *who* we are today. Given that Schleiermacher did not have at his disposal the insights of Freud and other subsequent theorists of the 'self,' his tentative steps toward a universal hermeneutic methodology founded on a dialogical conception of identity should be seen as a brave attempt to give the role of interpretation a philosophical credibility which it hitherto lacked.

2.2 Wilhelm Dilthey

While Schleiermacher's contribution to hermeneutic inquiry was not insubstantial, Wilhelm Dilthey

(1833–1911) was a thinker whose work, and its subsequent appropriations and applications on the part of leading philosophers, has had a most profound impact on the formation of twentieth-century hermeneutics. For it was Dilthey who argued that if hermeneutics is to be genuinely universal, it must have as its object all of reality. The text of reality is history itself, as that which interconnects the multifarious and disparate strands of human endeavor. History, on this reading, is mankind's document—its grand narrative. As all texts have a place in this document, it behooves the inquirer to try to understand how history coheres before trying to understand how individual texts cohere. In problematizing history thus, Dilthey dramatically rendered more complex the job of the interpreter.

Dilthey's methodological approach was determined in large measure by the advent of positivism—a school of thought which insisted on the primacy of the natural sciences (*Naturwissenschaften*) as a model for understanding the world and our relation to it. For it was his conviction that if the human sciences (*Geisteswissenschaften*) were to fend off the challenge coming from the natural sciences, they would have to adopt analogous methodological procedures as their natural counterparts. Only in so doing could one come up with an adequate defense for the efficacy of historical knowledge as encapsulated in the various human sciences. Dilthey is, therefore, faced with the problem of how to rescue the laws of history from the laws of science, or of how to distinguish scientific *explanation* from historical *understanding* (*Verstehen*).

In his quest to pinpoint what it is that marks understanding off from explanation, Dilthey argues that a human being is not known solely as a physical object amongst others; it cannot, that is, be reduced to the level of scientifically observable phenomena. In contradistinction to scientific data, the human being has a mind which exceeds the purview of the natural scientist or the positivist, a mind which attests to its being. Consequently, a person may be understood by other people who are free to interpret and decode that person's intentions and expressions, desires and volitions. It is the mental faculty of human beings, in other words, which permits them to be *understood* and not merely *explained*. Thus, for Dilthey it is *psychology*, as the science of the human as historical and sociological agent, which ought to act as the bedrock of the human sciences. In this, he remains faithful to Schleiermacher's privileging of interpretative psychology as the most efficacious means of understanding the intentions of an other.

Unlike our knowledge of the external world, which requires the mediation of the senses, knowledge of the inner world of psychological life is free from temporal vicissitudes. As such, it forms the basis of a universally fixed mental structure which may be accessed immediately. But the quandary which Dilthey faced in advancing such a theory was quite considerable. For

example, in order to legitimate his claims he had to put forward incontrovertible proof that there were in fact complex mental structures which were indeed self-evident, and which could be accessed in a neutral way by any thinking subject. Given that there has never been agreement among the practitioners of psychology as to the precise nature of such structures, let alone proof of their existence, it is hardly plausible to assert that they are universally self-evident.

In an effort to counter such dilemmas, Dilthey elects to prioritize hermeneutics as that which has the best chance of permitting access to the inner life of the mind, by way of external media such as signs and texts. For it is through such documents that the mental life of one different to the self is made manifest for analysis by the human scientist. The inner life of an other, in other words, is objectified in and through the traces which he or she leaves behind. Consequently, the interpreter has the capacity to reconstruct the life of the other by recovering what the other has deposited in textual form. The text, therefore, is that which bears witness, in external form, to the inner mental life of one who was formerly alien to the self. It is that by way of which the interpreter, or the human scientist, can arrive at a credible understanding of a life. The ultimate aim of the hermeneutic enterprise is to reproduce the life that one is endeavoring to understand. If this could be achieved, the objective validity of the human sciences would no longer be in any doubt. It would also serve to avert the pending crisis, which historicism and relativism threatened to engender.

3. Phenomenological Hermeneutics: Heidegger and Gadamer

3.1 Martin Heidegger

Dilthey's legacy was far-reaching and extensive. In the domain of philosophy, it was Martin Heidegger (1889–1976), a German student of the eminent phenomenologist, Edmund Husserl, who would do most to build upon and advance Dilthey's hermeneutic insights. While Dilthey emphasized the role of hermeneutics in the human sciences, Heidegger was to go one step further by inquiring into the ontological conditions of such sciences. In other words, Heidegger considered the human sciences to be a branch of epistemology (Greek: *episteme*) or the theory of knowledge. As such, they ought not to be the focus of genuinely fundamental philosophical analysis. Rather, the task of the hermeneutic phenomenologist was to inquire into the actual *being* of such sciences, their ontological (Greek: *on*) status. Indeed, this move towards *being*, and away from *knowledge*, was

Heidegger's most significant contribution, not only to phenomenology and hermeneutics, but to the history of twentieth-century philosophy.

Central to Heidegger's thought was the belief that the dualism between subject (the self) and object (the world beyond the self—the 'external' world) was misguided and mistaken. Although such dualisms are a regular feature in the history of philosophy, they are nowhere more apparent than in the thought of the seventeenth-century French philosopher, René Descartes. Descartes's contention that the thinking self (*Cogito*) could doubt away its environment in an effort to establish its own certainty, was primarily responsible for concretizing the subject–object divide. Even Heidegger's philosophical master, Husserl, structured his thought around this dualism; his emphasis on the role of intentional consciousness in the formation of the self's constitution was seen by Heidegger to be yet another unfortunate consequence of the Cartesian legacy, even if Husserl's original aim was to surmount the subject–object divide by leading us back to an originary experience of the world. If Husserl emphasizes consciousness as that upon which our primordial experience of the world is founded, Heidegger, in an effort to reconcile both subject and object, interprets this originary experience as a *being-in-the-world*. In so doing, Heidegger replaces the question common to Descartes, Kant, Dilthey, and Husserl—'What does it mean to *know*?'—with the question, 'What does it mean to *be*?' For Heidegger, there is no way the subject can, or should, try to extricate itself from the world in which it finds itself—from its natural environment. For it is through our basic interaction with the world that we come to a genuine and fundamental understanding of the 'who' of being.

The question of being, the question which first stimulated the early Greek metaphysicians, is thus what Heidegger intends to retrieve. He does so by underscoring our *being-there* (*Dasein*), our temporal situatedness *in* the world, as distinct from our consciousness *of* the world. Due to the fact that a human being is the only being capable of asking the question: 'What does it mean to be?', any examination of being must therefore proceed by way of an inquiry into the human self as a being-there (*Dasein*), as a being who is concretely submerged in the practical affairs of the everyday world. This helps to explain the title of Heidegger's *magnum opus* of 1927, *Being and Time* (1962).

One such way Heidegger approaches the question of the being of *Dasein*, is through an analysis of the category of 'understanding.' For Heidegger, 'understanding' does not denote conscious awareness or assimilation, but rather those 'moods' (*Stimmungen*) which characterize our basic lived experience. These moods take the form of concern, anguish, fear, guilt, excitement, etc., and are determined by Heidegger as ontological acts of *preunderstanding* (*Vor-Verständnis*), or the means by which we come to grips with the

world prior to the process of making the world an object for thought. In other words, Heidegger's phenomenological analysis strives to bring the moods of *Dasein*'s preunderstanding to the level of a reflective self-awareness. Like his nineteenth-century predecessor, Søren Kierkegaard, Heidegger turns Descartes's dictum—'I think, therefore I am' (*Cogito ergo sum*), on its head. For both Kierkegaard and Heidegger, we exist before we are objectively aware that we exist; our existence is preunderstanding, in the sense that we prereflectively interpret the world as a project of possibilities for our existence, before coming reflectively to understand it as such.

Heidegger's philosophical hermeneutics, unlike the methodological hermeneutics of Dilthey, will not, therefore, reflect upon the human sciences, but will attempt an examination and explication of the very foundations of those sciences. Moreover, for Dilthey, understanding has always to do with the understanding of another psyche or mind. For Heidegger, however, the problem of other minds is replaced with *Dasein*'s preunderstanding of the world into which it is 'thrown.' Understanding the world, thus, and not an other mind, is the fundamental goal of Heideggerian hermeneutics. To understand is not to understand facts, but to understand what possibilities are open to us in the situation in which we find ourselves. As such, human existence constitutes what Heidegger famously terms 'a hermeneutic circle,' in that it implicitly interprets itself in terms of its everyday moods and projects before it raises this interpretation to the level of philosophical speculation.

For Heidegger, it is by way of language that we interpret a thing *as* something which is intimately related to our project of being-in-the-world. Language should not be thought of in this context as mere assertion, but as interpretative of hermeneutic discourse. For on Heidegger's reading, the world never shows up for *Dasein* in some raw manifestation, but is always disclosed in and through the projects which *Dasein* sets itself. For example, Heideggerian discourse does not simply assert that an object possesses a series of objective characteristics such as weight, color, and width. More essentially, it interprets the object *as* something which is useful and meaningful for its existence. Hence, the object is described, interpreted, or defined, in its relation to *my* specific projects. A rock is thus seen *as* a weapon or a sculpting stone, depending on the use *I* make of it. If objective assertion treats things as objects present-at-hand (*vorhanden*), hermeneutic discourse recognizes them as instruments ready-to-hand (*zuhanden*)—or as things which aid us in our attempts to fulfill our everyday projects. Hermeneutic discourse, that is, reveals things in terms of their possible serviceability for me, and it does so by releasing them from the abstraction of a timeless present into the temporal horizons of my concrete historical concerns—retrieving the meaningfulness of these entities from my past experience or projecting

such meaningfulness into my future possible experiences.

Heidegger's great contribution to the history of hermeneutics was his insistence that the world discloses itself through interpretative discourse. He failed, however, to explain what repercussions and ramifications this might have for the human sciences and for culture as a whole. It would be left to his student, Hans-Georg Gadamer, to fulfill this task.

3.2 Hans-Georg Gadamer

In Gadamer (1900–), we see a movement away from Heidegger's preoccupation with the question of being, back toward more epistemological concerns. His *magnum opus*, *Truth and Method* (1975), is dedicated to asking how the Heideggerian question of truth, as developed through a hermeneutic framework, can accommodate Dilthey's methodological hermeneutics of the human sciences. According to Gadamer, it was not essential for the human sciences to develop an exact method if they were to compete with the natural sciences. For while the natural sciences proceeded by way of logical induction, the human sciences had no such starting point or *method*. The human scientist, in other words, used insight and tact as tools rather than the laws of induction. Gadamer places the blame for the decline of the human sciences at the feet of those who, like Kant and his successors, considered the natural sciences as being eminently more objective than their subjective and aesthetic humanistic counterparts.

In his attempt to resuscitate the human sciences, Gadamer relies heavily on Heidegger's contention that we come to understand ourselves through our projects and possibilities. Preunderstanding, thus, is the condition of self-awareness. As such, and this is what it means to be caught in the hermeneutic circle, we come to an understanding of ourselves and our world by virtue of the prejudices of our specific time and place; that is, because *Dasein* is always already temporally situated, its preunderstanding will be conditioned and prejudiced by the world into which a person has been born. For instance, the reason why I interpret a rock *as* a weapon is because those who have preceded me in my tradition interpreted it *as such*. Interpretation, we will recall, is never neutral.

The question which Gadamer prioritizes, however, concerns the veracity of such interpretation; in an effort to avoid a crude form of relativism, Gadamer asks what we must do in order to avoid being duped by fallacious preunderstandings. As a devout hermeneut, he does not, of course, subscribe to the belief that misunderstanding can be fully eradicated. Interpretation, by its very nature, involves misreading and misconstrual. What we need to guard against, however, is the general propensity to take our prejudices at face value. While we cannot escape the prejudices of

our preunderstandings, we can nevertheless subject those prejudices and biases to critical scrutiny. Gadamer is aware that the interpreters have no vantage point outside their time and place to evaluate neutrally the efficacy of their preconceptions and prejudices. They rely, therefore, on what he terms 'temporal distance'; with the insight of hindsight, we can discern what interpretations have positively withstood the test of time. While he is cognizant of the fact that temporal distance is by no means fail-safe or fully reliable, Gadamer nevertheless acknowledges that it is perhaps the best available strategy for critically discerning between rival interpretations. The task for the individual is to try to develop a dialectical accommodation between the self that the individual has become by being on the receiving end of a tradition, and the individual's capacity to assume a critical disposition in relation to that tradition. Becoming aware that one is historically conditioned, and that one's beliefs derive not from a divine source, but from one's predecessors, is the first step towards such an accommodation.

It is through the process of responding to the claims which my tradition makes upon me that I come to understand the self that I am. Self-understanding, for Gadamer, involves dialoging with all those whose voices speak through me. I come to an understanding of *who* I am by reading and responding to those into whose heritage and legacy I have been situated. Hence, I am always already engaged in conversation with others who have gone before. The self is, in other words, dialogical through and through.

The problem with method, according to Gadamer, is that it never takes sufficient account of dialog, of the ongoing dialog within and beyond tradition. The form such dialog takes is that of a dialectic between question and answer. This ensures that no position can ever assume that it is beyond critical appraisal. The answer in such a dialectic will always beg yet another question. By standing back from one's tradition, not outside it, one can ask the relevant questions of it from one's particular vantage point, thus paving the way for our successors to ask vital questions of our own position. If there were no such dialog, tradition would simply freeze over. It is precisely by virtue of the fact that we endeavor to understand ourselves through a critical dialog of this type, that we can talk of historical progress.

Temporal distanciation is, therefore, that which allows me to observe a world which, although related in many respects to my own, is in many other senses different from the one I inhabit. The dialogue which pertains between the two worlds—my own and that of my forebear—is realized in what Gadamer calls a 'fusion of horizons.' This suggests that no tradition, horizon, or world is totally closed in upon itself, that it is indeed porous and open-ended. It demonstrates also that tradition cannot inoculate itself against the tensions which emerge in the course of a critical dialog

with its successor traditions. Such is the way we are 'affected' by history (*Wirkungsgeschichtlichkeit*).

4. *Critical Theory and Critical Hermeneutics: Habermas and Ricoeur*

4.1 *Jürgen Habermas and Critical Theory*

One way of appraising the Heidegger–Gadamer tradition of hermeneutic thought is to observe the way in which it interacts with what is known as the 'critical theory' school, the main protagonists of which are Georg Lukacs, Theodor Adorno, Walter Benjamin, Herbert Marcuse, and Jürgen Habermas. Primarily, critical theory appropriates the dialectical methods of Hegel and Marx, so as to develop a distinctive brand of socially committed analysis. The ultimate meaning of our world, they contend, cannot be divorced from its historical and political context. Benjamin and Habermas each developed the dialectical method of humanist Marxism in its dual capacity as critique of ideology and a project of emancipation. As such, they owed their greatest debt to Marx's original recognition that it was only by combining our practical and reflective activities that we might effectively surmount prevailing forces of domination and control.

It is within the context of Habermas's critique of ideology that the main differences between hermeneutics and critical theory emerge most clearly. For Habermas (1929–), what blocks the way to genuine social relations are the dominant illusions that inhibit fair and equal communication between social beings. The way to achieve such a goal is to keep in focus the utopia of, what he calls, an 'ideal speech situation.' This amounts to a democratic system of communication in which all social agents would have the chance to speak and make themselves heard in an undistorted fashion. It would be made possible when all participants in discourse possess an equal opportunity to initiate communication and become transparent by their words and actions. Hitherto, communication has been distorted by unequal distribution of dialog opportunities which sustain privileged positions.

In articulating the demands of the ideal speech situation, Habermas utilizes the psychoanalytic technique of identifying the forces which systematically distort communication. This model of *Sprachanalyse* ('the analysis of speech') amounts to a 'metahermeneutic' which endeavors to disclose the subject's quest for self-understanding through a process of desymbolization and resymbolization. Such a technique goes beyond, in Habermas's view, both the romantic and phenomenological deployment of hermeneutics which are founded upon a spontaneous recovery of intersubjective agreement. Where Gadamer sought to surmount misunderstanding by way of a question and answer retrieval of some original dialogical understanding, Habermas opts for the more arduous route

through a critique of ideology leading to the possibility of genuine language. The notion of unrestrained communication remains for Habermas, therefore, a utopian ideal.

Romantic and phenomenological hermeneutics are, according to Habermas, hindered by their refusal to think through sufficiently the sociopolitical dimension of understanding. He believes that Gadamer's ontological and poetic approach to the question of language is naive, to the extent that it is predicated upon the erroneous assumption that a consensus of dialogical communication could be achieved by recovering our traditional 'belongingness' to being. For Habermas, the construction of genuine consensus cannot dispense with a project of historical action. Hence, where the romantic hermeneutic spoke of a retrieval of lost meaning, Habermas speaks of an anticipation of possible meaning. In contrast to Gadamer's view that misunderstanding presupposes a prior or preunderstanding, Habermas insists that where there is misunderstanding there may exist a posterior understanding if and only if we first undertake a critique of those ideological distortions which reside at the origin of misunderstanding. What is given is always already deformed communication. Habermas, that is, wishes to show how the ideal of communicative competence is not an ontological precondition of understanding but a historical possibility yet to be achieved. Only in this manner can we reconcile the philosophers who interpret the world and the social agents who change it.

4.2 Paul Ricoeur and Critical Hermeneutics

If Habermas criticizes romantic and phenomenological hermeneutics for being too focused on the past, and not sufficiently attentive to its ideological deformations, French philosopher Paul Ricoeur (1913–) tries to find a mid-passage between the metahermeneutics advanced by Habermas, and the hermeneutics of tradition evoked by Gadamer. In so doing, he develops a 'critical hermeneutics' which dissents from the romantic idea that we understand the past by reproducing in the present some original production of meaning, as if the temporal distancing of meaning could be in some way erased. A critical hermeneutics of tradition insists on the necessity to discriminate between true and false interpretations of history. This, of course, raises the crucial question of legitimation. To resolve this problem, Habermas appealed to an ahistorical ideal of undistorted communication. For Ricoeur, however, such a criterion of legitimacy may be deferred to an indefinite future without any grounds in history. He recommends, accordingly, that we interpret tradition's claim to truth in a nonabsolutist sense of a *presumption* of truth. This suggests that we accept the truth claims of tradition until such a time as a better argument prevails. The presumption of truth

refers to our basic attitude of credit or trust in the propositions of meaning legacies by the past—a primary response which precedes the critical moment of distancing and reminds us that we are not the originators of truth but that we always already belong to a context of what he terms, 'presumed truth.' Ricoeur believes that such a model bridges the divide between the finitude of hermeneutic imagination (Heidegger and Gadamer) and the validity of the ideal undistorted communication (Habermas).

Ricoeur inserts Habermas's critique of ideology into the heart of the hermeneutics of tradition. This is born of his conviction that such a project demands a fundamental respect for tradition if it is to safeguard itself against arbitrary or ahistorical voluntarism—that is, a future project completely divorced from the historical heritage of the past. Where Gadamer invokes the notion of a common understanding which precedes us, the critical consciousness of Habermas reinterprets it in terms of the ideal of unrestricted and unconstrained communication. This antithesis is, however, broken down if one espouses a critical hermeneutics that realizes that critical theory cannot take up a view from nowhere, but must stick to its professed principles by presupposing some form of historical memory. For critical theory, a historical memory would not be that of romanticism (as it was for Gadamer) but rather of the Enlightenment, understood as a project of emancipation.

Tradition, Ricoeur concludes, must be understood in the dynamic perspective of our being-affected-by-the-past, which in turn is related to our historical horizon of expectancy. In this larger dialectic between tradition and expectation, we rediscover suppressed potentialities of past meaning which give substance to the ideal of undistorted communication. Indeed, it is only in terms of such an interplay between memory and anticipation that the ideal image of a reconciled humanity can be invested with an effective history. A critical hermeneutics has thus the ethical duty of ensuring that the expectancies for the future are brought nearer to the present by being sensitive to the concrete actions which need to be undertaken so as to bring to a realization what is 'desirable and reasonable.' Second, it must continually strive to liberate the still untapped potentialities of inherited meaning.

In this way, Ricoeur's particular brand of hermeneutics provides an essential link between romantic hermeneutics and critical theory. His incisive analysis of myth throughout his multifarious writings shows precisely how such a critical hermeneutics can be deployed in the service of concrete sociopolitical objectives. The modern project of unmasking myth frequently takes its cue from the investigative methods developed by Marx, Nietzsche, and Freud—the 'three masters of suspicion' as Ricoeur likes to call them. Once a hermeneutics of suspicion has unmasked the alienating role of myth as an agency of ideological conformism, there remains, for Ricoeur, the task of a

positive interpretation. Hermeneutics, that is, has the double task of *suspecting* and *listening*. Having demythologized the ideologies of false consciousness it labors to disclose the utopian symbols of liberating consciousness. It thereby seeks to rescue mythic symbols from reactionary domination, and to show that once the mystifying function has been dispelled we may recover genuinely utopian anticipations of 'possible worlds' of liberty and justice. A positive hermeneutics of this sort offers an opportunity to rescue myths from the ideological abuses of doctrinal prejudice, nationalism, class oppression, or totalitarian conformism; and it does so in the name of a universal project of freedom—a project from which no creed, nation, class, or individual is excluded. The utopian content of myth differs from the ideological in that it is inclusive. It opens up human consciousness to a common goal of liberation instead of closing it off in inherited securities. That is, having eliminated the ideological abuse of myth as a false explanation of how things are, we are now free to appreciate the properly symbolic role of myth as an exploration of how things might be.

Heterosexism and Homophobia

Homophobia is a colloquial expression that refers to negative, fearful, or hateful attitudes and behavior toward gays and lesbians. Although homophobia is a common term used to indicate antilesbian and antigay prejudice, many social scientists object to the concept. Herek (1995), for instance, objects that prejudice against homosexuality is not a phobia in the clinical sense of the word; it is not based necessarily on fear, nor is it inevitably irrational or dysfunctional for the individuals who manifest it. He defines heterosexism as 'an ideological system that denies, denigrates, and stigmatizes any nonheterosexual form of behavior, identity, relationship or community.' Adam (1998), Plummer (1992), and Stein and Plummer (1994) find it useful to distinguish analytically and conceptually between heterosexism, which is defined as societal prejudice located in the structures, institutions, and material conditions of society, and homophobia, which is a manifestation of the individual-level attitudes and behavior reflective of heterosexism. Herek (1995) prefers the term 'psychological heterosexism' to denote individual-level antigay and antilesbian prejudice. Heterosexism and homophobia are mutually constitutive in that individuals feel that their antigay attitudes and behaviors are legitimate to the extent that these prejudices are entrenched in social institutions. Individuals are more likely to act out their prejudices when they consider them to be culturally legitimate and shared by others (Berrill 1992). Expressions of antigay prejudice reinforce ideologies and practices of intolerance and hostility and reinscribe homosexuality as something that should be despised and feared and should remain hidden.

1. Attitudes and Expressions of Homophobia

One common stereotype is that homosexuality is related to gender-role nonconformity. It is assumed frequently that lesbians manifest characteristics defined as masculine and gay men exhibit behavior associated with feminine characteristics. For many people, this presumed gender nonconformity is reason enough to be suspicious and intolerant of homosexuals. Gay men are also often assumed to be hypersexual, animalistic, promiscuous, overly visible, and conspiratorial. Lesbians are assumed to be man-haters, aggressive, socially nonconforming, and sex-

ually cold (Herek 1995). Until 1973 the American Psychiatric Association considered homosexuality to be a form of mental illness. Many people continue to hold this belief and also believe homosexuality to be immoral and antisocial. Expressions of homophobia include verbal assaults and derisive joking, negative stereotypical media representations, discrimination in employment, education, housing, medical research, legal defense, and custody rights, physical attack, and tacit approval of all forms of discrimination, including gay bashing. Various studies, including surveys of gays and lesbians based on probability samples, indicate that nearly half of all respondents have experienced some form of discrimination in employment or housing based on their sexual orientation. A meta-analysis of 24 questionnaire studies showed that a median of 44 percent of the respondents have been threatened with violence and 80 percent have been verbally harassed (Berrill 1992). All of the respondents attribute these discriminatory actions to the perpetrators' perceptions that the target was homosexual. In 1987 the US Department of Justice reported that homosexuals are the most frequent victims of hate violence.

1.1 *Containing Sexuality*

Several theorists have observed that homophobia is an expression of a culture that is confused and inconsistent about sexual behavior. Attitudes and actions reflect both obsession with and repression of sexual desire. One basis of tacit agreement is that sexuality is something that must be contained. Homosexuality, along with adultery, prostitution and pederasty, mark the boundaries by existing outside culturally approved forms of sexuality—what poet Rich (1980) refers to as compulsory heterosexuality. Social historians (e.g., Boswell 1980, D'Emilio and Freedman 1988, Katz 1976) note that the emergence of a sexual binary in the nineteenth century posits heterosexuality as natural and socially desirable by contrasting it with homosexuality, which is characterized as unnatural and immoral. This binary represents the general tendency in modern western thought to conflate morality and nature. According to this cultural equation, sexual desire is a manifestation of a natural drive to reproduce. The moral, disciplined individual contains this desire within the bounds of heterosexual monogamy. These attitudes are reflected in clinical, social and religious definitions of the homosexual as cursed, perverted, sexually obsessed, and evil and, until recently, mentally and physically sick.

2. *Institutional Heterosexism*

Pervasive negative stereotypes regarding lesbians and gay men suggest that these attitudes and beliefs are

rooted in cultural ideologies and social practices. All of these attitudes and expressions reflect the prevailing belief that sexual desire for the opposite sex is expected and normal; sexual desire for someone of the same sex is abnormal and problematic. The lingering belief that homosexuality is dysfunctional and that it constitutes a state of anguish for the individual can be traced to the medicalization of homosexuality and its treatment as an illness. Many medical practitioners and clinicians continue to offer treatments intended to 'cure' lesbians and gays of their 'affliction.' These practices reflect the cultural belief that individuals will be unhappy and maladjusted if they do not experience sexual desire for persons of the opposite sex. Medical assessments that treat homosexuality as a form of disease reinscribe the notion that sexuality is primarily physiological and that heterosexuality is the healthy manifestation of human physiology.

Most contemporary religions also treat homosexuality as problematic. In some cases a distinction is made between homosexual feelings and homosexual acts (e.g., Catholic Catechism 1989). The experience of homosexual inclinations may be considered an affliction—a 'cross to bear'—but to act on one's homosexual feelings is considered a sin. Many religious leaders advocate celibacy for those 'afflicted' with homosexual tendencies. Some religious organizations sponsor intensive therapy programs intended to help the individual who is 'suffering' from homosexuality to recover. Similar to medical institutions, religious institutions take heterosexuality for granted as the normal and desired form of sexual organization and treat homosexuality as deviant, undesirable, dysfunctional, and, additionally, sinful.

Legal practices also reflect a cultural ideology that supports heterosexuality as normal and denigrates homosexuality as abnormal. The most prevalent indication of compulsory heterosexism is the widespread lack of legal protection from antigay/lesbian discrimination. Lesbians and gays who experience discrimination in employment, housing, education and immigration frequently find it difficult to obtain justice. In the US it is still legal to ban lesbians and gays from various public institutions including service in the military and employment in various educational domains. Another indication of cultural heterosexism is public resistance to attempts by lesbians and gay men to reduce discrimination and to seek justice. In the 1990s US citizens in several states voted against ballot initiatives that would ensure equal legal protection for lesbians and gays. The rhetoric employed to defeat these initiatives was that lesbians and gays were seeking 'special rights and privileges.' The logic underlying this argument was that the US constitution already guarantees every individual equal protection under the law. While this is the case in theory, advocates of the equality initiatives point out that in practice this protection is often not extended to lesbians and gays. In fact, many social officials,

including employers, housing agencies and health care providers actively refuse to grant lesbians and gays equal rights and openly cite deviant sexual orientation as the basis for this discrimination. US courts have routinely upheld these decisions

Not only does the law fail to uphold the rights of lesbians and gays, but it has been enforced differentially as a means of punishing lesbians and gays. One example of differential enforcement is the enactment of sodomy laws. A majority of states still have laws that proscribe oral or anal sex. In most cases, these laws refer only to the behavior and not to the gender of the participants. However, the only recorded arrests in the past several decades based on these archaic laws have been gays and lesbians. When challenged, several states (Kentucky, Louisiana, Michigan, and Texas) have ruled sodomy laws as unconstitutional. However, in 1986, in the case of *Bowers v. Hardwick*, the US Supreme Court upheld a Georgia sodomy law in a narrow vote of 5 to 4. The majority opinion, written by Chief Justice Warren Burger expresses the general legal failure to separate the expression of private individual sexual behaviors from perceived cultural expectations. In his brief he writes: 'To uphold that homosexual sodomy is somehow protected as a fundamental right would be to cast aside millennia of moral teaching' (quoted in Singer and Deschamps 1994).

Court decisions such as *Bowers vs. Hardwick* galvanized many US citizens who were concerned with the implications of court-mandated moral behavior and invasion of privacy. As a consequence, in the 1990s lesbians and gays have fought actively against discrimination. Several gains have been made, but these gains have been matched in intensity by antigay and antilebian legislation. The intent of initiatives such as Colorado's Amendment 2 (enacted in 1992) is to legally prohibit lesbians and gays from seeking legal protection for discrimination based on their status as homosexuals. This is the first proactive legislation in the history of US law that actively denies the pursuit of civil rights based on a single specific category—homosexuality. In an address to Congress regarding legislation intended to protect persons from discriminatory violence (hate crimes), Senator Dannemeyer makes clear this categorical prejudice. He notes: '(I)t is a Federal responsibility to ensure the equal protection of all citizens regardless of their race, religion, or ethnic origin. It is not a Federal obligation to protect citizens in their sexual orientation' (US Congress 1988, p. 12).

2.1 Permissible Prejudice

The extent to which homophobia is an institution is indicated in the decisions of law enforcement officials and judges who consider homosexuality sufficient grounds for justifying acts of prejudice, discrimination,

and violence. This tacit approval constitutes a form of permissible prejudice. Persons presume their prejudices to be legitimate or permissible when these prejudices are condoned by persons in positions of authority. Not only do the words of Justice Burger and Senator Dannemeyer reveal the extent to which heterosexuality is considered normal and legitimate, they suggest that homosexuality is a form of deviance that is wrong and shouldn't be tolerated. These institutional practices buttress individual feelings of fear and hate and send the message that discrimination and violence will be tolerated. In contrast, legal and cultural practices in many countries and some states in the US reflect the intent to extend equal rights to all citizens. Gay and lesbian marriages are legally recognized in Denmark and the Netherlands, for instance, and of the 16 countries that comprise the North Atlantic Treaty Organization, only the UK and the US ban lesbians and gays from service in the military.

2.2 Internalized Homophobia

In a climate of permissible prejudice, many lesbians and gays live in a continual state of fear. The entrenchment of heterosexist expectations and the corresponding active prejudice against homosexuality also induces feelings of 'internalized homophobia.' Internalized homophobia is a form of self-disgust and hatred experienced by many lesbians and gays. The phrase 'internalized homophobia' suggests that individuals who are trying to come to terms with their homosexual desires absorb or take in attitudes of cultural prejudice and use these attitudes as a basis of self-judgement. If the prevalent cultural story-line is one of intolerance and debasement, then individual lesbians and gays are likely to have to deal with this in formulating their own sense of themselves. In a culture that presumes heterosexuality, gays and lesbians must decide continually whether or not to voice information indicative of a deviant sexuality. 'Coming out' is an ongoing process. This process involves wrestling with and reconciling family, peer and religious expectations with personal feelings and experiences. Many lesbians and gay men fear negative consequences for revealing their sexuality. The majority experience rejection by their families, friends and religious and working communities when they reveal their homosexuality. Fear of rejection and a lack of positive role models can lead to confusion and self-hatred. Information compiled by the US Department of Health and Human Services in 1989 indicates that lesbian and gay youth are two to three times more likely to attempt suicide than their heterosexual peers. Gay and lesbian youth account for 30 percent of all completed youth suicides. In contrast, religious and community organizations that endeavor to understand and support gay and lesbian youth have been successful in reconciling family conflict and in integrating these youth into their schools and communities.

3. Explanations for Homophobia/Heterosexism

Adam (1998) delineates three theoretical approaches to understanding homophobia. Each approach is distinguished by a conceptual term denoting a specific theoretical orientation to anti-homosexual prejudice: Homophobia, Heteronormativity, and Heterosexism. Adam links these concepts to specific disciplines: Psychology, Cultural Studies (literary), and Sociology, respectively. The distinguishing aspect of each approach is the analytical unit: Personality, Discourse, and Social Structure. Explanations can be grouped accordingly. Within the field of psychology, Herek (1995) reviews the 'functional' explanations ('people hold and express particular attitudes because they derive psychological benefit from doing so'). Herek proposes three principle functions underlying attitudes about homosexuality: experiential, social identity, and ego-defense. A person's attitude may be a consequence of personal experiences (positive or negative); a prejudiced attitude may be intended as an expression of allegiance to a particular social group; or it may be a defensive response to personal psychological conflicts (such as gender expectations). He emphasizes that it is important to recognize the nexus between these functional attitudes and cultural heterosexism. The source and expression of these attitudes directly reflects a person's perceptions of cultural expectations.

The development of literary cultural studies in the 1990s has generated several interrelated theories which come together under the term, 'queer theory.' Queer theorists (e.g., Butler 1999, Sedgwick 1990, Seidman 1997) emphasize discursive practices that promote certain lines of thought and action and discourage or punish others. Heteronormativity is one of the most prevalent discourses in contemporary western culture. These theories focus on the manifestations of heterosexuality in art, media, education, legal discourse, religion, and so forth. According to these theories, the dominant cultural discourse is saturated with images and ideals that promote heterosexuality and condemn homosexuality (or anything that does not fit the expected monogamous, heterosexual, family idea). Queer theorists have particularly focused on the experience of the 'closet'—physical and discursive practices intended to keep homosexuality hidden and contained in separate spheres.

Adam subsumes the psychological and cultural studies approaches within the sociological. This approach emphasizes social structure, particularly the ways in which psychological attitudes and the values revealed in cultural discourses are manifest and maintained through institutional structures and practices. Change, he suggests, will be a result not only of education against prejudiced attitudes and transgressive acts intended as critiques of taken-for-granted cultural practices, but the extent to which this education and alternative expression permeates and unsettles existing institutional arrangements (such as the

family, law, and religion). Seidman et al. (1999) suggest that recent gay and lesbian social movements have not only served to challenge some of these existing arrangements, but that they may have the paradoxical effect of 'decentering' lesbian and gay identities. According to their logic, the conditions of the closet may compel individuals to make their homosexuality a primary focus and thus, to solidify it as a primary identity. Paradoxically, normalization of homosexuality may enable individuals to de-emphasize this aspect of their behavior.

3.1 Gender

Understanding homophobia is complicated by the strong link between gender and sexuality in this culture. Gender is the basic criterion by which we select sexual partners. The violation of expected gender behavior elicits taunting, prejudice, and physical and social abuse. Frequent targets of this prejudice include the mannish lesbian and the effeminate gay male. Both evoke stereotypes that represent violations of gender expectations and hint at sexual transgressions. Transgendered persons are frequent targets of violence (see *Transsexuality, Transvestism, and Transgender*). It is difficult to know if attackers are provoked by what they assume to be a sexual aberration or a gender violation. Given the tight connection between gender and sexuality, it is likely that any deviation is perceived as a threat to heterosexuality. In the 1990s Lambda Legal Defense documented several cases in the US of murdered transgendered persons in which the murderer was released by the courts. The rationale offered in each case was that to arouse sexual desire in another under 'false gender pretense' was to invite violent 'self-defense' when the pretense was revealed (Singer and Deschamps 1994). This rationale can be interpreted as a manifestation of homophobia; individuals who do not conform to the expected norms of gender and sexuality do not deserve social justice.

4. Social Movements

The social protests and political activism associated with lesbian and gay history can be interpreted as a response to widespread, organized manifestations of homophobia. Several observers have suggested that the struggle for gay and lesbian rights was the civil rights issue of the 1990s. This history represents a fight for rights that are constitutionally guaranteed to all Americans but frequently withheld from homosexuals. Many local and national lesbian and gay movements have been organized as a direct response to political initiatives designed to legalize discrimination against homosexuals. The Defense of Marriage Act introduced into US federal legislation in 1996 is one such case. Marriage between same-sex couples poses no legal threat or loss of benefits to heterosexual couples.

It is difficult to interpret the urgency with which states have pursued legislation to restrict same-sex marriages as anything other than a display of mass homophobia. In the early 1990s antigay/lesbian legislation appeared on the ballots of 41 states and the District of Columbia. This sort of legislation is indicative of the extent to which homophobia is culturally legitimated as an institutionalized form of prejudice. Critics who suggest that antidiscrimination laws are 'special rights' fail to comprehend the extensive reach of homophobic actions into the everyday lives of lesbians, gays, bisexuals, and transgendered persons.

Heuristics for Decision and Choice

Heuristics are approximate strategies or 'rules of thumb' for decision making and problem solving that do not guarantee a correct solution but that typically yield a reasonable solution or bring one closer to hand. As such, they stand in contrast to algorithms that produce a correct solution, given complete and correct inputs, if one exists. More specifically, heuristics are usually thought of as shortcuts that allow decisions or solutions to be reached more rapidly, even in conditions of incomplete or uncertain information—often because they do not process all the available information. Heuristics are most commonly studied in psychology within the domains of judgment and decision making, social cognition, and problem solving, and in computer-based applications in artificial intelligence (AI) and operations research (OR). This entry focuses on heuristics proposed as models of how people make decisions and choices.

1. Historical Overview

The term 'heuristic' (from a Greek root, 'to discover') was used for most of the twentieth century to refer to useful, even indispensable, strategies for finding solutions to problems that are difficult to approach by other means. Gestalt psychologists spoke of heuristic reasoning methods such as 'looking around' and 'inspecting the problem' to guide the search for useful information in the environment, while mathematicians employed heuristics including 'examining special cases', 'exploiting related problems', 'decomposing and recombining', and 'working backwards' (Groner 1983). These rather vague strategies were made more precise in computer-based models of human problem

solving and reasoning largely based on the means-ends analysis heuristic, which sought some way to reduce the distance between the current partial-solution state and the goal state (e.g., in Newell and Simon's early General Problem Solver system; see *Artificial Intelligence: Search*). Such general purpose or 'weak' methods proved insufficient to tackle many problems, so research in AI in the 1970s turned to collecting domain-specific rules of thumb from specialists in a particular field and incorporating these into expert systems. Around the same time, mathematicians working in OR faced new results from computational complexity theory indicating that efficient algorithmic solutions to many classes of challenging combinatorial problems (such as the Traveling Salesman Problem) might not be found; as a consequence, they too turned to the search for problem-specific heuristics, though through invention rather than behavioral observation (Müller-Merbach 1981).

After 1970, though, heuristics gained a different connotation in psychology: fallible cognitive shortcuts that people often use in situations where logic or probability theory should be applied instead. The 'heuristics-and-biases' research program launched by Tversky and Kahneman (1974, Kahneman et al. 1982) emphasized how the use of heuristics can lead to systematic errors and lapses of reasoning (see *Decision Biases, Cognitive Psychology of*) indicating human irrationality. The heuristics studied (see Sect. 2) were often vaguely defined and broadly applicable to judgments made under uncertainty in any domain, akin to the weak methods explored earlier in AI. This negative view of heuristics and of the people who use them as 'cognitive misers' employing little information or cognition to reach biased conclusions has spread to many other social sciences, including economics (Rabin 1998) and law (Hanson and Kysar 1999). More recently, a new appreciation is emerging within psychology that heuristics may be the only available approach to decision making in the many problems where optimal logical solutions are computationally intractable or do not exist (as OR researchers realized), and that domain-specific decision heuristics may be more powerful than domain-general logical approaches in other problems (as AI found). This has led to the study of precisely-specified heuristics matched to particular decision tasks (see Sect. 3), and the ways that learning and evolution can achieve this match in human behavior (e.g., Payne et al. 1993, Gigerenzer et al. 1999). The existence of such evolved adaptive heuristics has already been widely accepted for other animals in research on rules of thumb in behavioral ecology (Gigerenzer et al. 1999).

2. Heuristics for Probability Judgment

Since the rise of the heuristics-and-biases research program in the 1970s, the heuristics most widely studied within the social sciences are those that people

use to make judgments or estimates of probabilities or other quantities in situations of uncertainty where they do not have complete, exact information (Tversky and Kahneman 1974). The representativeness heuristic is a means to assess the probability that an object A belongs to a particular category B (e.g., that a person described as meek is a pilot) or that an event A is generated by a particular process B (e.g., that the sequence HHTTTT was generated by throwing a fair coin). This heuristic produces probability judgments according to the extent that A is representative of, or similar to, B (e.g., meekness is not representative of pilots, so a meek person is judged as having a low probability of being a pilot). The availability heuristic can be used to produce assessments of class frequency or event probability based on how easily instances of the class or event can be mentally retrieved (e.g., plane crashes may seem like a frequent cause of death because it is easy to recall examples) or constructed (via the simulation heuristic). The anchoring-and-adjustment heuristic produces estimates of quantities by starting with a particular value (the anchor) and moving away from it (e.g., people asked to quickly estimate either $8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1$ or $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8$ give a higher value in the former case, which could come from estimation based on multiplying the first few values together, creating a higher or lower anchor, and then adjusting upwards, which yields a higher overall estimate of the first product).

Most researchers agree that such heuristics are widely used because they usually lead to good choices without much time or mental effort. Despite this, most of the large body of evidence amassed that is consistent with the use of these heuristics comes from showing where they break down and lead to errors (e.g., availability judgments can be manipulated by vivid examples like plane crashes, and anchoring can lead to different choices solely due to the order of information presentation—see *Decision Biases, Cognitive Psychology of*), leading many to conclude that people are poor decision makers after all. These heuristics have also been criticized as being vague redescrptions of observed choice behavior that are therefore difficult to falsify; however, more specific versions (e.g., testing whether availability works in terms of ease of recall or number of items recalled) are also being explored.

3. Heuristics for Choice between Alternatives

Specifying decision tasks in more detail—for instance, choosing between two (or more) alternatives on the basis of cues or pieces of information known about each—allows still more specific heuristics to be investigated. The typical normative approach to such choice decisions involves weighting and combining (typically adding) all of the available cues, with the weights determined by a process such as multiple regression. Heuristics can shortcut this process in two main ways.

First, rather than weighting all cues differentially, positive and negative cues for each alternative can merely be tallied (Dawes 1979). Second, not all cues need be used—instead, a stopping rule can indicate when enough cues have been considered to allow a choice (see below). Despite these simplifications, such heuristics often perform very well when compared to expert human decision makers (Dawes 1979), traditional benchmarks (Payne et al. 1993), or objective measures of correct answers (Gigerenzer et al. 1999).

There are several forms of stopping rules that can be used to limit the information considered by choice heuristics. The recognition heuristic (Gigerenzer et al. 1999) only ever considers the single cue of recognition: when one alternative is recognized and the other is not, this heuristic chooses the former (and otherwise guesses). One-reason decision mechanisms (Gigerenzer and Goldstein 1996) compare both alternatives on a single cue-dimension (or reason) at a time and stop at the first dimension that distinguishes between the alternatives (i.e., where their cue values differ, allowing a decision to be made). Accumulator or horse-race models (Busemeyer and Rapoport 1988) tally the cues in favor of each alternative until a specified difference in positive evidence is reached (e.g., until one alternative is three reasons ahead of the other). Elimination heuristics (Tversky 1972, Gigerenzer et al. 1999) begin with a set of alternatives and successively remove subsets that do not match a specified cue value until a single choice remains (e.g., to choose a restaurant, eliminate all those in town over some price threshold, then eliminate all those beyond some distance away, and so on until one restaurant is left). In every case (aside from the recognition heuristic), a search rule must also be specified to determine the order in which cue dimensions are considered; this order can (among other possibilities) be random, or based on recently used cues, or on cue validity or correlation with the choice criterion (which, when combined with a one-reason stopping rule, yields a lexicographic strategy such as the Take The Best heuristic—Gigerenzer and Goldstein 1996).

4. Heuristics for Sequential Search

When choice alternatives are encountered sequentially over time rather than simultaneously (e.g., in comparison shopping by driving from one store to the next), heuristics can be used to decide when to stop searching and select an available alternative. The traditional normative approach is to search until one finds an alternative below a precalculated reservation price balancing expected benefit of further search against its cost; this requires full knowledge of the search costs and distribution of available alternatives. Heuristics that use a simplified version of the reservation price calculation (e.g., replacing an integral with a weighted sum) come very close to normative

performance (e.g., at selecting good prices, Moon and Martin 1990). Other heuristics require less knowledge, such as ‘Keep searching until the total search cost exceeds 7.5 percent of the best price found’ (Moon and Martin 1990). Herbert Simon’s bounded rationality principle of satisficing (see *Bounded Rationality*) suggests setting an aspiration level equal to an alternative that is good enough (rather than optimal) and searching until that aspiration level is met; exactly how the aspiration level can be set varies with the search setting (e.g., whether it is a one-sided search like shopping, or a two-sided mutual search like finding a mate, Gigerenzer et al. 1999). Finally, another type of search heuristic that people use stops search after a particular pattern of alternatives is encountered, rather than after some threshold is exceeded (despite the fact that pattern should not matter from a normative perspective). For instance, the ‘one-bounce’ and ‘two-bounce’ rules say to keep searching for a low price until prices go up for the last or two last alternatives, respectively (Moon and Martin 1990).

5. Further Directions

Decision heuristics have been studied in different research traditions, in particular one that has focused on when and where verbally described heuristics can break down and yield deviations from classical norms of rationality (Kahneman et al. 1982), and another that has investigated how specific computationally modeled heuristics can exploit structured information to yield fast and accurate decisions (Gigerenzer et al. 1999). Further research should explore not only those aspects of decision environments that lead to different levels of performance, but also what factors lead people to use heuristics at all (e.g., time pressure, Payne et al. 1993), to choose between different possible heuristics (e.g., the influence of domain-specific emotions or social norms), and to learn or develop new heuristics (e.g., through social imitation).

P. M. Todd

Heuristics in Social Cognition

‘Heuristics’ are strategies of simplifying judgments that allow individuals to make decisions under sub-optimal circumstances. The discovery of heuristics has had a profound impact on social psychology (see *Social Psychology*), especially in the field of ‘social cognition,’ which studies the attempts by individuals to make sense of others (see *Mental Representation of Persons, Psychology of*). This article describes the general idea of heuristic information processing, looks at three specific heuristics, and examines the importance of heuristics for social psychology.

1. Judgments under Suboptimal Conditions

Whereas traditional theories of human decision-making (see *Decision Making, Psychology of*) have focused on the normative aspects of valid judgments while neglecting the context in which they occur, the ‘heuristics’ approach has directed its attention to the psychological processes that enable individuals to make judgments and decisions under situational, motivational, and cognitive conditions that are less than optimal. Because decisions typically are made in a state of uncertainty, it has proven fruitful to identify

the strategies that individuals actually use to arrive at solutions that do not represent the best possible outcome but simply meet specific criteria. The study of these simplifying rules of thumb, called ‘judgmental heuristics,’ has been spearheaded chiefly by Tversky and Kahneman (1974). Because the concept of heuristics is associated closely with these authors, the application of this term is often limited to the specific mechanisms they have identified. However, the underlying logic of heuristic processing also applies to other strategies that serve the same purpose, that of simplifying human judgments and making them feasible under suboptimal conditions.

Because generally it is not possible to identify the use of a heuristic procedure from the outcome of a judgment, researchers have had to create specific conditions under which heuristics lead to errors. As a result, heuristics have often been associated with the supposed irrationality of human reasoning (e.g., Nisbett and Ross 1980). However, just as visual illusions do not testify to the deficiency of human perception, the errors produced by judgmental heuristics are not proof of the inadequacy of human judgment in general; instead, they point to mechanisms that allow individuals to make acceptable decisions under natural constraints.

The discussion that follows will introduce the three most prominent heuristics.

2. The Availability Heuristic

In assessing the frequency or probability of an event (or the co-occurrence of several events), individuals often employ a strategy that is based on the ease with which bits of information can be retrieved or generated from memory. An employer wishing to gauge the rate of unemployment in their community may go to the trouble of obtaining the relevant information from official sources. But if they are not motivated or able to do that, they can try to think of unemployed friends or acquaintances. The more easily they are able to do so, the higher will be their estimate of the rate of unemployment. Tversky and Kahneman (1973) called this judgment strategy the ‘availability heuristic.’

Additional judgmental phenomena in the social domain are connected to the availability heuristic. One example is a risk whose assessment depends on the frequency with which a type of event occurs. Thus, riding a motor bicycle is risky to the extent that accidents occur frequently. However, the actual frequency of an event and the ease with which it comes to mind may be dissociated if certain events are more likely to be reported in the media. For example, Lichtenstein et al. (1978) found that causes of death frequently reported in the press were greatly overestimated in terms of their frequency. While heart disease causes 85 percent more deaths than accidents,

only 20 percent of those surveyed thought that heart disease was the greater risk. The conspicuousness of events also influenced their availability. For example, in the study by Lichtenstein et al. (1978), the overestimated causes of death were especially dramatic and sensational (murder, flood, automobile accident), while the rather inconspicuous causes of death (heart disease, cancer, diabetes) were underestimated. Events that are known from personal experience are also more readily available (and therefore judged more likely to occur) than events that are only known through third parties (Greening et al. 1996).

It should be noted that 'availability' has two psychological components that usually are confounded: the content that comes to mind and the ease (or effort) experienced while retrieving the information from memory (Schwarz et al. 1991). Several studies from the domain of health psychology demonstrate the direct influence of experienced ease of retrieval on the assessment of risk. For example, Rothman and Schwarz (1998) found higher ratings of risk for contacting a heart disease when participants were asked to list three (easy to generate) instead of eight (difficult to generate) factors that increased their own risk.

Attitudinal judgments (see *Attitude Formation: Function and Structure*) about everyday topics are also made on the basis of the availability heuristic under certain conditions. Wänke et al. (1996) reported more positive attitudes towards public transportation on the part of subjects if they had been asked previously to generate three instead of seven arguments in favor of public transportation. These experimental examples were constructed such that the retrieval of more information was associated with less experienced ease of recall. The results suggest that under suboptimal conditions, judgment is based on the experience of information retrieval and not on the content of what is retrieved.

Another example refers to the ease with which we are able to imagine a different course of events. Let us look at the following example of counterfactual thinking: 'If I had gotten up five minutes earlier this morning I would not have missed the train, I would not have been late for the exam and would have been able to read the one additional problem I needed to pass the exam.' What is crucial is that the ease with which an event can be undone mentally influences affective reactions to this event. While the person in this example would presumably feel a great deal of anger over being five minutes late, a person who overslept an hour instead of five minutes would be less angry. For a detailed account of recent findings on contrafactual thinking see Roese and Olson (1995).

Apart from these examples of judgments and affective reactions on the basis of the perceived ease of cognitive operations, the 'availability principle' in its general form, that is, the finding that increased accessibility of contents (see *Priming, Cognitive Psy-*

chology of) and cognitive structures influences judgments, has stimulated a host of research in social psychology. This pertains, for example, to work on the categorization of persons, causal attribution (see *Attributional Processes: Psychological*), the constancy of opinions after they have been discredited, or the testing of hypothesis.

3. The Representativeness Heuristic

The representativeness heuristic refers to people's tendency to simplify categorical judgments by relying solely or excessively on similarity. For example, a person who wants to determine the profession of another person may use the target person's similarity to the typical member of this profession. Consequently, a student might decide that a fellow student at the next table in a university cafeteria is a business administration major if they display the characteristics of a typical MBA student, such as reading the business section of the paper and talking about the stock exchange. Although this strategy has a logical basis, it tends to neglect other types of relevant information, such as base rates. For example, this university may have many more students of law than of business administration. Information about such a frequency distribution should affect the judgment in the same way as information about the target person. However, research by Tversky and Kahneman (1982) has demonstrated that such base rates largely are neglected even if the individuating information is not very diagnostic.

This neglect of base rates is strikingly similar to findings from attribution research. A number of studies discovered that when people identify the causes of an observed behavior, they attribute it to characteristics of the person and neglect situational influences. This response tendency implies that judges underestimate 'consensus information' (Kelley 1967) that reflects the power of situations. 'Consensus information' describes how other people behave under the same circumstances and serves as a basic determinant of causal attributions (see *Attributional Processes: Psychological*). Specifically, if everybody shows the same behavior in a given context there is little reason to attribute an action to the unique characteristics of the actor. The tendency to neglect such base-rate information in social judgments and to give it less weight than it should have under normative considerations can be understood as a manifestation of the representativeness heuristic because it consists of drawing inferences on the basis of similarity ('a person who behaves aggressively is aggressive') at the expense of base-rate information (see *Person Perception, Accuracy of*).

The relationship between this attributional bias and heuristic processing was demonstrated subsequently by varying the conduciveness of the judgmental

situation (for a review, see Gilbert and Malone 1995). Researchers demonstrated that the neglect of situational influences depended on judges' cognitive resources, such that this bias was more likely to occur when people were distracted.

The use of the representativeness heuristic may also result in violations of logical principles. In one study by Tversky and Kahneman (1983), judges had to assess the probability of the joint occurrence of two characteristics of a target (a liberated woman). One feature was highly representative ('She is a feminist') while the other was not ('She is a bank teller'). In line with the representativeness heuristic, judges considered it less likely that the target person was a bank teller than that she was a feminist bank teller, which is, of course, logically impossible.

Other effects of the representativeness heuristic concern the misperception of chance and the neglect of sample size (Tversky and Kahneman 1974).

4. Anchoring and Adjustment

'Anchoring and adjustment' describes the phenomenon that judgments are assimilated toward a value that was initially considered. For example, a person who has to estimate the proportion of African nations in the UN may arrive at a higher percentage if they have been exposed previously to a high rather than a low standard of comparison. While such an influence would be hardly surprising if this 'anchor' is offered as a piece of information that is relevant to the judgment in question, Tversky and Kahneman (1974) were able to show that the resulting assimilation effect occurred even if relevance was ruled out by presenting the anchor as the outcome of a probabilistic process.

The psychological process that was suggested by Tversky and Kahneman (1974) for this phenomenon is an insufficient adjustment of the final judgment. Alternatively, Strack and Mussweiler (1997) have proposed a mechanism that is related to the availability heuristic, the so-called selective accessibility model. Here the anchoring effect involves two stages. In the first stage, judges engage in biased hypothesis testing when they consider the anchor as a possible value of the target. In this process, semantic information consistent with the anchor is activated. As a consequence of this selective activation, consistent information will be more accessible in a second stage when information for the final judgment will be retrieved. In this perspective, the anchoring effect is not the result of a numeric influence or a mere effect of insufficient adjustment but caused by a mechanism of semantic priming that has been demonstrated in many studies in social cognition (e.g., Higgins et al. 1977).

These supporting findings are not only important because they reflect the dynamics of many negotiation situations in which an initial offer greatly affects the

final outcome but also because they are helpful in understanding the consequences of merely considering a possibility before forming a judgment. For example, it has been demonstrated that explaining a hypothetical event leads people to expect its actual occurrence (Ross et al. 1977). Similar outcomes were obtained for imagining a particular event (Carroll 1978). More dramatically, it was shown that merely thinking about an attitude object may lead a person to adopt more extreme attitudinal positions if he or she holds a schema about the object (e.g., Tesser et al. 1995). Perhaps the most relevant social domain is that of social comparisons (see *Social Comparison, Psychology of*). Here, work on the anchoring heuristic suggests a mechanism that explains why and under what conditions comparing ourselves to another person will make us appear similar to that person (Mussweiler and Strack 2000). The anchoring effect has also been invoked to explain the so-called hindsight bias (Fischhoff 1982).

5. Other Heuristics in Social Psychology

In the previous sections three basic judgmental strategies were introduced that were identified by Kahneman and Tversky as devices employed to form sufficiently accurate judgments under adverse conditions and with little cognitive effort, although under certain circumstances these strategies can lead to systematic distortions. The idea of heuristic information processing has been expanded subsequently to other heuristic cues, with lasting influence on theory formation in broad areas of social psychology.

A prominent example is the use of feelings as information. Specifically, it has been argued that under suboptimal circumstances, judges resort to their subjective experiences to generate a judgment on a different dimension. This has been demonstrated for both affective (e.g., Schwarz and Clore 1983) (see *Emotions, Psychological Structure of*) and nonaffective feelings, such as familiarity and mental effort (e.g., Strack and Neumann 2000). As discussed before, it has been shown that the availability heuristic operates through the use of the mental effort experienced by an individual engaged in a specific mental operation (Schwarz et al. 1991).

The idea of heuristics has become effective in a second line of research in social psychology. The study of persuasive communication (see *Communication and Social Psychology*), in particular, has profited from the distinction between heuristic and systematic processing (Chaiken 1987). In this domain, the reliance on peripheral cues (such as the expertise of the communicator or the length of the message) instead of on central features (i.e., the strength of the arguments) was shown to occur under suboptimal conditions. Similarly, it has been shown that the use of stereotypes

(see *Stereotypes, Social Psychology of*) obeyed the same regularities, such that people were more likely to use them when they were unwilling or unable to process individuating information (Bodenhausen and Lichtenstein 1987).

A final application and extension of the heuristics idea can be found in the domain of social influence (see *Social Influence, Psychology of*). As Cialdini (1993) has argued, people's proclivity to simplify their judgments can be exploited by agents of social influence. For example, an advertising agency may deliberately attempt to increase the ease with which certain information (presumably about their own product) may be brought to mind or try to associate positive feelings with the product. Cialdini has identified and described many more such strategies, which he called the most effective 'weapons of influence.'

6. Conclusion and Future Directions

Over the years, the concept of heuristics has generated many insights into the cognitive dynamics of social behavior. At the same time, however, the idea of heuristic processing has gone far beyond the three mechanisms described by Kahneman and Tversky and it has been claimed that the use of heuristics may possess biologically adaptive value (Gigerenzer and Todd 1999). In a more general perspective, a universal psychological principle has emerged that sheds light on the flexibility of human information processing under divergent epistemic goals. However, the work of finding the laws of this flexibility and integrating it into psychological theorizing still needs to be done.

Hidden Curriculum in the Classroom

Long after I've forgotten to use the power rule to derive an equation, or that the animals are classified by kingdom, phylum, class, order, family genus and species ... I will remember the other lessons I've learned, the lessons that taught me how to live (Jenny Lobasz, senior student at Dreyfoos School of the Arts).

The hidden curriculum generally refers to student learning that takes place in school as a result of actions by school personnel, parents, students, and other community agents. What is learned in the classroom is largely a function of the prevailing school conditions and classroom dynamics as well as such demographic factors as the social class, race, ethnicity, language, gender, and condition of disability of all school participants. Compared with the formal school curriculum, the hidden curriculum is not written, does not have explicit objectives, and varies considerably from one school setting to another. The hidden curriculum often referred to as the 'covert' or the 'informal' curriculum, is a most powerful influence in the classroom; it is estimated that up to 90 percent of what is learned is due to this influence (Massialas 1996).

1. The School and Classroom Dynamics

In many cases the formal curriculum is antithetical to the hidden curriculum. For example, the formal curriculum of the school explicitly promotes such values as academic learning, fairness, and good citizenship; the latter expressed as democratic participation in decisions affecting the individual. The hidden curriculum, on the other hand, teaches the students how to manipulate the system, i.e., how to cheat without being caught, how to 'apple polish the teacher,' and how to comply with the rules without questioning the legitimacy of the authorities for making them (Jackson 1983). The formal curriculum preaches democracy but the hidden curriculum imposes autocracy. The formal curriculum emphasizes scholarship and an equitable grading system but the hidden curriculum teaches students that scholastic attainment expressed through grades is a political process of give and take and of bargaining with the teacher. In this environment it is clear that if students do not master the lessons and the techniques of the hidden curriculum they are destined to fail.

Jackson (1983), being one in the first groups of researchers who studied the hidden curriculum in depth concluded that 'Learning how to make it in

school involves, in part, learning how to falsify our behavior' (p. 50). He found out that teacher–student relations in the classroom are hierarchical—the teacher being at the top of the hierarchy and the students at the bottom. He observed that classroom activity in elementary schools usually centers on seatwork, group discussion, teacher question and answer sessions, as well as teacher demonstrations. Students may learn about the three Rs but they also learn other things, things that are not spelled out in formal instruction. For example, they learn to work in crowds and they learn to accept praise or reproof. They also learn how power is distributed in the system, that is, how certain students gain special privileges. Students also learn how to be patient and how to conform to institutional requirements and to tolerate minor frustrations.

Many studies confirm the claim that schools indirectly teach students to be obedient, passive, and compliant. In this they are supported by other social institutions that directly relate to the life of the students, e.g., the family. One author recognizes that, on the one hand, modern society seeks to develop self-reliant and critical thinking individuals. On the other, it promotes, through the schools and other socialization agencies, obedience. 'Little notice is taken of the legions of overly obedient children in the schools; yet, for every overly disobedient child, there are probably twenty who are obeying too much. There is little motivation to encourage the wheels to develop as noisy, creative, independent thinkers who may become bold enough to disagree' (McCarthy 1998, pp. 56–7).

A review of research on the influence of the hidden curriculum in schools in the Arab world revealed that these schools, much like their Western counterparts, impart passivity and obedience among the students (Massialas and Jarrar 1991). For example, in a study conducted in Morocco it was found that the 'primary school imparts the values and behaviors of the society, especially the home—absolute dependence on patriarchal commands, suppression of creative thought, strict compliance with rules, both written and unwritten, acceptance of things as they are' (Massialas and Jarrar 1991, p. 137). Similar values to those transmitted in the Moroccan schools were reported in studies in other Arab schools, e.g., in Saudi Arabia, in Lebanon, in Qatar. On the basis of these studies it is apparent that the Arab classroom replicates to the extent possible the patriarchal family structure. The teacher is invariably the dominant figure, the patriarch who conveys awe, respect, and obedience.

2. Social Class and the Hidden Curriculum

Student background factors such membership in a social class invariably affect how students are treated in school and their relations with the teachers and other school personnel. A study conducted in New Jersey, USA, found that social class clearly influenced

the values learned in school through the hidden curriculum (Anyon 1983). The study identified four types of schools—working class, middle class, affluent professional, and executive elite. Working class schools emphasized mechanistic, step-by-step instruction conducive to memory type of work. Class work was quite structured. There was very little in trying to provide an explanation of the world. The middle class schools emphasized the ‘right answer’; instruction was largely teacher-directed; the majority of the lessons were drawn from the textbook. In the professional-affluent schools the emphasis was on fostering creativity and independent thought in the classroom. Students were constantly asked through projects to apply concepts in explaining their world. The executive elite school emphasized critical thinking, conceptual development, and decision making. Instruction stressed analysis of social issues and problem solving. The study concluded with the observation that the working-class schools prepared students to assume positions as laborers, whereas the professional and executive schools prepared students to be intellectuals and professionals. Thus the school, in a major way, reproduced the larger system of unequal social relations. One of the few advantages that students in the working-class schools could have was learning the ‘methods of resistance.’ ‘These methods are highly similar to the “slowdown,” subtle sabotage, and other modes of indirect resistance carried out by adult workers in the shop ...’ (Anyon 1983, p. 163).

Several other research studies on the influence of social class in learning confirm Anyon’s conclusions above. Although some studies recognize that there are variations in community and school expectations of what students should learn, there is evidence that working-class communities placed their priority ‘on acquiring credentials and following rules, whereas the higher-SES communities ... placed emphasis on students’ gaining particular kinds of knowledge and skills’ (Knapp and Woolverton 1995, p. 553). The research clearly indicates that in the working-class school students are taught through the hidden curriculum ‘that little is expected of them ... they are not highly valued; they cannot be trusted to guide their own learning or conduct themselves responsibly in the class, and they must accept low-level positions in a rigidly controlled hierarchy’ (Knapp and Woolverton 1995, p. 553). The higher-status school, on the other hand, encourages students to develop a greater sense of self-worth, higher expectations for school success, and a wider range of possibilities for fitting into hierarchies of control at different levels’ (Knapp and Woolverton 1995, p. 563).

3. Cultural Minorities and the Hidden Curriculum

Students who are members of ethnic, racial, or linguistic minorities are usually adversely affected by the hidden curriculum of the schools. The grading

system, the standardized tests, the reward and punishment measures, the textbooks, the school rules, all influenced by the hidden curriculum, normally have a negative effect on minorities. Available research clearly indicates that these and other educational instruments discriminate against minorities. For example, about 45 percent of Hispanics in the United States are expected to drop out from high school (Sleeter E et al. 1998). ‘In-school factors such as poor academic performance and disliking school account for 56 percent of dropouts among Black, male students’ (Massialas 1996, p. 69). School suspensions and expulsions, strong instruments of the hidden curriculum, also impact adversely racial, ethnic, and linguistic minorities. There is usually a disproportionate number of students from minority groups being punished through these measures. Language minority students are also adversely affected by the hidden curriculum in the classroom. For instance, one study on the topic indicated that in a classroom which had a mixture of mainstream and limited English proficient students, ‘the teachers interacted less frequently with the ESL students than their native-English counterparts ... the interactions with ESL students tended to be managerial in nature rather than instructional’ (McKeon 1994, pp. 25–6). Also reported in the literature is the negative result that ensues from the disability of teachers to understand the flow of discourse between them and students who have different patterns of linguistic interactions. ‘... when the patterns of language use or the patterns of social interactions that children bring to the school are ignored or denigrated by their teachers, the ensuing relationship may threaten the students’ academic development’ (Pease-Alvarez and Vasquez 1994, p. 93).

4. Gender and the Hidden Curriculum

The hidden curriculum has a very strong influence in school learning when mediated through gender. Gender-appropriate roles are conveyed through the formal curriculum as well as the hidden. Upon reviewing the works on the subject, Banks (1995, p. 622) stated, ‘Research indicates that sex-role attitudes and gender associations develop early, and that teaching materials, the mass media, and society at large often reinforce sex-role stereotyping’

5. Condition of Disability and the Hidden Curriculum

Students with learning disabilities, e.g., students with visual or hearing impairment, emotional disturbance are also affected by the hidden curriculum. Whether placed in classes with mainstream students (inclusion classes) or in special education classes there is always a built-in bias in their relations with teachers, other

students and in the school-related expectations which influence in a significant way what is to be learned, how, and for what purposes. There is an overrepresentation of cultural minorities in the special education programs that clearly point to the influence of the hidden curriculum in student selection and placement.

6. Conclusion and Outlook

Recently there have been many attempts to attend to the negative influences on learning of the hidden curriculum. Programs for teachers seek to make them aware of these often-negative influences and to take appropriate measures to alleviate them from the school settings. Instructional approaches such as 'cooperative learning,' 'peer tutoring,' and portfolio assessment are all attempts to combat the negative effects of the hidden curriculum on student learning.

Hierarchical Models: Random and Fixed Effects

1. The Basic Statistical Model and its Probability Interpretation

The model that has dominated statistical practice recently supposes that data x have, for each value ψ of a parameter, a known probability distribution dependent on the unknown ψ . The distribution may be described by the probability density

$$p(x|\psi) \quad (1)$$

where p is a generic symbol for a density of the quantity, here x , before the bar; the symbol after the bar describing the conditions applying to the distribution, here the supposed value ψ of the parameter. Statistical inference then consists in making some statement about the parameter on the basis of the data; such as a point estimate for ψ , or a test that ψ assumes specified values. An important, special case has x a vector $(x_1, x_2, \dots, x_n)$, of n components, and ψ chosen such that, given ψ , the components are independent and identically distributed (i.i.d), when Eqn. (1) assumes the special form

$$\prod_{i=1}^{i=n} p(x_i|\psi) \quad (2)$$

The Bayesian approach would include, in addition to the density (1), a probability distribution for ψ expressed through a density $p(\psi)$. Statistical inference then consists of calculating $p(\psi|x)$ by Bayes's theorem, inverting the roles of x and ψ in (1).

A distinction is often made between the nature of the probabilities involved in Eqn.(1), and more particularly Eqn. (2), and those in $p(\psi)$. In view of the repetitions under similar circumstances of $x_1, x_2, \dots, x_n$, their probability is associated with frequency and the x_i thought of as successive realizations of a single random variable. Alternatively, $(x_1, x_2, \dots, x_n)$ is viewed as a random sample from a population. In contrast, ψ is a fixed, but unknown, quantity and, when introduced, $p(\psi)$ expresses beliefs about the values it might assume, without reference to frequency or populations. The disparity between random, for x , and fixed, for ψ , has played an

important role in the development of hierarchical models, leading to different inferences depending on whether the effect is supposed fixed or random. In the Bayesian approach there is no distinction and all probabilities express beliefs; the special case Eqn. (2) reflecting the belief in exchangeability among the observations x_i .

2. The Hierarchical Model

To illustrate the need for a hierarchical model, consider data consisting of repeated observations divided into groups. Let x_{ij} denote the j th observation in group i ($i = 1, 2, \dots, m; j = 1, 2, \dots, n$), with n observations in each of m groups, and suppose that within each group the values are conditionally i.i.d with distributions that may vary from group to group. A popular, special case has

$$x_{ij} \sim N(\theta_i, \sigma^2) \quad (3)$$

with the x_{ij} being independent given $\psi = (\theta_1, \theta_2, \dots, \theta_n, \sigma^2)$, so that they are normally distributed with common variance σ^2 but with means that depend on the group. This model is the basis for one-way analysis of variance where inference may well concentrate on whether the means are truly different and, if they are, of what these differences consist. As it stands, this model is just a special case of Eqn. (1) with x the set of x_{ij} and ψ as above; but now contrast two cases that differ in respect of the nature of the groups. In the first, the study is one investigating the potency of a drug and the groups correspond to dilution levels. In the second, the milk yields of cows are measured and the groups correspond to different sires. In both cases, it may be reasonable to think of the duplicate measurements within a group as i.i.d, forming a random sample from a possible population, in agreement with Eqn. (3). But there are differences between the nature of the groups; for in the dilution experiment, the levels are fixed, whereas, with the sires, those selected may be thought of as a sample from a population of sires. In the language of the last paragraph, the θ_i are fixed in the dilution experiment, but random with the cows. In the latter, it might therefore be reasonable to suppose that the means are capable of a frequency description and a probability distribution. A possible, simple case is to suppose that, in addition to Eqn. (3),

$$\theta_i \sim N(\mu, \tau^2) \quad (4)$$

with the θ_i being independent given μ and τ^2 . The frequency interpretation is inappropriate in the dilution experiment, where the levels have been organ-

ized, for example at levels $1, \frac{1}{2}, \frac{1}{4}$ etc. It is also possible that inferences in the two experiments could be directed to different ends. Thus the variability among sires expressed through τ^2 is meaningful, but not in the dilution experiment. There are many other possibilities besides Eqn. (4) for the second-stage distribution. For example, one group may be a control and the remainder correspond to new treatments. In this case, the distribution for the control mean may differ from that for the others. Outside the Bayesian view, only the latter may have a frequency interpretation. It is this flexibility that helps make hierarchical modeling so attractive.

The probability judgements in Eqns. (3) and (4) together form a hierarchical model with two stages to the hierarchy, the first expressing the dependence of the data on the group means in Eqn. (3), the second describing the variability of those means in Eqn. (4). The hierarchical model has been thought by some to be appropriate in studies of milk yield, but not in dilution studies, because the means are random in the former but fixed in the latter. The general form of a two-stage, hierarchical model has data x dependent on parameters (θ_1, ϕ_1) expressed through

$$p(x|\theta_1, \phi_1) \quad (5)$$

at the first stage, with θ_1 having a distribution

$$p(\theta_1|\theta_2, \phi_2) \quad (6)$$

at the second stage. The parameters of the second stage, θ_2, ϕ_2 are often called hyperparameters. Notice that in this formulation some of the parameters at the first stage are fixed, ϕ_1 , whilst others, θ_1 , are random and have their probability structure expressed in the second stage in terms of the fixed hyperparameters. In the normal example, Eqns. (3) and (4), θ_1 here corresponds to the group means there, and ϕ_1 to the common variance. The hyperparameters are $\theta_2 = \mu, \phi_2 = \tau^2$, the values σ^2 and τ^2 describing the within- and between-groups variances. There may not be any fixed parameters at the first stage, as when the within-variances are supposed different, at σ_i^2 , and given a distribution at the second stage, as with the means. It is possible to extend the number of stages in a hierarchical model, for example by adding a third stage to Eqns. (5) and (6) by supposing θ_2 depends on (θ_3, ϕ_3) expressed through

$$p(\theta_2|\theta_3, \phi_3) \quad (7)$$

Such an extension would be appropriate for a two-way analysis of variance; the first stage describing the variation within cells of the two-way layout, the second concerning the row and column means (the main

effects), the third involving the interactions between the main effects. Any Bayesian model is, in a sense, hierarchical, the two stages being $p(x|\psi)$ and $p(\psi)$ respectively, but the terminology is usually confined to the models just described. A further extension is to include regression effects. For example, Eqn. (5) may be extended to

$$p(x|z, \theta_1, \phi_1)$$

where z is an observed regressor variable. Similar regression effects may be introduced at other stages in the hierarchy.

Returning to the two-stage model in Eqns. (5) and (6), notice that x and θ_1 are random, whereas ϕ_1, θ_2 and ϕ_2 are fixed, and the stages describe the joint distribution of the random quantities, given the fixed ones, θ_2 and ϕ_2 having no effect on x except through θ_1 . This lack of effect can be expressed in the form of a directed graph, or influence diagram, which clarifies the hierarchical form. The two-stage model is represented in the figure, the lack of links from x to θ_2 and ϕ_2 expressing the feature. The extension to more stages is easily apparent.

As with the basic model in Eqn. (1), the Bayesian approach would add a probability distribution $p(\phi_1, \theta_2, \phi_2)$ for the fixed parameters and hyperparameters. A joint distribution for all the quantities, random and fixed, is not thereby specified unless the additional assumption is made that, given (θ_1, ϕ_1) , x is independent of (θ_2, ϕ_2) . This assumption is usually made, often tacitly. The independence assumption is also reflected in the directed graph by the lack of links already mentioned. There may be additional links unless the quantities $(\theta_1, \theta_2, \phi_2)$ are independent. Since the probability structure is complete, it follows that every quantity has its probability structure defined, under any conditions expressed in terms of the quantities of the problem, which probability can be found following the usual rules of the probability calculus. In particular, the posterior distribution of any of the parameters or hyperparameters, given the data, may be determined.

3. Inference in Hierarchical Models

We now return to the simple case where the observations are divided into m groups, each of size n , and possess the normal, independent distributions des-

cribed by Eqn. (3). Suppose that the common variance within groups, σ^2 , is known. The extension to unknown variance presents complications that do not affect the general thrust of what follows. If the means $\{\theta_i\}$ are fixed, then (3) completes the specification of the model and inference about them is ordinarily performed either by least-squares, or by maximum likelihood, the two methods here being equivalent, with the result that θ_i is estimated by the group mean

$$x_{i.} = \sum_{j=1}^n x_{ij} / n \quad (8)$$

with variance σ^2/n . Suppose, in contrast, the means are random and this randomness is expressed by the second-stage assumption (4), where again τ^2 , the between-group variance, is supposed known. Applying either of the inferential methods here gives another estimate for θ_i , namely

$$\left(\frac{nx_{i.} + x_{..}}{\sigma^2 + \tau^2} \right) / \left(\frac{n}{\sigma^2} + \frac{1}{\tau^2} \right) \quad (9)$$

with variance $(n/\sigma^2 + 1/\tau^2)^{-1}$, in the form of a weighted average of the group mean $x_{i.}$, which was the estimate in the fixed case, and the overall mean $x_{..} = \sum x_{ij}/m$, the weights being inversely proportional to the variances, σ^2/n and τ^2 respectively. It is often said that the effect of randomness in the group means is to shrink the fixed estimates towards the overall mean. An important feature of the shrinkage is that the apparently best (worst) groups with highest (lowest) values of $x_{i.}$ will have their estimates decreased (increased) and, as a result, the group differences will be diminished. Notice that if τ^2 is large, the shrunk means approach the usual ones. The shrinkage feature is important in comparisons of the θ_i , for example in the construction of league tables (Goldstein and Spiegelhalter 1996), or in census returns for different communities (Ericksen et al. 1989).

In the Bayesian paradigm all the unknown quantities will have a probability distribution, in particular $(\theta_1, \theta_2, \dots, \theta_n, \sigma^2)$ in the normal, one-way case in Eqn. (3), irrespective of whether the means are fixed or random. One possibility is for the θ_i to be provided with the second-stage distribution (4) and finally (μ, σ^2, τ^2) given a distribution. If, as above, the variances are known, only the distribution of μ needs additionally to be specified. If it too is supposed normal and the variance taken to be large in comparison with σ^2 and τ^2 , Eqn. (9) is the mean of θ_i , given the data (and σ^2, τ^2). Thus the Bayesian approach favors the shrunk estimate whenever the second-stage distribution is thought to be of the form in Eqn. (4), which might be appropriate for sires but not with the dilution experiment. For a Bayesian, there is no real distinction between the fixed and random effects; what differences

there are depends on the specific form of the second-stage distribution, and perhaps on the quantities of interest. For example, interest may centre on τ^2 , the variance between means, rather than on the individual values θ_i . The situation is in marked contrast to other views where, as we have seen, the estimates of the means depend on whether or not the means are fixed or random; also the sample variance-components in the analysis of variance have different interpretations, in the fixed case being a measure of the differences between the specific means, in the random case referring to the population variance τ^2 .

Returning to the general, statistical model in Eqn. (1) with data x and parameters ψ , it is often hard, especially when the data are numerous, to specify the required density $p(x|\psi)$. In general, whenever there are a number of quantities $u_1, u_2, \dots, u_s$, it is difficult to describe a joint density $p(u_1, u_2, \dots, u_s)$; an easier course often being to think about the quantities in some order and structure a series of conditional distributions $p(u_1)$, $p(u_2|u_1)$, $p(u_3|u_1, u_2)$ etc. This is essentially a hierarchical model except that, as explained earlier, it is usual to have the distribution of one quantity dependent only on the immediately previous one and not on all the previous ones; $p(u_3|u_2)$ without reference to u_1 . In general, the order in which the quantities are introduced may be arbitrary, but in the hierarchical case this does not arise since the order is naturally dictated by the situation. For these reasons, hierarchical models have proved very popular in the description of complicated cases, enabling them to be broken down into stages, each of which is simple, and yet where they combine together to form a whole that reasonably describes complicated reality.

4. Types of Hierarchical Models

There are few hierarchical models in which it is possible to obtain explicit, analytical results for the inference desired. An exception is the normal, linear model of which Eqns. (3) and (4) provide a special case. Generally, at the first stage

$$x \sim N(A_1\theta_1, C_1) \quad (10)$$

where x ($n \times 1$) and θ_1 ($s \times 1$) are vectors, and A_1 ($n \times s$) and C_1 ($n \times n$) are matrices. A_1 is known, θ_1 is unknown. Usually C_1 is known, the simplest case, or known up to an unknown multiplier, though it is possible to describe the distribution of its elements in a second stage. Equation (10) expresses the usual linear dependence of x_1 on θ_1 and is basic to least squares, where θ_1 is estimated by $(A_1^T C_1^{-1} A_1)^{-1} A_1^T C_1^{-1} x$. The second stage imposes a similar structure on θ_1 ,

$$\theta_1 \sim N(A_2\theta_2, C_2)$$

with obvious extensions to further stages as required. Explicit results are provided by Lindley and Smith (1972) using Bayesian ideas, though many of the results can be interpreted sensibly without invoking a distribution on the final hyperparameters, as was seen in the special case.

Similar ideas had previously been used, starting in the 1960s, by Henderson in genetics and specifically in animal breeding; see Henderson (1984). These were outside the usual statistical paradigms and remained unappreciated in broader contexts. An admirable statistical survey of Henderson's and related work is provided by Robinson (1991).

Another field in which explicit results have been obtained, though usually of an asymptotic form, is that of Empirical Bayes. This is not always considered a hierarchical model but does fit into the general framework above. We illustrate with a simple case again involving several groups and data $\{x_{ij}\}$ but this time with independent, Poisson distributions of means μ_i , the same for all observations in group i . This describes the first stage of the hierarchy. At the second stage, the μ_i are supposed i.i.d with some unknown density $p(\mu)$. The model might be suitable when the groups refer to runs in an industrial process. A distinction from the model above is that hyperparameters are avoided and a nonparametric approach adopted at the second stage; no restrictions, other than of a mild nature like continuity, being placed on $p(\mu)$. The observed distribution of the group means $\bar{x}_i$ provides information about $p(\mu)$. Despite the nomenclature, the analysis is ordinarily not Bayesian. A good account is provided by Maritz and Lwin (1989). The term has also been used in connection with the equation-based approach mentioned later in Sect. 5.

Hierarchical models have also been successfully applied to stochastic processes. These may be spatial but here an exposition in the more usual temporal terms will be used. It is often reasonable to suppose that there is an underlying development process taking place over time, but that one's observation of it is disturbed by error, these two features providing the two stages of the hierarchy. A simple example is to suppose an observation x_t at time t depends on the state θ_t of the process then, with a superimposed error ε_t ,

$$x_t = \theta_t + \varepsilon_t, \quad \varepsilon_t \sim N(0, v_t), \quad (11)$$

whereas the process is linear, autoregressive with

$$\theta_t = a_{t-1}\theta_{t-1} + \eta_t, \quad \eta_t \sim N(0, w_t), \quad (12)$$

$t = 1, 2, \dots$. Equation (11) is termed the observational equation, (12) the system equation; the two sets of error terms being supposed individually independent and independent of each other. The approach is

usually Bayesian with $\{v_i\}$, $\{w_i\}$ and $\{a_{i-1}\}$ supposed known, at least in the simpler cases, and an initial distribution supposed for θ_0 . If this last is normal, it is straightforward to update by Bayes to obtain successively the distributions of θ_i given $x^{(i)} = (x_1, x_2, \dots, x_i)$, the observations up to time i . Often the primary purpose of the study is to forecast the future state of the process, θ_{t+1} , given the current data $x^{(t)}$,

$$p(\theta_{t+1}|x^{(t)}) = \int p(\theta_{t+1}|\theta_t)p(\theta_t|x^{(t)})d\theta_t$$

involving the system equation and the posterior distribution of θ_t . A full account is provided by West and Harrison (1989).

As previously mentioned, hierarchical models are especially useful in describing complicated, but realistic, situations, where the individual stages in the hierarchy are relatively easy to assess. Nevertheless, apart from the cases outlined here, analytical results are difficult to obtain because the integrals that arise in the probability calculations are not expressible in standard forms, so that resort has to be made to numerical methods. In one sense this is no hardship, since the data are already numeric and in any application one only requires answers for that specific data set. On the other hand, the integrals are typically in high dimensions where numerical results are hard to come by. An important, recent advance has been to use Markov-chain, Monte Carlo (MCMC) methods which themselves depend, like the hierarchical models, on conditional distributions. There has therefore been a recent explosion of papers using MCMC to handle these models. A summary is given by Brooks (1998).

5. Equation-based Approaches

Hierarchical models are often described in an alternative terminology as multilevel, our stages being replaced by levels. An example is provided by students, at the first level, being in classes at the second, which form schools at the third. It is also common to alter the emphasis and not talk in terms of probability, as here, but in terms of equations which incorporate a probabilistic element, so that Eqn. (3) would be written

$$x_{ij} = \theta_i + \varepsilon_{ij} \quad (13)$$

with ε_{ij} being an error term, of zero mean. Complete adherence to Eqn. (3) would in addition require the error terms to be independent, normal and of constant variance. It is usual to employ matrix notation, as in Eqn. (10), and a popular model is

$$y = X\beta + Zu + \varepsilon \quad (14)$$

Here y , replacing x , is the observed data, dependent on observed covariates X and Z ; whilst β is a set of unknown, fixed parameters, u a set of random quantities and ε the error term. Thus ε is at the first level and u at the second level. A further complication, that X is only observed with error, is sometimes included, so that

$$X = x + \eta$$

in terms of the unknown, true value x and error η at another level. This generalizes the problem of regression with both quantities subject to error. We shall refer to this whole approach as equation based, rather than probability oriented, though it is possible to pass from one to the other, as between Eqns. (3) and (13). These ideas have been used in longitudinal studies where several observations are made on an individual over time, forming one level of variation, another level being that between individuals.

The distinction between the approaches is not confined to the model description but includes the analysis, where manipulations of equations replace the probability calculus. Thus Eqns. (14) leads to estimates $\hat{\beta}$, $\hat{u}$, $\hat{\beta}$, u given by

$$X^T X \hat{\beta} + X^T Z \hat{u} = X^T y$$

and

$$Z^T X \hat{\beta} + (Z^T Z + I) \hat{u} = Z^T y$$

under simple assumptions about u and ε . Some of the methods that are used do not employ the full probability structure but only refer to the first and second moments, a popular variant of least squares being quasi-likelihood. Other methods are based more closely on likelihood and variants thereof and often embrace ideas associated with the general, linear model. Lee and Nelder (1996) provide a good account with a lively discussion in which R. L. Smith suggests disagreement between their results and those produced by the fully Bayesian approach. This is not surprising since, as has been shown in Sect. 3, Bayesian procedures employ more shrinkage than some other methods.

An issue of the *Journal of the Royal Statistical Society A* (162, 1999, 269–448) is devoted to articles on ‘Applications of random effects/multilevel models to categorical data in social science and medicine’ and provides many examples of the ideas here briefly described. The book by Goldstein (1995) is relevant; he and his colleagues have provided a computer package (1998) to handle many models. Similar ideas have been put forward by Bryk and Raudenbush (1992). Best et al. (1996) present a Bayesian approach,

whilst Spiegelhalter et al. (1998) supply some computer facilities.

D. V. Lindley

Hierarchies and Markets

Whether the first market entailed the exchange of nuts for berries on the edge of the forest or the first hierarchy involved leadership for the hunt of a wild boar, it is clear that markets and hierarchies go back to antiquity. It is also clear that organizational innovations in both markets and hierarchies have contributed significantly to economic progress.

As between the two, markets have the better reputation among economists. That goes back to Adam Smith (1922) and continues today. Thus, whereas Smith celebrated autonomy, specialization,

and the marvels of the market, he had grave concerns over the separation of ownership and control in large joint stock companies and the excesses of managerial discretion that accrued thereto. Indeed, but for grudging acceptance of economies of scale due to technology, hierarchy has been under a cloud since. Only recently has a symmetrical approach to organizations of all kinds—markets, hierarchies, bureaus—begun to emerge.

1. Foundations

The neoclassical theory of the firm that had taken shape by the 1930s described the firm in technological terms—as a production function—to which a profit maximization purpose was ascribed. The adverse consequences of monopoly, monopsony, and monopolistic competition were all readily displayed with this abstract apparatus, but issues of organization—hierarchy—were scanted by this black box construction.

That, however, began to change with the appearance of radical new ideas about organization by economists (Coase 1937, Commons 1932), lawyers (Llewellyn 1931), and organization theorists (Barnard 1938). Coase advanced the proposition that firms were not pre-existing technological entities but that firms and markets were alternative modes of organization. Whether the firm should make-or-buy was, thus, not technologically determined (although the condition of technological separability between stages was relevant) but needed to be derived. Coase further averred that the choice between market and hierarchy was decided principally by transaction cost differences. The canonical problem, then and since, for the theory of markets and hierarchies, was that of vertical integration.

In principle, this choice was easy: holding technology constant, the firm should produce to its own needs when the transaction costs in the firm were less than in the market, and it should buy in the market when this difference was reversed. Awaiting, however, a predictive theory of when transaction costs went one way rather than another, that remained a tautological construction. Thus, although after-the-fact choices could always be rationalized in transaction cost terms, that was undisciplined and such ad hoc explanations were understandably met with grave skepticism. The twin ideas of treating firms and markets as alternatives and of appealing to transaction costs to explain the allocation of activity between them nevertheless turned out to be very fruitful.

Coase went on, moreover, to pose two deep puzzles. If the market is a marvel, why do we see so much activity organized in firms? And if the firm enjoys management advantages over markets, why is not everything organized in one large firm? Any would-be

theory of firms and markets needed to come to terms with both of these issues.

Commons' approach to economic organization was different than but also complementary to that of Coase. Commons was intensely aware of the tensions that beset organization and averred that 'The ultimate unit of activity...must contain in itself the three principles of conflict, mutuality, and order. This unit is a transaction' (1932). Not only does the triple to which Commons referred—conflict, mutuality, order—prefigure the idea of governance, in that governance is a means by which to achieve order, thereby to mitigate conflict and realize mutual gains, but viewing the transaction as the unit of analysis turns out to be very instructive.

Llewellyn took exception with the legalistic way in which both lawyers and economists viewed contract. Rather than interpret contract in the prevailing legal rules tradition, Llewellyn advanced the more elastic concept of contract as framework—according to which a contract between two parties 'almost never accurately indicates real working relations, but...affords a rough indication around which such relations vary, an occasional guide in cases of doubt, and a norm of ultimate appeal when the relations cease in fact to work' (1931). Llewellyn's ideas prefigure the concepts of incomplete contracting (as against the complete contracting tradition in both law and economics) and of private ordering (as against court ordering).

Barnard brought his experience as a businessman and his instincts as a social scientist to the study of complex organization. Interestingly, both the economist Hayek and the organization theorist Barnard were in agreement that adaptation was the central problem of economic organization. But whereas the adaptations to which Hayek (1945) referred were autonomous adaptations in the market, the adaptations to which Barnard referred entailed 'the kind of cooperation among men that is conscious, deliberate, purposeful' (1938). These two work out of different mechanisms. Autonomous adaptations of a spontaneous kind are made in response to changes in relative prices signaled by the market; co-operative adaptations of an intentional kind are implemented through administrative processes within firms. Adaptations of both kinds being crucial to a high performance economy, there is a need to treat hierarchies and markets in a combined way.

This collection of deep insights—from economics, law, and organization theory—provided an interdisciplinary foundation for a science of organization. Aside, however, from work at Carnegie (by Simon (1947, 1957) and by Cyert and March (1963)), much of which was inspired by Barnard, such a program was slow to take shape. Instead, many of the prescient insights from the 1930s remained fallow for the better part of the next 35 years. The pressing but unmet needs were (a) to combine and (b) to operationalize these

profound insights. Law, economics, and organization theory needed to inform one another, thereafter to be joined in a predictive theory of economic organization.

2. Operationalization

Work of a combined kind got under way in the 1970s (Williamson 1971, 1975, 1979; Alchian and Demsetz 1972; Jensen and Meckling 1976; Klein et al. 1978) and has grown exponentially since. Six key moves in the progressive operationalization of the markets and hierarchies research program are sketched here.

2.1 Human Actors

According to Simon (1985), 'Nothing is more fundamental in setting our research agenda and informing our research methods than our view of the nature of the human beings whose behavior we are studying.' Both the cognitive and self-interestedness features of human actors are crucial to the economics of organization. Bounded rationality, according to which behavior is intendedly rational but only limitedly so, gradually has supplanted hyper-rationality as the basic cognitive condition. Opportunism, whereby economic actors are sometimes given to strategic behavior, has come into common use to describe self-interestedness. Bounds on rationality notwithstanding, economic actors are also presumed to possess foresight, which is crucial to the Commons triple. Taken together, these three attributes lead to the following: (a) all complex contracts are unavoidably incomplete (bounded rationality), (b) contract as mere promise unsupported by credible commitments poses hazards (opportunism), and (c) parties who are alert to prospective hazards will work out the ramifications and factor these into the organizational design (foresight).

2.2 Transactions

If the transaction is the basic unit of analysis, then the key dimensions with respect to which transactions differ need to be named and the ramifications worked out. Among the main attributes of transactions are: (a) the frequency with which transactions recur, (b) the uncertainty (disturbances to which transactions are subject), and (c) the condition of asset specificity. This last attribute has reference to the degree to which the assets that are used in support of a transaction can be redeployed to alternative uses and users without loss of productive value. Asset specificity takes several forms, of which physical asset specificity (specialized dies), human asset specificity (firm-specific learning), site specificity (locational), dedicated assets, brand name capital, and temporal specificity are leading types. A condition of bilateral dependency develops

when significant investments in transaction-specific assets are made. Intertemporal governance complications arise as a consequence.

2.3 Organization

Alternative modes of organization are described not in marginal but in discrete structural terms, which is to say that each mode of organization—market, hybrid, firm, bureau—is described as a syndrome of internally consistent attributes. Key dimensions for describing alternative modes of governance include (a) incentive intensity, (b) administrative controls, and (c) the contract law regime (Williamson 1991). (The market mode—with strong incentives, limited controls, and legalistic dispute settlement—favors autonomous adaptation; the firm mode—with weak incentives, extensive controls, and internal dispute resolution—favors co-operative adaptation.) The upshot is that alternative modes have distinctive strengths and weaknesses. They differ from one another in kind rather than in degree.

Whereas standard economic theory describes the firm as ‘a point or at any rate a black box,’ the economics of organization maintains that ‘firms are palpably not points. They have internal structure. This structure arises for a reason’ (Arrow 1999). The markets and hierarchies research paradigm describes the firm as a complex hierarchy in which both governance and specialization purposes are served. Cognitive and behavioral variance among the human actors in the population presents opportunities for specialization; and transactions for which co-operative adaptations are needed (namely, those for which assets are highly specific and need to be adapted to successive disturbances, given that contracts are incomplete) are ones for which added governance supports are needed. The concept of firm-as-governance structure—as a means by which to induce order, relieve conflict, and realize mutual gains for transactions that are in need of co-operative adaptations—thus comes to the fore.

2.4 Refutable Implications

Most of the refutable implications pertaining to governance are derived from the discriminating alignment hypothesis, according to which transactions, which differ in their attributes, are aligned with governance structures, which differ in their cost and competence, so as to effect a (mainly) transaction cost economizing result. Vertical integration in intermediate product markets is the canonical case, in relation to which a large number of variations on a theme have been worked out—for labor markets, capital markets, vertical market restrictions (such as franchising), regulation (and deregulation), economic reform (especially privatization), and public bureaus. More

generally, any problem that arises as or can be posed as a contracting problem can be examined to advantage in transaction cost economizing terms.

A second class of predictions arise in conjunction with specialization. Upon making provision for variance among human actors (in cognitive and self-interestedness respects), many opportunities to realize economies by matching the attributes of human agents to the needs of a task present themselves. This second class of predictions has been less thoroughly worked out but constitutes a promising research opportunity.

2.5 Empirical

Some theories of economic organization make little effort to advance refutable implications. Among those that do, few are empirically tested. Simon (1991) evidently believes that transaction cost economics is remiss in empirical respects: awaiting empirical testing, the new institutional economics and related approaches are acts of faith, or perhaps of piety.

Coase had registered similar concerns about the dearth of empirical work on contract and organization 20 years earlier, but that was before the operationalization of transaction cost economics had begun and predicted alignments were advanced. Empirical applications of transaction cost economics got under way in the 1980s and have grown exponentially since. It could have been otherwise, but the theory and evidence display remarkable congruity (Masten 1995). As Joskow (1991) puts it, ‘this empirical work is in much better shape than much of the empirical work in industrial organization generally.’

2.6 Full Formalization

The 1930s was the decade when the informal ideas for a new science of organization took shape, the 1970s was the decade when these ideas were worked up in a preformal way, the 1980s was the decade of semiformal analysis, and the 1990s witnessed a burgeoning of work of a fully formal kind. The paper by Grossman and Hart (1986) on *The Costs and Benefits of Ownership* was the first fully formal model of an incomplete contracting kind. Hart’s book on *Firms, Contracts, and Financial Structure* (1995) elaborates upon and develops these ideas. Additional work of this kind has been published since and more is in progress. As matters stand presently, however, there is a huge gap between the semiformal and fully-formal stages.

A leading reason for the break is that the fully formal analysis of incomplete contracts relies entirely on property rights assignments to assess comparative efficiency. Not only are the discrete structural differences in organization among alternative modes of governance denied, but the proposition that adaptation is the central problem of organization (of which

two types are distinguished) is ignored. These differences are consequential, whence Kreps (1999) concludes that 'If Markets and Hierarchies has been translated into game theory using notions of information economics, it is a very poor translation... In particular, mathematical-based theory still lacks the language needed to capture the essential ideas of bounded rationality, which are central to... transaction costs and contractual form.' Kreps (1999), nevertheless, remains sanguine that formal efforts will succeed eventually, possibly with the benefit of new mathematical apparatus.

3. Conclusions

Whereas once it was customary to talk about markets or hierarchies, where the former denoted decentralization and the latter central planning, that has changed. Now it is more customary to talk about markets and hierarchies. That entails much more than a replacement of the conjunction 'or' by 'and.' It represents a veritable sea change in the way economic organization is studied. The combined study of law, economics, and organization that is herein described (a) involves comparative institutional analysis in which economizing is the main case and the action resides in the attributes of human actors, transactions, and governance structures, (b) generates numerous refutable implications, (c) invites empirical analysis, (d) has many public policy ramifications, and (e) invites progressive formalization. Many economists are now persuaded that the study of economic organization needs to be studied in a combined way in which law, economics, and organization are joined. Legal scholars have incorporated many of these ideas into contract law, corporate governance, antitrust enforcement, and regulation. And organization theorists have come to appreciate the pervasive reach of economizing reasoning.

Real headway notwithstanding, new problems and challenges appear to be unending. Productive tension between transaction cost economics and each of the parts on which it stands—law, economics, and organization—can be projected safely into the future.

High Performance Computing

Many scientific and engineering applications require a higher computing power than standard computers can provide. So in the last three decades of the twentieth century specialized computer architectures for high

performance computing (HPC) have been built. They are mainly optimized to execute floating-point operations at very high speed. The fastest HPC systems are also called supercomputers (the term supercomputing is sometimes used as a synonym for HPC). High performance is obtained by vector computing, parallel computing, use of special fast technologies or by a combination of these techniques. This article reviews the history of HPC systems, explains the most important high-performance computer architectures, and presents some typical HPC applications.

1. History of HPC

Figure 1 demonstrates that the performance of HPC systems based on the LINPACK benchmark (Dongarra 1990) was raised from about 0.1 GFlop s^{-1} (billions of floating-point operations per second) in the 1970s to more than $1000 \text{ GFlop s}^{-1}$ in the last decade of the twentieth century; so every decade the performance was increased by two orders of magnitude.

In the second half of the 1970s the introduction of *vector computers* marked the beginning of the HPC era. They offered a performance advantage of an order of magnitude compared to standard computer systems of that time, reducing the cycle time by introducing *pipelining* in the processor architecture and supporting high-level operations on complete vectors (e.g., component-wise addition or multiplication) by hardware. Typically, several functional units (FU), each dedicated to a particular arithmetic operation, are available in a vector processor (see Fig. 2(a)) and two or even more result vectors can be computed simultaneously. To achieve a high performance, the pipe-

lines of all FUs must be filled and emptied again at very high speed. Thus, input/output data and intermediate results are read from and written to fast vector registers each holding a fixed number (mostly 64 to 256) of vector elements. Separate load/store units perform an independent and overlapped data transfer from/to memory.

The first vector computer, Cray 1, was introduced in 1976. It is composed of six FUs and one load/store unit and is realized in fast emitter coupled logic (ECL) technology operating at 80 MHz. In later vector processor architectures, such as Cray 2 (1985), Cray Y-MP (1988), NEC SX-3 (1990), and NEC SX-4 (1994), performance was further increased by using up to 16 FUs and up to eight load/store units. Also the clock cycle time was decreased (e.g., by using liquid-cooled processors). During the 1980s, the number of vector processors installed in vector computers grew from one to eight and later to 16. Although they could communicate via a shared memory, it was difficult to use several processors on a single job, so mainly the throughput was increased by running several jobs in parallel.

As an alternative to vector computers, in the 1970s massively parallel processing (MPP) systems appeared as a new class of high-performance computers. Here a large number (typically ranging from 256 to 65,536) of processors, interconnected by a static network, operate in parallel to compute one task. The memory is distributed among the processors. In the first MPP systems the SIMD (single instruction multiple data) operation principle was used. The instructions are broadcast from a control unit (CU) to very simple processors (called processing elements or PEs) where they are executed simultaneously in lock-step mode on different local data items (see Fig. 2(b)). PEs are based on simple arithmetic units operating on words of limited length (often only of 1 bit). Operations on integers or floating-point numbers are performed by software routines that take several clock cycles depending on the length of the operands. Thus the power of such machines does not result from the PE itself but from the enormous number of installed PEs. So SIMD-type MPPs perform excellently on applications based on large matrices of short data elements, such as signal or image processing.

One of the first commercially available SIMD-type MPP systems was the distributed array processor (DAP) with up to 4096 PEs arranged in a 64×64 grid. The most famous machine of this class is the Connection Machine CM-1 (1985) and CM-2 (1987) with up to 64k simple one-bit processors connected by a hypercube network (Hillis 1989). For certain applications the CM-2 offered a higher performance than the CRAY Y-MP (see Fig. 1). MasPar MP-1 (with 4-bit PEs, 1990) and MP-2 (with 8-bit PEs, 1992) represent the last important machines of this architecture class, which disappeared from the market in the first half of the 1990s.

Figure 1

Performance of various high-performance computers from 1975 to 2000 for the solution of linear equation systems, measured in billions or trillions of floating-point operations per second (GFlop s^{-1} or TFlop s^{-1} , respectively)

Figure 2
Architectures of high-performance computers

At the same time a new kind of HPC systems was proposed: MPPs based on advanced microprocessors operating according to the MIMD (multiple instruction multiple data) principle. In contrast to SIMD architectures the processors execute different tasks asynchronously. A few hundred or thousand cheap off-the-shelf processors designed for high clock-frequencies are interconnected by a network of high bandwidth. However, the communication is much slower than in SIMD-type MPP systems because there is a high overhead for initializing each communication and for synchronizing the processors.

In the first MIMD-type MPP systems, such as Intel's iPSC series with up to 128 processors or the nCube/2 system (1990) with up to 8,096 processors, the d -dimensional hypercube was the preferred topology. Here each processor can be reached in at most d steps; also two- and higher-dimensional grids can be embedded easily. Later systems were provided with additional communication controllers in each node and used new routing techniques so that the communication time became less dependent on the distance

between nodes. Topology was no longer important (if contention is ignored) and cheaper topologies such as a grid or a torus were favored. The Intel Paragon (1992) consists of up to 4,000 Intel i860 processors connected by a two-dimensional (2D) grid. The Cray T3D (1993) and T3E (1997) systems are based on a three-dimensional (3D) torus with up to 2,048 Alpha processors. In the second half of the 1990s, sometimes several workstations or PCs connected by an Ethernet or fiber Channel network were used instead of many integrated processors. Conceptually, this network of workstations (NOW) is not different from a distributed-memory MPP system, but the communication latency is higher.

The advantages of MIMD-type MPP systems are a good price/performance ratio and a good scalability of the architecture. On the one hand cheap and small systems with a few processors and a medium level of performance can be built easily; on the other hand the high performance of expensive vector computers can be reached or even exceeded at lower cost by using a sufficiently large number of processors. Due to the

large communication overhead, MIMD-type MPP systems are well suited for applications with a coarse-grain parallelism.

Since about 1995 several companies started to sell symmetric multiprocessor (SMP) models of their workstation families. In the first systems a rather small number (typically 4 to 16) of microprocessors access a shared memory built from several memory modules by using a central system bus (see Fig. 2(d)). Here each variable can be read and updated by each processor, which is supplied with a local cache to reduce the memory access time. The main problem in SMPs is to ensure that each variable remains consistent in all caches, especially when it is updated by one processor. This *cache coherency problem* is solved via a special protocol. Instead of a single bus often a set of several buses or even a crossbar network are used to reduce the risk of bus contention and to increase the collective bandwidth between memory and processors.

At the end of the twentieth century SMPs with a larger number of processors and a hierarchical interconnection structure became available. Here clusters of tightly-coupled processors are interconnected by a less costly and also slower network. Typical examples are Sun's HPC series (1997) and Hewlett-Packard's V-class series (1998). SMPs offer a high performance at low price. However, the scalability is limited: only a medium number of processors can be installed. So the performance levels of MPPs and vector computers cannot be reached (compare Fig. 1).

2. Programming HPC systems

On vector computers any existing sequential code can be used although it should be optimized manually to achieve high performance. For MPPs, SMPs and NOWs, however, the program must be parallelized based on either the data-parallel programming model or the message-passing model.

Data-parallel programs express all operations on vectors and matrices from a global point of view. The compiler automatically maps the data structures onto the parallel architecture. No manual synchronization or communication between the processors must be programmed, so the design of such data-parallel programs is rather simple. Examples of data-parallel languages are the several dialects of C offered by the manufactures of SIMD systems and High Performance Fortran (HPF).

In parallel programs based on the message-passing model the user must distribute tasks and data structures among the available processors. The user must also program each synchronization and communication explicitly by sending messages between the parallel tasks running on different processors. Each task can be implemented in a standard programming language such as C, C++ or Java. For the exchange of messages between tasks several standardized lib-

raries such as PVM (parallel virtual machine) or MPI (message passing interface) are available.

3. HPC Applications

In the beginning of the HPC era most applications involved the solution of large systems of linear or (partial) differential equations. Later other computation-intensive applications have emerged, such as the simulation of chemical and nuclear physical models, image processing, virtual reality, and optimization. Also artificial intelligence applications can be accelerated by parallelism—for instance, in 1997, IBM's MIMD-type MPP system Deep Blue consisting of 32 processors and 512 chess co-processors defeated world chess champion Kasparov. Deep Blue used a parallel alpha-beta tree search algorithm, tuned with expert knowledge, and could generate and evaluate 200 million chess moves per second (Hamilton and Garber 1997).

The simulation of artificial neural networks (ANN) represents another typical HPC application. Many ANN models (such as multi-layer perceptrons or radial-basis function networks) have been proposed that can be applied to many classification, approximation and optimization tasks without a formal treatment of the underlying problem. The training of ANNs by examples requires a high computational power, and many researchers have successfully simulated such ANN training on various parallel computer architectures (for an overview, see Šerbedžija (1996)). ANNs involve an inherent massive parallelism that can be exploited for a parallel implementation on different levels: either the *neurons* (basic ANN operating elements), the *synapses* (weighted connections between neurons), the *layers* (in case of a multi-layer network), or the *patterns* of the training set can be mapped onto different processors. However, especially at the first two levels, the communication/computation ratio is rather high because only simple operations are performed in each synapse or neuron between two communication steps. So, in particular, SIMD-type MPPs are well suited for a parallel implementation on all levels because of their good communication capabilities. High performance on MIMD-type MPPs, SMPs and NOWs can only be achieved by a pattern-parallel implementation; however, this technique can be applied to just a few neural learning algorithms. So for ANN simulation the paradoxical situation exists that older (and no longer available) SIMD-type systems are more suitable than modern HPC computer architectures.

The importance of high-performance computers is also steadily increasing in computational neuroscience. Complex biology-oriented neural models can be simulated on HPC systems in acceptable periods of time. Examples are: highly detailed single-cell models (such as a cerebellar Purkinje cell with 4550 compart-

ments (De Schutter and Bower 1994), medium-sized networks of neurons modeled at a less detailed level (such as hippocampal circuits with up to 128 pyramidal cells described by 70 compartments (Traub et al. 1996) or very large networks of neurons modeled at a higher abstraction level (such as the cat's primary visual system with 16384 integrate-and-fire neurons (Niebur and Brette 1994). In all cases discrete-time approximations to the solutions of a large set of nonlinear differential equations must be found.

Furthermore, HPC systems can accelerate several computation-intensive tasks in psychology such as simulating complex models of cognitive processes, simulating realistic models of visual perception, or analyzing electromagnetic activities in the brain. Especially the evaluation of psychological models and the estimation of model parameters yielding a best fit to data requires high computing power (for recent such applications, see Edwards (1997)).

4. Perspective

In the last three decades of the twentieth century, high performance computing was marked by a strong dynamic with a continuous appearing and disappearing of manufacturers, systems, and architectures. This rapid change will probably continue in the near future. Due to technological progress faster microprocessors will become available each year and cheap HPC systems with a few processors will offer a performance that could formerly be achieved only by expensive vector computers or MPP systems. Thus, high-performance computers will no longer be specialized architectures but be the high end of a continuum of fast desktop systems and servers. Scalable architectures can easily be adapted to the performance requirements of most computation-intensive HPC applications. However, for algorithms with high inter-processor communication demands (such as the simulation of ANN), it is not obvious if future HPC systems will be able to provide a sufficiently low communication latency to allow efficient parallel implementation.

A few special applications (such as weather prediction and computational fluid dynamics) require a still higher computing power than near-term HPC systems can provide. In 1996, the US Department of Energy's Accelerated Strategic Computer Initiative (ASCI) launched a program for a three-fold increase in computing performance every 18 months over a 10-year period using commercial hardware only. The first systems, ASCI Red (1997) and ASCI White (2000), consist of more than 7000 microprocessors and exceed 1 TFlops⁻¹ (see Fig. 1).

The scope of HPC applications will be further extended in the future. New applications will emerge, not only in science and engineering, but also in commerce (in areas such as information retrieval,

decision support, financial analysis, or data mining). *Data-intensive* algorithms are used here; they must operate on very large databases containing massive amounts of information (e.g., about customers or stock prices) that have been collected over many years. In particular, the rapid future increase in the amount of data stored worldwide will make HPC indispensable.

High School Dropout

Dropping out of high school, that is, leaving school without graduating, is a central educational issue in almost all industrialized countries, although large differences between educational systems make cross-national or cross-cultural comparisons problematic. Nevertheless, there is broad international agreement that dropping out increases the risk of subsequent criminal behavior and drug abuse, lower occupational

and economic prospects, lower lifetime earnings, and becoming a member of the underclass. Furthermore, dropping out increases the probability of lower levels of mental and physical health. Studies investigating the consequences of high school dropout at a macro-level have shown that higher dropout rates result in lower tax revenues and increased expenditure for governmental assistance programs. Against the backdrop of all these negative consequences, sociological, educational, and psychological researchers have investigated the reasons for dropping out. The reasons identified can be classified as school-related, family-based, or personal. Researchers agree that the risk of dropping out begins to develop early in a student's life and that intervention programs to prevent dropout should therefore be initiated at an early age.

1. Problems in Calculating the Dropout Rate

A major challenge facing any study of high school dropout is how to define and identify the dropout population. There is some agreement, among American researchers at least, that students who were enrolled in grades 10, 11, or 12, but left school without graduating are to be defined as dropouts. However, this definition is often not viable in other countries. In international comparison, school systems not only differ with respect to the organization of primary and secondary schools, forms of ability grouping, and curricula, they also differ in terms of the age at which students are allowed to leave school. While students in the UK and most states of the USA are legally obliged to attend school until the age of 16, for example, students in other countries (e.g., Germany) are not allowed to leave school until they are 18. As a consequence of the different lengths of compulsory schooling, the probability that a student will drop out between the ages of 16 and 18 varies from country to country. Furthermore, there is some evidence that high schools tend to overestimate the percentage of dropout (e.g., Rumberger et al. 1990), and it has been argued that 'dropout data are probably the least reliable information available today regarding the reality of schools' (Frymier 1996, p. 4).

Beyond these problems of definition, it is characteristic of almost all industrialized countries that school participation rates increased continuously during the twentieth century. In the USA, for example, the proportion of 14- to 17-year-olds enrolled in high school increased from 11 percent in 1900 to 94 percent in 1978. However, dropout rates have been relatively stable since the beginning of the 1970s (between 5 and 10 percent in industrialized countries).

2. Factors Influencing High School Dropout

Three major directions of research into the antecedents of high school dropout can be distinguished, although

there is substantial theoretical overlap between the three approaches. While the first two types of research concentrate on family background and school variables from the sociological perspective, the third—more psychological—approach focuses on individual characteristics in terms of achievement and motivation.

2.1 Family Background and High School Dropout

Where family background is concerned, the determinants found to be of importance for academic achievement have also been considered with respect to dropout (e.g., Rumberger 1983, Rumberger and Thomas 2000). Parents' level of education represents a potential predictor of dropout, that is, better educated parents spend more time with their children, thus supporting their accomplishments and increasing the likelihood that they will remain in school. Furthermore, these parents influence the academic performance of their children by imparting the values, aspirations, and motivation needed to succeed and remain in school. With regard to parental income, children from poor families probably feel more pressure to contribute to the family income, and thus leave school to seek work at an earlier stage. Family structures are also important, in that children from broken homes where one or both parents are absent are less likely to receive the support and encouragement needed to stay in school. The absence of parents, however, is often combined with financial problems that might explain the dropout. In a more detailed analysis of family influences, Rumberger et al. (1990) investigated the interaction styles between parents and children and the consequences for dropout. Dropouts were more likely to live in households characterized by a permissive or an authoritarian parenting style, their parents were more likely to use extrinsic punishments as a reaction to poor grades, and reacted with more negative emotions to both good and bad school grades. Furthermore, dropout students reported that their parents were less involved in their education and gave them less help with their homework.

In the USA, in particular, relations between ethnic group membership and high school dropout have been investigated, and higher percentages of dropout have been reported for Hispanic and African-American students. In a study investigating primary reasons for dropout, Rumberger (1983) found out that African-American females most often cited marriage and pregnancy as reasons for leaving school. However, if SES and individual achievement are held constant, the relationship between ethnic background and dropout diminishes or reverses, thus suggesting that the association is mainly mediated by family background and individual levels of achievement (e.g., McNeal 1995).

2.2 School Characteristics and High School Dropout

School characteristics have been investigated in research on school effectiveness. Authors agree that not only academic achievement, but dropping out of school is a reliable indicator of school effectiveness. Rumberger and Thomas (2000) identify school resources, structural characteristics of schools, and school processes as factors, which can influence high school dropout. With regard to the financial resources of schools, research shows that the student-teacher ratio is positively related to high school dropout. Furthermore, there is some evidence that a higher percentage of teachers with advanced degrees increase the likelihood that students will remain in high school.

Structural characteristics such as school location (urban, suburban, rural), size, and type (state vs. private) also seem to influence dropout, even when important individual and family characteristics are controlled. Research by Pittman and Haughtwout (1987) revealed a positive correlation between high school size and dropout rate. Mediation analyses demonstrated that this effect was mediated primarily by the social climate (sense of cohesion, level of student participation in school activities, interaction with faculty, the magnitude of certain problems at the school), and indicated that smaller schools had a better social climate and consequently lower dropout rates. Private schools usually have lower dropout rates than state schools (e.g., Rumberger and Thomas 2000), and students attending urban schools are more likely to drop out than their counterparts in suburban schools (e.g., Frymier 1996).

Research on school processes has identified a number of school-related variables that influence dropout rates. A higher level of cooperation between teachers and students seems to reduce dropout rates and, with regard to the academic climate, Bryk and Thum (1989) found that dropout rates were lower in schools in which students took more advanced courses and reported doing more homework. Bryk and Thum also reported that high schools with serious staffing problems had higher dropout rates.

Rumberger and Thomas (2000) suggested that because schools are anxious to show that their students' test scores are improving, they actively reduce the membership of low-achieving students through a process of discharge. This process affects not only low-achieving students, but also hard-to-educate students. Since both variables are confounded with SES and ethnicity, these school processes usually lead to higher dropout rates for students with low SES, and for Hispanic and African-American students.

2.3 Individual Determinants of High School Dropout

Although many background and school variables are important antecedents of dropout, a more psycho-

logical view of the problem suggests that the concrete decision of whether or not to carry on or leave school is guided by individual characteristics such as attitudes and motivational states. Schools, parents, and teachers provide an academic environment, and students' perceptions of this environment determine their achievement motivation, their behavioral intentions, and their academic behavior and choices. In one of the few psychological studies on reasons for dropout, Vallerand et al. (1997) proposed a model assuming self-determined academic motivation to be an important factor influencing behavioral intentions and dropout behavior. Their study suggests that students who perceive their parents, teachers, and school administrations as supportive develop a higher level of perceived competence and academic autonomy, and that this leads to higher intrinsic academic motivation and a lower likelihood of leaving school without graduating.

Expectancy-value models (e.g., Wigfield and Eccles 2000) suggest that academic choices are based mainly on expectancies of success in the domain of choice, and on how students value the domain. Both expectancies and values are based on family background, school and class variables, and previous individual achievement-related experiences. Low expectancies and values with respect to the future school career increase the probability of dropping out.

3. Prevention of High School Dropout

Low levels of academic achievement (e.g., Caliste 1984) and high absenteeism (e.g., Bryk and Thum 1989) are the strongest behavioral predictors of high school dropout. Several authors (e.g., Simner and Barnes 1991) have pointed out that the earlier a student with low achievement levels and high absenteeism can be identified, the more likely is it that dropout prevention will be successful. An effective 12-week prevention program proposed by Caliste (1984) first identifies at-risk students (grade-point averages below 1.0 on a 4.0 scale). These students receive extra tuition from their teachers and participate in group counseling sessions. Topics discussed during the weekly counseling sessions include motivation, relevance of school, academic problems, career goals, and study habits. In the tutoring sessions, students are primarily assisted with current coursework and given some remedial instruction.

Participation in out-of-school activities, particularly sports clubs, can also prevent dropout. McNeal (1995) argues that higher social integration in both school and in non-academic clubs influences whether or not students remain in school. His analyses show that for low-achieving students (one standard deviation below the population mean) not involved in sports clubs, the probability of dropout is $p = 0.25$, while for members of sports clubs the probability is only $p = 0.17$.

Finally, authors agree that children from disadvantaged family backgrounds need particular social and financial support. Females, especially African-Americans, often leave school without graduating because of marriage and pregnancy. Day-care programs are viable measures to prevent drop out here.

Higher Education

In most countries, teachers of the most prestigious institutions of higher education are assigned both teaching and research tasks, whereby 'academic freedom' is held in high esteem. A trend towards systematization notwithstanding, curricular approaches have remained varied across countries, fields and institutions, regarding the academic or professional emphasis, their adaptive or critical role to the world of work, the degree of specialization and the role higher education plays for personality development beyond the cognitive domain. Recent reforms react to trends of internationalization and globalization, increase the role of practical experiences, life-long education, distance education and use of new technologies.

Universities are often called surprisingly persistent institutions, though their organization is often weak and anarchic. The continental European tradition of a weak university leadership amid a major role of government and academic freedom of scholars gave way in the 1980s to reduced governmental bureaucratic control and increased formal autonomy of the central management of higher education institutions amid growing pressures for efficiency, accountability, and social relevance.

1. Definition

'Higher education' became a popular term in the second half of the twentieth century depicting the intellectually most demanding stage of pre-career education. Terms such as 'post-secondary,' 'tertiary,' or 'third-level' education underscore stages of learning: upon completion of primary and secondary education, i.e., after 10–14 years of schooling, varying according to national systems, students might enroll in the third stage of education, as a rule prior to embarking regular employment. The term 'higher,' however, suggests a specific quality, expecting students to learn questioning prevailing rules and tools and to understand theories, methods, and substance of 'academic' knowledge. Higher education also often serves a twofold function: teaching and 'research,' i.e. the creation and preservation of systematic knowledge.

2. History

Institutions and programs of advanced learning existed in various countries more than 1,000 years ago. However, the core elements of today's higher education, i.e., teaching and learning of 'analytic,' 'rational,' 'systematic,' 'critical,' 'skeptical,' and 'innovative' thinking, emerged from the European universities of the Middle Ages.

Around 1800, a new historical stage can be noted when substantial changes of the European universities occurred. The British model of the Oxford and Cambridge approach regained strength which puts emphasis on the trained mind and the personality development through close communication between the teachers and the students. The French university, reformed under the Napoleonic regime, combined strong state coordination of organization and curricula leading to state-coordinated degrees with a decentralized organization within the university, thus reinforcing a divide between the faculties and notably intellectual and cultural approach of the *facultés des lettres* and sciences on the one hand and on the other the professional emphasis of other faculties inside the universities and *écoles* outside the universities. The German model, mainly the 'unity of teaching and research' approach of the Humboldtian university, was based on the idea that academic freedom and institutional autonomy guaranteed by the state help to secure the university's most appropriate service to society, and also underscored the freedom of learning, i.e., the student's ability and responsibility of independent learning in communication with the professor. The German model became the internationally most influential in the nineteenth century.

The models spread through adaptations and misunderstandings which turned out to be creative in some instances. Notably, the US approach of being 'as British as possible' as far as undergraduate education is concerned and 'as German as possible' by combining teaching and research, and in establishing graduate schools as a completely new element, tends to be viewed as the most successful one in the twentieth century (Ben-David 1977).

The development of higher education after World War II is often regarded as the third stage of the history of modern higher education. Higher education was no longer expected to serve a small number of academics and socially exclusive professions, but rather became a 'mass' or an almost 'universal' phenomenon (see Trow 1974). Whereas less than 5 percent of the respective age group enrolled around 1950 in most industrial countries, the respective proportion was even more than 50 percent in some countries at the end of the twentieth century. The number of doctoral-granting institutions in the world had risen to about 10,000 and of other institutions to even a higher number, and the total number of students was more than 80 million in 1995.

3. Quantitative and Structural Developments

3.1 Access and Admission

According to OECD statistics (OECD 2000), about 80 percent of the corresponding age group on average of the OECD member states successfully completed

upper secondary education in the late 1990s. Upper secondary education varied between countries structurally, i.e., 'horizontal' (graduates of all institutions and programs are eligible for entry to higher education) or 'vertical' (specific types and programs preparing for higher education), as well as according to the role vocational training plays and the way it is organized.

Modes of admission to higher education can be classified according to three types (see Teichler 1988).

(a) If secondary education is organized horizontally, the large numbers of those successfully completing secondary education are eligible to apply for admission to higher education, whereby entry to higher education is the major point of selection within the education system. The entry decisions rest with the higher education institutions (in the USA) or their departments (e.g., in Japan), and might be based on school grades, combinations of school subjects, admission tests, interviews, etc.

(b) If secondary education is vertically organized, those successfully completing the academic track (being awarded the *Abitur*, *Matura*, *Baccalaureat*, etc.) tend to be entitled to enroll at institutions of higher education (e.g. Germany and The Netherlands). As a rule, entry is a nondramatic point of allocation, and selective admission applies only for few fields and institutions.

(c) Finally, some countries provide for both selective secondary education and selective admission at entry to higher education (e.g. the UK).

At all modes, most of those applying for higher education will eventually enroll. The admission system in industrialized countries is not primarily a gate-keeper of the overall quantity of enrolment, but rather allocates primarily with respect to type, institutional prestige or field of study.

3.2 Enrolment, Drop-out, and Graduation

The 'youth' in most countries acquire entry qualification for higher education at the age of 17 to 19 years. The average age of new entrant students varies in industrial countries between 18 and 23 years.

The OECD reports an average 'net entry rate' to higher education in terms of programs leading to a (at least bachelor) degree of 40 percent in industrialized countries for 1998. In addition, almost 20 percent begin short tertiary-education studies. Altogether, women have enrolled as frequently as men, on average, in industrialized societies since about 1990. UNESCO calculated a gross enrolment rate, by comparing enrolment figures of young people within five years of the normal school-leaving age: 63 percent enrolled in 'more developed regions,' 38 percent enrolled in countries in transition and 7 percent enrolled in 'less developed regions' in the mid-1990s.

About two-thirds of those enrolling in degree programs in industrialized countries are eventually

awarded a degree. The estimated dropout rates are 10 percent in Japan (lowest) and about 65 percent in Italy (highest).

In 1998, 22 percent of the respective age group on average across industrial countries eventually was awarded a degree (in comparison, 1 percent on average were awarded a doctoral degree). In addition, 11 percent completed other tertiary education programs.

3.3 Diversity of Levels, Programs, and Institutions

Universities, i.e., multidisciplinary institutions in charge of both teaching and research, entitled to award advanced academic degrees (notably the doctorate) and, where applicable, entitled to award subsequent degrees qualifying for senior academic positions (the 'doctor scientiae' or the 'Habilitation'), are considered the key institutions of higher education. Except for France, where *Grandes Écoles* lead to the highest professional careers, entry to university is viewed as most prestigious. Most other institutions, i.e., mono-disciplinary institutions of technology, theology, etc., initially viewed as less prestigious, often gained the same status over the years.

Since the 1960s, two developments reinforced a diversification of higher education. Pressure towards increasing systematic knowledge in the middle-level occupations led to an 'up-grading' of the institutions serving the training of these occupations. Concurrently, the university sector came under pressure to diversify because the growing student body became increasingly heterogeneous in terms of motivations, competencies and career prospects and because resources were not made available for an expansion of research-oriented higher education in tune with increasing students' enrolment (Teichler 1988, Meek et al. 1996).

In various countries, an additional sector of higher education was established, called for example 'polytechnics' in the UK (which eventually became universities in 1992), 'instituts universitaires de technologie' in France and 'Fachhochschulen' in Germany which initially were expected to provide applied educational programs, but not to undertake research. This sector was named 'short cycle,' 'non-university' or 'alternative' without any of these terms being generally appreciated.

Countries varied substantially, however, according to the extent of which differentiation of higher education was realized through:

- (a) types of higher education institutions;
- (b) curricular approaches of programs (e.g. academic versus professional-vocational);
- (c) levels of programs and degrees; (e.g. the OECD's 'non-university certification,' 'short first university degree,' 'long first university degree,' 'second university degree,' and doctoral or similar degrees);
- (d) length of programs (in terms of years of study or credits-points, etc.); and

(e) varied reputation and prestige among formally equal institutions and programs.

Higher education systems, for example, were characterized as 'unitary,' 'binary,' 'dual' or 'multi-type,' 'stage' or 'level,' 'comprehensive,' etc.

4. Knowledge, Teaching, and Learning

4.1 Learning and Pursuit of Knowledge

Students are expected to learn questioning the available wisdom and the established ways for problem solving and to be prepared for indeterminate work and other life tasks. A close link between teaching and research should ensure that teaching is at the 'cutting edge' of research development. In some countries, curricula are very open and teaching is conceived more or less as a by-product of research.

4.2 Trend Towards Systematization of Curricula

With the expansion of higher education, however, a trend could be observed towards systematization of content, structures, and processes. Study programs were divided into sequences and stages. Curricular regulations grew, and measures of informing and guiding students were extended. In many countries, teachers were expected to be trained in techniques of teaching, and regular evaluation of teaching practices often was introduced. The trend towards systematization affected initial course programs most strongly. But the US concept of graduate school for those preparing for a doctoral degree was also taken up or modified in most other countries in the latter half of the twentieth century (Clark 1995).

Yet major curricular approaches remained varied across and within countries, notably according to seven dimensions. First, curriculae may be directed more strongly towards preparation for research and the creation of knowledge or towards the reproduction of knowledge available. Second, curriculae may be geared closely to occupational preparation or not related to job roles at all. Third, objectives of higher education curricula differ according to the degree of specialization. Fourth, fields of study may be designed according to disciplines or take on a multidisciplinary character. In some countries (fifth), a common core of knowledge might be offered for all students. Sixth, views differ as regards the responsibility of higher education for the personality development of students beyond the cognitive domain. Finally, curricula vary according to the extent they aim to contribute to cultural enrichment of society.

The variety of curricular approaches had their pendant in the roles of the teachers and the students. Students might be viewed as young learners for which the university serves 'in loco parentis,' as customers or

as independent and self-responsible young members of the university community. Teachers might view themselves as scholars in the pursuit of knowledge, or as educators and counselors. Available research suggests that students have more similar views across countries on 'good' teaching and learning, and teachers on their role and function (Altbach 1997) than one would expect, taking into account the diversity of national systems of higher education.

4.3 *Expectation of Relevance and Utility Amid Uncertainty*

In the 1980s and 1990s, the conditions both for teaching and learning, as well as for research in higher education, changed substantially. First, pressure grew on teaching, learning and research to be more utilitarian than in the past. Public and private funds were moved increasingly towards research and establishments outside higher education, thus reducing the share of research expenditures spent in higher education in many countries to less than 20 percent. Thus, modes of research spread aiming to cut across disciplines, in spite of the persistence of distinct cultures of the disciplines (Becher 1989), and became more context aware and problem oriented (Gibbons et al. 1995).

Efforts to respond to the societal needs were often met by reinforcing a divide between basic and applied research or by a divide between academic and professional or vocational study programs, but these distinctions became blurred over time. While utilitarian pressures turn out to be imaginative for basic research in some cases, research aiming not to be applied often lay the foundation for practical use. Study programs not geared to certain professions are enriched by a confrontation with practical problem solving, both in classes and internships, while study aiming to be professionally useful is forced to become broader, owing to the uncertainties of future labor market conditions and work assignments—'key qualifications' is a widely used term underpinning this trend.

4.4 *Internationalization and Globalization*

Higher education could be viewed as very international in terms of cosmopolitan values, pride based on international reputation and global search for knowledge. However, the regulatory and funding context tends to be national, and curricula vary strikingly between countries. Kerr (1990) described a conflict between 'the internationalization of learning and the nationalization of the purposes of higher education.' International agencies, e.g. UNESCO, OECD or the World Bank often advocate concepts of convergence, but seem to be counterbalanced by a persistence of varied traditions and political options.

5. *Steering, Governance, and Organization*

5.1 *The Deliberately Weak and 'Fuzzy' Organization*

Universities are often called surprisingly persistent organizations and have survived for several centuries, though they seem to be weak or anarchic institutions in most countries. The links between the higher education institutions and the government or the society can be described as a peculiar mix of partial control and vague pressures, on the one hand, and safeguards of institutional 'autonomy' on the other hand. In the internal organization, accommodation prevailed in most countries between administrative supervision, a strong position of the professorate as a whole and the 'academic freedom' of the individual scholar.

The weakness was widely viewed as supportive for an ethos within the institution which allowed scholars to focus on the pursuit of knowledge without major concern about the social and organizational environment. The Humboldtian ideal was widely shared that a university protected from pressures of immediate utility was most likely to serve generation of knowledge and innovation eventually valuable for society.

5.2 *Traditional Modes of Governance and Administration*

Analyses of higher education governance often intend to describe both the relationships between higher education and society and the modes of governance within the institutions, thus underscoring that the internal mechanisms of power, cooperation, and communication are linked to the ways how higher education is steered from outside. Notably, US scholars have described traditional higher education systems according to four models:

(a) the collegial model—emphasizing nonhierarchical cooperative decision making, and a significant degree of self-determination by academic staff;

(b) the bureaucratic model—emphasizing legal-rational authority and formal hierarchies;

(c) the professional model—emphasizing the authority of experts and the importance of horizontally differentiated units linked to loose confederations;

(d) the political model—conceptualizing governance in terms of political conflict among interest groups with competing views and values' (Harman 1992, p. 1282).

Often, three actual modes of academic governance and administration are pointed out (see Ben-David 1977, Clark 1983). Both in the French and in the German traditions, governments, though largely respecting or protecting academic freedom, pursued certain visible ways of bureaucratic control of higher education institutions. The university leadership was

kept deliberately weak whereby the faculties in France and the chairs in Germany were the stronghold of academic freedom and institutional autonomy. In the British tradition, funds were allocated to the higher education institutions with little strings, the strongest power of the institution rested in academic collegiality, and the university leadership, though stronger than in continental Europe, exerted moderate control. The US model was characterized by a weak position of visible macrosocial forces, whereby the market seemed to play a stronger role than government and the trustees of the individual institutions of higher education, and by a strong power of the president and the deans along limited decision-making power of the academics.

Clark (1983) defined the patterns of control and coordination according to a triangle of market, state authority and academic oligarchy. He allocated US higher education as relatively close to the market, Germany to state authority, and Italy to academic oligarchy.

5.3 In Search of New Modes of Governance and Administration

Since the 1970, the climate around and within institutions of higher education has changed substantially. Obviously, institutions of higher education have lost much of their special character. They are expected to be more similar to other institutions, and the functions they perform are less exclusive. Higher education experienced:

(a) a loss of trust in the academic profession and in academic freedom. Counterbalances by other forces, scrutiny of job performance and of academic quality as well as direct incentives for social relevance and utility are viewed now as appropriate;

(b) a loss of confidence in governments' potentials of steering higher education successfully through detailed regulations and control of administrative processes; and

(c) a growing demand for efficiency in terms of serving extended duties of teaching and research with stagnating resources and for visible effectiveness.

Four major changes of governance and administration of higher education occurred. First, in the wake of the student protests in the late 1960s, various continental countries introduced models of participation whereby students, junior academic staff, and administrative staff got a substantial say, as was the case previously in various Latin American countries. This reform approach, however, lost momentum rapidly because the process of decision making seemed to become controversial and time consuming and because the actors benefiting often were disappointed as regards the limited real influence the formal decision-making process actually allotted to them.

Second, various governments in Europe moved from a 'control' approach, and in the UK from an

'institutional autonomy' approach, towards a 'supervision' approach (Neave and van Vught 1991). Mechanisms employed were, among others, political target setting, steering through indicator-based funding, contracts between the state and higher education institutions, and the establishment of evaluation systems allowing to identify the 'output' of higher education (Westerheijden et al. 1994).

Third, managerial actors (university leadership, deans) were strengthened and managerial mechanisms were established or extended. The internal processes of decision making and administration were expected to get close to industrial entrepreneurship, while respecting the specifics of a professional organization serving unpredictable innovation of knowledge.

Fourth, the setting of key actors increasingly grew complex. In addition to the state, the market and the professorate (Clark 1983), the management of the higher education institutions, and other internal actors (students, junior academic staff, and administrative staff) came into play as well as other 'stakeholders' (i.e., all other forces who could have a legitimate interest to be involved in higher education as a 'visible hand').

U. Teichler

Hindu Law

Hindu law claims one of the longest continuous histories of any legal system in the world. Indeed, for about 2,500 years it was based on the same primary sources. Yet, the attitude toward these sources has varied considerably over the centuries, with the result that Hindu law in 2,000 CE, is very different from what it may have been in 500 BCE.

1. The *Smṛtis*

Until the 1950s the main sources of Hindu law were contained in texts written in India's classical language, Sanskrit (Derrett 1973a, 1973b). The earliest of these texts, the *dharmaśāstras* (mostly in prose, and probably earlier) and *dharmasūtras* (exclusively in verse, and probably more recent) may be dated to approximately between 500 BCE and 500 CE. The Indian concept of *dharma*, for which there is no Western equivalent, is much broader than the Western concept of 'law.' A Hindu's *dharma* encompasses each and every rule people are supposed to live by and, even though the legal aspects of *dharma* are more and more treated in isolation in the *dharmaśāstras*, 'legal' prescriptions in these texts remain inseparable from other obligations, especially those which we would label 'religious.' A case in point is adoption, which is not valid unless accompanied by a ritual act, the *dattahoma*.

To understand the Hindu view of *dharma*, and of law in particular, it is essential to keep in mind that the *dharmaśāstras* and *dharmasūtras* are part of the revealed Veda. They make up the *smṛti* 'remembrance,' the authority of which is only slightly lower than that of the older Vedic texts, the *śruti* 'revelation.' They too, were considered to have been transmitted to mankind by *rishis* ('seers'). Like the Vedas themselves, the texts on *dharma* are perfect, eternal, and un-

changeable; they should not be interfered with by human beings.

The most important *smṛti* text is the *Manusmṛti* or *Mānavadharmasāstra* (ca. 200 BCE–200 CE), attributed to Manu, the progenitor of all Hindus (Bühler 1886). Chapters 8 and 9 of the *Manusmṛti* are entirely devoted to legal matters. Together with Chapter 7 they constitute the *rājadharmā*; the king is indeed the supreme justice in his kingdom. For the first time, an effort is made here to classify the causes of legal disputes, under 18 titles: failure to pay debts, deposit and pledge, sale without ownership, partnerships, resumption of gifts, failure to pay wages, breach of contract, rescission of sale or purchase, disputes between the owner and keeper of cattle, boundary disputes, physical assault, verbal assault, theft, violent crimes, sex crimes, rules for husband and wife, partition and inheritance, and gambling and betting (8.4–7). The subdivision into 18 'heads of litigation' is maintained in all later *dharmaśāstras*, with the difference that their eighteenth chapter is often called *prakīrnaka* 'miscellaneous,' to incorporate aspects of substantive law that were not dealt with by Manu. Only one *dharmaśāstra* is entirely devoted to law, the *Nāradaśmṛti* (Lariviere 1989). The *Manusmṛti* deals with procedure under the first head of litigation; Nārada devotes three introductory chapters to it. Most notable, in the chapters on evidence, is the highly detailed treatment of witnesses and ordeals.

In view of the later development of Hindu law, reference must be made here to one characteristic trait of *smṛtis* that has provoked much discussion in the scholarly literature. There are, in these texts, obvious contradictions, not only between different texts, but also within single texts such as Manu's translation of Lingat's 1967 work (see Lingat 1967). In one verse (9.104) Manu prescribes that, after the death of both parents, their sons divide the paternal estate equally. Without any transition, the following verse (9.105) says that the eldest brother takes the entire paternal property, while the others shall live under his authority as they did under their father's. After a few verses in praise of the eldest son, Manu continues: 'The eldest son takes an additional share of five percent, as well as the most desirable part of the estate; the next son gets half of that, the youngest one quarter' (9.112). Or, Manu acknowledges and describes in detail the duties of partners in a levirate marriage (9.60), and elsewhere rejects levirate marriages as *paśu-dharma* 'the *dharma* of cattle' (9.66). Scholars have attempted to expurgate the preserved Manu text so as to avoid the contradictions. In reality, Manu's three ways of inheriting paternal property, and his opposite views on levirate, may result from the fact that they were all *dharma* in different places, among different groups of people, etc. They all knew exactly which rule applied in their community, but all these rules were *dharma*, and deserved a place in authoritative texts on the subject (Rocher 1993).

2. The Commentaries

From about the seventh century CE onward, and well into the eighteenth century, the *smṛtis* become the object of voluminous commentaries. Both the commentaries on individual texts and the digests which treat of particular aspects of *dharma*, drew into their discussions the entire body of ancient *smṛti* texts. Among the several, often book-length, sections of the digests most often one or two are devoted to law: some deal with procedure (*vyavahāra*) and substantive law (*vivāda*) separately; others combine the two in a single treatise. There are even digests on specific aspects of substantive law, mainly on inheritance and on adoption.
